Embodied Energy is defined as the quantity of energy necessary to process and supply the material under consideration to the construction site. The energy inputs for a given material would include raw material extraction, processing and transportation to the construction site, the Embodied energy thus calculated being termed “cradle to site”. Similarly the embodied carbon is a measure of the CO<sub>2</sub> equivalents emitted from the extraction of the raw material through to the final manufacture of the product. [4].

LCEA is often used to estimate the energy use and savings over the life of the product or the building, and more importantly, to find out the energy/CO<sub>2</sub> payback period (the time spent for the initial embodied energy cost to be paid back by energy savings during operational and disposal/recycling stages). Life-cycle carbon assessment is likened to LCEA, and relies on prevailing energy structures to convert megajoules of energy to kilograms [3].

There are many data bases available in the public domain for use in a LCA or LCEA. However the problem lies in the variations in the numerous data bases due to the various assumptions that have been made in developing them. Among the more comprehensive data bases is the University of Bath’s inventory of carbon and energy. It is a more reliable data base for embodied energy and carbon associated with construction materials. Many designers who are concerned about the environment are making use of this facility to determine the carbon impact of their designs.

Two of the more common rating systems are BREEAM and LEED. BREEAM sets the standard for best practice in sustainable building design, construction and operation and has become one of the most comprehensive and widely recognized measurements of a building's environmental performance.

A BREEAM assessment uses recognized measures of performance, which are set against established benchmarks, to evaluate a building's specification, design, construction and use. The measures used represent a broad range of categories and criteria from energy to ecology. They include aspects related to energy and water use, the internal environment (health and well-being), pollution, transport, materials, waste, ecology and management processes.

BREEAM addresses wide-ranging environmental and sustainability issues and enables developers, designers and building managers to demonstrate the environmental credentials of their buildings to clients, planners and other initial parties. BREEAM uses a straightforward scoring system that is transparent, flexible, and easy to understand and supported by evidence-based science and research. It has a positive influence on the design, construction and management of buildings and defines and maintains a robust technical standard with rigorous quality assurance and certification [5].

Similarly LEED is a voluntary, consensus-based, market-driven program that provides third-party verification of green buildings. From individual buildings and homes, to entire neighborhoods and communities, LEED is transforming the way built environments are designed, constructed, and operated. LEED is comprehensive and flexible and addresses the entire lifecycle of a building. Participation in the voluntary LEED process demonstrates leadership, innovation, environmental stewardship and social responsibility. LEED provides building owners and operators the tools they need to immediately assess how their building impacts on the environment whilst providing healthy indoor spaces for a building's occupants.

LEED projects have been successfully established in 135 countries. International projects, those outside the United States, make up more than 50% of the total LEED registered square footage. LEED unites us in a single global community and provides regional solutions, while recognizing local realities.

Building projects earn points for satisfying green building criteria. Within each of the environmental LEED credit categories, projects must satisfy particular prerequisites and earn additional points. The number of points the project earns determines the level of LEED certification the project receives. Projects must earn at least 40 points on a 110-point LEED rating system scale to achieve basic certification. [6].

Although these rating systems which are not mandatory have had a positive environmental impact on the design and operation of buildings, both building rating tool systems have been deemed to be too complicated and time-consuming by certain segments of the industry which has discouraged a widespread use. This group would greatly prefer a 'quick and dirty' assessment option, one that is easily accessible, provides results instantaneously and requires little or no operator training [7].

Despite the rapid growth of building assessment schemes over the last 15 years, the construction industry is still undergoing a cultural shift towards the general use of such tools. While BREEAM and LEED Canada have been instrumental in fostering this change, these tools must continue to evolve in order to maintain the momentum developed thus far while at the same time it expands to include construction sectors and markets not currently undergoing assessment [7].

It is timely to make the available assessment tools mandatory if further impacts on the environment due to building and construction activities are to be prevented. This places a major responsibility on local planning authorities to ensure environmentally friendly building and construction. It is possible to achieve this objective by legislating for mandatory standards for the protection of the environment and for a sustainable society. Criteria could be imposed on new construction to minimize or totally negate the adverse impacts on the environment

#### **4. THE RESPONSIBILITY OF LOCAL AUTHORITIES TO ENSURE SUSTAINABILITY.**

Human behaviour in society has to be regulated by laws. Behaviour and activity has to be monitored and scrutinized to ensure compliance and punitive action taken when there is noncompliance. In civilized societies the social contract has been maintained in this manner. However where the environment is concerned there are hardly any laws to ensure a sustainable ecological footprint or to limit CO<sub>2</sub> emissions.

In 1990, global emissions were 38.2 gigatonnes, and in recent years it has been growing at a rate of three per cent per year. This increase has taken place despite the commitments by industrialised countries to reduce their emissions. For 2012 the global total of climate-disrupting emissions are estimated at 52 gigatonnes [8]. The consequences in the form of extreme temperature

and weather are a recurrent phenomenon. Sydney, Australia recorded the highest ever temperature of 46.5 degrees centigrade on Friday the 18<sup>th</sup> of January 2013 [9].

In the building construction sector at least some steps can be taken to enforce regulations targeted at minimising carbon emissions. This could be a significant step considering that building construction and operation accounts for almost 40% of the total world energy consumption.

Whenever an application is made to a local authority for the approval of a new development they must impose certain mandatory requirements. Based on the local average rainfall precipitation, it should become compulsory to harvest a minimum quantity of rainfall. A ceiling should be imposed on the treated pipe borne water that is supplied through the local authority.

An estimated value of the total operational energy per year during the operational phase of a new development should be tabled with the application process. A ceiling or cap calculated on the floor area and the use of the development should be imposed on the energy supplied through the national grid. The remainder of the operational energy requirements should be from alternate energy sources. The solar radiation in the locality could be taken into consideration and a component of this energy requirements should be supplied through the use of solar panels. Small scale wind turbines could be made mandatory. With wind turbines which generate power becoming the fastest growing alternate energy sector in the world it would be feasible to incorporate small scale wind turbines to supplement the alternate energy supplied through the solar panels.

An obligatory requirement when requesting for a building permit must include an embodied energy count for the proposed new development. The embodied energy count could be based on embodied energy values supplied by the local authority. A specific maximum value should be stipulated for a building based on its floor area and its nature as a commercial, housing or industrial construction. If the value stipulated is exceeded, the application should be rejected. The local authority could make use of the available data bases for embodied energy and modify it to suit the local conditions.

If garden space is available waste water could be directed through a simple filter and the water used for the garden. Sewage could be discharged to a septic tank soakage pit system. Small scale bio-gas units could be made mandatory if adequate space is available. A minimum area in proportion to the floor area of the building should be planted with trees and foliage. If it is a high rise building vertical gardens should be established on a specified minimum area of walling.

These are small measures that can be made without much delay. Stronger steps may have to be taken in the future if CO<sub>2</sub> emissions do not drop in the expected way.

Urbanisation has transformed the relationship between people and the planet we inhabit. Cities, built on just 2% of the world's land surface, use about 75% of its resources and discharge similar proportions of waste. In a world in which 50% of the world's people now live in cities and over 80% of the world's population live in the most industrialised countries, sustainable development has to be mainly and necessarily about sustainable urban development [10].

BedZED's (Beddington Zero Energy Development) new-build development of 83 mixed tenure homes (social, key worker, and for sale), plus some 3000m<sup>2</sup> of live/work, workspaces, retail, and leisure uses, occupies an urban brownfield site in South London. Its chosen high build-density reflects the importance of using limited land resources to the full, being based on the density needed for accommodating all the UK's projected new homes. It is built entirely on available brownfield sites, to avoid sacrificing any more limited greenfield amenity. Such high density helps build coherent communities and provides critical mass for facilities like public transport, while continuing to allow the massing and orientation needed for good passive solar and daylight access. Making the roof areas 'green' helps increase the site's ecological value and its carbon absorbing ability, as well as giving the occupants private gardens [11].

BedZED was conceived to show that in large-scale construction a high level of sustainability can be practical and cost-effective. If the sustainability concept is to have any sort of meaningful overall effect on the environment, it must move into the volume mainstream, satisfy economic and social objectives, and benefit all stakeholders. Nevertheless the ecological footprint of 4.36 ha is more than the global average of 2.4 ha but much better than the 6.19 ha for an average UK lifestyle based on a four person household [11].

It is recognized now that the ecological footprint has to be reduced for the wellbeing of humanity and that sweeping measures may have to be taken. BedZED is just a starting point. In the future it may even become necessary to ensure that all freehold land at the point of transfer on a sale or a legacy is made into a fifty year lease hold with the title passing to the local authority on the completion of the lease. Then all land will be vested with the Local Authority and they would be free to develop it in a sustainable eco-friendly manner.

Distances that need to be traversed between the home and the workplace using motor vehicles which greatly adds to the problem of pollution, cannot continue in its present form. This raises issues with respect to the concepts regarding the city, the workplace and the home which have to be rethought. Co-operation and community, social responsibility and civic sense, if it does not come naturally to people, may have to be brought about through the regulation of human activities. It may become imperative to change our habits and life styles if we are to avoid climatic catastrophes in the future and to ensure that our planet remains healthy.

The ideas suggested above which encompass the view of traditional societies albeit with a much higher input of technology, where work, home, space for leisure all remain within its own environs are worthy of consideration if we are to promote sustainable development.

Science and technology can detect the problem, and supply the solutions for remediation or management of the problem. An example can be seen in the manner in which Bio-fuels are made. The single celled blue-green algae referred to as Cyanobacteria have been used for the production of bio-fuels. It yields twenty times more biomass per day in comparison to Soyabean. This has been demonstrated by a company Bio fuel Systems in Alicante Spain. Their plant uses the CO<sub>2</sub> emitted by a neighbouring cement factory to grow the algae and is able to produce 2.5 barrels of carbon neutral crude oil per hectare of algae each day [12]. The gardens by the bay in Singapore are another excellent example of the use of science and technology to demonstrate the concept of sustainability so that its citizenry is made aware of the problem. However science and technology does not have the power to ensure a beneficial change or to protect the environment. That power lies with the legislators. It is obvious now that only the enforcement of mandatory requirements will provide for a sustainable future.

## 5. CONCLUSION

It is obvious that CO<sub>2</sub> levels are rising and global warming is a major problem confronting the world. The consequences of higher global temperatures can be seen in the changes in weather patterns, in floods hurricanes etc. that are increasingly common. The impacts from the building and construction activities that contribute to CO<sub>2</sub> emissions can be minimised in the short term if the steps outlined in this paper are implemented. Similarly in the long term, land holdings may have to be vested to the local authorities who will have to take the responsibility to design carbon neutral communities. The argument that more production is necessary to sustain larger numbers of people at a higher standard of living and that environmental degradation is collateral damage which has to be tolerated is no longer a valid argument. Environmental issues are no longer the purview of environmental activists. It is an issue that concerns everyone. What is required is for the powers that be to implement that which is necessary.

### ABSTRACT

*High economic growth in Indonesia drives development in multiple sectors triggering consumerisms which as a result increasing amount of waste generated per capita. A city of Depok originally designed as a suburb of Jakarta has a population around 1.8 millions with a total area of 200 km<sup>2</sup>. In 1998, amount of waste generated was 3400 m<sup>3</sup>/day while in 2012 has been increasing to 4,200 m<sup>3</sup>/day. With high amount of waste generation, the city of Depok develops a waste management program started in 2006 by building several material-recovery facilities (UPS /unit pengolah sampah). Activities occurs in the UPS are waste separation, recovery, and composting. With organic content on the solid waste is around 80%, it is obvious that composting is the best option to reduce amount of wastes going to landfill. However due to contamination and poor process, most of the compost produced cannot be used as organic fertilizer.*

*This study focuses to evaluate slope stability of Cipayung landfill, when compost is used as coversoil. Application of compost as coversoil will not only reduce CH<sub>4</sub> emission from the landfill but also stimulates full utilization of composts produced in Depok. The first part of the paper provides a survey of waste generation, composition, and quality of compost produced in the city of Depok. Based on the data, compost is mixed with soil which usually used as coversoil in the landfill. In addition, a simple slope stability model was analyzed. The results promotes further study on potential slumps and slides of waste mass that may cause as a significant constraint on construction and development of a landfill.*

### INTRODUCTION

Many cities in Indonesia nowadays facing big challenges in managing the increasing generation of solid waste. The high economic growth in Indonesia is not only causing development in many sectors, but also consumerisms which at the end increasing amount of waste generated per capita. One of the city is Depok which has population around 1.8 million inhabitants with total area of 200 sq km, and actually designed as a suburb of Jakarta. In 1998, amount of waste generated is 3,400 m<sup>3</sup>/day while in 2012 increase up to 4,200 m<sup>3</sup>/day. It means almost 9% of solid waste generated per year increased.

With the high amount of waste generated, City of Depok decided to develop their waste management program. Starting in 2008, they built 30 material recovery facilities (UPS/unit pengolah sampah) in many parts of the city. The activities include in the UPS are waste separation, recovery, and composting. On the other hand, most of the activities developed in the UPS do not go according to the government plan hence wastes transported to the landfill are still high.

One particular challenge is due to the lack of separation program in the household, hence most of organic wastes are contaminated which result in low quality of compost being produced. In addition it is widely known that recycling is worthwhile only if there is only a healthy market for recycle product but since no buyers willing to use the compost, the produced compost is end up also in the landfill.

Only one landfill (TPA/Tempat Pemrosesan Akhir) serving the city of Depok, named Cipayung located 20 km from Depok. With total area of 11.2 ha and used since 1997, it is reaching capacity level. With Depok's space constraints however, there is a limit to the land and resources that can be put aside for waste disposal.

Compost as cover soil has been extensively studied (Humer and Lechner, 2001; Gebert et al, 2011, Popov, 2005)). Compost is cost effective methane reductions for existing municipal solid waste landfill since it exploit the natural process of microbial methane oxidation through improved landfill cover design. Humer and Lechner (2001) mentioned that this promising complementary strategy can be applied to mitigate methane emission of smaller or older sites where the methane production is too low for energy recovery or flaring, and installation of a gas extraction system is inefficient.

Although using compost as biocover has many advantages, but there is no study analyze its impact on the landfill stability. Many factors can trigger waste-mass instability such as high leachate levels. In Indonesia, the recorded slope failures happened several times in a year especially in large landfills such as Bantar Gebang (located in Bekasi, West Java), Lewi Gajah (located in Bandung, West Java) , and Cipayung (located in Depok, West Java) although many of them had not formally reported ([http://www.indosiar.com/fokus/tpa-bantar-gebang-longsor\\_54694.html](http://www.indosiar.com/fokus/tpa-bantar-gebang-longsor_54694.html)). Jianguo et al (2010) studied that in humid regions in China, high rainfall infiltration result in high leachate levels in waste mass. Combine with an absence of effective facilities for rainwater interception and leachate drainage, the shear strength of the waste may be greatly reduced, causing landfill instability. All of those three landfills located in a regions with high annual precipitation and with lack of proper landfill design criteria led to significant loss of life.

This study aims to evaluate the slope stability of Cipayung landfill if compost is used as coversoil. Application of compost as coversoil will not only reducing CH<sub>4</sub> emission from the landfill but also “close the loop” of the compost produced in the city of Depok. The first part of the paper provides a survey of waste generation, composition, and quality of compost produced in the city of Depok. On the basis of those data, compost is mixed with the available soil that usually used as coversoil in the landfill and the simple slope stability were analysed. The results can be used to study the potential for slump and slides within the waste mass and which may represent a significant constraint on construction and development of the landfill.

## **METHODOLOGY**

### ***Waste sampling, characterization, data recording and analysis***

The study population consisted of all waste generated in the 7 UPS that actively operated over 8 day waste audits using SNI M-36-1991-03. Each of the waste sample collected has minimum weight of 100 kg and aggregated by students involved in the study into large garbage bags.

Waste samples were sorted and weighted according to 9 primary categories (Table 1) which include plastics, metal, rubber, glass, paper, wood, residue, textile, and organics.

Completed data collection forms were checked for errors and placed into standard spreadsheet data files (excel, Microsoft, U.S.A.). Subsequent analysis included computing and analyzing the mean waste composition within each UPS.

### ***Chemical and Physical Composition of Compost and mixture of Compost and Soil Used in the Study***

In this study, soil analysis of standard method and SNI (Indonesia national Standard) were applied for chemical and physical composition of compost used in the study.

Three possible scenarios of the soil and compost mixture were applied as cover soil in the Cipayung landfill.

### ***Slope stability analysis***

Slope stability of Cipayung landfill was analysed based on the landfill design criteria which are listed in Depok City masterplan which are listed on Table 5. There are two steps of the analysis: For the first step, the actual properties at Cipayung were applied with the variability of inclination to analyse the actual safety factor. The second step is finding the safest inclination of Cipayung landfill when compost is used as coversoil. The properties of Cipayung landfill are listed in Table 5. The safety factor were calculated using GeoStudio (2007) (Geoslope International Ltd.). All analysis were carried out using Morgenstern-Price method with half-sine interslice force functions.

## Result and discussion

On average, each of the UPS received 12-30 m<sup>3</sup> of waste/day with the mean composition (% by weight) of each material type recovered from UPS waste stream presented in Table 1. Almost 80% of the waste are organics, and only 20% are inorganics. All of the organics were composted using open windrow system however due to poor processing, all of the compost produced could not be used as organic fertilizer. High contaminant concentrations are the main reason that these compost were not saleable.

Table 1. Typical composition of solid waste in Depok

Categories	Percentage (%)
Plastics	10.8
Metal	0.3
Rubber	0.2
Glass	1.2
Paper	5.3
Wood	0.1
Nonrecyclables	1.3
Textile	0.9
Organics	79.8

Table 2. Typical properties of solid waste in Depok

Parameter	Range (kg/m <sup>3</sup> )	Typical value (kg/m <sup>3</sup> )
Moisture content (%w/w)	55-80	65
Density	160-220	185

## Compost quality

Particle Density	1.0891	gr/cm <sup>3</sup>
Porosity	21.862	%

### Properties of cover soil

Based on the Triaxial UU test, the mixture of soil and compost with the fraction of 1:1 has the highest cohesion value while the mixture of soil and compost with the fraction of 1:2 has the lowest angle of shearing resistance or angle of internal friction. On the other hand the mixture of soil and compost with the fraction of 1:1.5 has the lowest cohesion and angle of shearing resistance.

Table 5. Design Criteria of Municipal Solid Waste Landfill Parameters

Parameter	Cipayung landfill
Average height of fill (m)	30
Average annual precipitation (mm/year)	2684
Number of rainy days per year (days)	222
Porosity of solid waste material	
Saturated unit weight of MSW (kN/m <sup>3</sup> )	500
Ketebalan daily cover (cm)	30
Final cover (cm)	50
Average height of msw (m)	2

Soil : Compost = 1: 1.5	14.83	19	26
Soil : Compost = 1 : 2	15.41	22	27

### Stability analyses

Specification Analysis of Geostudio SLOPE/W and Comparison of Computed Safety Factor for Measured Slope Inclinations and Heights at Cipayung Landfills are presented in Tables 7 and 8 respectively.

Tabel 7. Specification Analysis of Geostudio SLOPE/W

No.	Type of parameter	Note
1.	<i>Analysis Type:</i>	<i>Morgensterd-Price, Bishop, Ordinary, and Janbu</i>
2.	<i>Setting: PWP Condition</i>	<i>Piezometric Line</i>
3.	<i>Slip Surface: Direction of Movement</i>	<i>Left to Right</i>
4.	<i>Slip Surface Option</i>	<i>Grid &amp; Radius</i>
5.	Grid & Radius	Determined by trial and error hence the safety factor resulted from the worst case condition

Table 8. Comparison of Computed Safety Factor for Measured Slope Inclinations and Heights at Cipayung Landfills Using Geostudio SLOPE/W

Surface length 40 m			Surface length 50 m			Surface length 60 m		
Slope angle (°)	Ratio of Soil to Compost	Safety factor	Slope angle (°)	Ratio of Soil to Compost	Safety factor	Slope angle (°)	Ratio of Soil to Compost	Safety factor
75	1 : 1	0.633	75	1 : 1	0.623	75	1 : 1	0.633
75	1 : 1.5	0.629	75	1 : 1.5	0.632	75	1 : 1.5	0.628
75	1 : 2	0.633	75	1 : 2	0.689	75	1 : 2	0.631
70	1 : 1	0.691	70	1 : 1	0.743	70	1 : 1	0.688
70	1 : 1.5	0.687	70	1 : 1.5	0.740	70	1 : 1.5	0.684
70	1 : 2	0.689	70	1 : 2	0.744	70	1 : 2	0.687
65	1 : 1	0.742	65	1 : 1	0.805	65	1 : 1	0.742
65	1 : 1.5	0.739	65	1 : 1.5	0.801	65	1 : 1.5	0.739
65	1 : 2	0.743	65	1 : 2	0.803	65	1 : 2	0.743
60	1 : 1	0.822	60	1 : 1	0.805	60	1 : 1	0.805
60	1 : 1.5	0.813	60	1 : 1.5	0.801	60	1 : 1.5	0.802
60	1 : 2	0.818	60	1 : 2	0.803	60	1 : 2	0.808

Based on the iteration, it is immediately apparent that all of safety factor values from twelve iterations are less than 1200 which means that actual condition of Cipayung landfill with slope angles of 75°, 70°, 65°, 60° and surface length of 40 m, 50, 60 m are not stable if mixture of compost and soil were applied as cover soil. In addition, there are no significant difference of the computed safety factor values for cover soil with fraction of soil and compost 1: 1, 1:1.5, and 1: 2 respectively.

The length of the surface does not influence the safety factor values but the slope angle does. For example, safety factor for the same length of surface but different slope angle resulted in almost the same values, on the other hand safety factor for the different slope angle but the same surface length give the significant difference values.

Trial and error iterations were conducted to find the slope angle that will resulted in the higher safety factor values with all of the previous conditions applied. It is found that with the slope angle of 40°, the landfill was stable and the safety factor value was 1.352.

However this analysis was limited in scope and assumed that the failure surface remains within the waste mass and any interpretation of the conclusions reached herein must be made bearing in mind these limitations.

## Conclusions

Simple slope stability analysis was applied to Cipayung landfill in Depok, Indonesia using Geoslope. Twelve possibilities of landfill conditions were used in the analysis along with mixture of soil and compost as cover material. It is found that the safety factor values for all of those twelve possibilities are lower than 1,200. Further assessment found that the highest of the slope angle is 40° if all of the design criteria will be applied according to Depok's solid waste master plan.

### ABSTRACT

*Land cover/land use classification is an effort to classify various types of land cover/land use into a similarity based on a particular method. Land cover/land use classification is used as a guideline or reference in the process of interpretation of remote sensing images for the purpose of mapping land cover/land use. Supervised classification is the process of classification which refers to the existence of classes defined as references. The usage of supervised classification used to classify land cover/land use has already got accurate field. The purpose of this research is to classify land cover/land use in urban areas from QuickBird image. The method used in the research is Supervised Maximum likelihood classifier. The results of the research show that the method is able to classify land cover/land use in urban areas with accuracy 75 % and 86.67 %.*

**Key word** : Land Use, Land Cover, Urban, Supervised, classification, Maximum Likelihood

### INTRODUCTION

Land cover/land use explore about what kinds of physical and material contained within an area. It is very useful concerning with infrastructure development and decision making in the area. In urban areas, frequently encountered obstacles in land cover/land use classification because the density and breadth of the area, so to be able to properly land cover/land use classification needed a satellite image or aerial photograph remote sensing (1). Remote sensing is a method to obtain information about an object, area, or phenomenon by conducting an analysis of the data obtained with a tool without direct contact. Remote sensing is a technique where developed to acquire and analyze information about the surface of the Earth. Remote sensing produced digital imagery that can be used to obtain information about the form of the Earth especially land cover and land use. Land use associated with the use of land within an area that encompasses with special functions, e.g. residential, green fields, catchment area, trading, industry, and others. (2).

To improve the capabilities in land cover/land use classification in urban area, Can be conducted using image with high resolution namely quickbird image. By using high resolution image, the process of separation of the image can be made more accurate because the same spectral variations can be reduce (3). The use of high resolution image spatial can help in land cover/land use classification and the result has been proved to be good accuracy. Problem that happens in image classification is the presence of disorder by clouds on existing image and similarity between each land cover/land use image. By using spectral image as well as uses the method classifications based on segmentation can increase its accuracy (4). By using multitemporal quickbird image, land cover/land use classifications can do better the problem related the occurrence of pixels nucleated can be reduced (5).

The utilization of satellite imagery to assist in land cover/land use classification, it is generally known two methods, namely supervised classification where in the process of classification refers to the existence of classes already defined before/as referrer and unsupervised classification where in the process use the classification groups of pixels image based on statistical

aspects, without the existence of classes as the referrer defined previously (6). Supervised method for land cover/land use classification already used and managed properly. Based on these studies, the accuracy in the analysis of land cover and use in urban areas is very important and became the basis of the development of the city. The purpose of this paper is to conduct land cover/land use classification on an urban area with QuickBird image.

## RESEARCH METHOD

### Supervised Image Classification Method

Supervised Classifications have the meaning classifications on certain supporting reference where category of objects in the image has been identified previously. Classifications done by inserting each pixel image into a category an object which is already known. The classification began with the study of early imagery that would be classified and compared it to the existing reference information. Based on existing reference information, then formed a set of samples of the elements consist of pixels-pixels that represent each of the categories of objects that have been identified, that is done by selecting pixels which have a great variety so that it reflects the character of the object. On a set sample, statistics value covering the average and kovarian matrix calculated for any object.

### Quickbird Imagery

Quickbird imagery is a high-resolution satellites use sensors BGIS-2000 with a resolution is 0.61 meters. Quickbird satellite have a band with diverse specifications (Table 1)

Table 1 Band specification of Quickbird *imagery*

Band	colour	Domain Spektral	Spasial resolution	Radiometrik resolution
1.	Blue	0.45-0.52 $\mu\text{m}$	2.44m-2.88m	11-bit/piksel
2.	Green	0.52-0.60 $\mu\text{m}$	2.44m-2.88m	11-bit/piksel
3.	Red	0.63-0.69 $\mu\text{m}$	2.44m-2.88m	11-bit/piksel
4.	NIR	0.76-0.90 $\mu\text{m}$	2.44m-2.88m	11-bit/piksel
Pan	VNIR	0.45-0.90 $\mu\text{m}$	0.61m-0.72m	11-bit/piksel

The Quickbird image was used because it can showing the description of the object, the Earth's surface and the symptoms that come with the appropriate layout of the actual conditions.

### Interpretation of imagery

The interpretation of imagery is examining aerial photographs or images with intent to identifying objects and estimate the importance of the object, by conducting a series of activities consisting of detection, identification and analysis. Detection is the observation of objects, identification is efforts to characterize the objects that have been detected by using a sufficient description, and analysis is the phase of collecting more information. The interpretation of imagery can be done visually or digital.

### Image Classification

Image classification is a process to obtain images or thematic map consisting of those parts of the States of an object or theme. Each object in the picture has a unique symbol that is declared with the particular color or pattern. For example Land cover/land use map consists of parts which stated area of forest, water, housing, industry, rice fields, road, etc.

#### **Maximum Likelihood Classifier Process**

Maximum Likelihood Classifier is one of method in image classification for the purpose analysis of land cover/land use classification. This method in classification process using assumption identifies features that are almost the same in class. The process land cover/land use classification in urban areas was carried out like in Figure 1.

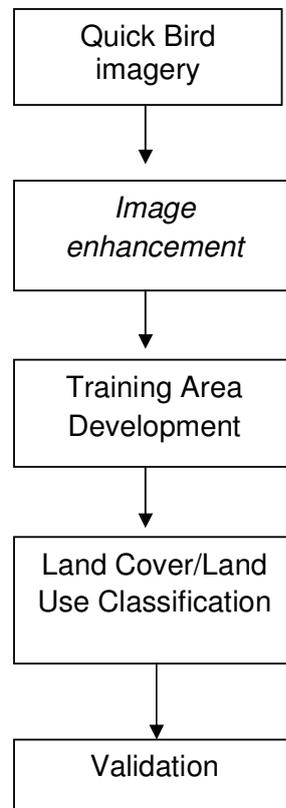

Figure 1, Supervised classification method with Maximum Likelihood Classifier Process

1. Data that uses is quickbird satellite images.
2. Repairing the quality of the image ( image ehancement ) by changing brightness, sharpening the image and etc. Image enhancement aims is to get a new image as expected for a variety of purposes of interpretation
3. On supervised classification set the sample to be used as a supporting reference, and pixels will be processed based on the sample area then bringing image pixel into a category regional sample., like the tree, settlements, asphalt and concrete
4. The use of Maximum Likelihood algorithm, in classification process, used training data as a means to estimate the mean and variance of class, then used to estimate the probability.
5. After classification process completed and produce thematic maps, then performed a test of accuracy/truthfulness (Accuracy Assessment) Supervised classification. Test accuracy/truth is used to find out how accurate the results of the classification has been carried out. Test accuracy/truthfulness is done by pasting the reference area is considered to be true and then compared with the provided class of software Erdas Imagine.

## RESULTS AND DISCUSSION

The data used in research consisting of two sample data i.e quickbird imager of Surabaya and quickbird imagery of meulaboh. The quickbird imagery used is recording in 2004. The selection of the two areas for example due because the two areas have land cover/land uses a diverse and a clear distinction between existing land use (Figure 2 and Figure 3).

**Figure 2** *Quickbir* imagery of Surabaya

**Figure 3** *Quickbir* imagery of Meulaboh

### **Improvement of Quickbird Imagery**

Imagery will be processed first improved quality using the software Matlab 7.6. As a result of improvements to the basic image is the image became more obvious differences between each class. Improvement of image make the image becomes lighter or darker, so as to make it easier in the next process.

### **Training Area**

Determination of training area is performed to retrieve the pixels-pixels on a specific area to be turned into a class. Pixel-the pixel will be a reference for other pixel whose value is almost the same. The workings of the training area that is by

looking for the lowest pixel value and the highest value of pixels in areas that becomes reference. Other pixel values between the lowest pixel value and the highest value of this pixel will fit into one class (Figure 4).

**Figure 2 Training area development**

To perform this method of classification with supervision, for a quickbird imagery of Surabaya divided into four (4) classes based on the value of the colors of the class. The task force consists of the classes that used the green colour to represent the class tree, open land and vegetation is green, the color of purple for the class Residential, buildings and land, gray color for the class of Highway and asphalt and white color for asbestos and concrete classes as in table 2.

## CONCLUSION

The conclusions that can be produced from research on land cover classification in urban areas with Maximum

likelihood classifier supervised method overall produce a good degree of accuracy and can classify existing classes as well. Confusion in classifying in classification, there are several classes that result is still not satisfactory as there the green vegetation in class of asphalt and also asphalt or highway that is classified as a class a roof, this happens because of the similarity of the color that is in the existing quickbird imagery. With the level of precision achieved 75% and 86.67% of course these methods prospected in classification of land cover and use in urban areas.

# Field Study on Undrained Shear Strength of Soft Soil around Micropiles

Yulian Firmana Arifin<sup>a</sup>

<sup>a</sup>Faculty of Engineering, University of Lambung Mangkurat, Banjarbaru 70714  
E-mail : yulianfirmana@yahoo.com

## ABSTRACT

*Micropile (Cerucuk) is widely used to increase the bearing capacity of soft soil in South Kalimantan. Some researchers have reported that the use of micropile can increase the bearing capacity of soft soil. However, most studies were conducted in laboratory. This paper discusses the influence of micropile on undrained shear strength in soft soil around the piles. The study was performed in the field.*

*In this study, cerucuk used was Galam (Malaleuca Leucadendron) that have a nature-lined leather-wrapped sticks, hard and heavy. Galam has a diameter (D) of 0,10 m and a length of 2 m. Piles were penetrated with different spacing (i.e., 2D, 3D, and 4D). Shear strength was measured directly in the field using the field vane shear. Considering time effect, measurements were made before installation, and 1, 7, 14, and 28 days after installation. The results show that the closer pile the greater the soil shear strength. The piles affect the soil shear strength at a distance up to 0.20 m from the pile. Soil shear strength increases by time up to 14 days.*

## Keywords

*Cerucuk, micropile, undrained shear strength, field vane shear test, pile distance, time effect.*

## 1. INTRODUCTION

Micropile (cerucuk) is widely used in South Kalimantan to increase bearing capacity of soft soil. It can be proved theoretically as in [1] using NAVFAC DM-7 [2] based on assumption of piles loaded laterally. However, based on laboratory model, Reference [3] reported that bearing capacity resulted in experiment was higher than that of theoretic calculation. Reference [3] also reported that the use of micropile increases the shear strength of soft soil. However, the conclusion was based on laboratory model.

Referenses [4] and [5] reported experiments on piles in the field. According to [4], the use of micropile resulted in increasing the bearing capacity of soft soil. It increases with increasing time. At the age of 4 days, bearing capacity increased by approximately 45%. The increase has reached 97% after the age of 15 days. According to [5], the distance of pile influenced the bearing capacity of pile in the field. For the same length of pile, the sorter the distance the greater bearing capacity of group piles. The study did not address changes in shear strength of the soil around the pile. In fact, this information is very important for the engineers in the calculation.

Reference [6] reported an effect of pile installation on the shear strength parameter of soil. The test was conducted in a triaxial apparatus. It was found that the cohesion and internal friction angle change due to installation of pile. It results in increasing soil strength and reducing settlement. The result was also concluded based on laboratory test. A field test to support the theoretical and experimental results is required. This paper discusses the changes in shear strength of soil around the pile. Distance and time of pile installation were considered in this study.

## 2. MATERIAL USED AND EXPERIMENTAL TECHNIQUES

### 2.1 Material Used

Micropile used in this study was the type of wood called Galam (*Malaleuca Leucadendron*). This type of wood is often used as a foundation or soil reinforcement in Kalimantan especially in South Kalimantan. The unique properties of this material is its strength maintained if submerged under water continuously. The pile used has diameter of 10 cm and length of 200 cm.

## 2.2 Soil Properties

A laboratory test was performed to the soil. The soil properties of soft soil are summarized in Table 1. According to Table 1, soil has very high water content, fine content, and compression index, and very low coarse grain, shear strength, and coefficient of consolidation. Table 1 also shows that the soil properties from depth of 0.5 to 3.0 m are similar.

Table 1: Summary of soil properties

Soil properties	Depth (m)	
	0.5-1.0	2.5-3.0
Specific gravity	2.6	2.6
Water content	% 96.8	101
Volumetric weight	Mg/m <sup>3</sup> 1.53	1.52
Grain size distribution		
Gravel	% 1.0	1.6
Coarse sand (0.6-2.0 mm)	% 0.7	1.7
Medium sand (0.2-0.6 mm)	% 0.8	1.4
Fine sand (0.05-0.2 mm)	% 4.5	3.9
Silt	% 41.7	22.7
Clay	% 51.3	68.7
Liquid limit	% 55	54
Plastic limit	% 43	46
Plasticity Index	% 12	8
Unconfined compression test		
$q_u$	kg/cm <sup>2</sup> 0.07	0.16
$q_r$	kg/cm <sup>2</sup> 0.03	0.7
$s_i$	2.13	2.34
Consolidation test		
$c_c$	0.82	0.55
$c_s$	0.09	0.14
$c_v$	cm <sup>2</sup> /s 0.02	0.01

## 2.3 Techniques and Procedures

Undrained shear strength of soil was measured using field vane shear test (FVST) apparatus. This test is the most widely used method for measuring the undrained shear strength of a soil, and is particularly appropriate for assessing very soft and sensitive clays, in case where a soil sample for laboratory testing cannot be obtained. The vane has diameter of 4 cm and height of 8 cm. The test procedures are described in ASTM Standard D-2573 [7]. The diameter effect on the  $s_u$  is included in the calculation as described in [7].

Piles were installed with the configuration as shown in Figure 1. "s" is distance of pile. Three different distance were used (i.e., 2d, 3d, and 4d, or 20, 30, and 40 cm, respectively) where d is pile diameter. FVSTs were performed in between the piles and also outside the group piles as shown in Figure 1.

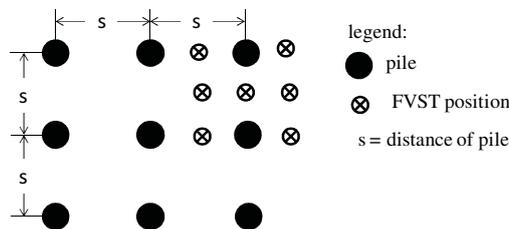

Figure 1: Configuration of pile installation and FVSTs positions

The distance of FVST is approximately 10 cm. For  $s = 20$  cm, there was one FVST in between the piles. For  $s = 30$  and  $40$  cm, there were 2 and 3, respectively (Figure 2). FVST were conducted after installation period of 1, 7, 14, and 28 days. To ensure that the soil is not disturbed, the test were performed to different group piles for different installation period. For the vertical distance, FVST was carried out each 20 cm to a depth of 200 cm as shown in Figure 2. Field procedures and calculation were performed based on ASTM standard [7].

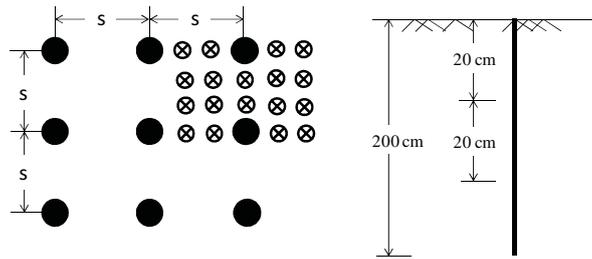

Figure 2: Configuration of pile installation, FVSTs positions, and vertical distance of FVST

### 3. RESULT AND DISCUSSION

Figure 3 shows typical undrained shear strength ( $s_u$ ) in kPa obtained from FVST per 20 cm. Sketch of nine FVSTs position is displayed in the right side of the figure. An independent measurement of FVST was performed before pile installation to obtain initial  $s_u$ . As shown in the figure, the initial  $s_u$  of the soil is approximately 1.8 to 2.0 kPa.

There are two main positions discussed in this study i.e., inside and outside group piles. Points placed inside group piles are 2, 4, 5, and 6, and points outside group piles are 1, 3, 7, and 8. Points 1 and 3 are placed about 10 cm from piles, whereas points 7 and 8 are placed about 20 cm from the piles. According to Figure 3,  $s_u$  at points 7 and 8 is similar to the initial  $s_u$ . Whereas  $s_u$  at points 1 and 3 is higher than that of initial  $s_u$ . It can be concluded that piles affect the soil at a distance of less than 20 cm. Similar result was obtained for  $s = 30$  and  $40$  cm. Figure 3 also shows that  $s_u$  at points 2, 4, 5, and 6 increases due to pile installation. Pile affects undrained shear strength of soil inside and outside group piles.

Figure 4 shows change of  $s_u$  due to installation of piles after 14 days. As shown in the figure, that  $s_u$  of soil is affected by time. Except for  $s_u$  at the points of 7 and 8, the values are not changed. This result supports previous statement that piles affect the soil at a distance of less than 20 cm.

Figure 5 shows effect of pile distance and time on  $s_u$  of soil. The data in the Figure 5(a) is the average of several measurements at the same position (i.e., in between two piles) and placed 10 cm from pile (e.g., Points 2 and 4 as shown in Figure 3). As shown in Figure 5(a),  $s_u$  slightly increases with depth. At this position, the  $s_u$  of soil is similar for different distance of piles. It seems that piles affects soil around it. Distance does not give significant effect at least up to a distance of  $4d$  (i.e., 40 cm) used in this study.

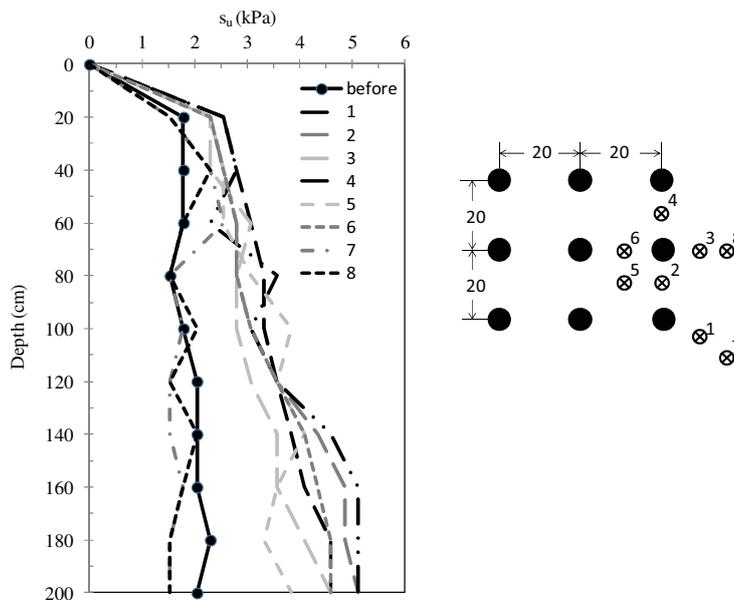

Figure 3: Undrained shear strength of soil by depth for  $s=20$ cm after 7 days

Figure 5(b) shows  $s_u$  of soil at the same position as data in Figure 5(a) performed at different time. After 1 day installation,  $s_u$  of soil is about 2 kPa. This is almost the same as  $s_u$  without pile.  $s_u$  increases to 3 kPa and 4-5 kPa after 7 and 14 days installation, respectively. After 28 days,  $s_u$  is about 4-5 kPa. The results shows that  $s_u$  of soil increases due to pile installation and influences by time. Increase of  $s_u$  is not significant after 14 days installation.

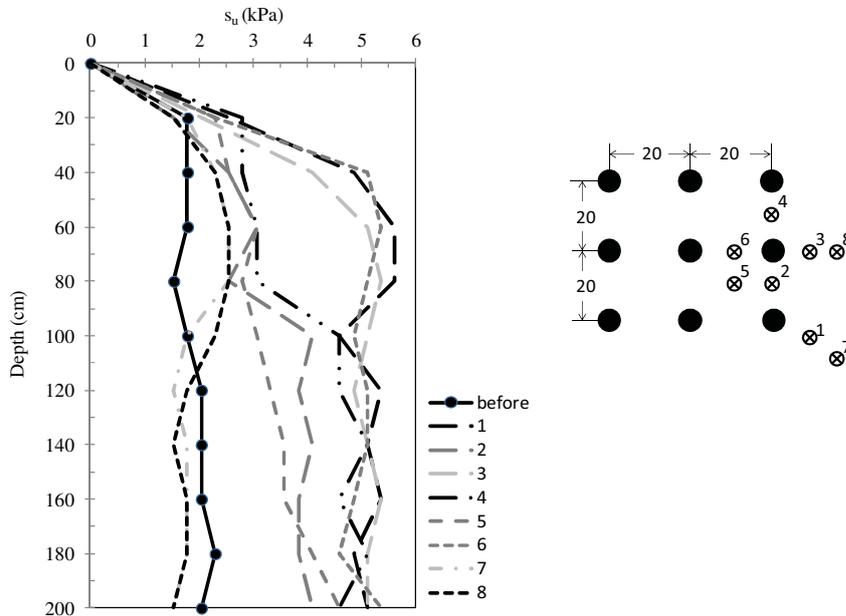

Figure 4: Undrained shear strength of soil by depth for  $s=20\text{cm}$  after 14 days

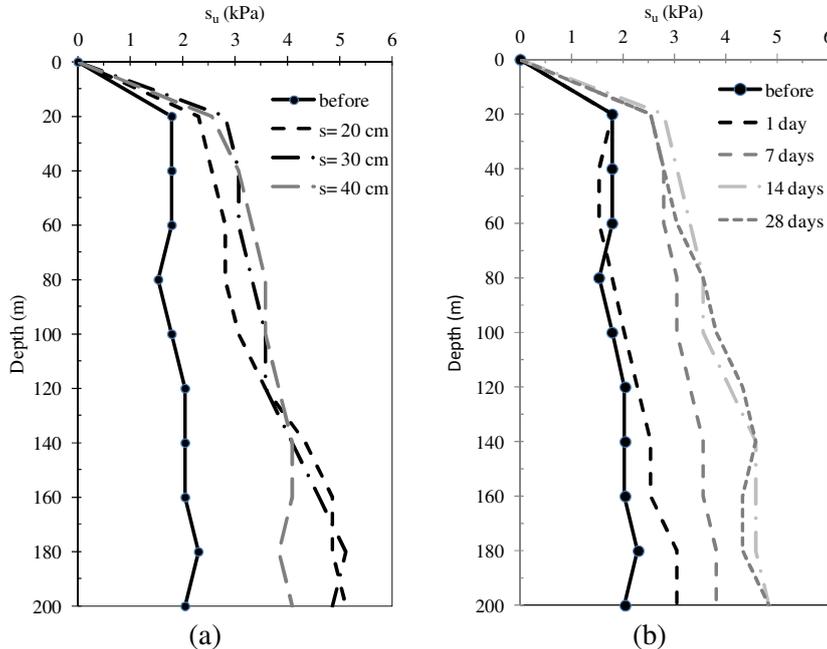

Figure 5: Undrained shear strength of soil (a) distance effect, and (b) time effect

Figure 6 shows  $s_u$  of soil as a function of time for different distance of pile. Figures 6(a) and 6(b) show average data of  $s_u$  at the same depth (i.e., 200 cm) at points 1 and 3 and at points 2 and 4 as shown in Figure 3, respectively. Figure 6(a) shows clearly that  $s_u$  increases significantly up to 4.5-5 kPa or 250% (i.e., 2.5 times the initial  $s_u$ ) up to 14 days. The similar phenomenon is shown in Figure 6(b).  $s_u$  increase significantly up to 5 kPa or 275% (i.e., 2.75 times the initial  $s_u$ ) up to 14 days.

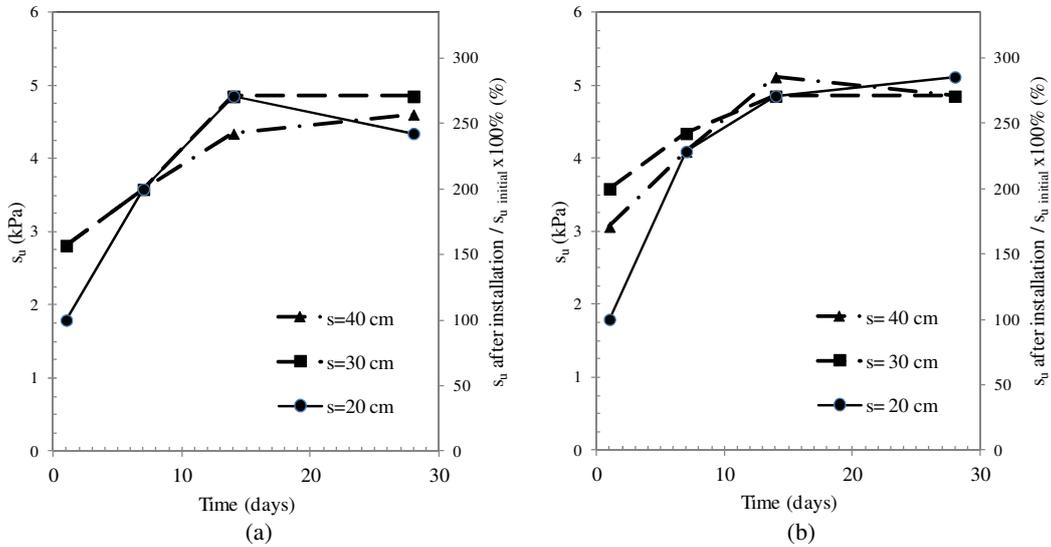

Figure 6: Undrained shear strength of soil (a) distance effect (b) time installation effect

Figures 7(a) and 7(b) shows effects of points position and pile distance on the  $s_u$  after 1 and 7 days pile installation, respectively. As shown in Figure 7(a),  $s_u$  of soil outside the group piles is less than those inside the group piles.  $s_u$  of soil in between 2 piles (points 2, 4, and 6) is relative the same as  $s_u$  of soil in between four piles (points 5). The value is slightly influenced by the distance of piles. After 7 days,  $s_u$  increases and similar for all positions inside and outside of group piles. Similar results are obtained for 14 and 28 days after installation of piles.

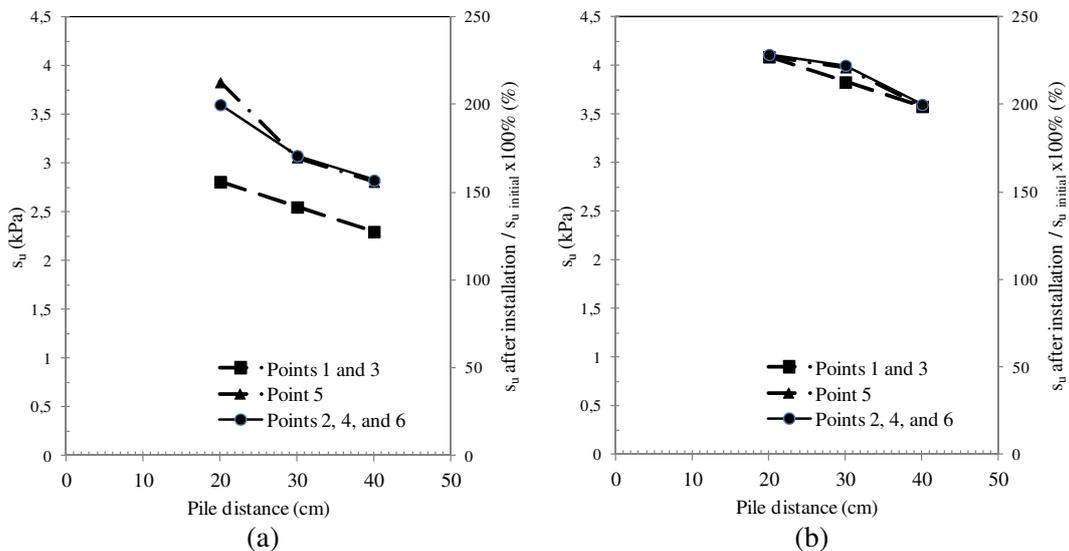

Figure 7: Effects of points position and pile distance (a) after 1 day, and (b) after 7 days installation

#### 4. CONCLUSION

Result of field test of micropiles effects on undrained shear strength of soil around the piles are presented. Distance of piles and time effect are considered in this study. The results revealed that group piles influenced the undrained shear strength of soil at a distance up to 20 cm outside the group. For soil inside the group piles, undrained shear strength increased from 2.5 to 2.75 times due to pile installation. Increase of shear strength was almost the same for different positions in the group. Pile distance influenced slightly on the values of shear strength. The closer the pile the higher shear strength of piles. Time installation

influenced significantly on the undrained shear strength of soil around the pile. The shear strength increased significantly by increasing time up to 14 days. There was no significant effect after 14 days installation.

## ABSTRACT

The Depok residual soil has been used as sub grade layer only for road pavement. By using soil cement stabilization, the Depok residual soil can be used as a sub-base layer to substitute the sand stone material in the future. The cement stabilization can be used as 10 percent of dry weight of soil and then the soil cement sample is compacted by Modified Standard Proctor around the optimum water content of 34.12 %. The soil samples were prepared in two conditions. The first condition, the soil sample was delayed in compaction for 0, 6, 24, 72 and 168 hours and then compacted and the second condition, the soil sample was compacted and then cured for similar time. After this stage, the laboratory testing such as California Bearing Ratio (CBR) and Unconfined Compression were conducted on the samples. The result from this test indicated that the soil sample was compacted and then cured is better than the soil sample was delayed in compaction and then compacted. Using cement stabilization, the Soaked CBR value increase from 13.23 % to 37.75 %, it is adequate as sub-base layer. It was found that cement soil stabilization increased the soil strength to support vehicle load.

## 1. INTRODUCTION

### 1.1 General Geology

Depok city as suburb is located in the south of Jakarta city and is growing very fast in infrastructure development and population. Based on the geologic map of Jakarta – Bogor area, the Depok soil area is consist of residual soil as part of volcanic material weathering where it covered Bogor regency to south of Jakarta area [1]. The Depok residual soil is well known as lateritic soil.

### 1.2 Soil Cement

Generally, the flexible pavement may consist of surface, base, sub base course and compacted sub grade. Sub base courses may consist of variety of materials and in some cases the sub grade itself might meet the requirement for a sub base or it may be treated by means of stabilization to function as a sub base. And on the other hand, cement-treated bases have been used with success under both concrete and asphalt pavement [2]. Cement and lime treatment has been extensively used for road construction purposes resulting in increased bearing capacity of sub grade [3]. Cement stabilization is widely used for road construction and cement requirement can be used in ratio of 6 – 8 per cent of silty clay for road construction [4]. The sub-base course layer is the part of the flexible pavement laid down between the sub grade and the base course and this layer usually is sand stone material. The Depok residual soil has been used for sub grade layer of road pavement structure. By using soil cement stabilization, the Depok residual soil can be treated for a sub-base layer to substitute the sand stone material. The 10 per cent cement stabilization of dry weight of soil is added and then the soil cement mix sample is compacted by Modified Standard Proctor around the optimum water content of 34.12 %. Based on the Standard National Indonesia (SNI), the minimum standard of Soaked CBR for sub-base layer is 35 % [6].

## 2. TEST PROCEDURE

The laboratory testing such as physical properties, California Bearing Ratio (CBR) and Unconfined Compression were conducted on soil and soil cement samples [7]. The variation of cement stabilization were used as 0, 5, 10, 15, 20 and 25

percent of dry weight of soil respectively and then the soil cement samples are compacted by Modified Standard Proctor. Based on the physical properties and soil cement compaction tests, the optimal percentage of cement is 10 percent of dry weight of soil will be implied. And the next the soil cement of 10 percent of dry weight of soil is compacted by Modified Standard Proctor around the optimum water content of 34.12 %. The soil samples were prepared in two conditions: (i), the soil sample was delayed in compaction for 0, 6, 24, 72 and 168 hours and then compacted and (ii), the soil sample was compacted and then cured for similar time. After this stage, the laboratory testing such as California Bearing Ratio (CBR) and Unconfined Compression were conducted on the compacted soil cement samples.

### 3. TEST RESULTS AND ANALYSIS

#### 3.1 Physical Properties

The test result of physical properties of residual soil is shown in Table 1.

Table 1: Physical properties of residual soil.

No.	Physical parameters	Value
1.	Color	red
2.	Specific gravity	2.69
3.	Atterberg Limits:	
	• Liquid Limit, LL (%)	81.32
	• Plastic Limit, PL (%)	57.91
	• Plasticity Index, PI (%)	23.41
4.	Sieve Analysis:	
	• Sand (%)	1
	• Silt (%)	83
	• Clay (%)	16

The result of physical properties of residual soil and soil cement are shown in Table 2. The relation between Plasticity Index versus Cement Content can be seen in Figure 1.

Table 2: Physical properties of residual soil and soil cement

No	Sample type and cement content	LL %	PL %	PI %
1	Residual soil	81.32	57.91	23.41
2	Soil cement (+ 5% cement)	72.43	53.22	19.21
3	Soil cement (+ 10% cement)	71.12	52.88	18.24
4	Soil cement (+ 15% cement)	73.21	55.71	17.32
5	Soil cement (+ 20% cement)	68.88	54.67	14.21
6	Soil cement (+ 25% cement)	63.18	55.15	8.03

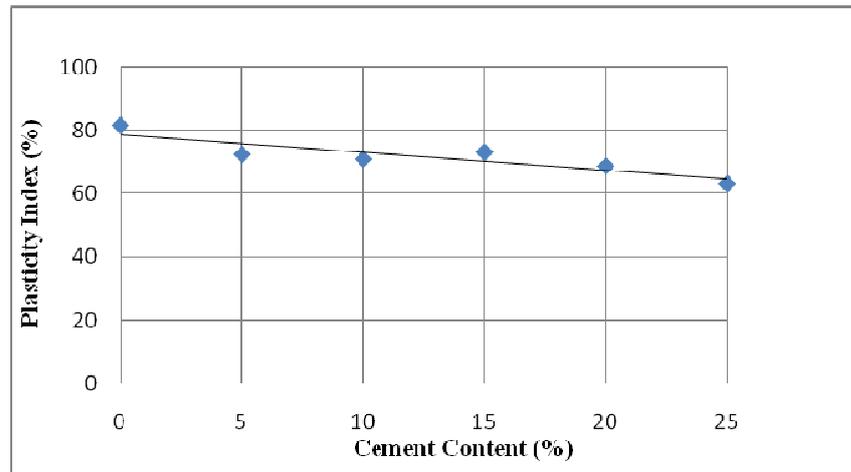

Figure 1: Relation between Plasticity Index and Cement Content

### 3.2 Soil cement

#### 3.2.1 California Bearing Ratio Tests

The relation between the Unsoaked and Soaked CBR value without Compaction Delay versus Cement Content can be seen in Figure 2. The Cement Content, Unsoaked and Soaked CBR value without Compaction Delay can be seen in Table 3. Using 10 percent cement stabilization of dry weight of soil, the Soaked CBR value increase from 13.23 % to 37.75 %. Based on the Standard National Indonesia (SNI), the minimum standard of Soaked CBR for sub-base layer is 35 %. The Soaked C.B.R. value of 10 percent cement content is met to SNI and therefore the treated soil cement may be used as sub-base layer. After preparing the soil samples, the Unsoaked and Soaked CBR tests were conducted on the compacted soil cement samples. The relation between the Unsoaked and Soaked CBR value of 10 percent cement content versus Compaction Delay/Curing Time can be seen in Figure 3 and 4 respectively. The value of Unsoaked and Soaked CBR and Compaction Delay/Curing Time, can be seen in Table 4.

Table 3: Cement Content, Unsoaked and Soaked CBR

No.	Cement content (%)	Unsoaked CBR (%)	Soaked CBR (%)
1.	0	39.57	13.23
2.	5	54.41	35.15
3.	10	46.86	37.75
4.	15	34.89	62.49
5.	20	50.77	97.89
6.	25	54.41	145.80

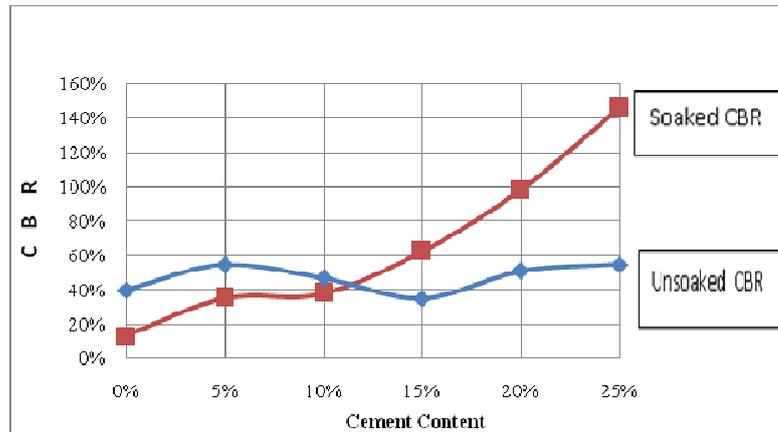

Figure 2: Relation between Unsoaked, Soaked CBR and Cement Content

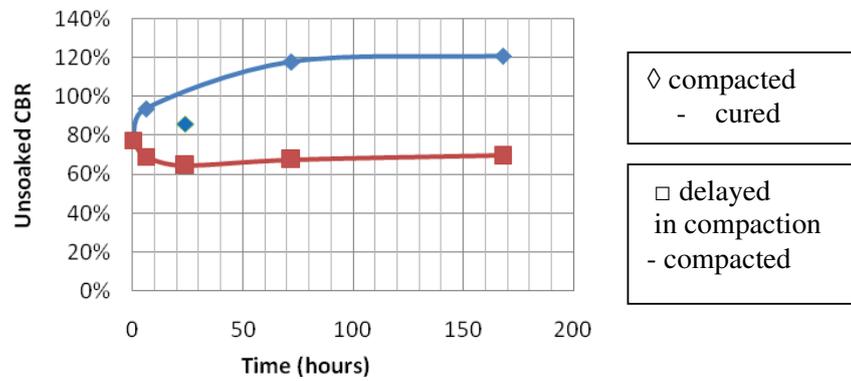

Figure 3: Relation between Unsoaked CBR of 10 percent cement and Compaction Delay/Curing Time

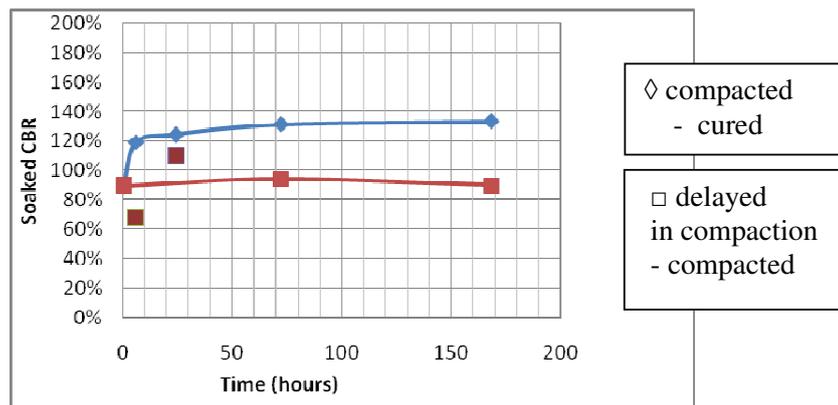

Figure 4: Relation between Soaked CBR of 10 percent cement and Compaction Delay/Curing Time

Table 4: Compaction Delay/Curing Time, Unsoaked and Soaked CBR of 10 percent cement

Sample Type	Compaction Delay /Curing Time	Unsoaked CBR (%)	Soaked CBR (%)

	( hours )		
(1) compacted	0	46.86	37.75
(2) compacted then cured	6	93.73	119.50
	24	85.92	124.19
	72	117.34	131.22
	168	121.07	133.17
(3) delayed in compaction then compacted	6	69.05	67.56
	24	64.44	104.51
	72	67.56	94.12
	168	69.51	89.92

### 3.2.2 Unconfined Compression Tests

The soil samples were prepared such as the requirement in test procedure. After this stage, the Unconfined Compression tests were carried out on the compacted soil cement samples of 10 percent cement content by using speed of 0.7 mm/minute until reached maximum of the unconfined compressive strength and reached axial strain of 6 %. The Unconfined Compressive Strength (UCS) value in unsoaked and soaked condition and Compaction Delay/Curing Time can be seen in Table 5. The Unconfined Compressive Strength value is range between 165 to 1301 kPa and the test results can be classified as low bound degree [6].

Table 5: Compaction Delay/Curing Time, Unconfined Compressive Strength on unsoaked and soaked condition of 10 percent cement

Sample Type	Compaction Delay /Curing Time ( hours )	unsoaked UCS ( psi )	unsoaked UCS ( kPa )	soaked UCS ( psi )	soaked UCS ( kPa )
(1) compacted	0	118.1	826.7	120	840
(2) compacted then cured	6	156.6	1096.2	49.6	347.2
	24 (1 day)	177.5	1242.5	109.6	767.2
	72 (3 days)	185.8	1300.6	116.5	815.5
	168 (7 days)	169.4	1185.6	89.82	624.4
(3) delayed in compaction then compacted	6	116.2	813.4	36.7	256.9
	24 (1 day)	106.4	744.8	36.7	256.7
	72 (3 days)	108.4	758.8	32.5	227.5
	168 (7 days)	111	777	23.7	165.9

## 4. CONCLUSION

- Using cement at a soil stabilization process can increase the soil strength quite significant. .
- Using cement stabilization with 10 per cent of dry weight of soil, the Soaked CBR value of Depok residual soil increase from 13.23 to 37.75 %.

- The soil cement sample was compacted and then cured is better than the soil cement sample was delayed in compaction and then compacted.
- The unconfined compressive strength value can be classified as low bound degree.

#### ACKNOWLEDGMENT

The authors would like to express the gratitude to the Soil Mechanics Laboratory and Civil Engineering Department, Faculty of Engineering, University of Indonesia for supporting this study.

## ABSTRACT

The study was conducted to explore the feasibility of using concrete sludge waste (CSW) and coconut fiber to manufacture paving blocks. The CSW were collected from a ready-mix concrete plant, while the coconut fibers were sourced from a coconut husk processing plant. The CSW was sun-dried for two days and only aggregates passing the No. 4 sieve were used to replace natural sand at replacement levels of 25%, 50% and 100% by weight with an aggregate/cement ratio of 1:3. The untreated coconut fibers were manually cut into a fiber length of 5 cm and were used in the paving block mix at proportions of 0%, 1%, 2% and 3% by weight of cement. The compressive strength, flexural strength, absorption and abrasion resistance of the resulting paving block specimens were tested to study whether or not the paving blocks has sufficient mechanical properties that allow them to have a quality classification grade under Indonesian national standards. The results of the study indicate that the paving blocks show sufficient compressive strength and abrasion properties to achieve a quality grade of A and B, respectively. However, the absorption level turned out to be the limiting constraint, where all of the paving block specimens resulted in an absorption level above the maximum allowable level under national standards.

### Keywords

paving block, concrete sludge waste, coconut fiber, fiber content, replacement level

## 1. INTRODUCTION

Construction wastes are increasing rapidly with the growth of the construction industry. Approximately 70% of these wastes are composed of concrete wastes [1]. One such waste originates from ready-mix concrete plants: Concrete Sludge Waste (CSW). One possible solution is to recycle CSW as a substitute for natural sand in the fabrication of paving blocks. Many studies have been carried out on the feasibility of using recycled fine aggregates as a replacement for natural sand and results regarding their strength properties have showed that they are suitable for low-strength concrete applications [2,3].

Cheap and locally available natural fibers, such as coconut fiber, can also be used for the fabrication of paving blocks. Extensive studies have been done that show that the use of coconut fibers helps improve the mechanical properties, such as compressive strength and durability, of concrete products [4,5,6]. Therefore, its use in the manufacture of paving blocks has the opportunity to increase the strength of the resulting mix and increase the block's grade classification.

According to SNI 03-0691-1996, paving blocks are building materials composed of a mixture of Portland cement or other hydraulic binders, water and aggregates with or without admixtures that do not reduce the quality of the paving block. Paving blocks shall have physical properties as seen in Table 1; where Grade A paving blocks can be used for roads, Grade B can be used for parking lots, Grade C can be used for pedestrian walkways and Grade D can be used for parks and other uses.

Table 1: Paving block grade-based physical properties requirements [7]

Grade	Compressive Strength (MPa)		Abrasion (mm/minute)		Av. Water Absorption (%)
	Mean	Min.	Mean	Min.	
A	40	35	0.090	0.103	3

B	20	17	0.130	0.149	6
C	15	12.5	0.160	0.184	8
D	10	8.5	0.219	0.251	10

The objective of this study is to explore the feasibility of using CSW and coconut fiber to manufacture paving blocks and whether the resulting paving blocks have sufficient compressive strength, absorption level and abrasion to allow them to have a quality classification grade under SNI 03-0691-1996. The flexural strengths and densities of the paving block specimens were also studied.

## 2. MATERIALS AND PRELIMINARY TESTS

### 2.1 Materials

CSW was retrieved from PT. Adhimix Indonesia's Ready-mix Concrete Plant in Lenteng Agung, Jakarta, Indonesia. The retrieved CSW were still in the form of sludge, or concrete slurry, and large chunks or lumps of semi-dried/hardened concrete. The CSW were transported out of the plant and were spread out on a non-absorbent surface and sun-dried for two days; reaching a moisture content slightly above a saturated surface dry condition. Some of the smaller lumps of concrete, that have not completely hardened, were crushed with a hammer during the first day of drying. The aggregates were then sieved, where only aggregates passing No. 4 sieve were used, and stored in non-absorbent bags until testing and fabrication of paving blocks.

The coconut fibers were retrieved from a coconut husk processing plant in Jl. H. Dimun No.2, Sukamaju, Depok. When retrieved, the fibers were already dried and processed (separated from the coconut's shell and outer skin). The fibers were then separated and cut up manually into lengths of  $5 \text{ cm} \pm 1 \text{ cm}$ . The fibers were untreated and stored in a styrofoam container until the fabrication of the paving blocks. Portland Composite Cement (PCC) was used and Jebrot Sand (a type of river sand found locally) was used as natural sand.

### 2.2 Tests on fine aggregates

Tests were performed to determine the properties of both the recycled and natural aggregates. These tests were performed in order to compare the properties of the recycled and natural aggregates; this in turn will aid the identification of the causes in the difference in the resulting paving block properties. All tests were performed on both CSW and natural sand. Only aggregates passing through sieve No. 4 were tested. The tests performed were: specific gravity and absorption (ASTM C128-12), bulk density (ASTM C29/29M-09), sieve analysis (ASTM C136-06), materials finer than No. 200 sieve (ASTM C177-04) and Organic Impurities (C40/C40M-1).

### 2.3 Trial-mix

Trial-mixes were performed in order to determine the cement-aggregate ratio that will be used for the paving block mix design. 50-mm cube specimens were used to evaluate the 7-day compressive strengths of mixes involving different cement-aggregate ratios (ASTM C109/C109M-11b). The cement-aggregate ratios that were tested are 1:3, 1:3.5, 1:4, 1:4.5 and 1:5. Only CSW were used as aggregates in the trial-mixes. The ratio that resulted in the highest average compressive strength was then used as the cement-aggregate ratio for the paving block mix proportions. Coconut fiber was not included in the trial mix. The amount of mixing water used during the trial mix was determined using the flow table test (ASTM C1437-07) as to produce a mortar flow of  $105 \pm 5 \%$ . The amount of mixing water is expressed as a weight percent of cement.

Table 2: Results of trial-mix

Cement-Aggregate ratio	Water/Cement	Av. Density (kg/m <sup>3</sup> )	Compressive Strength (MPa)		
			Min	Max	Average
1 : 3	0.75	1756	9.00	11.16	10.06
1 : 3.5	0.825	1759	8.88	10.17	9.53
1 : 4	0.85	1799	7.74	8.29	8.09
1 : 4.5	1.025	1757	6.13	6.72	6.38
1 : 5	1.075	1748	5.70	6.87	6.02

As it can be seen in Table 2, the water/cement ratio needed to maintain a flow value between 100%-110% increases as the proportion of CSW increases, which may be caused by the high absorption level of the CSW. It can also be seen in Table 2, the average compressive strength of the 50-mm cube specimens decreases as the proportion of CSW increases. This can be attributed to the increase in w/c with the increase in the proportion of CSW. The highest resulted from a cement-aggregate ratio of 1:3, corresponding to 7-day average compressive strength of 10.06 MPa. Therefore, a cement-aggregate ratio of 1:3 will be used as the cement-aggregate ratio for the paving block mix design.

### 3. EXPERIMENTAL METHOD

#### 3.1 Mix proportion

Table 3 shows the paving block mix proportions in order to manufacture 24 paving block for each paving block type. The mix proportion assumes that a 21 cm x 10.5 cm x 6 cm paving block has a mass of 3250 g and, as previously discussed, the mix uses a cement-aggregate ratio of 1:3.

Table 3: Paving block mix proportions

Paving Block Type	Cement (g)	CSW (g)	Natural sand (g)	Coconut fiber (g)	Water (mL)	Water/Cement
A-I	19,500	58,500	0	0	11,500	0.590
A-II	19,500	29,250	29,250	0	10,500	0.538
A-III	19,500	14,625	43,875	0	8,000	0.410
B-I	19,500	58,500	0	195	12,000	0.615
B-II	19,500	29,250	29,250	195	11,000	0.564
B-III	19,500	14,625	43,875	195	8,500	0.436
C-I	19,500	58,500	0	390	12,500	0.641
C-II	19,500	29,250	29,250	390	11,000	0.564
C-III	19,500	14,625	43,875	390	9,000	0.462
D-I	19,500	58,500	0	585	13,000	0.667
D-II	19,500	29,250	29,250	585	12,000	0.615
D-III	19,500	14,625	43,875	585	9,500	0.487

As it can be seen in Table 3, there are 12 different combinations of paving block specimens. The specimens have varying amounts of coconut fiber (0%, 1%, 2%, 3%) and varying mixtures of natural sand and CSW. The amount of coconut fiber used is expressed as a mass percent of cement and the rest of the mix design used in this study are also proportioned by mass. Therefore, a type D-III paving block has an aggregate content consisting of 25% CSW and 75% natural sand and a coconut fiber content of 3% of the mass of cement, while a type A-I paving block uses 100% CSW as its aggregate and no coconut fiber content. The amount of mixing water used in the paving block mix was determined during the fabrication of the paving block specimens. Since the fabrication of the paving block uses a machine that gives a combined vibrating and compacting action, the mixes were prepared with only sufficient water to produce a cohesive mix but with no slump/workability.

#### 3.2 Paving block fabrication

The paving block specimens were fabricated in a paving block plant located in Cileungsi, Bogor. All paving blocks in this study were fabricated using a machine capable of giving a compacting and vibrating action located at a paving block plant. The machine holds a mold that is able to produce 4 paving blocks at a time with dimensions of 21 cm x 10.5 cm x 6 cm.

Figure 2: Picture of machine and mold (left) and resulting paving block specimens (right)

The paving blocks were fabricated in batches based on combination type. First, the cement and aggregates were poured and mixed inside a mixer that is located on site. Sufficient water was then added until the mix has reached sufficient workability. For mixes containing coconut fiber, the fibers were added to the mix in small amounts along with small addition of water to maintain workability. The author found some difficulty maintaining a uniform mix for mixes with 2% and 3% fiber contents. The mix has the tendency accumulate to one side of the mixer, requiring manual mixing. There was also difficulty molding paving blocks with 3% fiber content, since the fiber has the tendency to get stuck in between the metal compactor.

After fabrication, the paving specimens were air cured for a day at the paving block plant, avoiding any direct contact with the sun. The blocks were then transported to the Department of Civil Engineering Universitas Indonesia where the specimens were moist cured (covered with moist fabrics) for 7 days and air cured then after until testing. Several tests required the specimen to be sawn. Any sawing was done on or after the specimens has reached a 28-day of age.

### 3.3 Paving block tests

The paving block compressive strength test is performed in accordance with SNI 03-0691-1996. Three types of specimens were used to perform this test for each paving block combination: eight whole paving block specimens, eight 6-cm sawn test cubes and three 4-cm sawn test cubes. Orientation of loading reflected orientation of loading of blocks when in use. The paving block absorption level test is performed in accordance with SNI 03-0691-1996. Five whole paving block specimens were used from each combination to perform this test.

The paving block abrasion test is performed in accordance with SNI 03-0691-1996 using calculations described in SNI 03-0028-1987 and following the procedures described in ASTM C944/C944M-99, using an abrasion process length of 6 minutes and an abrasion surface area of 49.48 cm<sup>2</sup>. The test uses a rotating cutter machine. Three whole paving block specimens were used from each combination to perform this test. These whole paving blocks were sawn in half, thus creating six test specimens. Leftover pieces from the abrasion test were cut into small cube specimens to be used to determine the density of the paving block specimens. The paving block flexural strength test is performed in accordance with ASTM C78/C78M-10, using third-point loading. Four whole paving block specimens were used from each combination to perform this test.

## 4. RESULTS AND DISCUSSION

### 4.1 Results

Table 4: Results of all paving block tests

Paving Block Type	Density (g/cm <sup>3</sup> )	Absorption level (%)	Abrasion (mm/minute)	Compressive Strength (MPa)			Flexural Strength (MPa)	
				Block	6-cm cube	4-cm cube	Crack	Failure
A-I	1.78	21.7	0.129	25.32	10.57	10.94	-	4.47
A-II	1.87	14.5	0.063	30.03	16.31	14.23	-	4.51

### 4.2 Absorption

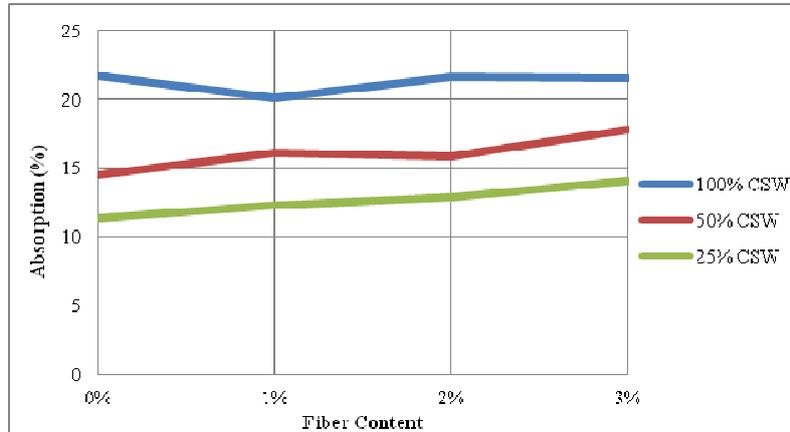

Figure 3: Absorption level vs. fiber content for different CSW replacement level

As it can be seen in Table 4 and Figure 3, there is an increasing trend in absorption level with an increase in fiber content for paving blocks with 25% and 50% CSW replacement level. However, this trend is very weak. Paving blocks with 100% CSW replacement level has a more horizontal trend compared to the other two. However, there is a slight decrease in absorption level from 0% to 1% fiber content for 100% replacement level. This may be caused by the difference in absorption levels between CSW and coconut fiber. It can also be seen that as the CSW replacement level increases, the paving block absorption level increases. However all paving block combinations resulted in absorption levels that are higher than the maximum allowed (10%), thus not enabling any of the resulting paving blocks to receive a quality grade under national standards.

### 4.3 Abrasion and density

As it can be seen in Table 4, there is generally a decreasing trend in density level with an increase in fiber content. This is specifically true for paving block with 50% CSW replacement level. However, the trend is slightly more ambiguous for paving blocks with 100% and 25% CSW replacement level. On the other hand, with closer inspection the difference in density values with increasing fiber content are smaller than  $0.05 \text{ g/cm}^3$ . Therefore, the introduction of coconut fiber into the mix has very little effect on the paving block's density. However, it can clearly be seen that as the CSW replacement level increases, the density decreases. The resulting difference in densities resulting from different replacement levels of CSW is comparatively larger than that resulting from different fiber contents.

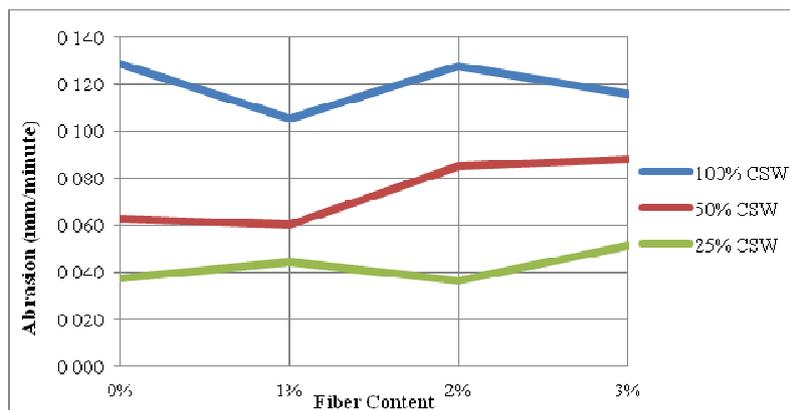

Figure 4: Abrasion vs. fiber content for different CSW replacement level

As it can be seen in Table 4 and Figure 4, it can clearly be seen that as the CSW replacement level increases the abrasion of the paving block increases. It can also be seen that there is no clear trend in abrasion with an increase in fiber content. However, any decrease or increase in abrasion with a change in fiber content (among paving blocks with the same CSW replacement level) is not big enough to change the quality classification of the paving block under national standards

#### 4.4 Flexural strength

When the flexural strength tests were done for Type C and D paving blocks, the author noticed two stages of failure for the specimens. The first is fracture in the tension face of the mortar and the second is complete failure, where the specimen broke into two halves. It seems the fibers embedded in the specimens prevented the specimen from breaking in two, even with significant mortar fracture. Therefore, the author decided to have two separate columns to distinguish these failures (as it can be seen in Table 4). These two stage failures were not observed for Type A blocks and the difference in loads for Type B blocks were too close which prevented the second stage to be detected.

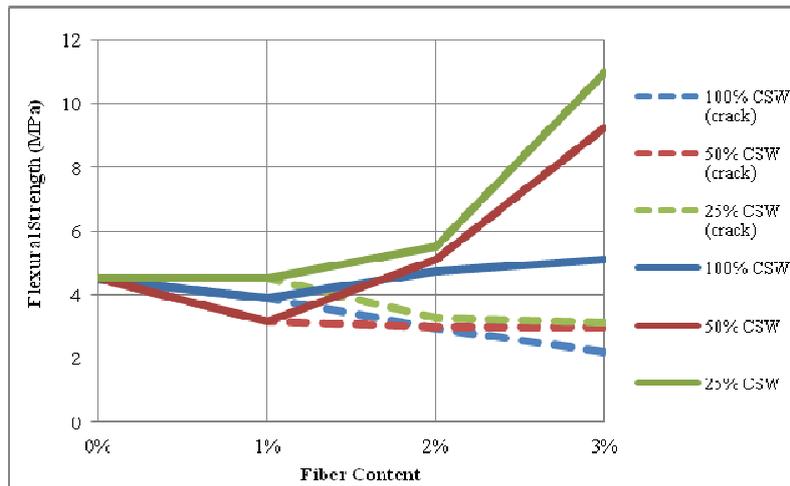

Figure 5: Flexural strength vs. fiber content for different CSW replacement level

As it can be seen in Figure 5, there is generally a decreasing trend in mortar failure for all CSW replacement level with increasing fiber content. This is caused by a decrease in mortar surface area that comes with an increase in fiber content. However, there is an increasing trend in flexural strength for block failure for 2% and 3% fiber contents. This increase is very substantial for both 50% and 25% CSW replacement level, compared to the lower increase involved with 100% CSW paving blocks.

#### 4.5 Compressive strength

As it can be seen in Table 4 and Figure 6, all CSW replacement levels show an increase and then decrease in compressive strength. However, the decrease in compressive strength for 50% and 100% replacement level occurred after 1% fiber content, whereas the decrease for 25% replacement level occurred after 2% fiber content. However, any decrease or increase in compressive strength with a change in fiber content is not big enough to change the quality classification of the paving block. All paving block combinations received a quality classification of B (based on compressive strength alone). A 25% CSW replacement level and 2% fiber content resulted in the highest paving block compressive strength.

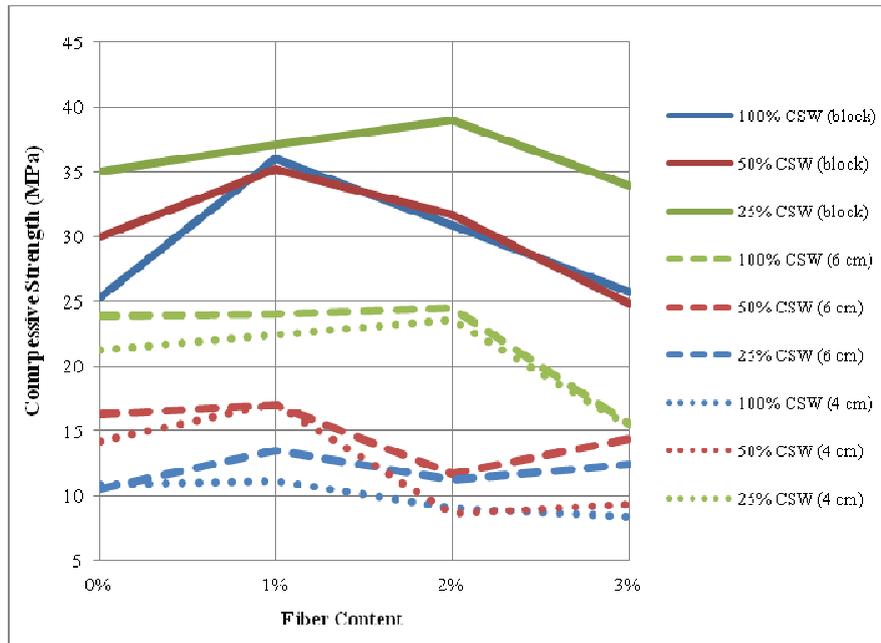

Figure 6: Compressive strength vs. fiber content for different CSW replacement level

For full block specimens, 25% CSW replacement levels show an increase and then decrease in compressive strength. This decreased occurred after 2% fiber content. The highest compressive strength for a 25% replacement level is at 2% fiber content. However, for 50% and 100% replacement level there is an increase after a decrease in compressive strength (for 2%-3% fiber content). The compressive strength for 2% and 3% fiber content is not lower than the compressive strength for 100% replacement level when there is no fiber present. However, The compressive strength for 2% and 3% fiber content is lower than the compressive strength for 50% replacement level when there is no fiber present.

There is a significant difference in the values and shape of the graphs for block specimens and 6-cm cube specimens. The difference in shape may be brought about by the difference in fiber behavior when the blocks are cut into smaller specimens. However, there is a significant difference in compressive strengths for specimens with 0% fiber content. Since the specimens do not contain any fiber, the effects of the presence of fiber cannot explain this difference. This may be brought about by a size factor or an effect brought about by the sawing process.

The compressive strength of 4-cm cube specimens has a similar shape to that of the 6-cm cube specimens. However, the 4-cm cube specimens have a slightly lower compressive strength than that of the 6-cm cube specimens. This confirms that the compressive strength (in terms of stress) of a specimen decreases with a decrease in specimen dimensions. This may imply that specimens with smaller dimensions are subjected to more disturbances due to sawing.

## 5. CONCLUSION

Based on the results of this study, the following conclusions can be drawn:

- The addition of coconut fiber to a paving block mix resulted in no clear trend to the paving block's abrasion resistance. However, any decrease or increase in abrasion with a change in fiber content (up to 3%) is not big enough to change the quality classification of the paving block under national standards. The resulting abrasion values were able to achieve a quality grade of A under national standards.
- The addition of coconut fiber to a paving block mix resulted in, generally, an increase to the paving block's absorption level.
- All paving block combinations resulted in absorption levels that are higher than the maximum allowed (10%), thus not enabling any of the resulting paving blocks studied to receive a quality grade under national standards. However, the resulting paving blocks may still be used in places that are exposed to no rain.
- A 2% and 3% fiber content resulted in paving blocks with high ductility (in terms of flexural strength and behavior).
- The density of the paving block decreases as the amount of CSW used increases.

- Paving block specimens with 25% CSW replacement level resulted in the best abrasion, absorption and compressive strength properties (as compared to specimens with 50% and 100% CSW replacement level) for all tested fiber contents.
- Paving block specimens with 25% replacement CSW replacement level and 2% fiber content resulted in the highest compressive strength (for all dimensions), which corresponds to a quality grade of B under national standards.

The author recommends to further study the mechanical behavior of paving blocks using CSW and coconut fibers using fiber lengths less than 5 cm (i.e. 2.5 cm), a cement:aggregate ratio of 1:3.5, fiber contents in the range of 1% to 2% by weight of cement and using paving blocks with height of 8 cm and 10 cm, in order to see the occurrence of a size factor. The author also recommends the finding of another added material that will lower the absorption level of paving blocks using CSW and coconut fibers.

# Estimation of Land Development Induced Subsidence in Northern Jakarta Areas

Widjojo A. Prakoso<sup>a</sup>

<sup>a</sup>Civil Engineering Department, Universitas Indonesia, Depok 16424  
 E-mail : wprakoso@eng.ui.ac.id

## ABSTRACT

Land subsidence has been identified as one of major geological hazards of Jakarta, and some areas in northern Jakarta are of great concern (subsidence maximum value and rate: 0.8 m and 0.28 m/year, respectively). The hypothesis of this paper is that the subsidence is primarily due to the compression of the normally consolidated, very soft to soft silt-clay deposits induced by the land development of the areas. Some recent geotechnical data from west Ancol to Kamal were compiled, and soil parameters along with their statistical properties were evaluated. The estimation of land subsidence is performed using the Terzaghi's 1-D consolidation theory and the secondary compression theory, coupled with the Monte Carlo approach. Ranges of estimated values, as well as their relevant statistical properties, were identified. The simulation results (final settlement: 1.6 m  $\pm$  0.7 m, subsidence rate: 0.22  $\pm$  0.16 m/year) were in the same range of field geodetical measurements confirming the paper hypothesis.

**Keywords:** compressibility, consolidation, time dependence, land subsidence, statistical analysis

## 1. INTRODUCTION

Land subsidence has been identified as one of major geological hazards of Jakarta. Geodetical measurements (MUBA, MUTI, and PIKA, see Figure 1) indicate that some areas in northern Jakarta are of great concern (e.g., [1]). The GPS-derived maximum subsidence between December 1997 and September 2007 is 0.8 – 0.9 m for MUTI and 0.3 – 0.4 m for PIKA, and the subsidence rates for the three stations are given in Table 1. These rates have been also observed using other satellite-based data and interpretation techniques (e.g., [2-4]). Natural consolidation, groundwater extraction, and land development related loads are identified as the major causing factors of the subsidence. In this paper, it is hypothesized that the subsidence is primarily due to the compression of the normally consolidated, very soft to soft silt-clay deposits induced by the land development of the areas. To confirm this hypothesis, the land development induced subsidence is estimated and subsequently compared to the measured subsidence. The focus areas are from west Ancol area in the east to Kamal area in the west which have relatively thick very soft to soft clay-silt soil deposits. It is noted that near surface groundwater extraction of the areas is assumed to be insignificant because the groundwater is brackish.

Table 1: Subsidence rate for GPS stations MUBA, MUTI, and PIKA (Source: [1])

Period	Subsidence Rate (m/year)		
	MUBA	MUTI	PIKA
2007-2008	0.28	0.15	0.18
2008-2009	0.14	0.10	0.11
2009-2010	0.15	0.08	0.07

Figure 1: Locations of GPS stations and geotechnical data

## 2. ESTIMATION METHOD

The estimation method consists of three subsequent steps. The first step is to compile and analyze the recent field and laboratory geotechnical data available from the area. The normally consolidated, very soft to soft silt-clay deposits are to be identified based on their N-SPT values; Kulhawy and Mayne [5] indicate that this type of deposits typically have N-SPT less than 4 blows/0.3m. The second step is to perform the estimation analysis using the Terzaghi's 1-D consolidation theory and the secondary compression theory described in [6]. The consolidation settlement is estimated by the following:

$$s_{\text{consol}} = CR \cdot H_{\text{soft}} \cdot \log \left( \sigma'_{\text{final}} / \sigma'_{\text{initial}} \right) \quad (1a)$$

$$\sigma'_{\text{initial}} = (\gamma_{\text{soft}} - \gamma_{\text{water}}) \cdot (H_{\text{soft}} / 2) \quad (1b)$$

$$\sigma'_{\text{final}} = \sigma'_{\text{initial}} + \gamma_{\text{fill}} \cdot H_{\text{fill}} \quad (1c)$$

in which CR = compression ratio,  $H_{\text{soft}}$  = thickness of very soft to soft soil layer,  $\gamma_{\text{soft}}$  = saturated unit weight of very soft to soft soil layer,  $\gamma_{\text{water}}$  = water unit weight,  $\gamma_{\text{fill}}$  = unit weight of fill materials, and  $H_{\text{fill}}$  = fill thickness. The time required to reach a certain consolidation time is estimated by the following:

$$t = T_v \cdot (H_{\text{soft}} / 2)^2 / c_v \quad (2)$$

in which  $T_v$  = theoretical time factor and  $c_v$  = coefficient of consolidation. The theoretical relationship between the degree of consolidation  $U$  and the time factor  $T_v$  proposed by Terzaghi [6] is adopted. The settlement due to the secondary compression at time  $t$  is estimated by the following:

$$s_{\text{secondary}} = C_{\alpha\epsilon} \cdot H_{\text{soft}} \cdot \log \left( t / t_p \right) \quad (3)$$

in which  $C_{\alpha\epsilon}$  = coefficient of secondary compression and  $t_p$  = time for completion of consolidation. The last step is to calculate the subsidence rate which is given by the following:

$$\text{Subsidence Rate} = [s_{\text{consol}}(t_2) - s_{\text{consol}}(t_1)] / (t_2 - t_1) \quad (4a)$$

$$\text{Subsidence Rate} = [s_{\text{secondary}}(t_2) - s_{\text{secondary}}(t_1)] / (t_2 - t_1) \quad (4b)$$

in which  $t_1$  and  $t_2$  = earlier time and latter time, respectively. It is noted that three implicit assumptions were made in the above equations for simplicity. First, as indicated by Equation 1b, the groundwater table is assumed to be at the ground surface level, and this assumption is reasonable for the northern Jakarta areas. Second, as indicated by Equation 1c, the land development induced load is due to placement of the fill layer only; building and surcharge loads are not considered because pile foundations are typically used to support those loads in the northern Jakarta areas. Third, as indicated by Equation 2, that only vertical consolidation drainage is considered, and the effect of prefabricated vertical drains is to be considered indirectly in the analysis.

As shown in Figure 1, the considered areas are vast and therefore it is expected that the actual soil conditions would vary. To consider this variation, the probabilistic approach is adopted and combined with the above equations; all soil parameters are to be considered as probabilistic variables, and the probabilistic approach to be employed is the Monte Carlo simulation approach.

## 3. GEOTECHNICAL DATA

The surface geology of the area is alluvial deposits, consisting of mangrove swamp deposits and nearshore marine deposits [7]. The geotechnical data for Sites 1 to 3 were collected from the library of Soil Mechanics Laboratory of Universitas Indonesia and author's file. The soil boring and N-SPT logs of all sites are shown in Figure 2, and the very soft to soft silt-clay deposits are identified as well in the logs. For each soil boring, the soil layer above the very soft to soft silt-clay deposit is assumed to be the fill layer. The thickness variation of the very soft to soft silt-clay  $H_{\text{soft}}$  and the fill layer  $H_{\text{fill}}$  is shown in Figure 3. The unit weight of both soil layers is given in Table 2. The compression ratio CR and the coefficient of consolidation  $c_v$  of the very

#### 4. ANALYSIS AND RESULTS

The analysis was conducted using the equations given above, and all seven parameters were treated as probabilistic variables. Based on the observed data distribution shown in Figures 3 to 5, the probabilistic properties of the soil parameters given in Table 3 were determined. The uniform distribution was used for two soil parameters, while the normal distribution was used for the remaining five soil parameters. As the Monte Carlo simulation approach was adopted, 1,000 random numbers were used for each variable, and the analysis was performed using MS-Excel<sup>TM</sup>. Random numbers generated were between 0 and 1, and they were transformed to their respective soil parameters using a linear relationship for soil parameters having uniform distribution and using the NORMINV function of MS-Excel<sup>TM</sup> for soil parameters having normal distribution.

The probability density function of final consolidation settlement  $s_{consol}$  is shown in Figure 6. The mean and standard deviation are about 1.6 m and 0.7 m, respectively. The mean and standard deviation of consolidation settlement from 56 to 96 percent degree of consolidation (or on average from year 1 to year 5 after fill placement) are about 0.65 m and 0.28 m, respectively. The validity of the estimation approach was checked by comparing final settlement  $s_{consol}$  to fill layer thickness  $H_{fill}$ , and it is found that the condition of  $s_{consol} < H_{fill}$  indicating relatively dry ground surface after consolidation is observed in about 96 percent of simulation results. The simulation results are in the same order of magnitude as the range of observed subsidence of from 0.3 – 0.4 m for PIKA up to 0.8 – 0.9 m for MUTI.

The probability density function of subsidence rate from year 1 to year 5 after fill placement (from 56 to 96 percent degree of consolidation) is shown in Figure 6. The rate varies from less than 0.05 m/year to about 1.0 m/year, but about 88 percent of the simulation results indicates a rate less than 0.4 m/year. The mean and standard deviation are 0.22 m/year and 0.16 m/year, respectively. The simulation results are in the same range as the observed subsidence rates for the three GPS stations ranging from 0.07 to 0.28 m/year [1] and the rates observed by other techniques [2-4]. It is argued that the results imply that the observed subsidence would be predominantly due to the land development of the area.

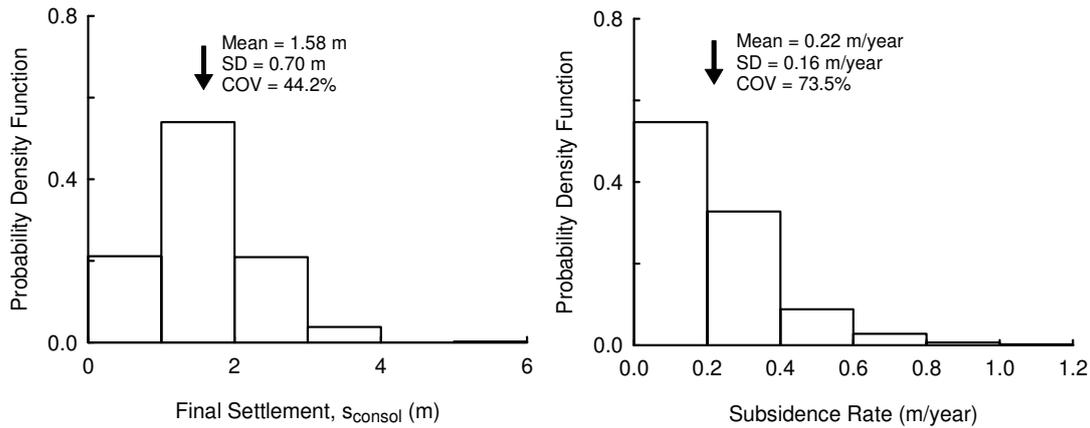

Figure 6: Probability density function of final settlement and subsidence rate for period between years 1 and 5

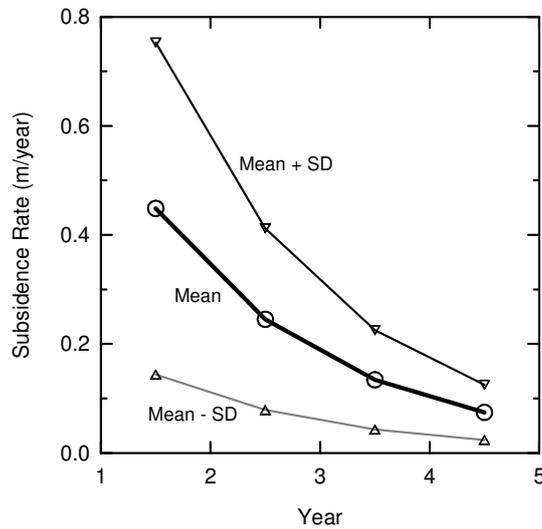

Figure 7: Subsidence rate for different periods

The observed subsidence rate tends to decrease with time, and additional analyses were conducted to evaluate this trend. Subsidence rates for the period between year 1 and 2 (from 56 to 76 percent degree of consolidation) through the period between year 4 and 5 (from 93 to 96 percent degree of consolidation) were individually analyzed. As shown in Figure 7, the general trend is that the subsidence rate decreases with time; for the period between year 1 and 2, the mean and standard deviation are 0.45 m/year and 0.30 m/year respectively and, between year 4 and 5, the mean and standard deviation are 0.07 m/year and 0.05 m/year, respectively. It is postulated that the period between year 1 and 2 after fill placement would likely be the construction period, and that the estimated subsidence rate would not be observed as the ground surface level might be adjusted during construction. However, the subsequent values of subsidence rate of 0.25 m/year to 0.07 m/year are in the same range as the observed subsidence rates of 0.07 to 0.28 m/year. These results would support the argument that the observed subsidence would be predominantly due to the land development of the area.

In addition, prefabricated vertical drains were used to accelerate the consolidation of the very soft to soft soil layers in many land development projects in northern Jakarta. The 90 percent degree of consolidation would be typically achieved in less than 6 months. This condition is equivalent to the period between year 3 and 4 which has the subsidence rate mean and standard deviation values of 0.13 m/year and 0.09 m/year, respectively.

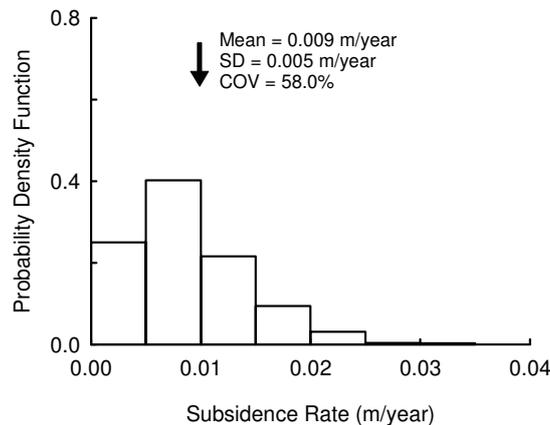

Figure 8: Probability density function of long term settlement rate

The long term subsidence rate was estimated assuming that the secondary compression theory applies and no additional loads are imposed. The probability density function for such condition in the period of between year 5 and 20 is shown in Figure 8. The mean and standard deviation are about 0.01 m/year and 0.005 m/year, respectively. The probability of subsidence rate of greater than 0.02 m/year is only less than 5 percent. These simulation results suggest that some degree of land subsidence would still be observed although the land development has finished for a period of time.

## 7. CONCLUSION

Land subsidence has been identified as one of major geological hazards of Jakarta, and the subsidence maximum value and rate observed in the area between west Ancol and Kamal, North Jakarta vary up to 0.8 m and 0.28 m/year, respectively. The hypothesis of this paper was that the subsidence is predominantly due to the compression of the normally consolidated, very soft to soft silt-clay deposits induced by the land development of the areas. Recent geotechnical data from three sites in the area were compiled, and field and laboratory soil parameters including their statistical properties were evaluated. The estimation of land subsidence was performed using the classic Terzaghi's 1-D consolidation and secondary compression theories, coupled with the Monte Carlo approach to consider the soil parameter variabilities. The statistical properties of all seven soil parameters used in the simulations were determined based on the compiled geotechnical data. Ranges of estimated values, as well as their relevant statistical properties, were presented. The final settlement mean and standard deviation values were 1.6 m and 0.7 m, respectively, while the subsidence rate mean and standard deviation values for a period between year 1 and 5 were 0.22 m/year and 0.16 m/year, respectively. In addition, it is suggested that some degree of land subsidence (< 0.02 m/year) would still be observed long after the completion of the land development. The simulation results were in the same range of field geotechnical measurements supporting the hypothesis of this paper.

### ABSTRACT

Liquefaction phenomenon could be analysed using strain-controlled loading method where informations about sands pore water pressure build-up were presented. Maintaining small deformation values whenever the soil is subjected to cyclic loading, this non-destructive method presents clearly the information about the increasing sands pore water pressure. It is concluded that liquefaction occurs whenever the pore water pressure reaches the same value with the soil effective stress ( $\sigma_3'$ ). Strain-controlled loading method introduces a fundamental parameter for undrained cyclic loading tests on fully saturated sands: shear strain treshold ( $\gamma_t$ ). This parameter divides the pore water pressure into two distinct zones, namely the constant pore water pressure and the increasing one. When cyclic shear strain amplitude ( $\gamma_c$ ) was set up lower than  $\gamma_t$  then pore water pressure remained constant. Contrastly, if specimen was subjected  $\gamma_c$  larger than  $\gamma_t$ , it obtained the increasing of pore water pressure. During the test, when Yogyakarta's sands as a material tested was performed in variation of relative density ( $D_r$ ) 25 %, 60 % and 80%, thereafter was applied an effective cell pressure  $\sigma_3' = 100$  kPa and frequency ( $f$ ) applied were 0.05 Hz and 0.1 Hz, shows it obtained  $\gamma_t = 1.5 \cdot 10^{-2}$  %. Whilst other test using  $D_r = 60\%$  and  $f = 0.1$  Hz confirmed that  $\gamma_t = 1.5 \cdot 10^{-2}$  % ( $50 \leq \sigma_3' \text{ (kPa)} \leq 100$ ) and  $\gamma_t = 5 \cdot 10^{-2}$  % ( $\sigma_3' = 200$  kPa). Last test using  $D_r = 60\%$  and  $f = 0.05$  Hz revealed  $\gamma_t = 1.2 \cdot 10^{-2}$  % ( $50 \leq \sigma_3' \text{ (kPa)} \leq 100$ ) and  $\gamma_t = 2 \cdot 10^{-2}$  % ( $\sigma_3' = 200$  kPa).

Threshold shear strain, dynamic loading, liquefaction, pore water pressure, sands

### 1. INTRODUCTION AND OBJECTIVES

There are a lot of research were done to analyze the liquefaction behaviour toward soil mass. Some methods which are usually used are cyclic shear-strain controlled, cyclic shear-stress controlled, and strain energy concept. Cyclic strain controlled testing is considered as a method which can describe the real condition of the soil. This method can predict the liquefaction occurrence based on the soil information about the behaviour of the pore water pressure. One of the key parameters in this method is the determination of threshold shear strain ( $\gamma_t$ ) because it can provide the information about the minimum value of cyclic shear strain which can cause the increasing of pore water pressure when cyclic loading is applied on fully saturated soils. The basic concept of cyclic shear strain method is by maintaining the soil's small deformation when it subjected the cyclic loading. Small deformation analysis which is caused by cyclic loading in the daily life can be represented as the effect of earthquake loading, pile driving vibration, traffic loading, ocean wave storm, machine foundation vibration, and other cyclic loading sources.

Table 1. Summarizes of some research of  $\gamma_t$  on some types of soils.

Study conducted by	Soil type	Plasticity Index, PI (%)	Cyclic threshold shear strain range, $\gamma_t$ (%)	Testing method
Ladd et al., 1989	Clean sand	NP	0.011	Undrained cyclic triaxial
Hsu et al., 2006	Cohesive soil	14 - 30	0.024 - 0.06	Direct simple shear
Uchida et al., 2001	Toyoura sand	NP	-	Undrained monotonic triaxial

Many researchers have tried to study the value of  $\gamma_t$  of different types of soil both to the clean sand and cohesive soils (Ladd et al., 1989; Hsu et al., 2006; Uchida et al., 2001). Based on the literature review study, the value of  $\gamma_t$  of the cohesive soil is higher than the clean sand. Hsu (2006) in his publication states that the value of  $\gamma_t$  on the cohesive soil was influenced by soil plasticity index (PI). Table 1 above summarizes the result of some research about the value of  $\gamma_t$  on some types of soils.

## 2. SOIL TESTED

The soil sample was collected from University of Muhammadiyah Yogyakarta's area and some of soil laboratory tests were conducted to identify the initial conditions of the soil sample. The results of the tests are as follows:

Table 2. Initial condition of Yogyakarta's sand.

No	Variables	Unit	Test Results
1	Water contents ( $w$ )	%	22.3
2	Density relatives ( $D_r$ )	%	64
3	Specific gravity ( $G_s$ )	-	2.66
4	Void ratio ( $e$ )	-	0.59
5	Dry density ( $\gamma_d$ )	gr/cm <sup>3</sup>	1,67
6	Wet density ( $\gamma_b$ )	gr/cm <sup>3</sup>	1,92

To get a more detail understanding about the physical soil characteristic, some advanced soil laboratory tests were taken. Visually, the soils used were assumed as granular soils with grain size distributions as shown in Figure 1. From that figure, it can be seen that the soils were categorized in a range which were potential for occurrence liquefaction. Further, according to *USCS* standard, the soils were classified as medium sands.

Table 3. Physical characteristics of soil sample.

No	Variables	Units	Test results
1.	Maximum void ratio ( $e_{max}$ )	-	0.810
2.	Minimum void ratio ( $e_{min}$ )	-	0.48
3.	Maximum dry density ( $\gamma_{dmax}$ )	gr/cm <sup>3</sup>	1.8
4.	Minimum dry density ( $\gamma_{dmin}$ )	gr/cm <sup>3</sup>	1.47
5.	Maximum wet density ( $\gamma_{bmax}$ )	gr/cm <sup>3</sup>	2.13
6.	Minimum wet density ( $\gamma_{bmin}$ )	gr/cm <sup>3</sup>	1.47
7.	Coefficient of uniformity ( $C_u$ )	-	4.34
8.	Coefficient of gradation ( $C_c$ )	-	1.14
9.	Atterberg limit	-	Non plastic
10.	Soil classification ( <i>USCS</i> )	-	SW

## 3. EXPERIMENTAL PROGRAM

Saturated specimens of Yogyakarta's sand were performed in 56 undrained strain-controlled cyclic triaxial tests to determine the pore water pressure build-up behaviour of sand. Variation of confining pressure ( $\sigma'_3$ ), density relative ( $D_r$ ) and frequency ( $f$ ) were applied to the specimen as a parameter which affected the behaviour of pore pressure build up. The shear strain threshold is the key parameter in shear strain controlled method which could determine the applied loading during the testing by using triaxial machine. The experimental program was formulated step by step by gradually increasing the value of cyclic shear strain amplitude ( $\gamma_c$ ). Some important parameters which will be researched are threshold shear strain ( $\gamma_t$ ), modulus degradation ( $G/G_1$ ) over a number of cycles ( $N$ ).

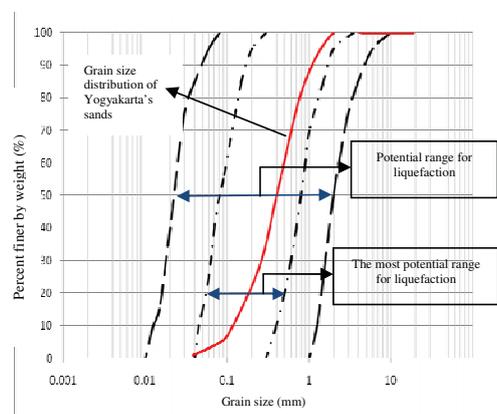

Figure 1: Result of the distribution grain test analysis of Yogyakarta's sand.

## 4. TESTING TECHNIQUE

This research was conducted by using cyclic triaxial apparatus which was equipped with a set of controller, consisted of controller axial load, a controller confining pressure, and a controller of backpressure. A remoulded sample was chosen to facilitate the preparation of the test specimen before the test was started.

### 2.1. Sample Preparation

This paragraph explains about the details of sample preparation. Some important points considered in the sample preparation are explained as follows:

1. The method of the sample preparation was dry pluviation by placing the mold soil sample of 50 mm internal diameter and 100 mm height by enclosing a rubber membrane which was then attached on the porous stone in the triaxial cell base. Water and sand were prepared adjusted to the value of  $D_r = 25\%$ ,  $60\%$ , and  $80\%$ . Then, the dry soil which already prepared was dropped into the mold through the air. During this process, the soil will absorb the water slowly. After the specimen has been prepared, then it was transferred to the triaxial cell. Before it was starting the next process, the triaxial cell must be fully fulfilled using de-aired and de-mineralized water.

2. Then, the specimens were isotropically consolidated which aim to uniform the pore pressure inside the specimen. This process was done for one night in triaxial cell by applying the cell pressure 50 kPa, 100 kPa, and 200 kPa. This stage was considered done if the volume change of specimen remained constant. The next stage was saturation process.

3. During the saturation process was applied, the back pressure and cell pressure gradually increased until reached the Skempton value greater than 0.95. Skempton value is the parameter which is proposed to ensure the sample used in the research is in the fully saturated condition.

### 2.2. Determination of the threshold shear strain ( $\gamma_t$ )

The value of threshold shear strain ( $\gamma_t$ ) is determined using the method introduced by Ladd et al. (1989) with undrained cycling testing stages as follows:

#### 1). Measurement using Very Small Strain

In this stage, a very small strain  $10^{-3} - 10^{-2}\%$  was used to identify the value of residual pore water pressure. Cyclic loading was applied 10 times then it was stopped. The measurement result obtained in this stage was  $\Delta u_r = 0$ . Thus, it can be said that the measurement in this stage was a non destructive one.

#### 2). Measurement of $\gamma_t$

In this stage, the value of  $\Delta u_r$  during and after the measurement was recorded. The number of the cyclic loading applied was in the same value as it was applied in the previous stage, but with a higher value of  $\gamma_c$  around  $1.10^{-2}\% < \gamma_c < 2.10^{-2}\%$ . It showed that the value of  $\Delta u_r$  increased although in a small value.

#### 3). Measurement of $\gamma_c > \gamma_t$

The value of cyclic shear strain amplitude applied in this stage was higher than stage 2. The number of the cyclic loading was done 100 cycles or the test was stopped when the soil meet the initial liquefaction. It revealed that the value of  $\Delta u_r$  increased significantly at this stage.

## 5. DATA INTERPRETATION

### 5.1. Threshold cyclic shear strain

Deleted:

Figure 2 shows the result of the research on Yogyakarta's sand which applying the effective confining stress ( $\sigma'_3$ ) = 100 kPa on the sample with different relative density 25%, 60% and 80% respectively. The difference between the two figures is the frequency ( $f$ ) of loading applied, which were 0.1 Hz (a) and 0.05 Hz (b). For those two frequencies, it shows that the increasing of the pore water pressure takes place when the threshold cyclic shear strain ( $\gamma_t$ ) reaches  $1.5 \cdot 10^{-2}$  %. The value of the relative density does not influenced the value of  $\gamma_t$  if the value of  $\sigma'_3$  applied was in the same value. From both figures, it can be obtained an information that if  $\gamma_c > \gamma_t$  was applied for every value of relative density, it can be reached a different residual pore pressure ratio value. Comparison between two condition of soil, soil on the loose state, the value of  $\gamma_c$  slightly greater than  $\gamma_t$ , and the residual pore water pressure will increase more significantly than dense soil.

Figure 3 provides the information about  $\gamma_t$  of Yogyakarta's sands in the condition  $D_r = 60\%$  and  $f = 0.1$  Hz and 0.05 Hz. The value of  $\Delta u_r$  was recorded on the different variation of  $\sigma'_3$ . This figure shows that  $\gamma_t$  has the same value around  $50 < \sigma'_3 < 100$  kPa. However, when the value of  $\sigma'_3 = 200$  kPa was applied, and then the value of  $\gamma_t$  will be higher. It can be assumed that by applying a higher confining stress, the soil strength to resist the shear stress will be higher. Thus, the cyclic shear straining amplitude needed is higher. The smaller the frequency of loading applied, and then the value of  $\Delta u_r$  also will be smaller. Thus, it can be said that if the frequency is smaller, there will be a lag time for soil for to neutralize the pore water pressure there will be no build up of pore water pressure.

### 5.2. Shear Modulus ( $G$ )

Shear Modulus is the parameter which represents soil resistance toward the shear stress applied to it. Figure 4 shows the relation between  $G$  and  $\gamma$  with  $D_r = 60\%$  and first loading cycle ( $N = 1$  cycle) and the  $\sigma'_3$  is applied in a different value of 50 kPa, 100 kPa and 200 kPa respectively. It shows there is a correlation between  $\sigma'_3$  and  $G$ . The level of  $\sigma'_3$  applied affect to soil resistance which is described by parameter  $G$ . More higher  $\sigma'_3$  applied, it means that the cyclic shear strain amplitude needed by the soil to meet the initial liquefaction will also be higher.

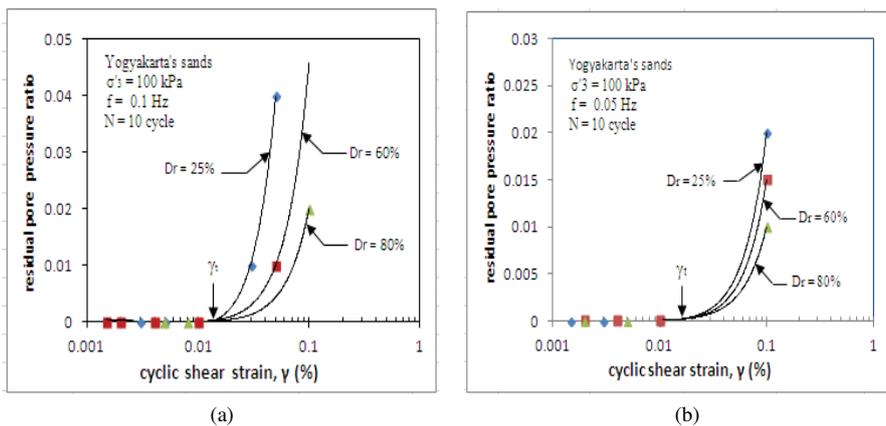

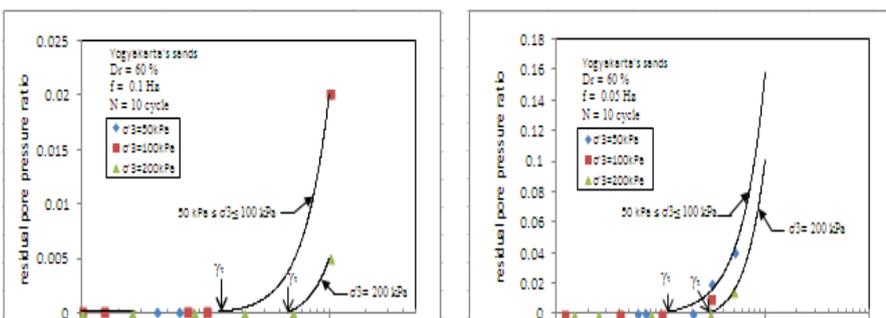

Figure 2:  $\gamma_t$  of Yogyakarta's sand for various density and frequency

## 6. CONCLUSION

The value of cyclic shear strain  $\gamma_t$  is the fundamental parameter because it can be used to find out the limit of the shear strain amplitude  $\gamma_c$  which is applied during the testing. Thus, it can be used to know the increasing of excess pore water pressure. If  $\gamma_c < \gamma_t$  is applied, then the pore water pressure will not be increased, but if the  $\gamma > \gamma_t$  is applied then the pore water pressure will be gradually increased.

From a set of research done to find out the value of threshold cyclic strain  $\gamma_t$  on Yogyakarta's sand, it results that the sands with cyclic frequency of loading ( $f$ ) were 0.05 and 0.1 Hz and  $\sigma_3' = 100$  kPa were obtained  $\gamma_t = 1.5 \cdot 10^{-2} \%$  for  $D_r = 25 - 80\%$ . For the sands  $\sigma_3' = 50 - 100$  kPa with  $D_r = 60\%$ ,  $f = 0.1$  Hz were obtained  $\gamma_t = 1.5 \cdot 10^{-2} \%$ , while for  $\sigma_3' = 200$  kPa was obtained  $\gamma_t = 0.05 \%$ . Moreover, for  $f = 0.05$  Hz shows  $\gamma_t = 1.2 \cdot 10^{-2} \%$  ( $50 \leq \sigma_3' \text{ (kPa)} \leq 100$ ) and  $\gamma_t = 2 \cdot 10^{-2} \%$  ( $\sigma_3' = 200$  kPa).

## 7. ACKNOWLEDGMENT

The writer would like to thank the Laboratory Soil Mechanics of Ecole Polytechnique Federale de Lausanne, Switzerland for giving the permission using the equipment for the cyclic triaxial cell test.

## ABSTRACT

*A simple method is developed in this paper to evaluate rainfall induces slope instability. The method dealt with one dimensional infiltration on the shallow slope. The study was focused on the study of the effect of rainfall pattern, duration, soils type and slope angle on the stability of slope. Two soil types, those were low and high permeability, and slope angle were selected to examine the proposed model. The results of the study show that the proposed model was simple model and suitable to assess rainfall induced slope instability especially shallow landslides type. The proposed model enable to estimate the infiltration and slope stability during the rainfall as the FEM results was more conservative. Infiltration was strongly affected by rainfall pattern, inclination of slope and the hydraulic properties of soil.*

**Keywords:** rainfall, infiltration, slope failure, seepage

## 1. INTRODUCTION

The climate change has been the worldwide issues including the extreme rainfall. This rainfall triggered many slopes and caused catastrophic disaster in many places in the world. Rainfall infiltration induced landslides are traditionally analyzed by using the two-dimensional limit equilibration numerical analysis. Attempts have been made to analyze the rainfall induces landslides by using coupling analysis of seepage and slope stability analysis. The common model to evaluate slope stability during rainfall was incorporated transient pore water pressure during the infiltration Modeling the infiltration and pore water pressure during rainfall was a complex analysis. Several investigators applied numerical modeling such as finite element method (FEM) to assess rainfall induces landslides [1-3]. However, the results of FEM were affected by several factors and much effort were required for performing calculation [5]. For practical purpose, a simple method is required as a rapid tool to assess the slope stability triggering by rainfall. Physically-based models coupling the infinite slope stability analysis with Green-Ampt infiltration modeling was developed in this research. Some investigators [6-8] have verified that the Green-Ampt equation could generate results, which were in good agreement with rigorous models such as Richard's equation. Hence, premier researches have been carried out on the shallow landslides analysis under steady and unsteady infiltration by applying the Green-Ampt equations [9-12]. In this paper, the effect of rainfall intensity and duration (rainfall pattern) on shallow landslides was investigated using the developed model. The study was focused on the study of the effect of rainfall pattern, soils type and slope angle on the stability of slope.

## 2. METHOD AND MODEL DEVELOPMENT

The method improved the previous model of Muntohar and Liao [11]. The improvement of analysis was made for calculation the pore water pressure (Part B) and slope stability analysis (Part C). The theoretical and derivation of the model has been clearly described in Muntohar and Liao [11,12]. The algorithm of the proposed model is presented in Figure 1. Principally the proposed model was based on the Green-Ampt infiltration model. The model was assumed one dimensional water flow through the slope. The slope stability analysis was modeled as infinite slope. In this study, the proposed model was then verified by using available numerical coupling model of SEEP/W and SLOPE/W [13-14]. The modeling of slope and boundary conditions are shown in Figure 2 for verification using two-dimensional finite element method. Three synthetic rainfall distributions including delayed, centralized, and advanced were selected to examine the effect rainfall pattern on the slope failure. The maximum rainfall intensity was 100 mm/h with total rainfall about 1250 mm. Two soil types, those were low and high permeability, and slope angle were selected to examine the proposed model. The soil properties are presented in Table 1. The hydraulic conductivity and soil water characteristic curves of the soil were illustrated in Figure 3.

### 3. RESULTS AND DISCUSSION

#### 3.1 Infiltration Characteristics

Typical the result of analyses are illustrated in Figure 4. It was clearly observed that the infiltration in high permeability slope (K1) was the same with rainfall intensities. The infiltration pattern was the same with the rainfall pattern. In contrast with the low permeability slope (K2), the infiltration is affected by the rainfall pattern. Delayed and centralized rainfall pattern show a similar infiltration pattern as shown in Figure 4(A,D, C,F). The infiltration is the same with the rainfall intensity at the beginning of rainfall, then decrease gradually after certain elapsed time of rainfall.

It was observed clearly from the figure that for high permeability slope (K1), the infiltration of the Green–Ampt (GA) was in agreement with the FEM computation. It is because of the rainfall intensity ( $I_t$ ) is lower than the saturated hydraulic conductivity of the soils ( $k_{sat}$ ),  $I_t < k_{sat}$ . Simulation using FEM has shown that the slope surface was unsaturated during the rainfall. Hence, all the rainwater infiltrate into the slope. For the case of low permeability slope (K2), the rainwater infiltration is controlled by the saturation at the slope surface. Saturation at slope surface will occur when the  $I_t$  is higher than the  $k_{sat}$  ( $I_t >$

$k_{sat}$ ). For this condition, the figures illustrated that the amount of rainwater infiltration from the proposed model was slightly difference with the FEM at the onset time of rainfall. The difference may be caused from initial suction head and volumetric water content at the initial state of the computation. In the GA infiltration model, the suction at slope surface and volumetric water content was assumed to be constant during the infiltration, while the FEM considered the change of suction, volumetric content and hydraulic conductivity during the calculation. But, after the slope surface saturated, the infiltration pattern for both model was the same. The deviation of infiltration from GA model and FEM was lesser for a slope with greater inclination as shown in Figure 4(D to F). The results indicated that the GA model is applicable for a sloping ground. The result is in agreement with Chen and Young [15]. It was observed in Figure 4(E) for K2 slope that the infiltration from GA model and FEM computation is relatively the same. The result indicated that the GA model is in good agreement when the slope surface is saturated at the beginning of rainfall.

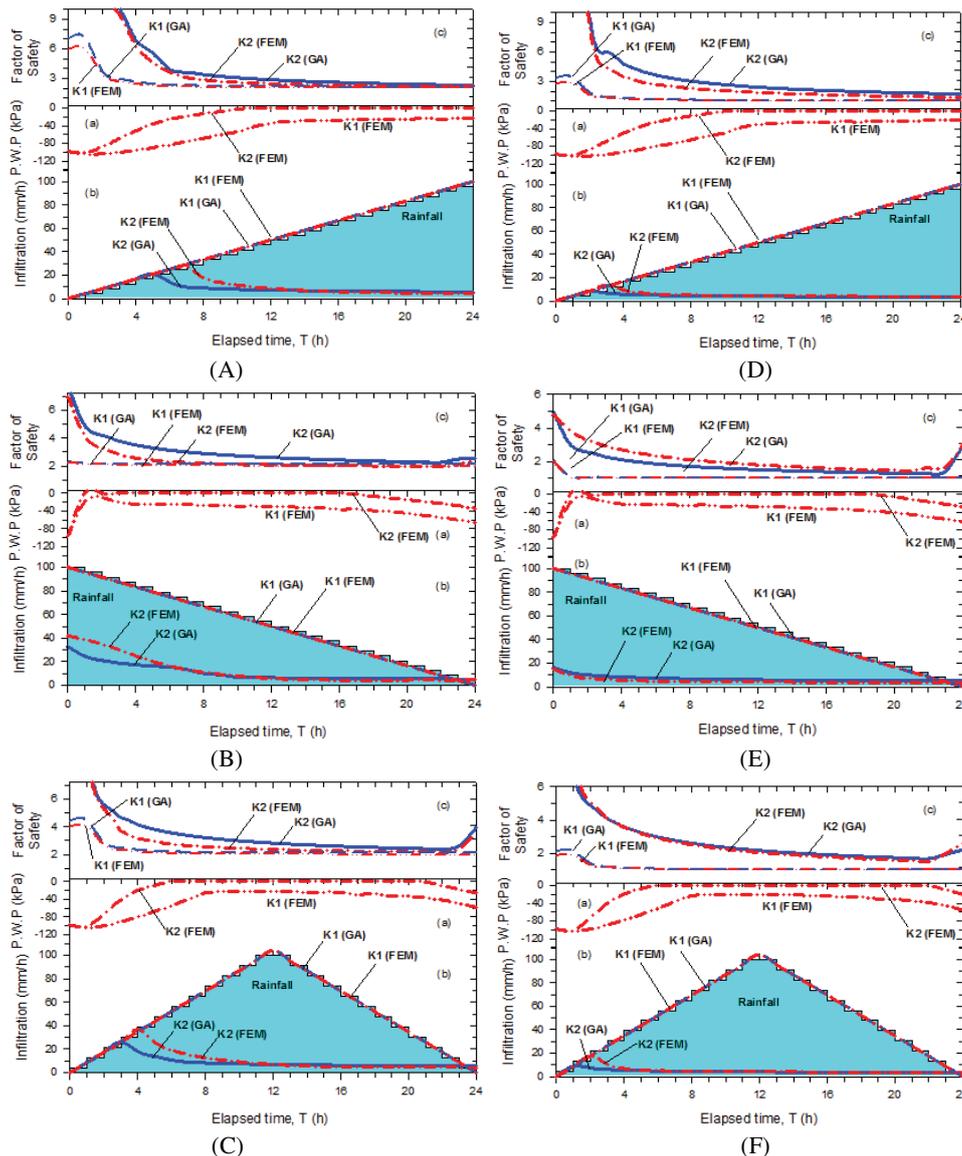

Figure 4 Typical of the result of the proposed model and two dimensional finite element analyses (A, D) delayed rainfall pattern, (B, E) advanced rainfall pattern, (C, F) central rainfall pattern.  
 Note: (A – C) for slope angle 20°, (D – F) for slope angle 40°.

### 3.2 Slope Stability

Slope stability is commonly represented by the factor of safety (FS). In the deterministic analysis, a slope will fail if the FS value is lower than one ( $FS < 1$ ). The results illustrated in Figure 4 show that the advanced rainfall pattern resulted in the

lowest minimum factor of safety for the given slope. Advanced rainfall generated rapid saturation on the slope surface at the beginning of rainfall, since the accumulated rainfall is greater than the saturated hydraulic conductivity of the slope. As the result, the pore water pressure increased drastically from 98.1 kPa to zero on the slope surface. Hence, the FS decreased significantly with the elapsed time of rainfall. It was observed for the delayed and centralized rainfall pattern, the factor of safety tend to increase at the end of rainfall. It was because of the decreasing of pore water pressure. The results indicated that rainfall pattern affected the slope instability. Slope failure rapidly occurred after the advanced rainfall pattern, while centralized and delayed rainfall pattern will generate a delayed slope failure. This finding is supported the research carried out by Tsai and Wang [16].

The effect of slope inclination was also observed from the relationship in Figure 4. For the slope inclination smaller than  $20^\circ$ , the estimated factor of safety from the FEM was more conservative than the results obtained from the proposed model for both K1 and K2 slopes. The analysis given in Figure 4 showed that the K1 slope was more prone to failure than the K1 slope subjected to the same rainfall intensities and duration. For the slope angle  $40^\circ$ , the factor of safety was observed to be dependent on the rainfall pattern. The factor of safety obtained from the proposed model was 5% lower than the results obtained from the FEM computation. In contrast with the K1 slope, the proposed model yield a lower factor of safety for K2 slope if compared to the FEM calculation. This result was completing the findings from the other research [1-3].

## 7. CONCLUSION

The proposed model has successfully estimated the infiltration and slope stability during the rainfall as wells as analysis of the FEM. Overall results were alluding to conclude that the proposed model was simple model and suitable to assess rainfall induced slope instability especially shallow landslides type. Infiltration was strongly affected by rainfall pattern, inclination of slope and the hydraulic properties of soil. For a high permeability slope which the saturated hydraulic conductivity of the soils ( $k_{sat}$ ) is greater than the rainfall intensity ( $I_t$ ),  $k_{sat} > I_t$ , infiltration was independent to the rainfall pattern. But for a low permeability slope, which the saturated hydraulic conductivity of the soils ( $k_{sat}$ ) is lower than the rainfall intensity ( $I_t$ ),  $k_{sat} < I_t$ , the rainwater infiltration is dependent to the rainfall pattern. The rainfall pattern controlled the saturation at the slope surface. For the slope angle smaller than  $20^\circ$ , the estimated factor of safety from the FEM was more conservative than the results obtained from the proposed model for both high and low permeability slopes. For the slope angle  $40^\circ$ , the factor of safety was observed to be dependent on the rainfall pattern. The factor of safety obtained from the proposed model was 5% lower than the results obtained from the FEM computation. In contrast with the high permeability slope, the proposed model yield a lower factor of safety for the low permeability slope if compared to the FEM calculation

## ACKNOWLEDGMENT

This paper was part of the research "Experimental and Numerical Model on Rainfall Infiltration Induces Slope Failure Slope". The research was granted by the Ministry of Education and Culture, The Republic of Indonesia for the financial support through Fundamental Research scheme in 2011-2012. Authors are thankful for the funding provided.

### ABSTRACT

Previous researches have shown that geosynthetic used as a reinforcement of asphalt pavement layer was able to hold propagation of crack and rut. However, in those researches, initial strain of the geosynthetic was not included as a parameter affecting the performance of asphalt pavement layer. The purpose of this study is to analyze the effect of strain on the service life of asphalt pavement layer; the influence of density of asphalt concrete on the modulus of elasticity; and the effect of initial strain and location of geogrid in the asphalt pavement layer on its ability to resist fatigue due to repetitive loads. This research is conducted on asphalt pavement layer type of Asphalt Concrete Wearing Course (ACWC) using Beam Fatigue Apparatus. The specimens in this test are the asphalt concrete beams reinforced with geogrid. The research results show that the increasing of strain in the ACWC layer decreases service life. The ACWC density affects the modulus of elasticity in a parabolic way. The result reveals that ACWC fatigue life becomes greater by increasing the initial strain of the geogrid placed in the layer of ACWC. The geogrid located at 2/5 thickness of the ACWC base layer provides the ability to hold repeated loads greater than the geogrid located in the middle layer of the ACWC.

**Keywords :** geogrid, asphalt concrete, initial strain, service life, modulus of elasticity

### 1. INTRODUCTION

Technology of reinforcement on overlay of asphalt pavement to resist reflection cracking has been developed in South Africa and America. Polyester nonwoven geosynthetic paving fabric has been used to hold the crack propagation in the upper layer of asphalt pavement that had block cracked on overlay work in South Africa in 1980 [5]. The use of polypropylene nonwoven geosynthetic types as interlayer had succeeded to prevent crack propagation in overlay work on the old road that has been crack [4] and [6]. Geosomposite put under layers of asphalt concrete pavement can increase the resistance to rutting [2]. The optimum layout of geotextile reinforcement in the asphalt pavement layer is at 1/3 the thickness of the layer [7].

These studies demonstrate the ability of geosynthetic ever to reinforce asphalt pavement layer. Geosynthetic is a sheet-shaped material and has good tensile strength. Geosynthetic tensile strength when installed will be effective if the condition is in a state of tension. Provision of initial strain at the time of installation of geosynthetic can strengthen the bond among the aggregates in the asphalt mixture. Geosynthetic tensile strength can help in restraining the resistance of asphalt tensile stress.

In previous studies the initial strain factor of geosynthetic not included as parameters that will affect the performance of asphalt concrete reinforced with geosynthetic. In this article will be presented results of the research, including (1) Effect of the strain on the service life of asphalt concrete layer (2) Effect of the density of the asphalt concrete on modulus of elasticity (3) Effect of geogrid initial strain in the asphalt pavement layer on its ability to resist fatigue due to repetitive loads (4) effect of the location of geogrid in asphalt concrete layer to its ability to resist fatigue due to repetitive loads.

Fatigue is reducing performance of building materials due to receive repeated load even though the same amount of load. Similarly, asphalt pavement materials will be fatigue after receiving the repeated vehicle load. Asphalt mixture is said to be flexible if it has a good long fatigue. Characteristics of asphalt mixtures fatigue is related to the modulus of elasticity. Modulus of elasticity is the ratio of stress to strain when the asphalt mixture receives bending loads.

Asphalt is a visco-elastic material. If the material is received stress, the shape will change. Changes in shape is a function of temperature and loading time [3]. At high temperatures and long loading time, it will be viscous liquids. In contrast to the low temperature and a short loading time, the asphalt will be elastic but brittle. Thus the modulus of elasticity of the asphalt mixture will depend on the temperature and time of loading. The characteristics of the asphalt mixture will also affect the modulus of elasticity. Density will also affect the modulus of elasticity of the asphalt mixture. The instrument used to test the

elasticity modulus of asphalt mixtures in this study is the Beam Fatigue Apparatus. The operating procedures of the tool is in accordance with AASHTO T321-1 [1].

Asphalt concrete mixture used in the study is asphalt concrete wearing course (ACWC) fine graded by the properties of the mixture as in Table 1.

Table 1. The properties of asphalt concrete wearing course

Mixture properties	Test result	Specification
Bitument content (%)	6.7	min. 5.1
Void in the mix (%)	4.6	3.5-5.0
Void in mineral aggregate (%)	19.5	min. 15
Void filled with bitument (%)	77	min. 65
Marshall stability (kg)	2.000	min. 800
Flow (mm)	3.4	min. 3
Marshall quotient (kg/mm)	580	min. 250

As the layers of asphalt concrete reinforcement material used Miragrid GX 60/60 which has a stress strain diagram as Figure 1. Geogrid has a tensile strength of 60 kN/m in longitudinal and transverse directions. The use of geogrid is expected to increase the tensile strength ACWC. Geogrid will effectively strengthen ACWC if the conditions is strained.

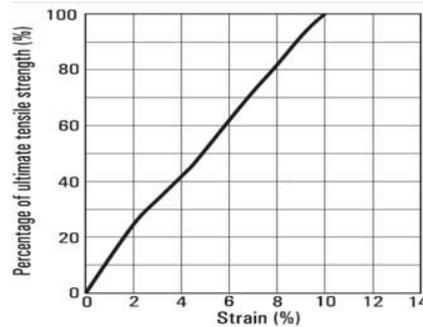

Figure 1: Relation between tensile strength and strain geogrid [8]

## 2. RESEARCH METHODOLOGY

### 2.1. Apparatus

1. Apparatus for making specimen (Figure 2). This apparatus is for making specimen by press system, so that the desired density of specimen can be created. In addition the specimen can also be made in two stages, allowing installation and giving the initial strain of geogrid placed in the asphalt concrete layer. Specimen is asphalt concrete beam with dimension 380 mm length, 63 mm width, and 50 mm thick. Geogrid placed 2 cm from the base of the specimen.
2. Beam Fatigue Test (Figure 3). Apparatus to measure the values of tensile stress, tensile strain, flexural stiffness, modulus of elasticity, and the dissipated energy of the asphalt mixture during receiving the repeated load. These apparatus is equipped with computer that can provide graphs the relationship between the number of loading cycles and the performance of asphalt mixture. This appliance test procedures in accordance with AASHTO T321-1 [1].

Figure 2: Apparatus for making specimen

Figure 3 : Beam Fatigue Apparatus

## 2.2. Procedure

Specimens loaded in 2 places with horizontal spacing 119 mm centre to centre. Load worked repeatedly with the 5-10 Hz frequency. In this test load used frequency of 10 Hz or 10 strokes per second. Load can also be set so as to provide a constant tension or constant tensile strain. This research used the load to provide a constant tensile strain. The parameters measured in this study is the tensile stress, flexural stiffness, modulus of elasticity, and the dissipated energy.

To determine the effect of the amount of load on the durability of asphalt ACWC, the specimen tested with 3 kinds of loading. The amount of loading on the test is not expressed with heavy loads carried on specimen, but expressed with a constant amount of strain that is given to the specimen. The bigger load is done, strain that occurs will be greater. This research used three control strain with the amount of each is 500  $\mu\epsilon$ , 600  $\mu\epsilon$ , and 700  $\mu\epsilon$ . The durability of asphalt mixtures is expressed by the number of loading cycles that cause the mixture flexural stiffness decreased to 50% of the initial flexural stiffness. By these criteria the specimen is considered to have significant decreasing of quality, and the service life has ended [1].

To determine the effect of the asphalt mixture density on the modulus of elasticity, fatigue beam tests performed with various values of specimen density. Modulus of elasticity was measured at 99% density (2.293 gr/cm<sup>3</sup>), 95% (2.20 gr/cm<sup>3</sup>), and 90% (2.08 gr/cm<sup>3</sup>). The tests carried out at a temperature of 25°C.

## 3. RESEARCH RESULTS AND DISCUSSION

### 3.1. Testing Results of ACWC without Geogrid

The results of testing the durability of ACWC as shown in Figure 4. From Figure 4. seen that the greater the strain acting on the ACWC the fewer number of load cycles can be received. The relationship between strain and the number of loading cycles is a linear equation :  $y = -268.39x + 193,599$ , with  $y =$  number of loading cycles, and  $x =$  strain that work in ACWC.

The results of testing the influence of the density on the modulus of elasticity is as shown in Figure 5. Elasticity modulus and density relationships is parabolic equation:  $y = -26,479x^2 + 120,396x - 134,792$ , with  $y =$  modulus of elasticity, and the  $x =$  density of asphalt concrete. The value of the coefficient of determination ( $r^2$ ) = 1. It indicates that the modulus of elasticity of ACWC strongly influenced by the value of density. With a parabolic equation, it means there is an optimum density will result the maximum modulus of elasticity. Figure 5 shown that the value of optimum density is 2.28 gram/cm<sup>3</sup> and the maximum modulus of elasticity of ACWC is 2.100 MPa.

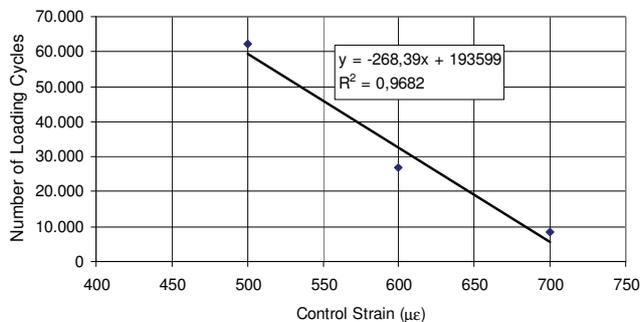

Figure 4 : Influence of strain on number of load cycles

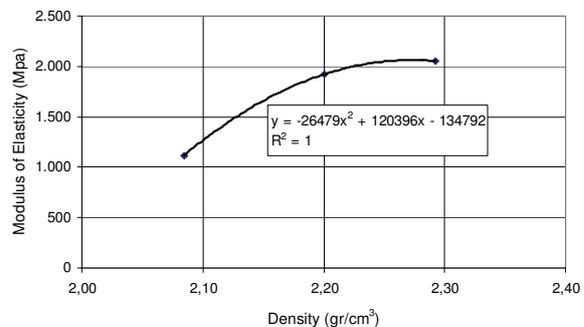

Figure 5 : Influence of density on modulus of elasticity

### 3.2. Fatigue Testing Results of ACWC Reinforced with Geogrid

The results of fatigue testing of ACWC for the control strain 500  $\mu\epsilon$  as shown in Figure 6., while the testing results for the control strain 600  $\mu\epsilon$  as shown in Figure 7. Figure 6 and Figure 7 shows the influence of initial strain and location of geogrid on the number of loading cycles of ACWC has reinforced with geogrid. Initial strain of geogrid 0% is ACWC layer without using geogrid reinforcement.

Both Figure 6. and Figure 7. show that the geogrid able to increase the resilience of the ACWC layer to repeated load. The number of loading cycles ACWC reinforced with geogrid greater than ACWC without geogrid reinforcement. The greater initial strain of geogrid, the number of load cycles can be held ACWC layer also increases. This is due to the additional of initial strain of geogrid will effect the increasing of tensile strength of geogrid that working in ACWC layer. With increasing geogrid tensile strength, the ability to withstand fatigue ACWC layer longer, so that the number of load cycles which can be held by ACWC also increases.

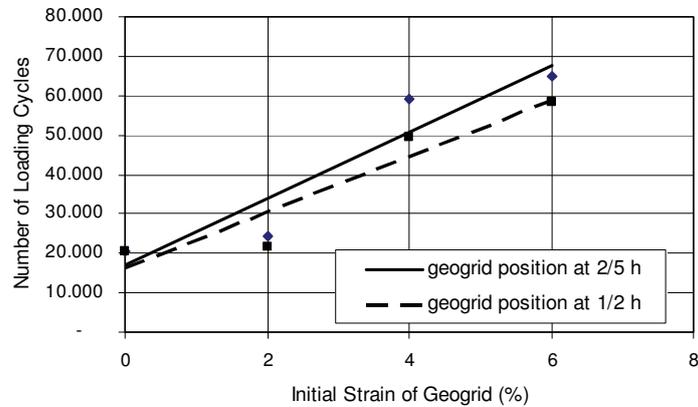

Figure 6: Influence of initial strain of geogrid on number of loading cycles at control strain 500με

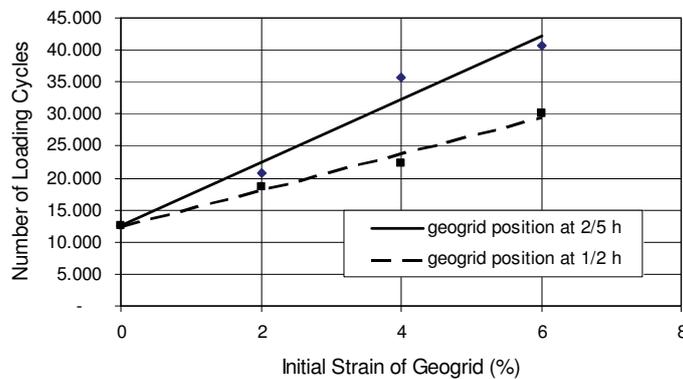

Figure 7: Influence of initial strain of geogrid on number of loading cycles at control strain 600με

The position of geogrid layers also affects reinforcement of geogrid to ACWC. The position of geogrid at 2/5 thick more effectively to give the reinforcement to ACWC layer if compared to the geogrid at 1/2 of a thick layer of ACWC. It's not much different from research results done by Moussa [7] and Khodaii [6]. It's concluded that the position of the geosynthetic reinforcement of asphalt concrete placed at 1/3 thick is the optimum position..

The amount of strain acting on ACWC layer will affect the service life ACWC layer. Strain aligned with the load acting on the lining ACWC. The greater the load acting on the layer, the greater the strain ACWC working on the ACWC layer. Thus automatically increasing the strain suffered by ACWC layer, the service life or number of cycles of load that can be supported by ACWC layer decreases.

Based on regression equations were created, the relationship between initial strain of geogrid and the number of loading cycles that can be retained by ACWC asphalt mixture is linear. In control strain 500 μ ε, equation relationship between initial strain and the number of loading cycles are as follows:

- a.  $y = 8,428x + 16,921$  for the position of geogrid at 2/5 thick, and
- b.  $y = 7,085x + 16,205$  for the position of geogrid at 1/2 thick

While in control strain 600 μ ε, equation relationship between initial strain of geogrid and the number of cycles the track are as follows:

- a.  $y = 4,964.5 x + 12,489$  for geogrid position at 2/5 thick, and
- b.  $y = 2,819.1 x + 12,426$  for geogrid position at 1/2 thick

The variable x is the amount of initial strain of geogrid, while the variable y is number of loading cycles that can be retained by ACWC layer.

From the regression equation obtained, it shows that the position of geogrid at 2/5 thick provide greater reinforcement compared to the geogrid at 1/2 thick. This applies to the control strain 500 με and 600 με .It can be seen from the slope of the

regression equation. The slope for the position of geogrid 2/5 thick greater than the slope for the position of geogrid 1/2 thick, both for the control strain 500  $\mu\epsilon$  and 600  $\mu\epsilon$ .

The layer ACWC receiving 500  $\mu\epsilon$  strain is able to serve a greater number of load cycles than that receiving strain of 600  $\mu\epsilon$ . It can be seen that the slope coefficient of the regression ACWC receiving strain 500  $\mu\epsilon$  larger than that receiving strain 600  $\mu\epsilon$ . This fact is true for both geogrid position at 2/5 thick and the position of 1/2 thick

#### 4. CONCLUSIONS AND RECOMMENDATIONS

##### 4.1. Conclusions

From the results of research carried out on Asphalt Concrete Wearing Course (ACWC) with geogrid reinforcement can conclude the following :

1. The greater strain that occurs in the layer of ACWC, the service life ACWC layer decreases linearly according to the equation  $y = -268.39 x + 193,599$
2. ACWC density affect the properties of the modulus of elasticity according to the parabolic equation  $y = -26,479 x^2 + 120,396 x - 134,792$
3. The greater the initial strain geogrid placed in layers ACWC will linearly enhance the ability of the ACWC layer to resist fatigue due to repetitive loads.
4. Location of geogrid at 2/5 thickness of the base layer provides the ability to support repeated loads greater than the location of geogrid at the middle of the ACWC layer.

##### 4.2. Recommendations

Base on the research results, further research are still needed to refine these research results. These researches include the following:

1. The effect of temperature on the modulus of elasticity of concrete pavement and asphalt concrete ability to support repeated loads.
2. Effect of asphalt concrete reinforcement with other types of geosynthetic on its ability to support repeated loads.
3. Effect of number of tack coat used between two layer of asphalt concrete reinforced with geosynthetic on its ability to support repeated loads.
4. Effect of asphalt concrete reinforced with geosynthetic on its ability to support rutting

## ABSTRACT

The new method to handle the problem of rigid pavement on soft soils has been proposed. It is called nailed-slab system. An advantage of this method is that the system makes the rigid pavement to keep contact with sub grade. Experimental modeling and analytical study have been done for nailed-slab system on soft clay to learn the effects of pile spacing and pile length due to the additional modulus of sub grade reaction. The models are presented as strip section of rigid pavement. The theory of beams on elastic foundation is used to calculate the slab deflection by using equivalent modulus of sub grade reaction  $k'$  then compared also with 2D numerical model developed in Plaxis 8.5 finite element analysis. Result show that the nailed-slab system tends to be stiffer by closer the pile spacing. The additional modulus of sub grade reaction tends to increase by decreasing the pile spacing. Pile length affects also the stiffness of the nailed-slab system. Longer the pile length increases the depth of reinforced soil. It gains stiffness of the nailed-slab system and reflects higher additional modulus. Significant effect is gained for centric loads.

**Keywords:** rigid pavement, soft clay, Nailed-slab System, modulus of sub grade, pile spacing, pile length, deflection.

## 1. INTRODUCTION

In order to gain the efficiency of construction implementation, Hardiyatmo [1] proposed the changing of the shell of fondasi cakar ayam (hen's claw foundation) by short-friction piles. The piles are installed under the slab. The slab has double functions: as pavement structures and all at once as pile cap. It is called Nailed-slab System. This method is utilized to apply in reinforcing the rigid pavement slab. The rigid pavement slab is nailed to the sub grade by short piles. And the composite system is made which consist of slab, piles, and soils surrounding the piles and slab. The installed piles under the slab increase the slab stiffness and make the slab keeps contact with the soils [2]. Hence, the height of slab is decreased. The decreasing of slab height can reduce the weight of the structure and will be beneficial for soft soils [3].

Experimental modeling and analytical study have been done for soft soils ([3], [1], [4], [5], [6], [7], [8], [2], [9], [10]). Deflection analysis of a nailed-slab by using equivalent modulus of sub grade reaction has been done by Hardiyatmo ([4], [5]) and Puri, et.al. ([9], [10]). This modular is the cumulative of modulus of sub grade reaction from plate load test ( $k$ ) and additional modulus of sub grade reaction due to pile installing ( $\sigma k$ ). Reduction of pile resistance is one of aspects that need to be considered in determining  $\sigma k$ . It is included in the relative displacement between the pile and soil. Hardiyatmo [5] used the additional modulus of sub grade reaction based on the relative displacement between the piles and soil and considered the reduction of pile resistance. Since the determining of these parameters for design purpose are difficult, Puri, et.al. [10] proposed a new approach where pile friction resistance is fully mobilized and the tolerable settlement is considered. Perhaps, more ease in designing the Nailed-slab System will be obtained. Puri, et. al. [10] concludes that the deflection analysis of the nailed-slab based on the additional modulus of sub grade reaction which considered the tolerable settlement, resulting in deflection fines in good agreement with observed deflections. Designing of the Nailed-slab System based on an analysis of the one row pile will produce a safe design. It is caused by higher pile group resistance and increases in slab stiffness according to multiple-row of piles installation. In practice, the Nailed-slab System would be constructed by multiple row piles.

This paper is aimed to discuss the effect of pile spacing due to the additional modulus of sub grade reaction. The experimental was conducted by model tests of one row pile nailed-slab system.

## 2. ADDITIONAL MODULUS OF SUB GRADE REACTION

The analytical approach in determining equivalent modulus of sub grade reaction ( $k'$ ) is given as follows ([5], [7], [9], [10]):

$$k' = k + \Delta k \quad (1)$$

Where  $k$  : modulus of sub grade reaction from plate load test ( $\text{kN/m}^3$ );  $\sigma k$  : additional modulus of sub grade reaction due to pile installing ( $\text{kN/m}^3$ ).

Fig. 1 shows the soil bearing pressure under an individual nailed-slab system. Hardiyatmo [5] proposed Eq. (2) in determining the additional modulus of sub grade reaction ( $\sigma k$ ). The relative displacement between pile and soil is considered.

$$\Delta k = \frac{\delta_0 A_s}{\delta^2 s^2} (a_d c_u + p_0 K_d \tan \phi_d) \quad (2)$$

Where  $\delta_0$  : relative displacement between pile and soil (m);  $\delta$  : deflection of surface of plate (m);  $A_s$  : surface area of pile shaft ( $\text{m}^2$ );  $s$  : pile spacing (m);  $a_d$  : adhesion factor (non-dimensional);  $c_u$  : undrained cohesion ( $\text{kN/m}^2$ );  $p_0$  : average effective overburden pressure along of pile ( $\text{kN/m}^2$ );  $K_d$  : coefficient of lateral earth pressure in pile surroundings (non-dimensional);  $\phi_d$  : soil internal friction angle (degree). The relation between  $\delta_0/\delta$  and slab deflection from pile model with a 4 cm diameter is also given by Hardiyatmo [5].

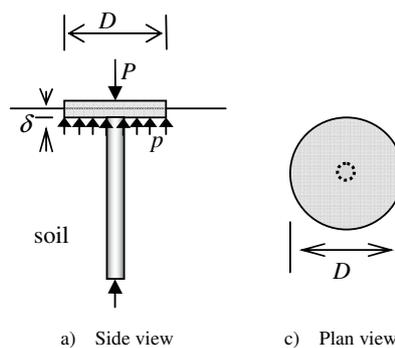

Fig. 1. Soil bearing pressure under individual nailed-slab [5].

In case of nailed-slab designing, the relative displacement between pile and soil is difficult to define. Puri, et.al. [10] obtained Eq. (3) to define the additional modulus of sub grade reaction which considered the tolerable settlement of rigid pavement slab ( $\sigma_a$ ). This approach is called Modified Hardiyatmo method.

$$\Delta k = \frac{0.4 f_s A_s}{\sigma_a A_{ps}} \quad (3)$$

Where  $\sigma_a$  : tolerable settlement of rigid pavement slab (m);  $f_s$  : ultimate unit friction resistance of pile shaft ( $\text{kN/m}^2$ );  $A_s$  : surface area of pile shaft ( $\text{m}^2$ );  $A_{ps}$  : area of plate zone which supported by single pile ( $\text{m}^2$ ). Nailed-slab resting on soft soils should consider the ignored end bearing resistance of pile. Ultimate unit friction resistance of the pile shaft in saturated clay is expressed by

$$f_s = a_d c_u \quad (4)$$

Where  $a_d$  : adhesion factor (non-dimensional);  $c_u$  : undrained cohesion ( $\text{kN/m}^2$ ).

## 3. TESTING INVESTIGATION

### 3.1. Soil and Nailed-slab Models Tests

Soft clay parameters are given in Puri, et.al. [9] and also published test result of one row nailed-slab without a vertical barrier. The nailed-slab model with one row of piles consists of 6 piles, 120 cm × 20 cm × 3 cm slab, 20 cm pile spacing ( $s/d = 5$ ), pile diameter  $d = 4$  cm, and pile length  $L_p = 40$  cm. The spacing between edge pile and the end of slab is a half of pile spacing ( $a=s/2$ ). The loading test set up and models of concrete slab supported by piles are shown in Fig. 2. Slabs and piles are made by reinforced concrete. Slab reinforcement was wire mesh with 3 mm-wire diameters, and 5 cm × 5 cm meshing. Pile models were reinforced by 3mm-aluminium wire diameter. Model scale for geometry was 1 : 5. Piles and slabs were connected monolithically. Other model tests were also conducted by different in pile spacing. Table 1 shows the variations in pile spacing and length including the model test of Puri, et.al [9]. All models are presented as strip section of the rigid pavement.

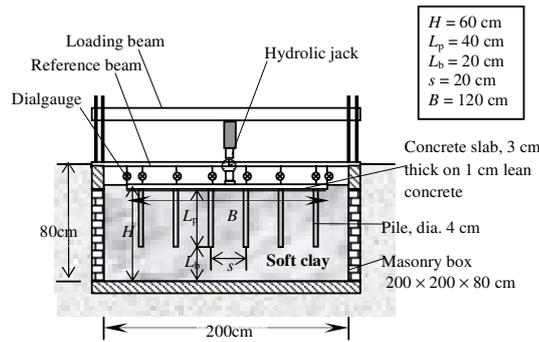

Fig. 2. Schematic set-up of loading test on Nailed-slab System [9].

Puri, et. al. [10] reported that the slabs and piles have the modulus of elasticity  $E_c = 17,000$  MPa. Soft clay has a 15,000 kPa/m modulus of sub grade reaction from plate load test with 30 cm in plate diameter. Lean concrete has a 71,100 kPa/m modulus of sub grade reaction from plate load test with 20 cm in plate diameter. These moduli of sub grade reaction was corrected due to the shape of the slab according to Das [11], and resulted in 16,250 kPa/m and 51,350 kPa/m for soft clay and lean concrete respectively [10]. For homogenous soft clay, correction due to depth of the foundation is not required. The steps of testing were described in Puri, et.al. ([9], [10]). The load was worked on the slab through a circular steel plate with 6.0 cm in diameter and 1.0 cm in thickness. Load positions were on the point A (centric load) and point B (edge load) as shown in Fig. 3a but they worked in different loading time.

Table 1: Variations of pile spacing and length for one-pile row Nailed-Slab models under the 120 cm × 20 cm × 3 cm Slab

Models	Number of Piles	Pile Spacing, $s$ (cm)	$s/d$	Pile Length, $L_p$ (cm)
1	12	10	2.5	40
2#	6	20	5.0	40
3	3	30	7.5	40
4	6	20	5.0	20

# Puri, et.al. [9].

### 3.2. Analysis of Deflections

The theory of beams on elastic foundation (BoEF) can be used to calculate the deflections due to the load acting on plate-supported piles ([4], [5], [8], [9], [10]). The deflection of the finite length of the beam resting on an elastic foundation due to a single concentrated load at any point by Hetenyi [12] was used in the analysis where the  $k$  was replaced by  $k'$  for analysis of nailed-slab system. The small distributed load was simplified by concentrated load. In the 2D finite element analysis (FEM), soft soil model was employed in the study. Likewise, the soil and material properties (model plate and pile) adopted in the model are shown in Table 2 and 3 respectively. Fig 3a shows a used mesh in plain strain FEM analysis and Fig 3b is one of deformed shape output.

Table 2: Soil properties in FEM analysis input

Parameter	Name	Clay	Unit
Material model	Model	Soft soil	-
Material behavior	Type	Undrained	-

## 4. RESULTS AND DISCUSSION

### 4.1. Loading Test Results

Distribution comparisons of deflection along the slab of a one-pile row nailed-slab system with different pile spacing are shown in Fig. 4. The others loads, the deflections have a similar behavior. The slab surface of Model 3 ( $s=30\text{ cm}$ ) was cracked under edge load  $P = 1.347\text{ kN}$ . The crack of slab surface was occurred over the outer of edge pile. Pile spacing affects the stiffness of the nailed-slab system; more close the pile spacing, stiffer the nailed-slab system and lower the deflections. The slab tends to be critical under edge loading. It is concluded that the deflection of the slab for edge loadings are to be more than 2 times the deflection of the center loadings. Generally, there is no significant uplift of the slab end. It means that the installed piles tend to keep the slab contact with the soil. The capability of the nailed-slab system is higher due to center loading than edge loading.

Distribution comparisons of deflection along the slab of a one-pile row nailed-slab system with different pile length are shown in Fig.5. This is between Model 2 and 4. The other loads, the deflections have a similar behavior. The nailed-slab system with longer pile has lower deflection. It is caused by increase in stiffness of system due to pile installation under the slab coincide with the increase of soil depth which reinforced by piles.

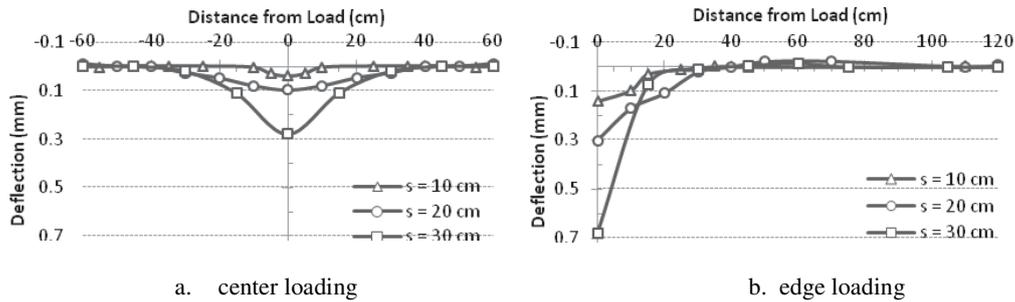

Fig. 4. Distribution of deflection along the slab of nailed-slab system in different pile spacing for  $P = 1.347$  kN.

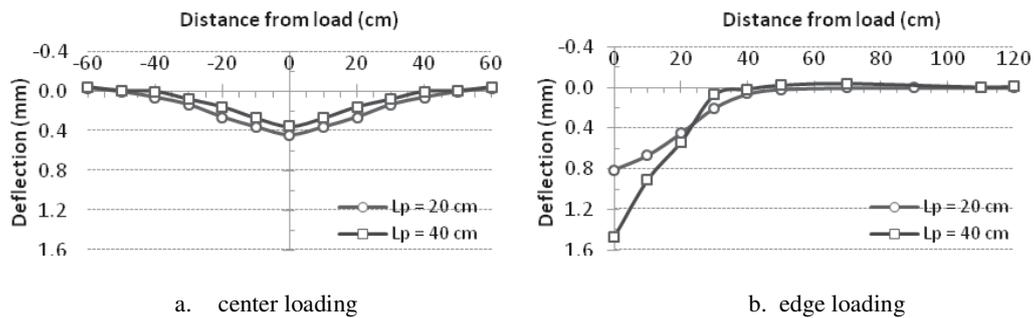

Fig. 5. Distribution of deflection along the slab of nailed-slab system in different pile length for  $P = 2.694$  kN.

#### 4.2. Pile Spacing Effects Due To Additional Modulus of Sub Grade Reaction

Additional and equivalent modulus of sub grade reaction due to pile installation was calculated by (2), and (3) for Hardiyatmo method and Modified Hardiyatmo method respectively, and results are shown in Table 5 and 6. The observed maximum deflections were taken as tolerable settlements ( $\delta_a$ ) in Modified Hardiyatmo method. Modulus of sub grade reaction for lean concrete is 51,350 kPa/m. According to Table 5, it is shown that  $\sigma k$  of Hardiyatmo method relatively constant eventhough the different in loading type. Otherwise, the Modified Hardiyatmo method (Table 6) the  $\sigma k$  decreases by increasing the displacement. These values tend to be lower for edge loadings. Pile spacing affects the  $\sigma k$  for all loading types. The  $\sigma k$  increases by decreasing the pile spacing. This is caused by decreasing the slab zone which supported by single pile, while the pile shaft area remains constant. The  $k'$  values in Table 5 and 6 are used to calculate the nailed-slab deflection by using BoEF. Both tables show also the results of calculated deflection.

Calculation results of deflection are also figured by Fig. 6 and 7 for center loading and edge loading respectively. Good results are obtained in the sense that the calculated settlement is in good agreement with observation. In case of edge loading, calculated settlement tends to be over-estimated at any pile spacing. Puri, et.al. ([9], [10]) and Hardiyatmo [5] also found that the calculated settlement for edge loading tends to be over-estimated. In case of finite element analysis, results show that the deflections tend to be under estimated for higher pile spacing. Finite element results are not in good agreement for edge loadings. Higher pile spacing tends to decrease the stiffness of this system. Hence, higher deflection is occurred.

Table 5: Additional modulus ( $\Delta k$ ) based on Hardiyatmo method and equivalent modulus ( $k'$ ) of sub grade reaction for  $L_p = 40$  cm

Analysis results from Modified Hardiyatmo method are better than results from Hardiyatmo method in predicting the nailed-slab deflections. The advantage of the Modified Hardiyatmo method is more practical for designing purposes.

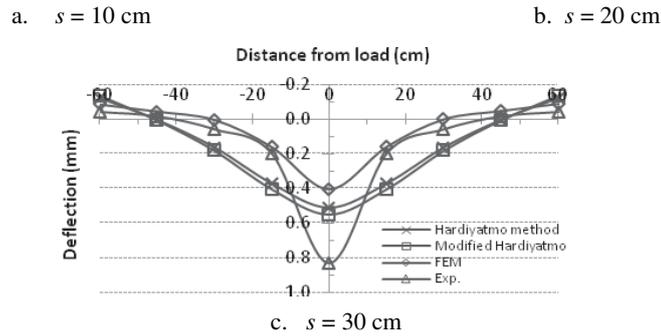

Fig. 6. Distribution of predicted deflection of nailed-slab for center loadings ( $P= 2.694$  kN).

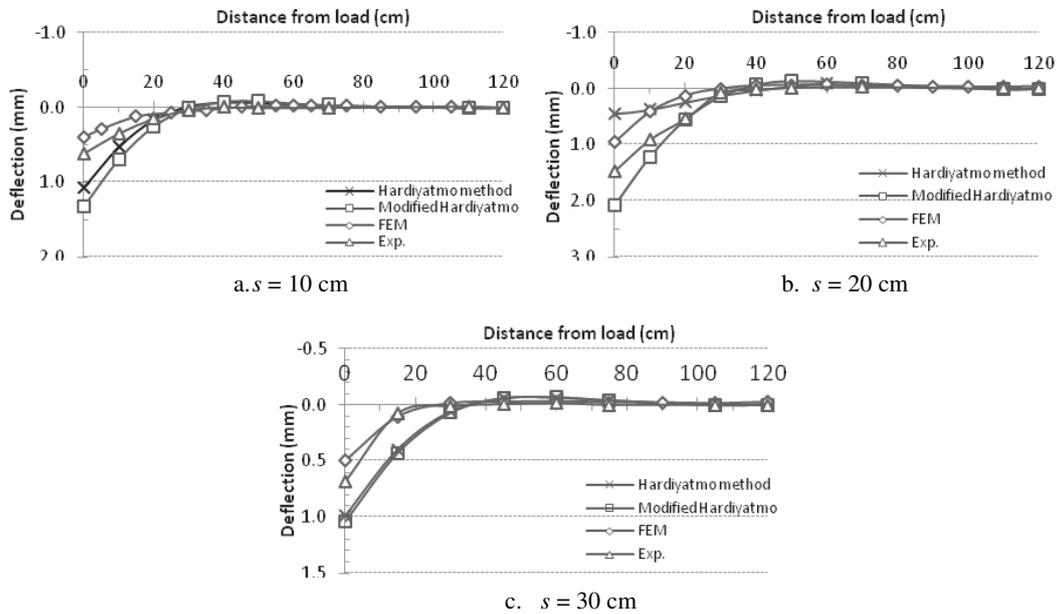

Fig. 7. Distribution of predicted deflection of nailed-slab for edge loadings ( $P= 2.694$  kN, except for  $s = 30$  cm  $P= 1.347$  kN).

### 4.3. Pile Length Effects Due To Additional Modulus of Sub Grade Reaction

Additional and equivalent modulus of sub grade reactions due to 20 cm pile length are shown in Table 7 and 8 including the calculated settlements. It is shown that  $k'$  and  $\sigma k$  relatively constant for Hardiyatmo method and tend to decrease by increasing displacement for Modified Hardiyatmo method. According to results from Modified Hardiyatmo method, these values tend to be lower for edge loading. Good agreement results find between calculated and observed deflections (Fig. 8). While the calculated deflections for edge loadings tend to be over-estimated. The nailed-slab which used longer pile is stiffer then shorter pile. In case of FEM results, the deflections tend also to be under estimated for edge loadings.

No.	Loading Type	Loads, $P$ (kN)	Observed $\delta_a$ (mm)	$\Delta k \times 10^3$ (kPa/m)	$k' \times 10^3$ (kPa/m)	Calculated $\delta_a$ (mm)	Dereference of Deflection (%)
1	Center	3.37	0.71	5.65	57.00	0.67	-5.33
		2.69	0.44	9.11	60.46	0.51	16.38
		1.68	0.22	18.22	69.57	0.29	30.44
2	Edge	2.69	0.82	4.89	56.24	2.10	155.84
		1.68	0.37	10.84	62.19	1.22	228.68

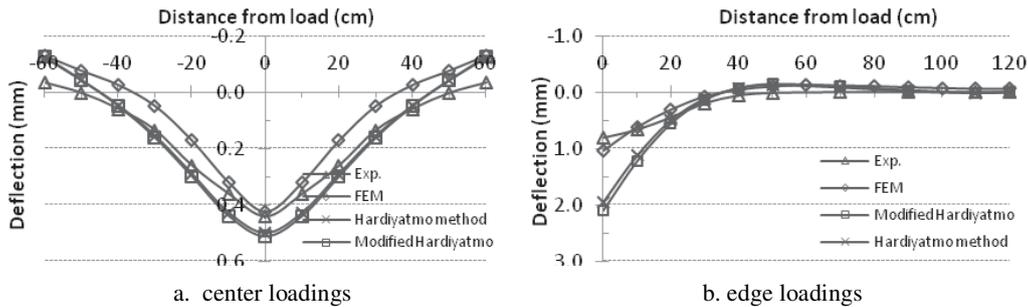

Fig. 8. Predicted distribution of deflection of nailed-slab with  $L_p = 20$  cm ( $P = 2.694$  kN).

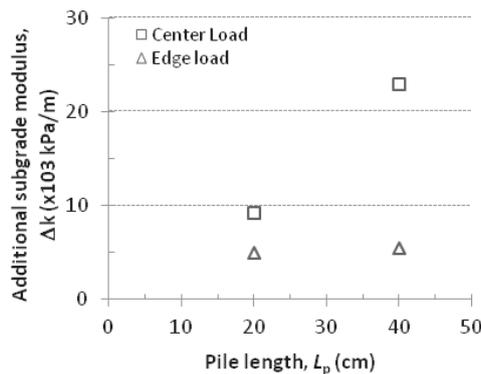

Fig. 9. Pile length effects due to  $\Delta k$  at  $P = 2.694$  kN.

Fig. 9 shows the increasing of  $\sigma k$  due to the increasing of pile length at  $P = 2.694$  kN. The other load intensities have similar trend. The  $\sigma k$  tends to increase by increasing the pile length. Increasing in pile length is affected significantly for center loading. This is caused by increasing the pile shaft areas, while the slab zone supported by single pile remains constant. Yet, increasing in pile length is affected less significant for edge loading. It is caused by the end of slab was acted as a cantilever slab, even though the pile length is increased.

## 5. CONCLUSION

The observations and analysis on the deflection of the Nailed-slab System model have been performed. The effects of pile spacing and pile length to the additional sub grade reaction modulus ( $\Delta k$ ) were analyzed. Pile spacing affects the stiffness of the Nailed-slab System; more close pile spacing, stiffer the Nailed-slab and lower the deflections. The slab tends to be critical under the edge loading. The additional modulus of sub grade reaction tends to increase by decreasing the pile spacing. This is caused by decreasing the slab zone which supported by single pile, while the pile shaft area of the single pile remains constant. Both Hardiyatmo method and Modified Hardiyatmo method can well predict the slab deflections. Good results are obtained in the sense of that the calculated settlement is in good agreement with observation. The Modified Hardiyatmo method is more practical.

Increasing in pile length is affected significantly to reduce the slab deflection under the center loadings, however pile length is affected less significant for edge loading. This paper will contribute to geotechnics research focusing on construction on soft soil.

## ACKNOWLEDGMENT

The author would like to give acknowledgment to all those involved in the project, especially to Prof. N. Yasufuku, and R. Ishikura, Ph.D. for their valuable advice.

## ABSTRACT

*Expansive soil is one of problems of soil mechanic and always found on civil engineering issues since they always destruct on building construction. Expansive soils have a large swelling potential. Expansive soil shows the behavior of extremely stiff soil in dry condition, however particle bonds of soil grain will be decomposed when they submerged by the water. This paper presents the study results performed at laboratory works on expansive soil from Cikarang Estate, Bekasi area with sand fraction of 0%; 10%; 20%; 25%; and 30%. CBR values from standard test can increase caused by sand addition of 25% or more. Generally, swelling potential can decrease with sand addition of 30% or more.*

**Keywords:** expansive soil, sand fraction, CBR, swelling potential

## 1. INTRODUCTION

Expansive soils are found extensively in tropical areas, likes Indonesia. The presence of expansive soils greatly affects the construction activities in many parts of Indonesia, especially around of the big city of Jakarta. More and more expansive soil regions are being discovered each year with an increase in the amount of constructional activities, particularly in the underdeveloped nations. These soils are characterized by the presence of a large proportion of highly active clay minerals of the montmorillonite group which are responsible for the pronounced volume change capability of the soils. The expansive soils are distributed geographically very widely, covering large areas.

Jakarta as the capital city and economic center makes this town becoming increasingly crowded, so that Governor of Jakarta launches a new program that Megapolitan city concept. Integration between government of Jakarta and local government around of this town to solve the existing problems, because of problems in Jakarta is not only from Jakarta but also from the area around Jakarta as urbanization increases. Economic growth is distributed around of the city of Jakarta ((Bogor, Depok, Tangerang, Bekasi and Cianjur or they called as Bodetabekjur area) to reduce urbanization. Good infrastructure is required to encourage the economic growth; however it was not easy to achieve the ideal condition.

Development of economic activity center, such as industrial estate area consists of many factories, real estate for housing and transportation infrastructure at Cikarang – Bekasi area finds some obstacles since soil foundation is expansive clay soil type. Expansive soil is one of the problems in the infrastructure development. Mitigation of the effects of expansive clay on structures built in areas with expansive clays is a major challenge in geotechnical engineering. Expansive clay has a large swelling potential, expansive clays are soils that expand when water is added, and shrink when they dry out. Expansive soil will also exert pressure on the vertical face of a foundation, basement or retaining wall resulting in lateral movement. Shrink-swell soils which have expanded due to high ground moisture experience a loss of soil strength or “capacity” and the resulting instability can result in various forms of foundation problems and slope failure. Expansive soil should always be a suspect when there is evidence of active foundation movement.

Recently, there are a lot of methods used to defend expansive soil problem, these are: chemical stabilization by cement; lime or salt treated, beside the other of mechanical stabilization method. One of methods to prevent expansive soil problem performed by this research is to design soil foundation improvement using addition of sand material. Paper focuses on the effects of mixing sand with some measure of the value of CBR and swelling potential of expansive soil is developed by several tests in laboratory models. Disturbed samples were taken from the area Cikarang Estate, Bekasi area. Compaction testings were performed by using two methods, standard and modified compaction method. Sand addition is expected to reduce the swelling potential at study area. Stabilization effect is focused on CBR value and swelling potential.

## 2. CHARACTERISTICS OF EXPANSIVE CLAY SOILS OF CIKARANG ESTATE, BEKASI AREA

Undisturbed and disturbed samples were taken from Cikarang eastate area (Figure 1). From Figure 1, it can be seen that generally soil type from alluvial to hydromorf, with a little fraction of podsolis and latosol soil types, which colours of soil were dominantly grey; brown; yellow; and red. Characteristics of undisturbed and disturbed samples are shown in Table 1.

Soil classification from USCS identified undisturbed samples from Cikarang Estate, Bekasi area is CH (clay of high plasticity, fat clay). Undisturbed samples condition shows water content of 47.8 % and specific gravity of 2.62. Liquid limit; plastic limit; and plasticity index are 103.3%; 40.9%; and 62.4%, respectively. Clay fraction is more than 40% and activity (A) value is around 2.1. From X-ray diffraction for clay mineralogy is obtained value of 34% fraction of montmorillonite (Table 2). Holtz and Gibbs (1956); Seed & Chan (1959); Seed et al (1962); Woodward & Lundgren (1963) Chen (1975, 1988) show that degree of expansion of undisturbed samples from study area has a very high soil expansivity and swelling values.

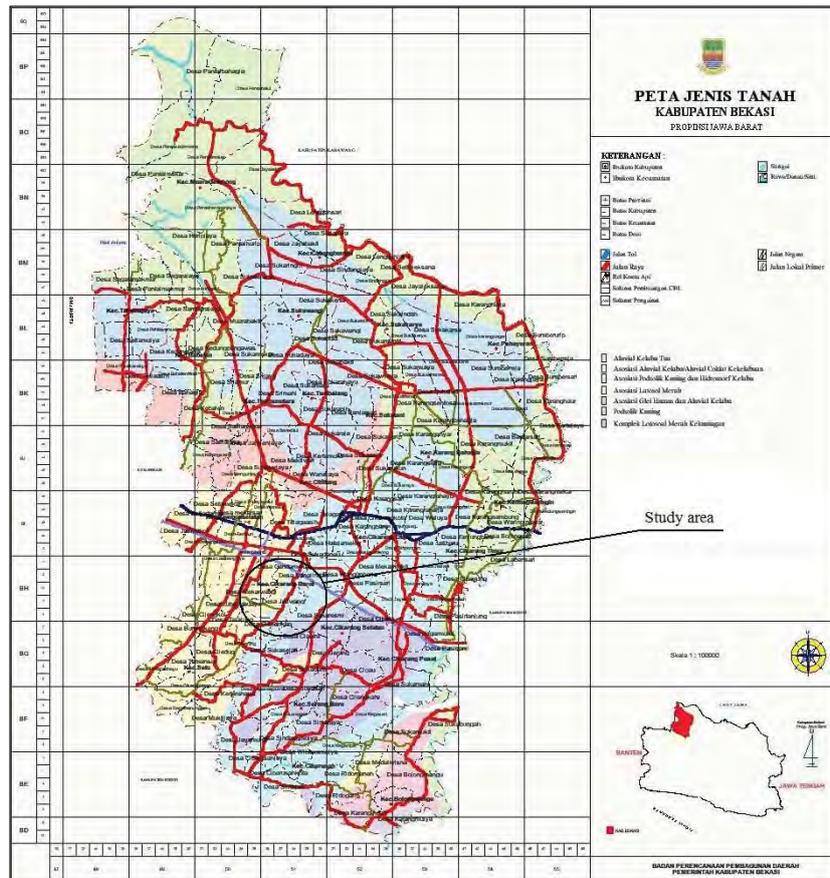

Figure 1. Locations of undisturbed and disturbed samples based on the Peta Jenis Tanah Kabupaten Bekasi (Source: Badan Perencanaan Pembangunan Daerah Kabupaten Bekasi, 2005)

Tabel 1. Summary of soil properties from study area

No.	Soil properties	Results
1.	Water content (w) (%)	47.8 – 48.5
2.	Weight volume ( $\gamma_m$ ) (gr/cm <sup>3</sup> )	1.8 – 1.9
3.	Specific gravity ( $G_s$ )	2.62 – 2.63
4.	Liquid limit (LL) (%)	102.4 – 104.2
5.	Plastic limit (PL) (%)	39.2 – 42.6
6.	Plasticity index (PI) (%)	61.6 – 63.2
7.	Shrinkage limit (SL) (%)	22.2 – 25.9
8.	Sieve analysis (% passed of No. 200)	48.3 – 58.6 (clay)
9.	Hydrometer analysis (% of diameter < 0.002 mm)	58.3 – 78.3 (clay)
10.	Activity (A)	1.6 – 2.0

Table 2. Mineral composition of expansive clay soil

No.	Mineral composition	Content (% of weight)
1.	Monmorillonite	34.03
2.	Halloysite	34.86
3.	Alpha Quartz	25.42
4.	Hematite	5.69

### 3. RESEARCH RESULTS

All tests were performed at Soil Mechanics Laboratory Test of Civil Engineering Department of State Polytechnic of Jakarta and Balai Pusat Pengujian Keramik (*Institution Center for Ceramic Test*), Bandung. Flow chart of research conducted is shown in Figure 2.

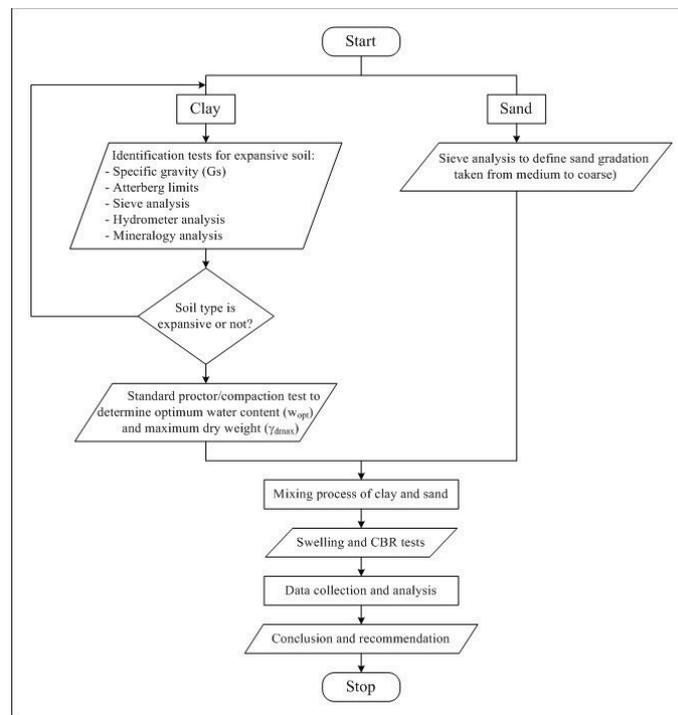

Figure 2. Research flow chart

CBR (*California Bearing Ratio*) test results shows in Figure 3 (a; b; c; and d). Based on Figure 3, it can be concluded that sand addition from 10.0 % to 17.7 %, CBR value of tends expansive clay soil to decrease. So, the sand addition of these ranges cannot contribute to increase soil bearing capacity. However, for sand addition more than 17.7%, CBR value of expansive clay soil can increase, it can be assumed that all sand grain filled pore spaces of expansive clay soil and stabilized clay mineral of montmorillonite, even though these assumptions has to be proven by a micro laboratory works.

From swelling tests, it can be shown that influence of sand contents of 10 and 20% will increase swelling potential values. However, when the sand contents reach 25 and 30%, expansive soil will decrease the swelling potential. It can be concluded that the influence of sand addition will cause decreasing of swelling potential after the optimal values of sand content. In this study, it can be known that to decrease swelling values can be reach if the sand content more than 30% (or > 30 %). So that, influence of sand addition more than 30% will decrease swelling potential and increase CBR values.

### CONCLUSION AND RECOMMENDATION

From laboratory research results, undisturbed and disturbed soil of Cikarang Estate, Bekasi area can be categorized as expansive soil. Influence of sand addition can decrease swelling potential values and increase CBR values after sand contents more than 30%.

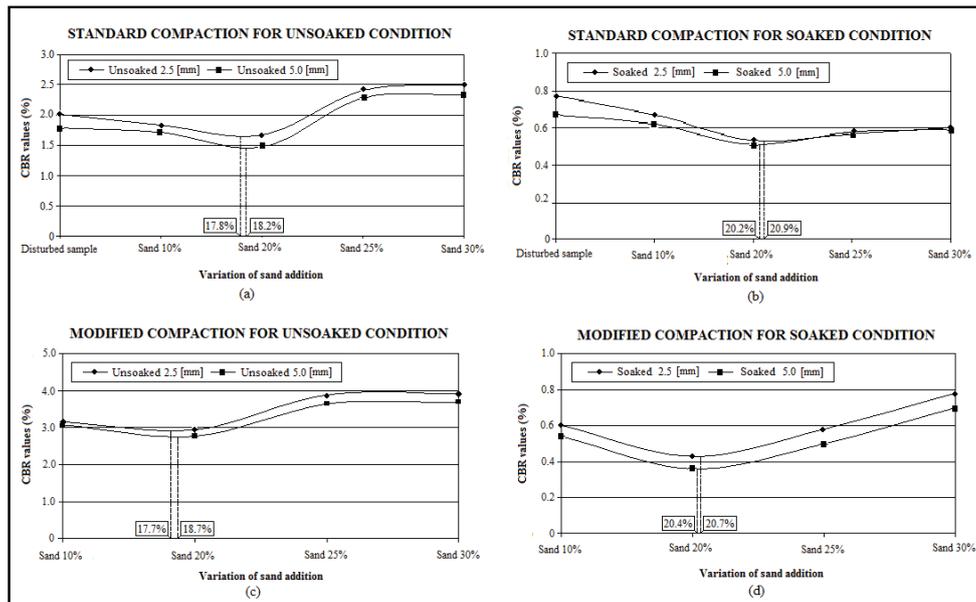

Figure 3. Typical correlation between variation of sand addition and CBR values in soaked & unsoaked conditions

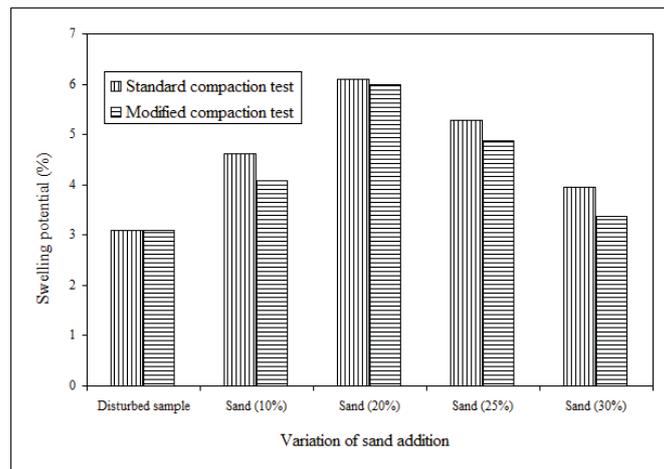

Figure 4. Variation of sand addition and swelling potential based on standard and modified compaction tests

The previously described analysis has clearly indicated that the index properties such as liquid limit, plasticity index and related parameters cannot satisfactorily predict the soil expansivity, as they do not consider the effect of clay mineralogy. The free swell ratio approach, in addition to predicting the soil expansivity more realistically and satisfactorily, gives additional information about the nature of the clay mineralogy of soils. The study should be compared with the stabilizing agents for expansive clay, such as: hydrated lime, portland cement, bitumen, and the others, however the stabilization using agents as mentioned above is quite expensive and requires precision and high accuracy work.

## ABSTRACT

*Car driver and motorcycle rider behaviour might be affected by external disturbances. These include the behaviour of other driver/ rider, the behaviour of pedestrian, the road condition, the existence of outdoor advertisement, people activities on road and surroundings, building lighting, etc. There were 100 respondents interviewed consist of university students, lecturers and employees. Both males and females were covered and both car drivers and motorcycle riders were covered. The questionnaire consists of social status (gender, age, marital status, residential status, health), economic status (monthly expenditure, education back ground, employment status), vehicle data (engine size and production year), driving/ riding skill (driving/ riding experience, driving/ riding license possession), driving/ riding habit (helmet/ safety belt use, equipment check), travel characteristics (daily driving/ riding distance/ time, daily departure and arrival time), risky behaviour (exposure to traffic violation/ accident, etc), and 9 other questions regarding external disturbances. Covariance based SEM (Structural Equation Modeling) will be used to analyzed the effect of repondents socio- economic characteristics, driving/ riding skill/habit/risky behaviour, vehicle/ travel characteristics to their attitude towards external disturbance. A free Partial Least Square (PLS) software available on web called Smart-PLS was used.*

## Keywords:

*External Disturbance, Car Driver Behaviour, Motorcycle Rider Behaviour, Structural Equation Modeling, Partial Least Square*

## 1. INTRODUCTION

Driving a car or riding a motorcycle has already been a multitasking activity [1]. Ones needs to concentrate in this kind of activity to ensure safe drive/ ride. Therefore any disturbance both internal or external disturbances should be minimized. Internal disturbance can be defined as disturbance caused by internal activities in the vehicle such as using mobile phone (initiate/ receive call, sending/ replying text, etc) as stated by [2], using other gadgets (observing map through GPS, using smartphone for various tasks, etc), operating audio visual equipments [3], engaged in internal activities with passengers [4], eating and drinking [5], etc. External disturbance can be defined as disturbance caused by activities/ things outside the vehicle such as behaviour of other driver/ rider, the behaviour of pedestrian, the road condition, the existence of outdoor advertisement, people activities on road and surroundings, building lighting, etc. In this paper the the effect of repondents socio economic characteristics, driving/ riding skill/habit/risky behaviour, vehicle/ travel characteristics to their attitude towards external disturbance will be discussed.

## 2. PREVIOUS STUDIES

Reference [6] shows that older motorcycle riders check the equipment before the ride more frequent compare to the younger one. They stated that whealtier rider tend to involve in less traffic rule violation. They aso stated that helmet use was associated with other responsible behaviour such as bring vaid license on ride, involve in less traffic rule violation and low accident exposure.

According to [7] younger rider was more likely to involve in fatal accident. This is confirmed by [8] that stated older riders tend to conduct safe riding.

According to [9] law enforcement might increase helmet use. At the end, this increase will lead to less number of head injuries.

According to [10] higher rider education could increase possession of valid license. It also increase helmet use rate. According to [11] possession of license would improve riding performance.

According to [12] younger rider, lower road class and male rider tend to fall into low helmet use group. Meanwhile according to [13] law enforcement could decrease fatal and non-fatal injuries. Further they said that rider education and lower speed limit would decrease non-fatal injuries.

Reference [14] shows that less riding experience/ riding skills and poor license system would increase accident risk. They also found that female rider tend to have less experience.

Reference [15] shows that younger female drivers with less experience and more speeding and parking offences tend to be more inattentive and more dangerous. Some of these characteristics confirming the finding of [16]. Meanwhile, [17] stated that younger and wealthier drivers with speeding and traffic rule violation history tend to involve in more accident.

Reference [18] shows that street lighting increase car speed, decrease driver concentration and decrease accident rate. Another road condition such as road segment homogeneity might maintain car speed stability [19].

According to [20], driver stress might increase driving error and driving violation. Meanwhile, [21] stated that drivers with dangerous and speeding habit were usually young, wealthy, less likely to use seat belt and involved in more traffic rule violation and accident. They also stated that experienced and well educated drivers tend to be less dangerous although driving in higher speed.

According to [22], less ability in accident probability judgement, less concern, less worry and security and less emotional reactions formed more risky behaviour. Furthermore they stated that risky behaviour was reflected by unsafe driving and social pressure, speeding and traffic rule violation.

Reference [23] shows that driver who rarely use seat belt tend to involve in severe crash and severe injury. Meanwhile, according to [24] unbuckled caucasian drivers tend to involve in red light running.

Reference [25] shows that driver with more risky driving behaviour tend to conduct speeding and violate traffic rule. They also stated that risk perception was reflected by worry and concern.

Provocation by other road users might lead to speed acceleration by the provoked drivers [26]. However, male driver tend to accelerate faster [27].

According to [28] more speed limit violation was done by non seat belt user. Meanwhile, driver risky behaviour was usually stronger in less educated and less wealthy communities [29]. According to [30] drivers with more traffic violation history tend to involve in crashes.

Higher education was related to higher safety belt use rate [31]. Moreover, older driver with higher job level and higher wealth level was related to higher safety belt use rate [32].

Variable message sign would increase driver alertness [33]. However, truck drivers utilized more time to read roadside displays [34].

Street level advertisement was attracting more driver attention compare to raised level advertisement [35]. In general, outside distractions tend to trigger more absence of hand on steering wheel and cause more lane wandering [5].

### 3. METHODOLOGY

There were 100 respondents interviewed consist of 73 university students, 12 university lecturers and 15 university employees. There were 66 males and 34 females. There were 49 car drivers and 51 motorcycle riders were covered.

Based mainly on the literature review with necessary modification, the questionnaire consists of :

- social status (gender, age, marital status, residential status, health)

- economic status (monthly expenditure, education back ground, employment status)
- vehicle data (engine size and production year)
- driving/ riding skill (driving/ riding experience, driving/ riding license possession)
- driving/ riding habit (helmet/ safety belt use, equipment check)
- travel characteristics (daily driving/ riding distance/ time, daily departure and arrival time)
- risky behaviour (exposure to traffic violation/ accident, etc)
- attitude towards external disturbances (include the behaviour of other driver/ rider, the behaviour of pedestrian, the road condition, the existence of outdoor advertisement, people activities on road and surroundings, building lighting, etc.).

Covariance based SEM (Structural Equation Modeling) was used to analyzed the effect of repondents socio- economic characteristics, driving/ riding skill/habit/risky behaviour, vehicle/ travel characteristics to their attitude towards external disturbance. A free Partial Least Square (PLS) software available on web called Smart-PLS was used. Only indicators with standardized loading factor (SLF) equal and above 0.5 were considered.

Car models were separated from motorcycle models. During data inputting, for both models there were two methods, using limited ordinal scale and using widen ordinal scale (for example for data with wide range of values such as responden age, vehicle production year, etc). Therefore four models were produced. In this paper only visual model for widen ordinal scale will be presented due to the limited pages allowed. However the indicators with  $SLF \geq 0.5$  were presented both for limited ordinal scale models and widen ordinal scala models.

#### 4. RESULTS AND DISCUSSIONS

Figure 1 shows the full model for car with widen ordinal scale whilst Figure 2 shows the final model for motorcycle after all indicators with  $SLF < 0.5$  (including negative SLF's) removed. Figure 3 shows the full model for motorcycle with widen ordinal scale whilst Figure 4 shows the final model for motorcycle after all indicators with  $SLF < 0.5$  (including negative SLF's) removed.

Table 1 shows the summay of all indicators with  $SLF \geq 0.5$  both in car and motorcycle models. The models consist of limited ordinal scale models and widen ordinal scale models. It can be seen that in car models all indicators reflect economic characteristics latent (education attainment, monthly expenses and job level), whilst in motorcycle model only job level was significant.

Marital status was a significant indicator forming social status in car and motorcycle widen ordinal scale models. In car and motorcycle limited ordinal scale models, age was the only significant indicator forming social status.

Except for car model with limited ordinal scale, in all other models, production year was the only indicator significantly forming vehicle characteristic latent. For all models, driving/ riding experience was the only significant indicator reflecting driving/ riding skill latent.

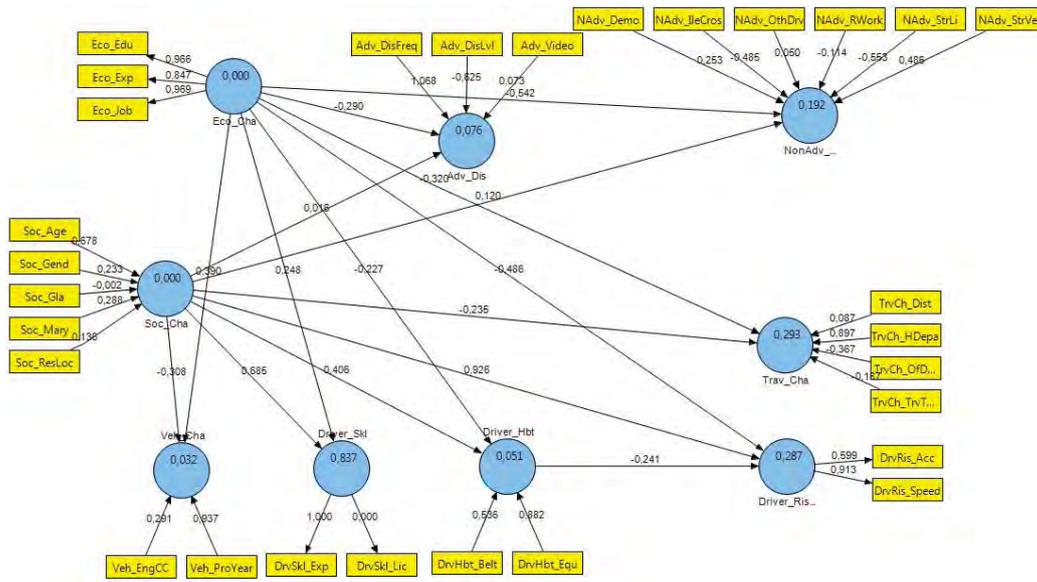

Figure 1: Full Model for Car-Widen Ordinal Scale

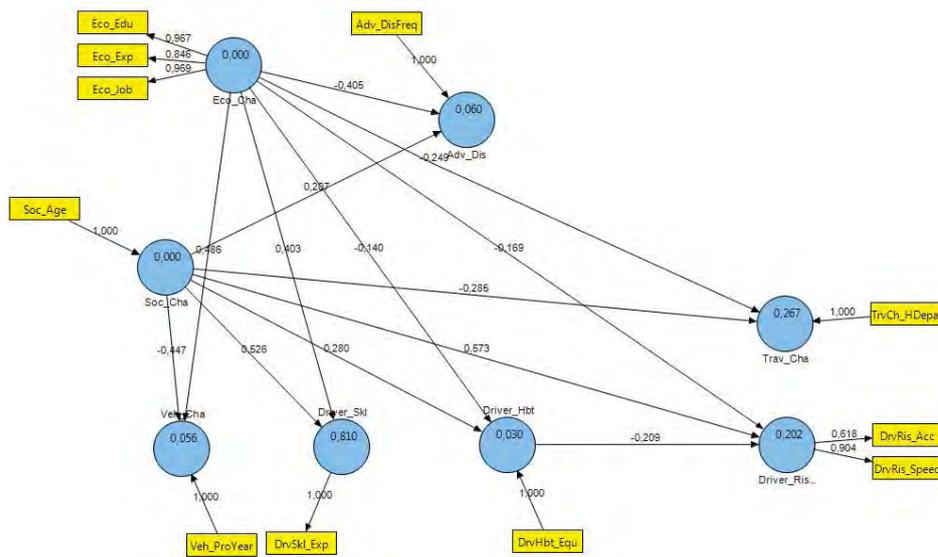

Figure 2: Final Model for Car-Widen Ordinal Scale

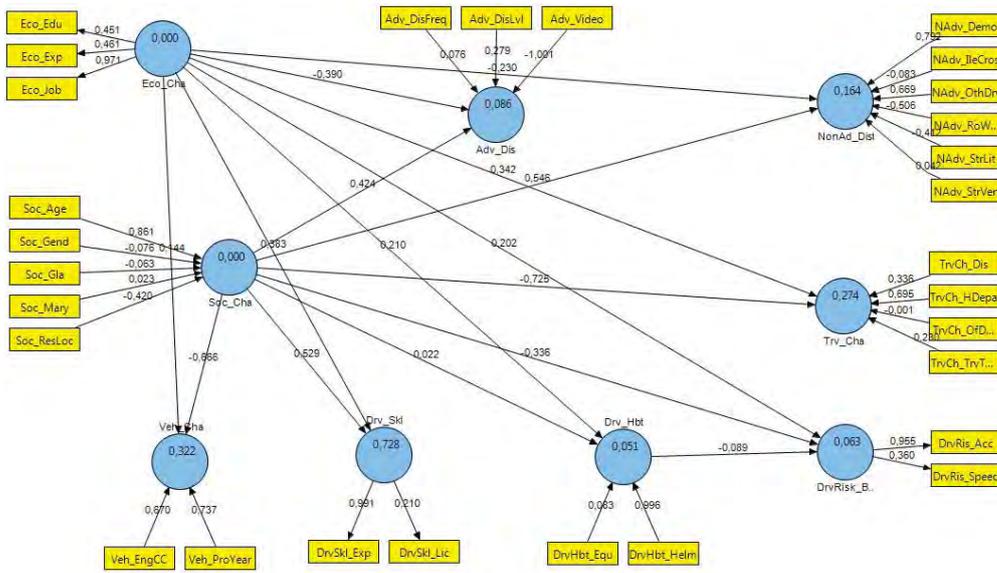

Figure 3: Full Motorcycle Model-Widen Ordinal Scale

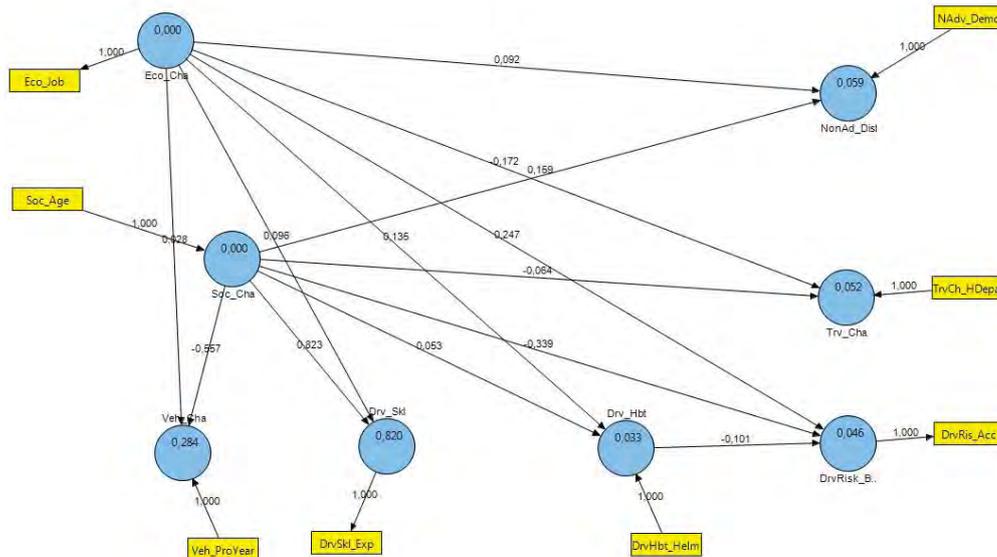

Figure 3: Final Motorcycle Model-Widen Ordinal Scale

For all car models, equipment check before driving was the only indicator significantly forming driving habit latent. For all motorcycle models, helmet use was the only indicator significantly forming driving habit latent.

For all widen ordinal scale models, accident involvement history was a significant indicator reflecting driver/ rider risky behaviour latent. However in car model, driving in a speed more than 100 km/hour was another significant indicator. Driving in a speed more than 100 km/hour was the only significant indicator reflecting car limited ordinal scale model.

For all models, departure time was the only significant indicator forming travel characteristic latent. For all car models, advertisement disturbance frequency was the only significant indicator forming advertisement external disturbance latent (there were no significant indicator for motorcycle models for this latent). For all motorcycle models, demonstration disturbance was the only significant indicator forming non-advertisement latent ((there were no significant indicator for car models for this latent).

In general, economic characteristic latent influence social characteristics, vehicle characteristics, driving skill, driving habit, driver/ rider risky behaviour, travel characteristics, advertisement disturbance and non-advertisement disturbance latents. Social characteristic latent influence all other latents except economic characteristics. Driving habit latent influence driver/ rider risky behaviours.

Table 1: Summary of Indicator with  $SLF \geq 0.5$

Latent Variable	Car-Limited Ordinal Scale	Car-Widen Ordinal Scale	Motorcycle-Limited Ordinal Scale	Motorcycle-Widen Ordinal Scale
<b>Economics Characteristics</b>	Education Expenses Job	Education Expenses Job	Job	Job
<b>Social Characteristics</b>	Marital Status	Age	Marital Status	Age
<b>Vehicle Characteristics</b>	- <sup>1)</sup>	Production Year	Production Year	Production Year
<b>Driving Skill</b>	Experience	Experience	Experience	Experience
<b>Driving Habit</b>	Equipments Check	Equipments Check	Helmet Use	Helmet Use
<b>Driver/ Rider Risky Behaviour</b>	Speeding	Speeding Accident Involvement	- <sup>1)</sup>	Accident Involvement
<b>Travel Characteristics</b>	Departure Time	Departure Time	Departure Time	Departure Time
<b>Advertisement Disturbance</b>	Frequency of Disturbance	Frequency of Disturbance	- <sup>1)</sup>	- <sup>1)</sup>
<b>Non-Advertisement Disturbance</b>	- <sup>1)</sup>	- <sup>1)</sup>	Demonstration	Demonstration

1) SLF for all of the indicators in this latent are negative or below 0.5

## 7. CONCLUSION AND RECOMMENDATION

It can be concluded that except for economic characteristics latent and driver risky behaviour latent, all other latents have only single valid indicator to form or to reflect each of them. One of the possible cause was the use of non-standard questionnaire without statistical validation test. In further research this statistical validation test should be carried out.

## ABSTRACT

The objective of the study is to develop a signal-control strategy and its application for road closure area on two way two lanes roads which is treated as an isolated intersection during severe over saturation. The study developed a method which introduces a ratio between cumulative departure and cumulative arrival ( $R$ ). With the same arrival and saturation flow data, the method introducing in this study has a better performance results comparing amongst the Discrete Minimal Delay Model and the Maximum Throughput Model. The simulation results show that the optimum arrival detection period is 240 seconds and the optimum cycle time is 240 seconds. The study indicates the percentage of increasing total delay, decreasing of average throughput and decreasing of over saturation period if there is a change of cycle time from 240 seconds to less than 240 seconds and the maximum road closure length that can be accommodated by signalized traffic control in over saturation traffic condition based on total Degree of Saturation ( $DS$ ), average speed on lane closure area ( $S_w$ ).

## Keywords

signalized traffic control, road closure areas, oversaturated.

## 1. INTRODUCTION

Road activity which requires the closure of one of the two ways two lane roads need a special effort to maximize the capacity of bottleneck areas, especially on over saturation traffic condition. To overcome the problem arises on an oversaturated two way two lane road closure areas, this study developed a two steps of green time planning method which is introducing a ratio between cumulative departure and cumulative arrival ( $R$ ) on its signalized traffic control strategy.

## 2. RESEARCH OBJECTIVE

The objective of the research is to evaluate the application of a ratio of vehicle's cumulative departure to cumulative arrival ( $R$ ) value as a switch over point parameter on oversaturated two way two lane road closure areas (RCA) as a signalized traffic control strategy with the speeds on RCA are 20 km/h and 30 km/h.

## 3. ROAD CLOSURE AREA (RCA) TRAFFIC CONTROL

Portable traffic signals use of the red clearance interval, or "all red" period to allow vehicles that have entered a RCA under a green or yellow indication to safely pass through and exit the one-lane RCA. The factor that determines duration of the red clearance interval is the speeds at which motorists will drive through the one lane RCA. The lay out of signalized traffic control on two way two lane RCA installation is shown on Figure 1, whereas Figure 2 displays the time needed in both directions to clear the road closure areas.

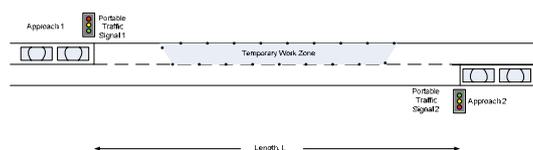

Figure 1: Portable Traffic Signal Installation for Road Closure Area Control

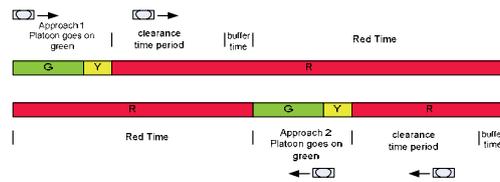

Figure 2: Complete Signal Cycle for Portable Traffic Signal Installation

$$\text{Maximum Wait Time (each direction)} = 2Y + 2R + 2B + G_{\max} \quad (2)$$

where

- $Y$  = yellow clearance time (applies to both directions), seconds
- $R$  = red clearance time (applies to both directions), seconds
- $B$  = buffer time (applies to both directions), seconds
- $G_{\max}$  = maximum green time in the opposing direction, seconds

Ginger et al [3] indicates that the maximum wait time (i.e., before driver confusion and possible violation) is approximately four minutes.

#### 4. SIGNALIZED TRAFFIC CONTROL ON OVERSATURATED TRAFFIC FLOW

##### 4.1. Previous Studies

The previous studies of signalized traffic control on oversaturated traffic flow were conducted by Chang and Lin [1] and Talmor and Mahalel D [6] which is summarized on Table 1.

Table 1: The Previous Studies Of Signalized Traffic Control On Oversaturated Traffic Flow

	Chang TH and Lin JT (2000).	Talmor I and Mahalel D, (2007),
Objective	minimize the total delay on the intersection during the oversaturated period by deriving a basic discrete minimal delay model and a performance index model	to maximize the average throughput of the intersection during the oversaturated period
uniqueness	Appication of bang-bang like control, by which signals are operated alternatively and sequentially, with minimal maximal green time, significantly outperforms conventional equal timesharing dispersion control; and not all provided cycle lengths are applicable to oversaturation control, since some may fail to meet the warrant of simultaneous dispersion indicated by Gazis	Application of discharge-flow functions instead of saturation-flow functions. Maximum throughput is achieved, based on the best balance between the decrease in discharge flows and the saving in lost time.
conclusions	The discrete type performance index model, which results in bang-bang like control, is quite appropriate for oversaturation control. The performance of this model is rather robust even when the input data appear to be slightly biased. The proposed model can also determine the optimal cycle length and the optimal assigned green time.	Control based on the maximization of throughput enables an optimization of traffic operations as long as congestion persists, without the need for any further knowledge of existing or future demand. This capability is important and significant, since congestion is often random and may occur without any prior information of its existence or duration.

##### 4.2. Demand and Service Approach

The traffic signal service equation is describing the service rate from the beginning until the end of the oversaturated period. The curve of cumulative arrival of vehicle and service of traffic signal control at oversaturated period presented at Figure 3. Beginning of oversaturated period happened at the time of  $T=0$  and oversaturated period end at the time of  $T=n.c.$  ( $n$ =total number of cycle time and  $c$ = cycle time).

At  $T = n.c.$ ,  $Q = G$

$$-(a_1 + a_2).t^2 + (b_1 + b_2).t = (\gamma_1 + \gamma_2)t$$

$t = n.c.$ , then

$$-(a_1 + a_2).(n.c)^2 + (b_1 + b_2).(n.c) = (\gamma_1 + \gamma_2).(n.c) \quad (5)$$

$$\begin{aligned} \gamma_1 &= \frac{g_1 s_1}{c}, \quad \gamma_2 = \frac{g_2 s_2}{c} \quad \text{and} \quad g_1 + g_2 = c \\ \gamma_1 &= \frac{(c - g_2) s_1}{c} \\ -(a_1 + a_2) \cdot (n \cdot c)^2 + (b_1 + b_2) \cdot (n \cdot c) &= \frac{(c - g_2) s_1 + g_2 s_2}{c} \cdot (n \cdot c) \\ -(a_1 + a_2) n \cdot c + (b_1 + b_2) &= \frac{(c - g_2) s_1 + g_2 s_2}{c} \end{aligned} \tag{6}$$

where

- $G$  = Total Cumulative service function, pcu
- $G_{1,2}$  Total Cumulative service function of movement 1 and 2, respectively, pcu
- $\gamma_{1,2}$  = Service rate (throughput) of movement 1 and 2 respectively, pcu/hour
- $a_{1,2}, b_{1,2}$  = Constants of the polynomial functions

$C$  is an input value, whereas the value of  $a_1, a_2, b_1, b_2, s_1, s_2$  is determined based on field data. If the equation fulfill the equation  $g_1 + g_2 = c$ , the value of  $n, T$  and  $\gamma$  can be calculated. Based on the assumption that that both approaches disperse the queues at the same cycle, hence the value of  $\gamma_1, \gamma_2, g_1$  and  $g_2$  also can be calculated.

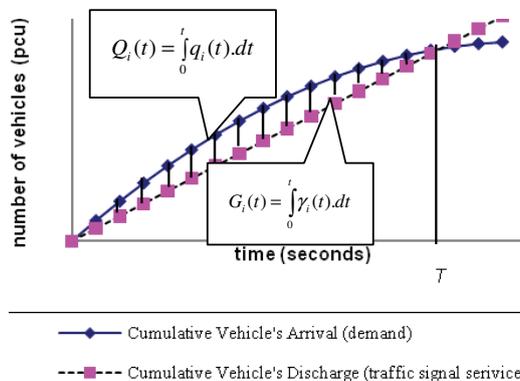

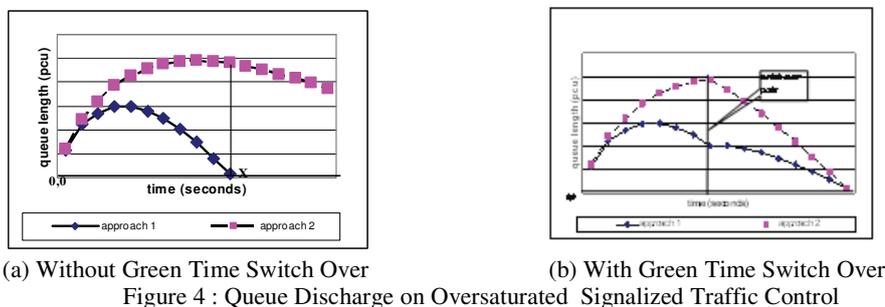

Figure 3: Vehicle's Cumulative Arrival and Cumulative Service of Traffic Signal Control at Oversaturated Period  
**5. SWITCH OVER POINT APPROACH**

Figure 4 show the queue length in an intersection with 2 phase signalized traffic control along the oversaturated period. The first phase serves the movement from the left of RCA (will be termed as first movement) and the second phase serves the movement from the right of road closure area (will be termed as second movement). As shown on Figure 4a, the traffic signal control on oversaturated period with single green time often cannot disperse the queue at both approaches concurrently. It can be seen that at  $T=X$ , the all queue at 1<sup>st</sup> movement has been discharged, but at the 2<sup>nd</sup> movement the queues still exist. To overcome this, the two step green time method with switching of green time at certain point has been developed. This point is called as switch over point (Figure 4b).

**5.1. Ratio Of Cumulative Vehicle Arrivals to Cumulative Vehicle Discharge**

As already mentioned above, the study developed a parameter to determine the switch over point named  $R$ , which is defined as ratio of cumulative vehicle arrivals to cumulative vehicle discharge.

Performance parameter calculated at any cycle time (iteration) is :

1. Vehicle discharge on the  $i$ th of green and  $j$ th iteration ( $VD_{i,j}$ )

$$VD_{i,j} = \frac{s_m}{3600} \times G_i(m) \quad m = 1,2 \quad (7)$$

where

- $VD_{i,j}$  = Vehicle discharge on the  $i$ th of green and  $j$ th iteration  $j$ , pcu
- $s_m$   $m = 1,2$  = Saturation flow of approach 1,2 pcu/hour
- $G_i(m)$  = Green time of approach  $m$  on the  $i$ th green time,  $i = 1,2$  (1 for before switching and 2 for after switching)

2. Queue length on the  $i$ th of green time and  $j$ th iteration ( $Q_{i,j}$ )

$$Q_{i,j} = CA_{ij} - CA_{i,j-1} + Q_{i,j-1} - VD_{i,j} \quad (8)$$

3. Ratio of cumulative vehicle arrivals to cumulative vehicle discharge on the  $i$ th of green time and  $j$ th iteration ( $R_{i,j}(m)$ )

$$R_{i,j}(m) = \frac{CD_{i,j}}{CA_{i,j}} \quad (9)$$

where

- $Q_{i,j}$  = queue length on the  $i$ th of green time and  $j$ th iteration, pcu
- $CA_{i,j}$  = cumulative vehicle arrivals on the  $i$ th of green time and  $j$ th iteration, pcu
- $CD_{i,j}$  = cumulative vehicle discharge on the  $i$ th of green time and  $j$ th iteration, pcu

Switch over point will be done if the value of  $R_{i,j}(m)$  at one of the two approaches has already achieved the determined value of  $R_{i,j}(m)$ . Which its value is in the range of zero to one ( $0 < R_{i,j}(m) < 1$ )

## 5.2. Simulation Scenario

### 5.2.1. R Value

The simulation was done on the various value of  $R_{i,j}(m)$  as follows:

$$R_{i,j}(m) \geq 0,1; 0,4; 0,5; 0,65; 0,75; 0,85; 0,9; 0,95; 0,97$$

The example of Chang and Lin [1] and Talmor and Mahalel D [8] is applied in the simulation as shown on Table 2. The example assumed an intersection of two one way streets with a two-phase signal control. One street is denoted as approach 1, and the other street as approach 2. No left turn is considered. Approach 1 has a saturation flow of 1400 vehicle/hour and approach 2 has a saturation flow 1000 vehicle/hour. In this study the saturation flow was converted into 1400 pcu/hour and 1000 pcu/hour, respectively. The cycle time is 150 seconds. In order to compare with the other model, the simulation was done with the value of zero in the length of RCA.

Table 2: Input Data

Cumulative time period (second)	Cumulative vehicle arrival (pcu)	Arrival flow (pcu/hour)	Saturation flow (pcu/hour)	Degree of Saturation	Cumulative vehicle arrival (pcu)	Arrival flow (pcu/hour)	Saturation flow (pcu/hour)	Degree of Saturation
	Approach 1				Approach 2

### 5.2.2. Simulation on RCA

To accommodate various variation of lane width, this study applied the total Degree of Saturation (DS) value to substitute the values of saturation flow and passenger car equivalent of each vehicle type. DS is sum of ratio of arrival flow to saturation flow on each movement or each approach. Therefore, the research's simulation scenario is as follows:

- a. Variation of vehicle arrival is represented by total Degree of Saturation and the Degree of Saturation (DS) of each approach.
- b. The observation time of the vehicle's arrival is 1 hour (3600 seconds) and the over saturation period is assumed happen on the first 300 seconds. The vehicle's arrival after the first 300 seconds is assumed as unsaturated flow, with the value of total Degree of Saturation is 0.71.
- c. The variation of DS on the first 300 seconds are as follows:
  - $1 < DS < 1.5$  (represents by DS=1.44)
  - $1.5 < DS < 2$  (represents by DS=1.86)
  - $2 < DS < 2.5$  (represents by DS=2.26)
  - $DS > 2.5$  (represents by DS=2.76)
- d. The simulation applies at various length of RCA, speed at RCA and cycle time as follows:
  - Length of RCA : 10, 15, 25, 50, 75, 100, 125, 150, 175, 200 meter
  - Speed at RCA: 20 km/tour
  - Cycle time: 120, 150, 180, 210, 240 seconds
  - Vehicle's Detection Period : 120, 180, 240, 300 seconds

## 6. PERFORMANCE INDICATOR AND R VALUE

The simulation results on Table 3 and Figure 4 show that the various of R do not give a significant trend of both average throughput and total delay. The simulation results also show that although average throughput has a maximum value on the value of  $R \geq 0.95$ , but the difference is very small. The two performance indicators, those are average throughput and total delay, do not have any special trend in result regarding with the difference of the R value. The first simulation results show that green time determination has a significant difference if be chosen based on the minimum total delay value. The minimum total delay was happened on the value of  $R \geq 0.95$ .

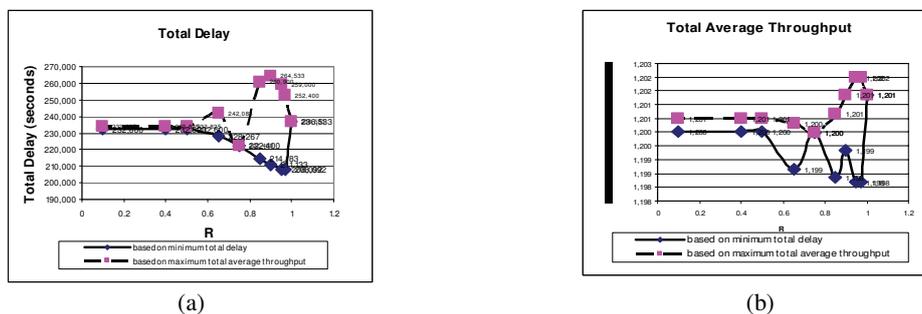

Figure 4: Total Delay and Total Average Throughput of Various R Values

Table 3 shows the performance results of the study and the two other methods, i.e. Discrete Minimal Delay Model [1] and Maximum Throughput Model [6] based on the same input data. The results then compared to the based result, which is Minimal Delay Model [1]. The difference in percentage to the based result was done also presented in this Table.

Comparing with Discrete Minimal Delay Model [1], this study has improved some of performance indicators of signalized traffic control, those are 5,88% better in length of over saturation period, 1,46% in average throughput, 13,57% in number of vehicles in the queue and 12,80% in total delay. This performance also better than Maximum Throughput Model [6]

Table 3: Performance Results

Performance Indicator	Discrete Minimal Delay Model	Maximum Throughput Model	Research, R=0,95
Over saturation period (second)	2550.00	2434.80	2400.00
throughput (pcu/hour)	1181	1195	1198
Number of vehicles in the queue (pcu)	1609	1566	1391
total delay (second)	238,625	233,035	208,092
Comparison to Discrete Minimal Delay Model			
Over saturation period (second)	-	4.52%	5.88%
throughput (pcu/hour)	-	1.16%	1.16%
Number of vehicles in the queue (pcu)	-	2.69%	13.57%
total delay (second)	-	2.34%	12.80%

Source : Talmor I & Mahalel D [8] & Result of the Study (2009)

Evaluations of the first simulation are as follows:

- Green time determination has a significant difference if be chosen based on the minimum total delay value.
- The minimum total delay was happened on the value of  $R \geq 0.95$ .
- The ratio of vehicle's cumulative departure to cumulative arrival (R) value as a switch over point parameter could be applied on a two phase oversaturated signalized traffic control strategy.
- The research method, which was applied a ratio of vehicle's cumulative departure to cumulative arrival (R) value of 0.95, has improved the performance of the previous methods, i.e. the Discrete Minimal Delay Model and the Maximum Throughput Model.
- The research method could be applied to oversaturated two way two lane road closure areas signalized traffic control strategy by inputting the length of road closure area and the average journey speed in the road closure area.

### 6.1. Optimum Detection Period

The simulation results show that minimum total delay is achieved when the detection period is more than 240 seconds. When  $DS < 2$  the minimum total delay is 300 seconds, but at  $DS > 2$  the minimum total delay of 240 seconds and 300 seconds vehicle's detection period has the same value of minimum total delay. The percentage of increasing total delay comparing to 240 seconds of detection period at cycle time 240 seconds is shown on Table 4.

Table 4 Total Delay on Various Detection Periods Comparing to Detection Period of 240 seconds= 240 Seconds

DS	Lw	Total Delay (seconds)				oversaturated period	average throughput	% comparing to detection period of 240 seconds			
		detection period (seconds)						detection period (seconds)			
		meter	120	180	240			300	seconds	pcu/hr	120

### 6.2. Optimum Cycle Time

The simulation results of cycle time variation, are as follows:

- Cycle time of 240 seconds resulting the smallest total delay at most of variations, except on the following scenarios, which the smallest total delay occurred on cycle time of 210 seconds:
  - Length of RCA 10 meter and 25 meter on  $1 \leq DS \leq 1.5$
  - Length of RCA 25 meter on  $1 \leq DS \leq 1.5$  and  $2 \leq DS \leq 2.5$ .

- b. Cycle time of 240 seconds resulting the largest total average throughput at all variations.
- c. Cycle time of 240 seconds resulting the smallest oversaturated period at all variations.

Based on the simulation results mentioned above, the cycle time of 240 second is chosen as the optimal cycle time. Total delay, total average throughput and oversaturated period on Various Cycle Time Comparing to Cycle Time of 120 seconds is shown on Table 5.

*Table 5: Total Delay, Total Average Throughput and Oversaturated Period on Various Cycle Time Comparing to Cycle Time of 120 Seconds*

Length of RCA	Cycle time	Total Delay	average throughput	Length of RCA	Cycle time	Total Delay	average throughput	Length of RCA	Cycle time	Total Delay	average throughput
meter	second	second	pcu/hour	meter	second	second	pcu/hour	meter	second	second	pcu/hour

### 6.3. Prediction Of Delay, Throughput And Oversaturation Period

The simulation results show that the length of RCA (Lw) that could be accommodated by a signalized traffic control on two way two lane RCA at oversaturated period is limited and depend on the value of the total Degree of Saturation (DS) of the two approach. The approaching model of total delay and length of RCA relationship is an exponential equation, while for the total average throughput and length of RCA relationship is a linear equation.

The equations to predict the total delay and average throughput based on the value of DS and the length of RCA on observation period 240 seconds and cycle time 240 seconds are shown on Table 6. The value of oversaturated period is presented on Table 7.

*Table 6 Equation of Total Delay and Average Throughput Prediction*

DS	equation		Lw can be accommodated
	total delay	throughput	
	second	pcu/hour	meter
$1 \leq DS \leq 1.5$	$y = 23286 e^{0.0128 x}$	$y = -2.523 x + 1653$	$Lw \leq 125$
$1.5 \leq DS \leq 2$	$y = 74325 e^{0.0102 x}$	$y = -2.523 x + 1653$	$Lw \leq 100$
$2 \leq DS \leq 2.5$	$y = 150682 e^{0.0068 x}$	$y = -2.511 x + 1653$	$Lw \leq 75$
$2.5 \leq DS \leq 3$	$y = 280113 e^{0.0077 x}$	$y = -2.482 x + 1652$	$Lw \leq 50$

*Table 7: Oversaturated Period Based on the Length of RCA, DS and Sw on Observation Period 240 Seconds and Cycle Time 240 Seconds*

Length of RCA meter	over-saturated period (seconds)			
	$1 \leq DS \leq 1.5$	$1.5 < DS \leq 2$	$2 < DS \leq 2.5$	$2.5 < DS \leq 3$
10	960	1,440	1920	1920
25	960	1,680	2160	2160
50	1,200	1,920	2640	2640
75	1,440	2,400	3120	3120
100	1,920	3,120	-	-
125	2,880	-	-	-

## 7. CONCLUDING REMARKS

A signal-control strategy for road closure area on two way two lanes roads which is treated as an isolated intersection during severe over saturation was developed using ratio of vehicle's cumulative departure to cumulative arrival (R) value as a switch over point parameter could be applied on a two phase oversaturated signalized traffic control strategy.

With the same arrival and saturation flow data, the switching method introduced in this study has a better performance results comparing with the Discrete Minimal Delay Model and the Maximum Throughput Model. The application of a ratio of vehicle's cumulative departure to cumulative arrival (R) value of 0.95, has improved the performance comparing with the two previous methods.

The switching method could be applied to signalized traffic control strategy on oversaturated two way two lane road closure areas by inputting the length of road closure area and the average journey speed in the road closure area.

The results of simulation to the various lengths of road closure area and the average journey speed in the road closure area are that minimum total delay is achieved when the detection period is more than 240 seconds and the optimal cycle time is 240 seconds

The length of Road Closure Area (Lw) could be accommodated by a signalized traffic control on two way two lane RCA at oversaturated period is limited and depend on the value of the total Degree of Saturation (DS) of the two approach. The approaching model of total delay and length of RCA relationship is an exponentials equation, while for the total average throughput and length of RCA relationship is a linier equation.

## ABSTRACT

*It is crucial to applied risk guarantee to infrastructure projects for the reason that assurance in the handling of various risks is vital in infrastructure development especially in a scheme of public-private partnerships. Government attract private sector participation as a scheme of policy solutions to budgetary limitations by incentives such as debt guarantees, Minimum Revenue Guarantee (MRG), or direct cash support. The incentive system is an important factor in determining the success of infrastructure projects but still not lucrative in the bidding process due to the failure of traditional capital budgeting theory such as Net Present Value (NPV) analysis in evaluating the value of collateral. This is because the NPV analysis can not reflect the characteristics of a contingent guarantee agreement. This study is to develop a model of risks guarantees of highway infrastructure with binomial real options to evaluated the value of MRG by considering the asset uncertainty , and using detailed level of volatility with a monte carlo simulation approach. Finally, real options models appear to offer a practical and theoretical framework in evaluate MRG agreement and assist governments establish policy of public-private partnership and provision the right bidding strategy in the investment.*

**Keywords :** risk guarantees, minimum revenue guarantee, real options.

## 1. Introduction

Availability of reliable and adequate infrastructure has a very substantial role, sometimes even decisive, for productivity and economic development of a country and the quality of life [1]. [2] estimates that a 1% increase in infrastructure investment associated with 1% increase in Gross Domestic Product (GDP). Similarly, governments in developing countries and industrialized countries in the rest of the world, the Indonesian government also recognizes the importance of infrastructure for national economic growth. GDP growth in the 2004-2009 period, on average, expected to reach 6.6%. To achieve these targets, the required infrastructure investments worth approximately Rp. 1300 trillion [3]. Meanwhile, the fiscal capacity of the Government and other domestic financing from banking institutions, insurance companies, pension funds, and mutual funds can only cover respectively about 17% and 21% resulting in a gap of approximately 62% of total funding needs. The private sector is expected to cover most of the gap in order to achieve the investment target.

Infrastructure development projects, involving the private sector often foundered on the risks difficult to overcome by the respective parties. Thus, in its development needs assurance from the government directly or involve a third party. Assurance government itself set up infrastructure projects in the two existing legal framework. In order to accelerate the development of infrastructure deemed necessary to support the government (government support) to encourage the participation of enterprises and increasing investment in infrastructure provision. Furthermore, government support is financial compensation or other compensation given by the government to businesses through risk sharing scheme for the implementation of joint infrastructure projects.

Guarantee risk is very important, because without the certainty of handling the risks mentioned above as well as the provision of the parties will bear those risks, it would be difficult to convince the private sector, or potential investors and the fund provider (financier) to invest or finance the project or participate in infrastructure projects. It is quite urgent applied to infrastructure projects, especially in Indonesia, the risks perceived by investors are still relatively high. The purpose of this study was to develop a model of risk assurance highway infrastructure with binomial option for evaluating the value of assets MRG by considering uncertainty, and use a more granular level of volatility with monte carlo simulation approach. Finally, based on the results and analysis, real options model developed seems to provide a practical and theoretical framework to

evaluate the quantitative MRG agreement and help the government build public-private partnership policy better and help make the right bidding strategy in the investment.

## 2. Toll Road Infrastructure in Indonesia

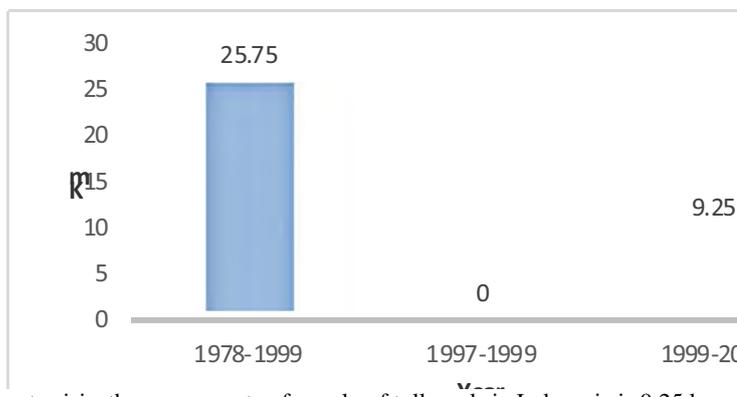

Due to the financial crisis in July 1997 which resulted in the government should suspend highway construction program with the issuance of Presidential Decree. 39/1997. Due to delay construction of toll roads in Indonesia stagnant, as evidenced by the establishment of only 13.30 km of highways in the period 1997-2001. In 1998 the government issued Presidential Decree No.7/1998 on Public-Private Partnership in the provision of infrastructure. Furthermore, in 2002 the government issued Presidential Decree. 15/2002 concerning forwarding infrastructure projects. The government also evaluated and forwarded to the exploitation of toll road projects were delayed. From 2001 to 2004 awakened 4 roads with a total length of 41.80 km. In 2004 issued Law No.38 of 2004 on the road instead of the establishment BPJT regulator role that had been held by PT Jasa Marga.

The process of re-entering the highway construction acceleration phase began in 2005. On June 29, 2005 established the Toll Road Regulatory Agency as a regulator of toll roads in Indonesia. Continuation of the 19 toll road construction projects postponed in 1997 took place. In the future the government will fund the construction of toll roads using three approaches, namely full financing by the private sector, public-private partnership program (Public Private Partnership / PPP) and the financing of the construction of the Government and by private-maintenance operation. Phase development of toll roads in Indonesia brief seraca can be seen in Table 2.1 below.

Table 1 History of Toll Roads in Indonesia

Phase	Period	Specification
I	1978 – 1983	Toll facility entirely funded through the government budget
II	1983 – 1987	Toll facilities financed using a combination of public funds and bonds Jasa Marga
III	1987 – 1994	Toll road market open to domestic private investors
IV	1996 – current	Toll road market was opened to foreign investors of private sector land acquisition

The pace of construction of toll roads in Indonesia can be distinguished in the condition as shown in Figure 2.1, the pre-crisis (1978-1998), during the crisis (1998-1999) and post-crisis (1999-present). In the pre-crisis levels, the average rate of supply of the highway is at 25.75 km per year, during the supply crisis relatively highway so that growth is the growth rate equal to zero.

While the post-crisis, the average rate of supply of toll roads in Indonesia is 9.25 km per year

Figure 1 Growth in toll roads per year

### 3. Government Guarantee Assessment Project Financial Analysis with Real Option

#### 3.1 Analysis of Net Present Value (NPV) and Internal Rate of Return Analysis (IRR)

Traditional analysis Discounted Cash Flow (DCF), NPV analysis works well when the risk of the assets remained stable over time. Traditional assessment methods are sufficient for the investment decisions regarding the assets in place if the operation ensures a relatively stable cash flow [4,5]. NPV analysis also works well for a typical engineering investment as replacement equipment if the main benefit is cost reduction. However, sometimes the project creates the possibility of a contingency such as delay, abandon or expand the project by changes in management decisions. And, changes in future cash flows as a result of development or new information is received. In this case, the NPV analysis have either underestimate or ignore the value of this management flexibility [6,7,8,5]. After starting role in the investment risk, the NPV analysis can accommodate risk attitudes using risk-adjusted discount rate for discounting the expected cash flows. In the real world, in general, many companies classify different risk categories of the project and set the price of each of the different categories to reflect the risks involved [7] or using different discount rates in different periods to reflect changes in interest rates nominal [9]. Even as the NPV analysis has been widely used in almost every industry as an effective method of project appraisal, there was also some criticism that can be leveled against it.

Along with the analysis of NPV, Internal Rate of Return (IRR) is a popular approach to the analysis of capital budgeting as intuitive as with rate of return. Generally, the NPV decreases with increasing discount rate. At some value of the discount rate, the NPV of a certain cash flow stream is zero. This is the discount rate that makes NPV equal to zero is called IRR. That is, the IRR is the rate of return on investment of the project is reflected in a set of future cash flows [9,10]. If the IRR is higher than the required rate of return, then the project is considered acceptable. In general, the required rate of return earned by the cost of borrowing for similar projects plus a few percentage points higher than the cost of borrowing to compensate for the risk, time, and the problems associated with investment [11]. Unlike NPV analysis, this approach can help to eliminate the problem of selecting the appropriate discount rate but still produces more questions in a way to determine a reasonable hurdle rate to be used as a standard to estimate if the IRR is high enough to agree to the project.

#### 3.2 Monte Carlo simulation approach

Monte Carlo simulation approach, as one of the extensions of the NPV analysis, is to explain the uncertainty [12,7] and was originally proposed by [13]. The simulation procedure is used to identify the key variables that determine the cash flow of the project and then simulate the variables to obtain the distribution of the cash flow generated or NPV. It is an analytical approach that relies on repeated random sampling from the probability distribution of the main variables underlying cash flows of the project to arrive at a risk profile, which is a distribution of cash flows or NPV [14]. This simulation reflects real-world setting decisions using mathematical models to capture the essential characteristics of the project as it progressed through time and encounter various random events. As a common type of simulation approach, Monte Carlo simulations generally follow the following process [14,7]. The first is to identify all the variables of uncertainty in project cash flow setup, noting the interdependencies between different variables and any serial dependence. In the second process, for each variable is uncertain, it defines the possible values of with probability distribution. Here, the type of distribution is selected based on the nature of the uncertainty of that particular variable. The third, and then selected a random value for each variable bound by a probability distribution to calculate the net cash flow for each period and then the NPV. Eventually, this process will be repeated for a number of iterations, which produces a probability distribution for the project NPV.

#### 3.3 Assessment of Real Option Analysis

Option Pricing theory, designed in financial assets by [15] and [16], are the building blocks of the concept of Real Option Theory to figure out the interaction between the behavior of option holders maximize profit "Theory of Option real." , An asset uncertainty, and market discipline. Financial concept imported to evaluate the real assets of physical investment, which was then called "options." So, the real option theory is the application of financial option pricing theory as a management tool to evaluate investment real assets [6]. Real option analysis, in many respects, be considered as an effective tool to evaluate embedded options and flexibility in projects such as oil and gas, pharmaceutical, manufacturing, aviation, mining, real estate, and other industries. In financial assets such as stocks, bonds, currencies and so on, the choice is right, but not the obligation, to perform certain actions in the face of uncertainty. Likewise, in tangible assets, tangible, like a project or a business relative to financial assets [17], real option is the right, but not the obligation, to take some specific action. This is referred to as "management flexibility" as delay, abandon, or expand a fee for a certain time [18].

Real options theory provides a framework for analyzing strategic capital investment by identifying the flexibility of management to be handled as a valuable opportunity [19] so that decision makers can keep the investment options open in the face of uncertainty and is done after finishing with a time of uncertainty or further information [20]. When the present value of the cost of decision making changes during construction or operation outweigh the additional cost to design flexibility into the investment opportunities in the beginning [21], the options actually available.

The main difference between real option analysis and NPV analysis comes from some of the effects of different variables to the model. For example, the higher the uncertainty, the greater the interest rate, or more time before doing a project does not necessarily make the investment opportunities are less valuable in the analysis of options, as well as the NPV analysis [7]. That is, although each of these factors have a negative effect on the NPV of the investment opportunities, these factors may increase the value of the choices made by the managerial flexibility.

#### 4. Qualitative Risk Assessment

A qualitative risk assessment (qualitative risk assessment or QRA) consists of several stages, ranging from risk identification and risk analysis qualitatively. QRA approach is taken to facilitate the respondents, especially those from the industry, in an opinion which is very valuable to get the global information about the risks of toll roads.

Of the 27 (twenty seven) types of risks identified can be drawn perspective possible, land acquisition delays risk factors (R3) be a risk factor ranks highest, followed by the risk of late payment (R4), and the risk of cost escalation (R10). Meanwhile, the risk of low traffic volume only sorted on the 11th although this risk is often a major concern for prospective investors considering the difficulty of prediction of traffic volume carried, not only for the long term but in the short term. Meanwhile, the impact of the dimensions of the event, delay in land acquisition risk factors (R3) again ranked top, followed by the risk of the claim (R6), which has ranked second level in terms probability and risk financing (R1) was third. This survey shows that the two main risk factors in the toll road business is a risk and the risk of higher land acquisition costs. Furthermore, the trend of the probability and impact is calculated based on the arithmetic average of each factor for subsequent mapping (mapping) that terdiri four groups: a) high-probability high impact, b) low-probability high-impact, c) low-probability high-impact high, and d) low-impact low probability. This mapping is useful to determine what mitigation measures are most appropriate. For example, if a risk factor known to have a high risk of impact despite having a low probability, risk transfer to third parties, for example, is one of the mitigation options that could be considered. The results obtained can be seen in Figure 2.

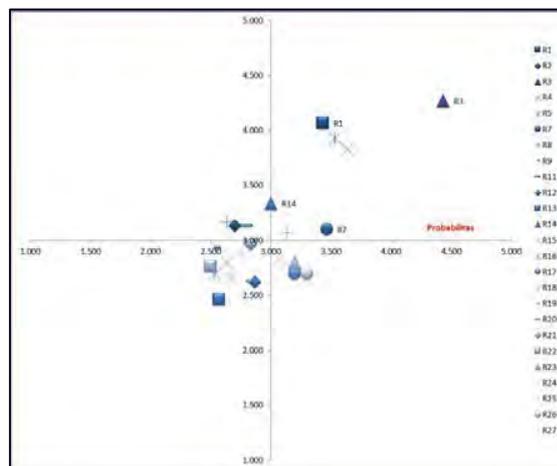

Figure 2 Diagram Risk Probability and Impact Factor

#### 5. Model Government Guarantee

Government guarantee on infrastructure projects set in two existing legal framework. First is PP67/2005 Article 17 and PMK 38/2006. Article 17 of Presidential Decree No. 67/2005 states the government can provide fiscal support to the PPP project by

asserting that such support should follow the principles of risk management and its mitigation and within the framework of the state budget or the budget. This task should be done by the Minister of Finance, or the Head of Unit in the Region.

Meanwhile, PMK 38/2006 states that in order to accelerate the development of infrastructure deemed necessary to support the government (government support) to encourage the participation of enterprises and increasing investment in infrastructure provision in Indonesia. Furthermore, PMK 38/2006 states that government support is financial compensation / or other compensation given by the government to businesses through risk sharing scheme for the implementation of joint infrastructure projects (article 1). As for the types of risk that needs to be risk sharing schemes between government and business entities in the provision of infrastructure is the political risk, the risk of project performance, and demand risk. The risk of project performance by PMK 38/2006 is the location of risk and operational risk. While the demand risk are: 1) if actual revenues is lower than the minimum revenues. 2) the realization of revenue is higher than the minimum acceptance.

Given the nature of the conditional payment, warranty or guarantee of characteristics that are similar to a derivative financial instrument option (option). Options are contracts that give the right, but not the obligation, to the holder (holder) to buy (call) or sell (put) a particular asset (the underlying asset) at a specified price, known as the exercise price at a specific time or:

$$Q_c = \begin{cases} Q_{\min} - Q & \text{bila } Q < Q_{\min} \\ 0 & \text{bila } Q \geq Q_{\min} \end{cases} \quad (1)$$

Since Q in Equation 1 is uncertain (stochastic), the amount of Qc is also stochastic. Because of this contingent liability insurance is often called "conditional on some future event."

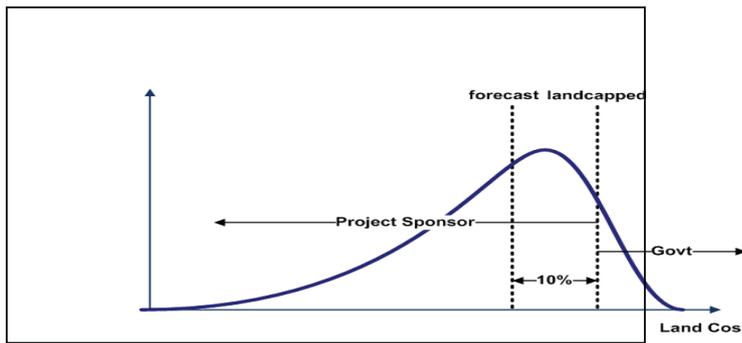

Figure 3 Risks Sharing the Land Acquisition Costs

For example, cases in this study used the Project Cileunyi-Tanjung Sari-Sumedang with basic assumptions used remained the same or if duplicated here:

Table 2 Probability Function Assumption of Risk Factors

Risk	distribution	Parameter
inflation rate	Lognormal	Mean=8,8%, standar deviasi=3,4%
Interest rate (BI rate)	Lognormal	Mean =9,8% dan standar deviasi =1,7%
Accuracy construction costs	Triangular	Minimum=5%, most likely=0%, maximum=15%
Escalating cost of land acquisition	Uniform	Minimum=20%, maximum=70%
volume of traffic	Triangular	Minimum=nilai pesimistik, most likely=nilai moderat, maximum=nilai optimistik

In the simulation, the government intends to use the numbers to guarantee minimum traffic volume 80% of moderate value for all of the concessions and give landcapping Rp. 75,000 per m<sup>2</sup> (these values are preliminary estimates before adjusting with escalating expectations of 45%). Table 3 shows the differences in the major statistical indicators before and after guarantee eligibility. As can be seen, the average IRR increased slightly from 12.12% to 12.37% IRR atan will be in the interval between 8.49% (percentile 5) and 17.28% (percentile 95) (see Table 4.3). When used MARR of 10%, the level of confidence only increased from the previous 75% to 79%. In the model used, the provision of guarantees to the value of the fixed course for business entities, the project still has a negative value which meant that the project remains viable despite there landcapping and minimum traffic guarantee as mentioned.

Table 3 Summary Statistics Difference Simulation (1000 iterations)

Statistics	Before Guarantee		After Guarantee	
	NPV	IRR	NPV	IRR
Trials	1000	1000	1000	1000
Mean	-243.049	12,12%	-220.823	12,37%
Median	-242.215	11,86%	-219.053	12,07%
Mode	---	---	---	---
Standard Deviation	19.691	2,82%	18.668	2,81%
Variance	387.729.715	0,08%	348.511.752	0,08%
Skewness	-0,2887	0,9180	-0,3301	0,9035
Kurtosis	2,68	4,63	2,76	4,57
Coeff. of Variability	-0,0810	0,2325	-0,0845	0,2274
Minimum	-304.541	6,14%	-281.220	6,44%
Maximum	-200.898	27,62%	-174.686	27,76%
Range Width	103.643	21,48%	106.534	21,31%
Mean Std. Error	623	0,09%	590	0,09%

## 6. Conclusion

Finally, with real option models that use the IRR, NPV adjusted with the Indonesian Government policy can be used to measure security against the risk of the development of the necessary infrastructure highway.

### ABSTRACT

Indonesia is one country that the growth of passenger air transport is very fast in the world, with the domestic air passengers grew on average 12,8 % and international air passengers 15,7 % per year the airport infrastructure would be necessary. However, the allocation of state budget for the transportation sector is still limited, budgeting for airport infrastructure only Rp. 19,5 trillion meanwhile the need for the development of 233 airports in Indonesia during 5 periods amount Rp. 54 trillion, it means there is the financing gap Rp. 34.5 trillion or more than 63% of the funds needed are not covered.

The purpose of this paper to explore the funding gap on development the airport infrastructure in Indonesia and discuss the problems of any obstacles on involving the private sector on Indonesian airport infrastructure development with considering the characteristics of the Indonesian airport

Therefore it required to think how the important efforts of the Indonesian Government could be conceived to create a more conducive climate to stimulate the private sector to invest in the Indonesian airport infrastructures.

#### Keywords:

Airport infrastructure, Funding Gap, PPP, Indonesian Airports.

### 1. INTRODUCTION

Infrastructure development is an important and vital aspect for the economic development of a country. It plays also an important role for the driving of the economic growth. The economic growth of a country can not be separated from the availability of infrastructures such as transportation, telecommunications, sanitation, and energy. Therefore the development of this sector is a key dimension to push further the economic development.

The 1997-1998 economic crisis that south-east asiatic countries faced yielded many consequences, especially concerning the funding of infrastructure in Indonesia. The infrastructure projects funded by both the private and the state budget were reduced drastically. The state budget for this sector has declined by approximately 80% compared with the situation before the crisis. In 1994, the central government spends nearly 14 billion U.S. dollars for construction, 57% were for infrastructure. In 2002 the development expenditure reached only roughly 5 billion U.S. dollars and only 30% of the previous amount for infrastructure. Infrastructure development has provided the foundation for supporting the economic and socio-cultural life of society. Nevertheless there are still many challenges in Indonesia, especially when the infrastructure is not functioning properly because there are still many the isolated regions.

This paper deals with the airport infrastructure needs in Indonesia, and especially it investigates the possibility of finding a solution to fund them. Section 2 shows how the airport infrastructures are important in Indonesia: they are the conditions of the economic growth of the country. They are also a source of growth for many economic sectors.

Section 3 presents the financial needs of Indonesia concerning transport infrastructure. In fact, Indonesia faces a financial gap. The private sector could be a solution, but there are some important institutional constraints to take into consideration. Section 4 deals with the current situation of airport infrastructures in Indonesia, which could be seen as a kind of puzzle, but has to be conceived as a network. The sector of airport infrastructure knows a dynamic growth for its activity. The last section is

concerned with the PPP solution. It develops the institutional framework and details the different involve parties and their functions.

## 2. The Current Situation for the Airport Infrastructure in Indonesia

The system of air transportation infrastructure consists of the airport, which have a function of node and the air space that have a function of an organized air traffic space. In Indonesia, the airports were differentiated by function, utilization, classification, status, management and the activities. Based on the hierarchy of functions, the airports are grouped into the hub airport category (distribution centers) and the spoke airport category (non distribution center). The hub airport is divided on the service scale of primary, secondary and tertiary, depending on the importance of traffic, while the spoke airports play the role of collectors and one of the support infrastructures in servicing the local activities. The criteria hub and spoke airports based on the number of passengers (hub airports = 5 Million passengers >X ≥500 thousand passengers per year and spoke airport = >500 thousand passengers/year).

Another categorization is possible when the type of utilization is considered as a criterion. Airports can be grouped into two different categories the international airport and the domestic airport. The international airport is the airport which serves the domestic and the international flights and the domestic airport is the airport which serves only the domestic flights. If the status is considered, the airport can be categorized on the public airport and the special airport. The public airport is the airport which is opened for the public interest and the special airport is the airport that owned for the private interest for example only used for the operational of company (the oil company, manufacturing company, etc)

Based on Ministry Regulation No. 11 of 2010 on the National Airport System, followed the data of airports of 2010 on the categories function and utilization by the big island in Indonesia. (Table 1).

Table 1: The Number of Airport in Indonesia by Function and Utilization

No	Island on Indonesia	Domestic		International	
		Hub	Spoke	Hub	Spoke
1.	Sumatera	7	27	8	2
2.	Jawa	3	7	6	1
3.	Bali-Nusa Tenggara	5	11	4	0
4.	Kalimantan	12	19	4	0
5.	Sulawesi-Malut	7	24	2	0
6.	Papua-Maluku	7	73	4	0
Total		233			

Source: Ministry Regulation No. 11 of 2010, 2010.

It can be drawn many highlights from the table 1. First, there is a high number of airports in Indonesia. Few of them can be considered as a national hub or a node of connections for the country. The most of part of them play a role of connection (a frontier spot inside the web of airport infrastructures in Indonesian. and the second the degree of openness towards outside countries concerns only a minor of them. The majority of airports are oriented towards domestic considerations. We have to conclude that airport situation is hugely segmented with some implications in terms of traffic, connexions with outside countries, and their role of node. Obviously this high diversity means consequences concerning the business of each category of airport infrastructures, but also the interest of the private sector in investing in such a project. Some implications for the institutional framework have to be into consideration.

The second important fact concerns the importance of the number of passengers. In 2009, almost one hundred million of passengers used the airport transport infrastructure. Roughly 83% of the total concerns domestic transportation (table 2 and table 3). Over the period 2005-2009 domestic air transportation increased by 42,58 %. This increase was superior to 42,63 % for international air transportation. It emphasizes the existence of huge opportunities for the private sector.

Table 2: Development of Domestic Air Transportation Passengers in 2005-2009

Airport Operator	2005	2006	2007	2008	2009	% growth fifth annual
DGCA	3.282.812	7.878.049	6.276.658	9.363.021	9.468.693	188,43%

Source: Statistic of Ministry of Transportation, 2009.

The current situation of the market for airport infrastructures is characterized by a complex system of airports linked through different connections and by different categories of airports. They are not homogeneous, meaning without doubt the existence of high variability of economic activities, and the existence of markets. Second, these markets know a very level of expansion. Third, each market are not independent, they belong by a network embedded in pregnant institutional framework.

### 3. Airport facilities and services as a bundle of revenues a self-funding source

In the long term perspectives of growth in air transport industry represent an important reason for the private sector to be present and to be interested in airport business. When comparing within air transport industry, airport have significantly better results in operating margin ratio than airlines (Graham, 2008). Moreover airport infrastructures represent complex entities providing a wide range of business activities. They can provide a bundle of goods and services. These goods and services can be categorized in core (or aeronautical) as well as non-core (or commercial) ones (Akintoye, A & Beck, M, 2009). Most airports provide retail shops and parking facilities not only for airline passengers and their visitors but also to residents of the area. They are also retail outlets and airport free zones which are bonded areas, adjacent to the airport premises which, as the name suggests, are duty free areas promoting industry and other commercial activity. For example, at Heathrow International Airport London as the Mega Mall in the world class, so that someone who wants to buy clothes of the famous French products not needed to be to Paris. Indonesia of course can imitate these things mainly can be developed in the big cities and tourist destinations in Indonesia which is of course needed the integrated planning between the actor of businesses and relevant agencies (Dikun, 2007)

Marketing all these provisions of goods and services permit for airports to optimize their revenue and to exceed all direct and indirect operating costs, including general administration etc, and so provide for reasonable return on assets (before tax and cost of capital) to contribute toward necessary capital improvements (PPP Model of Indian Airports). The International Civil Aviation Organization (ICAO) recognizes the continuing importance for airports of deriving income from such sources as concessions, rental of premises and "free zones" (ICAO, 2001). ICAO encourages also a policy of autonomy for airports by marketing such activities and becoming independent from the public realm. However it is quite uncertain that the marketing of goods and services will be enough to cover the current financial needs.

### 4. The Private Public Partnership Scheme as a Solution?

According the report of the ICAO the overall passenger growth was 5.7 % over the period 1999-2000 and after 6 % per year, it is almost uncontrollable growth in demand for air transport services has prompted countries across the world, from Australia to Zimbabwe, to consider seriously the selling of their airports to private entrepreneurs. It is distinctly possible that, in keeping with this trend, hundreds of airports may be sold over the next few years. Indonesia faces huge financial needs to complete the investment program for developing airport infrastructures.

The vision of the regulation of planning national airport in Indonesia rests upon a vision of airport as a reliable, integrated, efficient infrastructure. It has to support global competitiveness by promoting regional and national development of the Indonesian archipelago (DGCA Ministry of Transportation Indonesia, 2010). With the review of the regulation planning of national airports, the Indonesian government plan to distinguish the different air traffic services concerning the activities of airport services/ single Air Traffic Service Provider (DGCA Ministry of Transportation Indonesia, 2010). It is expected that the private sector could help in completing the financial gap the authorities face.

However, although the participation of private capital could be very helpful in funding the investments and could be involved in the management of airport infrastructure, such involvement has to be aligned with the lines of development defined by the government. Consequently, the private operation of airport infrastructure and the participation of private capital holder would be constrained by a strong institutional framework, which would influence the contracting dimension with the private sector. Indeed the Indonesian government still has some doubts to involve fully the private sector in managing the airport because the government through the state owned enterprise (SOE/BUMN) privileged this way to operate the commercial airport for obtaining income and Technical implementing units (UPT) of the Directorate General of Civil Aviation for operating the non commercial airport. Consequently, the current main source of funding for the transport infrastructure development is derived from the government budget (APBN). However public transport infrastructure investments have a tendency to involve large amounts of money with a very low rate of return. It does not help in solving the financial gap previously described. It explains why some other policies are followed and that some of them encourage the participation of private sector, the community and

the local government in developing and operating infrastructure and transportation facilities. However they have to maintain and keep paying attention to aspects of public services which represents an important duty for the government. Nevertheless the Aviation Act No. 1/ 2009 stated that the government will let an important role to the private sector related to the transfer of management and ownership. It implies also to limit the public sector investment, to free the access to commercial markets, to circumscribe the government control, and have competitiveness on airport business (Indonesia Aviation Act, 2009). It is expected such openness to the private sector could help in answering the requirements related to the development of airport infrastructure and services while being in conformity with the political constraints defined by the government. However, the pattern and how the financing scheme that will be used in accordance with the characteristics of airports in Indonesia is not currently defined. It implies the pattern for the private sector's role and the contracting dimensions of such intervention have to be defined and negotiated. It implies also to find an appropriate pattern for associating successfully government and the private sector and defining the financial scheme (Yescombe, 2002). Moreover public private partnerships scheme can be considered as being a specific channel through which transnationalization of airport business become possible for Indonesian airports and put them as global airport players (Tomova, 2009). In this sense, the Indonesian airports would benefit from a new dimension with a private provision.

## 5. CONCLUSION

Indonesia as the biggest archipelago country in the world with more than 17,000 islands makes the infrastructure a key factor for economic development and for regional development purposes. Infrastructure, especially transport and connectivity, are crucial for regional cooperation and integration. At present, the conditions in Indonesia in terms of transportation infrastructure, especially concerning its funding could not support the growth of transportation sector meanwhile transportation is one of a network chain in the distribution of goods and passenger movement. Therefore the inadequate transportation infrastructure and facilities has important consequences for economy (reduced economic competitiveness of exports, constraint on GDP/GRDP), for operation of airports (increased costs of operations), the quality of services (queuing, availability, capacity, etc), and the performance of airports (increased delays, lower safety, reduced comfort, etc). The private funding is an unavoidable solution.

## ABSTRACT

Many cities in Indonesia have an airport located near the downtown area. Those airports certainly propagate noise disturbance to the environment included the residential areas. Housing units were built without silencer elements gain considerable noise emissions. Ahmad Yani Airport in Semarang city changed its status from National Airport to International Airport. As a result, housings surrounding the airport are increasingly disturbed by the noise, because the flight intensity is increase. Based on the flight schedule issued by PT. Angkasa Pura, there were about 68 scheduled flights a day. This study is a modeling research that measure values of noise reduction on the building model created in the field with the certain value of Sound Transmission Loss (STL). Analyses of the research were obtained by using Completed Randomized Design (CRD) or Compare Means Sample. With these methods, it established the rating result that the angle rotations of simple building models could significantly reduce the noise level received by inhabitants in the housings.

**Keywords:** Simple model constructions, STL, Compare Means, Angle orientation Rating

## 1. INTRODUCTION AND BACKGROUND OF STUDY

This environmental acoustic research had been done in 2011. Based on preliminary observations, it was found out that the housing near the airport had been disturbed by the noise generated by airport activity at the time when the air plane landed and took off. The research carried out at the time showed results that the difference in orientation of buildings to the runway would have any differences in the sound level received by inhabitants in buildings. Building materials become the other variables that affect the level of noise.<sup>1,2</sup>

Due to the existing house has limited variety of angles to the runway orientation, hence researchers then made building models that have a value of STL (Sound Transmission Loss) similar to houses on the real conditions. These models could be rotated on their axes so that the varying orientation angles could be observed accurately. This full paper will discussed in detail the methodology of research conducted by the researchers, starting from the description of graha padma residence, the housing near the noisy airport as an object sample, and concluded with the output rankings of angle building orientations based on the Compare Means Sample method that was found through this experimental research.<sup>3,4</sup>

## 2. NOISY HOUSING NEAR THE AIRPORT AND RESEARCH AIM

Noisy Housing taken as a sample in this study was Graha Padma Residence, because this Residence is getting the highest sound level than other housings around Achmad Yani Airport in Semarang. Graha Padma has several clusters; one of them is Avonia cluster that is very close to the airport runway. The cluster is just about 310 meters from the runway. Noise level received by inhabitants in the Cluster is between 80-90 dB.<sup>1,2</sup>

According to the Minister of Environment Decree No. 48/MENLH/11/1996, it is about the Ambient of Noise Level Standard, noise level standards for the housing function area is 55 dB.<sup>5</sup> Based on field measurements, the highest Sound Transmission Loss (STL) value of the existing housing units is ranged to about 29-30 dB, so that the sound level received in the building is still high for about 50-60 dB. This value is still above the noise limit allowed under the Decree No. 48/MENLH/1996. Below is the location of the cluster Avonia toward the airport runway:

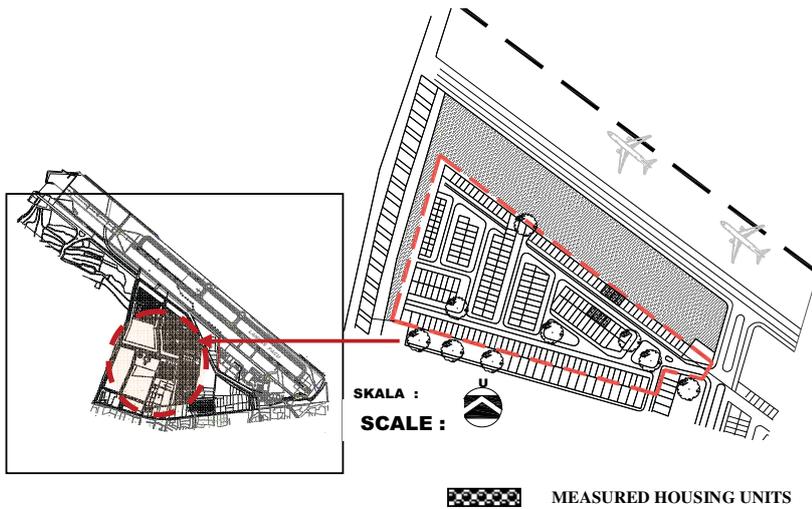

Figure 1: Avonia Cluster Site Plan at Graha Padma Residence

In the figure 1 above, it is only a few angle of the housing orientations can be observed, they are:  $0\sigma$  ,  $180\sigma$  and  $66\sigma$  . This limitation would greatly complicate the analysis because it can only produce a very few number of the data output. In this case, researchers must create building models that have similar value of STL (Sound Transmission Loss) to the actual buildings in the cluster. In order to get the same value with the real STL belong to cluster housings, then the material of the models use the same type of material with the housings material in the real condition. Researchers made the models with the aim of observing the various angle of orientations easily. Therefore, building models should be able to rotate on their axes. Shortly, this study is aimed to find the rating of the orientation angles of housing towards the runway, as an effort to reduce the noise level emitted by the aircraft in both take off and landing.

### 3. RESEARCH METHODS

#### 3.1. Research Limitations

The study draws on the acoustic grand theory, The Inverse Square Law, where the sound level will be inversely proportional to the square of the distance between the sound source and sound receiver.<sup>6,7</sup>

The grand theory contains the understanding that the greater the distance to the sound source, the smaller the sound level received by recipient. And, the smaller the distance to the sound source, the greater the level of sound received by recipient. In the understanding of the theory, and in relation to the distance aspects within the sound source and the building, so the housings close to the airport will have various effective distances to the noise source depend on the angle of orientation and configuration of the building blocks toward the airport runway. The housings as the object of noise will be closely linked with the theory above. Aircraft moving on the airport runway is assumed as the moving sound source. The sound level is considered as the equivalent sound level ( $L_{eq}$ ) in certain period of measurements. Doppler Effect accompanying the movement speed and change of the aircraft position during the period of measurements, is considered negligible.<sup>7</sup>

Meanwhile, the climatic conditions in tropical areas with considerable wind movement will result in changing the behavior of sound in air. The winds that move would lead to changes in the composition and structure of the particles and the air density. The difference in air density will result changes in the rate of sound waves in the air.<sup>8</sup>

#### 3.2. The Real Condition of Housing Type in the Cluster

mission Loss) of about  
 buses:<sup>1</sup>

Figure 2: Housing Types in Graha Padma Residence's Cluster

Follows are the Sound Transmission Loss (STL) of Clivia: <sup>2</sup>

Table 1: Sound Transmission Loss (STL) of Clivia Type in Graha Padma Residence

PERIODS	TYPE OF CLIVIA		DISTANCE FROM RUNWAY (M)	STL (dB)
	INDOOR (dB)	OUTDOOR (dB)		
I	55,25	83,21	373	27,96
II	54,11	83,84	373	29,74
			Σ STL	57,90
			STL mean	28,95

### 3.3. The Replica of Building Models

The Replica Models were mocked based on the observations demand of the sound level in a variety of building orientation angle toward the runway. Researchers made four models, and then divided them into two groups. The first group, as a single model, was considered as a model of control, while the second group was a united- three models represented building blocks as it was in an actual condition. Here is a detail picture of building model created by researchers: <sup>2</sup>

Figure 3: Model Delivery process to the research field

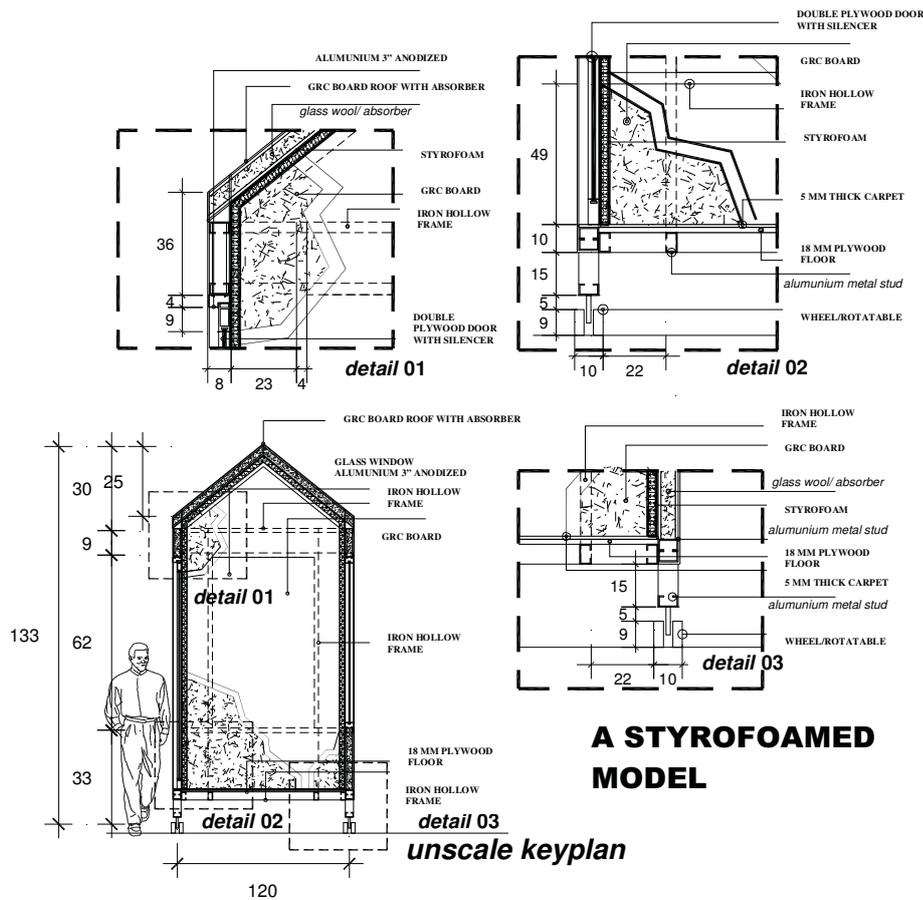

Figure 4: The Detail of Model imitating the real housing<sup>2</sup>

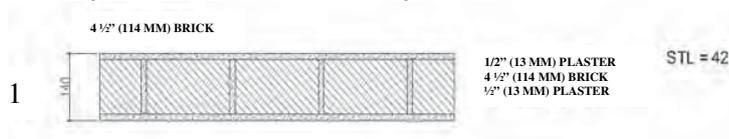

### 3.4. Research Instruments

The research instruments used in this study are :

- a. *Manual Dry – Wet Thermometer.*
- b. *Sound Level Meter* ex Lutron SL-4001 4 units, that are calibrated by KIM-LIPI Laboratory.
- c. *Thermo Anemometer* Ex EXTECH – CFM/CMM serial product: AN – 100
- d. *Camera Digital* that can recorded the movement of airplane.
- e. *Hot wire Anemometer* Ex Extech
- f. *Dry Wet Thermo – Hygrometer* Ex Krisbon

### 3.5. Sound Transmission Loss (STL)

According to L. Doelle, STL values are indicated on each wall construction states the average value, and derived from test results reported by leading experts working in the field of research and testing acoustic.<sup>9</sup> The information shown in the reference table is issued by: A Guide to Air-borne, Impact, and Structure-borne Noise Control in Multi-family Dwellings, National Bureau of Standards, Washington, D.C,1967, and the National Research Council of Canada, Ottawa, in the note of Building Research entitled: Transmission Loss of Plasterboard Walls, 1968. While according to S. Kurra, Selma and N. Tarner that in determining the design of the insulation there are 3 things that need to be addressed: the type of the sound source, the sound level on the facade, as well as the function space.<sup>10</sup> Here are a comparison between some of the materials for this study which are relevant to this study:

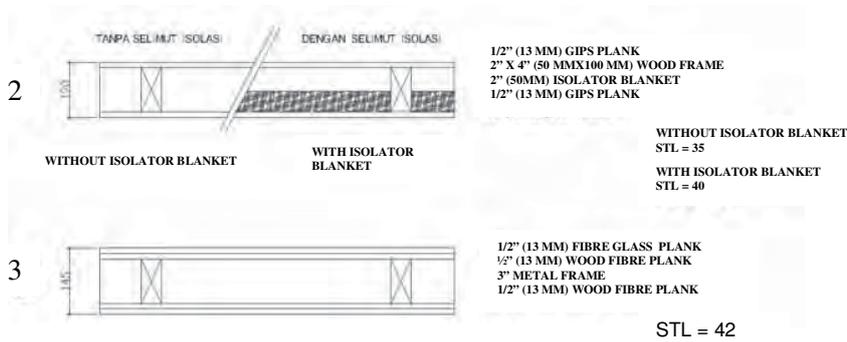

Figure 5: Sound Transmission Loss (STL) Value of models materials<sup>8</sup>

Then the model and then coupled with absorber layer. Absorber used to enhance the value of STL is Styrofoam sheet.

Table 2: Sound Transmission Loss (STL) of Styrofoamed Model

PERIODS	HOUSING MODEL		DISTANCE (M)	STL (dB)
	INSIDE (dB)	OUTSIDE (dB)		
I	52,21	81,45	1	29,24
II	51,66	80,56	1	28,90
III	51,00	80,54	1	29,54
IV	53,72	81,25	1	27,53
V	52,45	81,98	1	29,53
			Σ STL	144,74
			STL MEAN	28,95

This result compares favorably with the values obtained before the models get additional layers styrofoam. With this result, it can be concluded that the model can reduce the sound of 28.685 dB of noise level received at the outer surface of the wall model. These results indicate significant considerable value. As the comparison, it is represented the value of STL on the Clivia (see Table 1).

### 3.6. Relative Value (R<sub>v</sub>)

In order to determine the ranking of the orientation angle of the models, then the models must be able to rotate on their axes. The formula used to determine how much value is the effectiveness of the model in response to the sound level is the Relative Value (R<sub>v</sub>). The Relative value (R<sub>v</sub>) changes due to the velocity of sound is obtained by comparing the value of the sound level model to the sound level value of un-rotated model (control factor).

$$R_v = \frac{L_\alpha}{L_0} \dots\dots\dots(1)$$

- R<sub>v</sub> : Relative Value
- L<sub>α</sub> : Noise Level of model having an orientation angle of α° in deci Bell
- L<sub>0</sub> : Noise Level of model having an orientation angle of 0° in deci Bell

$$\bar{R}_v = \frac{\sum R_v}{\sum x} \dots\dots\dots(2)$$

- R<sub>v</sub> : Relative Value
- $\bar{R}_v$  : Means Relative value
- x : The amount of measurement data

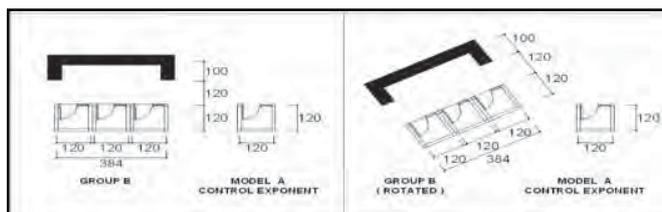

Figure 6: Rotation of the united-model and a control model  
 Equipped with the wall in front of it<sup>2</sup>

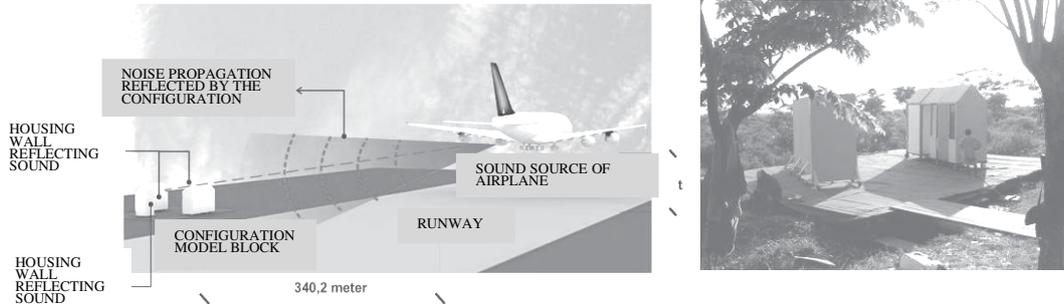

Figure 7: Model position toward the airport runway

Rating the relative values was analyzed using the comparative method of Compare Means Samples (Compare Means). In the field of statistical science, this method is commonly used in the analysis of experimental research. The method is applied measurement data and compares them with a group of control variables.<sup>11, 12</sup>

#### 4. THE RATING OF ORIENTATION ANGLES

The rating of the orientation angles have been established either at the time of takeoff or landing. To give a brief overview but does not reduce the flow of the discussion; the researchers will present the rating results of orientation angles at the time of take off.

Table 3: Rating of the orientation angles outside the models when the airplane take-off

Tukey HSD(a)	KONFIGU	N	Subset for alpha = .05

	Sig.		0.721	0.066	0.058

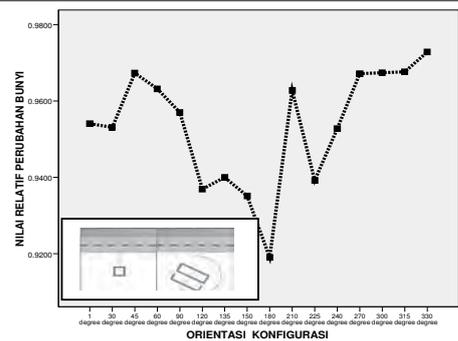

Figure 10: Rating of the orientation angles in the opened-window conditions when the airplane take-off

Table 4 illustrates the relative value ratings changes sound, with the lowest value at 135° angle with the value of  $R_v$  0.835 and the highest value at 270° angle with  $R_v$  value of 1.042. This suggests that the orientation of the runway 135° very effective in reducing the level of noise received on the building. Angle of 45° have a high enough value for its position facing perpendicular to the airplane's position at the top of the sound experience, the position of the plane when it takes off. Table 5 illustrates the relative value ratings changes sound, with the lowest value at 135° angle with the value of  $R_v$  0.703 and the highest value at 270° angle with  $R_v$  value of 1.076. The angle of 30° and 45° lies in the relatively position perpendicular to the sound source. So the value of  $R_v$  average angle is quite high, namely 0.751 to 0.790. The value  $R_v$  300° angle high, because of its position perpendicular to the sound source. Table 6 illustrates the relative value ratings changes sound, with the lowest value at 180° angles with the value of  $R_v$  0.919 and the highest value at 330° angle with  $R_v$  value of 0.973. 330° angle that the conditions outside and inside the building have low  $R_v$ , on the condition of an open window reaches the highest average  $R_v$ . This is caused by the reflection factor of the open window.

That the lowest orientation angle of 135° on the outside and inside the building, and the opposite to the runway orientation (180°) has a Relative Value sound with a significant change in the condition of an opened window, while the other orientation, which forms various angles to the runway has various relative values.

## 5. WIND AND SOLAR DIRECTION REVIEW

Since this is a research study of noise in the airport, then according to the results of the preliminary study on the effects of solar orientation of the noise is not significant, because the pattern of the sound level is influenced by the orientation of the sound source, not the orientation of the sun. On the other hand, that the wind is an aspect that significantly affect the level of sound received by the residents of the housing. Housing and airport locations in this study is located on the north coast city of Semarang, and apply the phenomena as follows:

1. At takeoff, the sound level is influenced by the wind direction of 69.5%. Sound level increases when the sea breeze moves in the opposite direction at the rate of the plane.
2. At the time of landing the sound level is influenced by the wind direction of 67.5%. Sound level will increase if the wind direction at the rate of the plane landed.

## 6. CONCLUSION

From the description of the study, the researchers concluded the following:

That the lowest orientation angle of 135° on the outside and inside the building, and the opposite to the runway orientation (180°) has a Relative Value sound with a significant change in the condition of an opened window, while the other orientation, which forms various angles to the runway has various Relative values.

## ACKNOWLEDGMENT

The authors would like to thank the creating of the models by the contractors with the materials of Glass Reinforced Cements (Gresik cements plastered board) and glass wool sound-proof inside the models. The opinion and analysis presented in this paper are those of the authors.

## ABSTRACT

*Conceptual cost estimates as the basis of project evaluation, engineering design, and cost management, play an important role in project decision at the beginning of design phase of construction project, under a limited definition of scope and constraints in available information and time, and the presence of uncertainties. Conventional tools such as regression analysis have been widely used to tackle the problems. However, recent statistical studies show that errors in cost estimation have not decreased significantly. This paper proposes the utility of an artificial intelligence approach, the neural network model to improve cost estimation accuracy in early phases of building design process. A total of 9 input variables were identified and datasets of 18 office building constructed from 2006 to 2012 in Indonesia were used in estimating the construction cost. Several neural network models were developed using various combination of the number hidden layer and neurons, and the best neural network model with an accuracy of 92.21% was achieved. The predictive behaviour of the model was visualized by sensitivity analysis to reveal how the model capture the impact of variables on the construction cost.*

## Keywords

*Conceptual cost estimates, building construction project, neural network, accuracy*

## 1. INTRODUCTION

The accuracy of conceptual cost estimate is a critical factor in the success of the construction project [1]. During the preliminary or conceptual phase, minimal information is available which makes these estimates less accurate. However conceptual cost estimates are important to project feasibility studies and impact upon final project success. Such estimates provide significant information that can be used in project evaluations, engineering designs, cost budgeting and cost management [2]. According to Holm et al [3] the expected accuracy range of conceptual estimate is  $\pm 10-20\%$ , while AACE 18R-97 [4] states that the accuracy range of budget estimate is  $\pm 10-30\%$ . Abundant studies to improve the accuracy of early cost estimates have been done. Statistical methods have traditionally been used to develop cost estimating models, while regression analysis represents a common alternative. Regression analysis is a very powerful statistical tool that can be used as both an analytical and predictive technique, although it is not appropriate when describing non-linear relationship, which are multidimensional, consisting of a multiple input and output problem [5].

Neural network as an alternative branch of artificial intelligence, has appeared as a viable alternative for estimating construction cost during the 1990s. Neural network is distributed information processing system in which modeling is viewed as a mapping from one multivariate space of information (input variables) to another (output variables). Neural network provide excellent facilities for approximating data, learning knowledge from data, capturing non linear and complex interactions, approximating reason, and parallel processing. In order to develop of high quality neural network models is difficult. Several design factors including selection of input variables, architecture of the network and quantity of training data, significantly impact the accuracy of neural network prediction. The main problem is that there are no fixed rules for

determining the appropriate architecture of its parameter values [6]. This forces the model developer to try different networks configuration to find an optimal setup. The adequacy of relations suggested by the models must be determined by the predictive behaviour of the models. The Predictive behaviour of model is crucial particularly as the model has the potential to present unnecessary complex relations, especially when they are trained with sparse data [7]. For cost estimating, user always wants to know the most sensitive variables affecting the construction cost. Such information is very valuable for designer in developing cost-effective designs [8].

The purpose of this paper is to demonstrate the use of neural network model to improve conceptual cost estimation accuracy. In this study the trial-and-error process was adapted for determining networks parameters and several neural network models were developed using various combination of the number hidden layers and the neurons in hidden layers to achieve the best model. After determining the best model, the predictive behaviour of the model was visualized by sensitivity analysis to reveal how the model capture the impact of variables on the construction cost.

## 2. NEURAL NETWORK

Neural network is a massively parallel distributed processor made up of simple processing units, which has a natural propensity for storing experiential knowledge and making it available for use [9]. Neural network is a computer system that simulates the learning process of human brain and it consist of a large set of interconnected neurons. These neurons are arranged in many layers and interact with each other through weighed connections. NN are trained by the presentation of a set examples of associated input and output as target values. The hidden and output layer neurons process their inputs by multiplying each of their inputs by the corresponding weights, summing the product and then processing the sum using non linear transfer function to produce the result. The S-shaped sigmoid function is commonly used as a transfer function. The neural network learns by adjusting the weights between the neurons in response to the errors between actual output values and target output values.

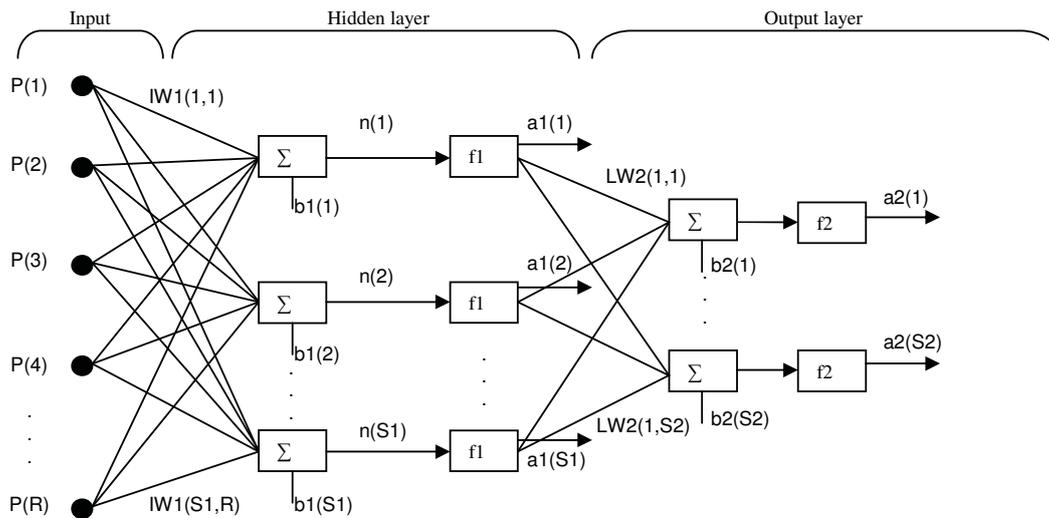

Figure 1 : Architecture configuration of neural network

A typical artificial neural network is shown in Figure 1. The network shown above has R inputs (R neurons in the input layer), S1 neurons in the hidden layer, and S2 neurons in the output layer. The number of hidden layers can be varied based on the application. A network can have several layers. The outputs of each intermediate layer are the inputs to the following layer. Each layer has a weight matrix W, a bias vector b, and an output vector a. Each element of the input vector p is connected to each neuron input through the weight matrix W. The *i*th neuron has a summer that gathers its weighted inputs and bias to form its own scalar output *n*(*i*). The various *n*(*i*) taken together form an S-element vector *n*. Finally, the neuron layer outputs form a column vector *a*. The column vector *a*1 as the input of layer 2 can be determined by equation (1):

$$a1 = f1(IW1*P+b1) \quad (1)$$

And the vector *a*2 as the output layer can be determined by formulation given in equation (2):

$$a2 = f2(LW2*a1+b2) = f2(LW2*(f1(IW1*P+b1))+b2) = Y \quad (2)$$

The layers of a multilayer network play different roles. The layer that produces the network output is called an output layer. The layer that gets the inputs is called input layer. All other layers are called hidden layers. It is common for the number of inputs to a layer be different from the number of neurons.

There are two main phases in the operation of a neural network : learning and training. Learning is the process of adapting the connection weights in response to a number of examples being presented at the input layer and optionally at the output layer. The task is to arrive at a unique set of weights that are capable of correctly associating all example patterns used in learning, with their desired output patterns. The most common neural network model is the multilayer perceptron or known as a supervised network because the network is presented with some input examples and their desired responses. The desired outputs are used in this case to teach the network the correct responses. The multilayer perceptron learns using backpropagation algorithm. This algorithm incorporates a learning algorithm called generalized delta rule, which is responsible for training the network and uses a gradient descent method to determined a unique set of network weights that enables the network to produce outputs that are very close to the the desired outputs associated with a number of training examples. The backpropagation usually incorporates a non-linear sigmoid transfer function to calculate the output of each neuron except for the input neurons. For the training refers to the process that repeatedly applies input vectors to the network and calculates errors with respect to the target vectors and then finds new weights and biases with the learning rule. It repeats this cycle until the sum-squared error falls beneath an error goal, or a maximum number of cycles/epochs have occurred. At the end of this training phase, the neural network represents a model, which should be able to predict a target value given the input value.

### 3. MODEL APPLICATION

A total of 18 office building construction projects developed by a contractor company in Indonesia specially in the city of Jakarta, Tangerang, Bekasi and Bandung, during 2006 to 2012 were taken as case studies [10]. The datasets were divided into two parts by random sampling. The first group of data (16 datasets) as data training were used to develop the model and the second group (2 datasets) as data testing that were used to test the model. And a total of 9 input variables were identified whereas the output variable is the contractual construction costs (in IDR), (See Table 1).

Table 1: Variables description

Variables	Description	Range
P1	Location	1 = Jakarta, 2 = Tangerang, 3 = Bekasi, 4 = Bandung
P2	Type of foundation	1 = bored pile, 2 = driven pile, 3 = mat foundation
P3	Gross floor area	1752 - 111489 m <sup>2</sup>
P4	Number of storey	3 - 42
P5	Number of basement	0 - 5
P6	Type of roof construction	1 = Concrete, 2 = Steel Structure
P7	Finishing grade	1 = Average, 2 = Good, 3 = Luxury
P8	Year of construction	2006 to 2012
P9	Duration of construction	3 - 21 months
Y (Output)	Contractual construction cost (IDR x 1000)	7513241 – 248050000

In order to develop neural network model Matlab R2009a software was chosen for its ease of use, speed of training and host of neural network architectures, including backpropagation with flexible user selection of training parameters. A total of 18 variants were developed using the neural network method based on the variations of the number of hidden layers and the neurons in hidden layers. In this study the experiments run should set parameters such as architecture configuration, learning and training parameters as described in Table 2.

Table 2 : Neural network parameter settings

Parameters	Values	Description
Architecture configuration parameter:		
No of input neurons	9	Number of input variables
No of output neuron	1	Number of output variable
No of hidden layers	1 and 2 hidden layers	
No of neurons in hidden layers	Min 2 and max 12	
Learning parameter:		
Learning algorithm	Backpropagation	
Activation function	Sigmoid bipolar	
Learning function	Gradien Descent Momentum	
Learning rate	0.5	
Training parameter:		
Maximun epoch	5000	
Goal (min MSE)	10 <sup>-3</sup>	

#### 4. RESULT AND DISCUSSION

The accuracy performance of all models using data testing is based on Mean Absolute Percent Error (MAPE), given in equation (3):

$$MAPE = \frac{1}{n} \sum \frac{|actual\ cost - predicted\ cost|}{actual\ cost} \times 100\% \quad (3)$$

The result from MAPE 16 data training and 2 data testing are summarized in Table 3.

Table 3 : Comparisons of MAPE for all models

No	Architecture of configuration	MAPE of 16 Data Training	MAPE of 2 Data Testing
1	9 - 2 - 1	14.02%	26.24%
2	9 - 3 - 1	7.45%	123.02%

In this study 18 neural network models were implemented to compare the estimation error rates using various combination of parameters including number of hidden layers and number of neurons in hidden layers. The best configuration of the neural network model was determined to be 9-4-1 model configuration which means that there were 9 neurons in input, 1 hidden layer with 4 neurons in hidden layer and 1 neuron in output as shown in Figure 2. This result appropriate to Hegazy et al [11] that one hidden layer is sufficient to generate an arbitrary mapping between inputs and outputs. Out of 18 models, the result of the 9-4-1 model gave the best performance with 7.79% for MAPE data testing, it means that this model has an accuracy of 92.21%, although the amount of data training was limited. According to Holm et al [3] the expected accuracy range of conceptual estimate is ±10-20%, while AACE 18R-97 [4] states that the accuracy range of budget estimate is ±10-30%. Comparing with these references, the proposed model has performed very well.

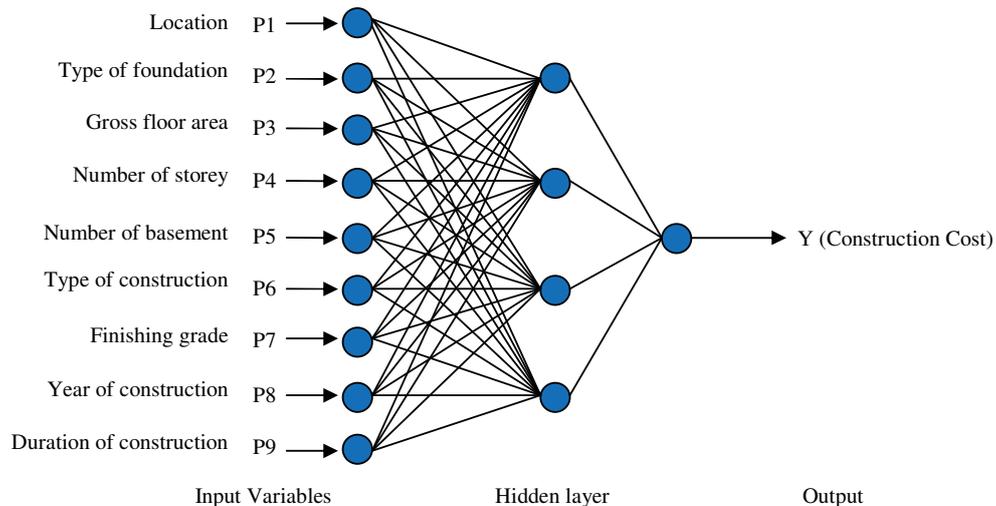

Figure 2 : Neural network model with 9-4-1 configuration

Finally the predictive behaviour of the best model (9-4-1 configuration) was visualized by sensitivity analysis to reveal how the model capture the impact of variables on the construction cost. Sensitivity analysis of model as described in Figure 3, was performed by plotting the outputs of the model against varying levels of several variables, such as (a) number of basement, (b) gross floor area, (c) finishing grade and (d) number of storey.

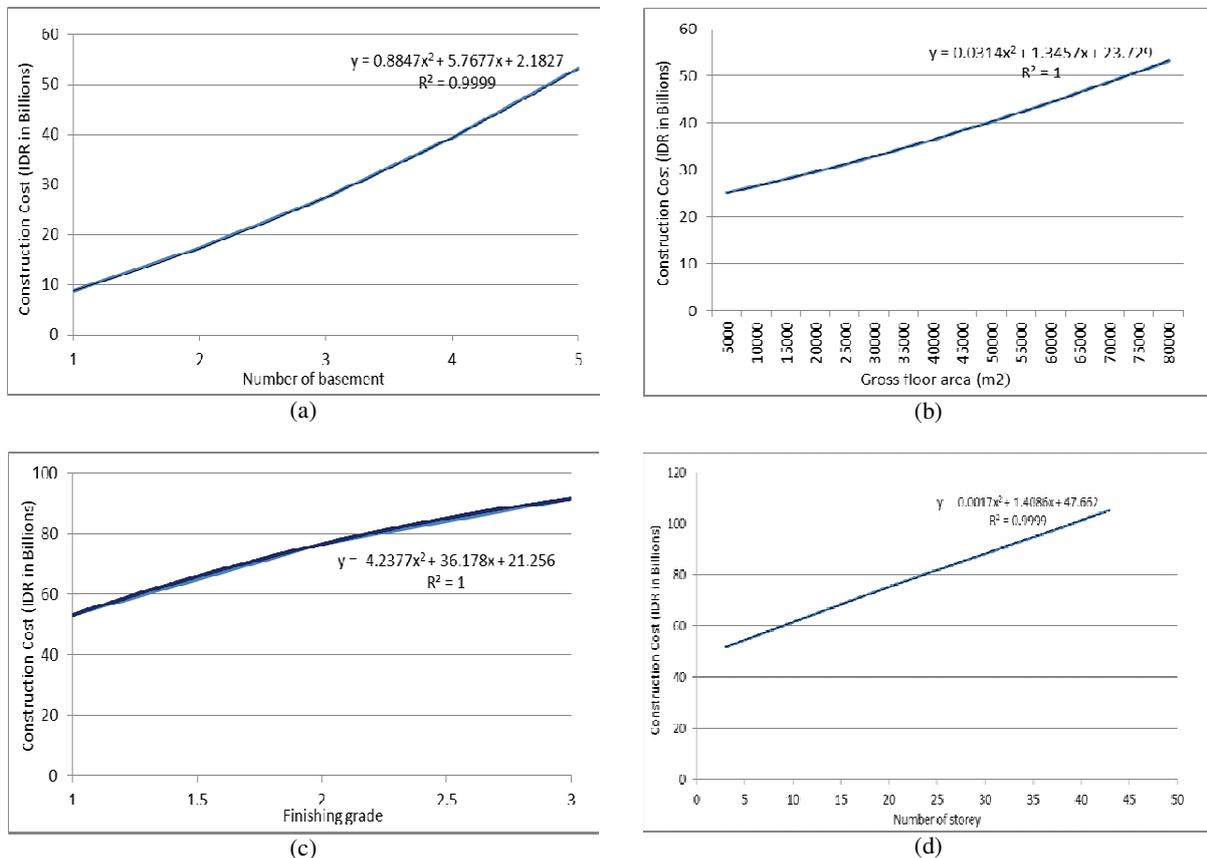

Figure 3 : Sensitivity analysis of model

In general, the plots of the model illustrate non linear relationship between the input variables and the output variable (construction cost). The sensitivity of each variable to the construction cost as shown in Figure 3 provides the useful information for a building designer to identify cost sensitive attributes. With such information, the design process can be guided with the directions to achieve cost-effective designs, rather than to be conducted with an inefficient blind search process.

#### 4. CONCLUSION

The neural networks have the capability of capturing the relations between input variables and output variables. The neural networks require the historical data of cost and data of variables influencing the cost. The neural network is trained with the historical data of past projects so that it can capture the relations between variables and the cost. One of the important decisions about neural network is related with the network architecture. Designing the network architecture is not a straightforward approach, it actually requires some trial and error. One method for determination of the neural network model architecture is training several networks with different architectures and then selecting the neural network with the best prediction performance.

In this study, a neural network model was developed to estimate construction cost of the office building using only information typically available at conceptual design phase. The model could be used to estimate early project cost when detailed construction drawings are not available and detailed cost estimates cannot be performed. A comprehensive set of variables

influencing to the cost of construction such as location, type of foundation, gross floor area, number of storey, number of basement, type of roof, finishing grade, year and duration of construction were included in the model formulation. For the study, data of 18 office building construction projects developed by a contractor company in Indonesia during 2006 to 2012 were taken. The model configuration with one hidden layer and four neurons in hidden layer presented the best performance with 7.79% for MAPE data testing. Predictive behaviour of the neural network model had been visualized by sensitivity analysis and the result was that the model demonstrated adequate relationship between the input variables and construction cost.

### ABSTRACT

*The use of synthetic fibers and natural fibers as composite materials have been proven to increase strength and save the basic material needs of the building. Research has previously stated that the fiber has a high tensile strength and has the potential to increase the cohesive and tensile strength of the asphalt mixture. Previous research suggests that the value of Skid Resistance is influenced by changes in asphalt penetration. The addition of coconut fiber used in this study was short decorticated fibers/pulp fibers. Short Coco fiber measuring 0.5-1.25 cm mixed with asphalt pen 60/70 on the fiber content of 0%, 0.75% and 1.5%. Fibrous asphalt is mixed with aggregate specification of Asphalt Concrete Wearing Coarse. Asphalt concrete mixture is molded and compacted with a compactor Wheel Tracking at 8.16 tons vehicle standard axle loads. Specimens were then tested with a British Pendulum Tester at a temperature of 26 °C, 30 °C, 35°C, 40 °C, 45 °C, 50 °C. Skid resistance value will decrease when an increase in temperature on the surface of the pavement. The addition of 0.75% coconut fiber on the asphalt mixture can improve the skid resistance value but does not increase the resistance to increased temperature on the road surface.*

## ABSTRACT

Concrete become one of alternative construction materials that often used. The use of concrete as construction materials makes waste nemed Concrete Sludge Waste (CSW). There is a lot of CSW that produced by use of concrete. The huge amount of CSW in order to not to pollute the environment, so we have to reuse CSW to become something useful. Nowadays a lot of construction is using high quality concrete. CSW from this high quality concrete can reused to produce medium or low quality concrete. CSW will added in mortar as substitute of fine aggregate. Beside CSW we can also reuse Rice Husk Ash (RHA). RHA is product that produced by burning of rice husk. As agricultural country, Indonesia can produce lots of rice husk that produced from rice milling. All this time, rice husk was used as cleansing ashes. RHA will added in mortar as substitute of cement, so we can reduce the use of cement. Physical and mechanical properties of mortar that will tested are compressive strength, absorption, shrinkage and density. Based from the result of this research, mortar with composition 92% cement, 8% RHA, 30% CSW and 70% fine aggregate, is the best mortar composition. The compressive strength that produced from this mortar is 17,052 Mpa at 28th day. For absorption test, this mortar could absorb 134 gram/100cm<sup>2</sup>. Moreover this mortar have the least of shrinkage, 0,126%. And from the result of density test, the density of this mortar is 1,869 g/cm<sup>3</sup>. From this research, based on SNI for non-structural concrete, mortar with composition 92% cement, 8% RHA, 30% CSW and 70% fine aggregate can produce non-structural materials such as paving block.

## Keywords

Rice Husk Ash, Concrete Sludge Waste, compressive strength, Absorption, shrinkage, density.

## 1. INTRODUCTION

The high rate of construction is causing high rite of concrete usage. And the high rate of concrete usegae is also causing high rate of concrete sludge waste (CSW) that wasted in every concrete plans. This is causing problems, because if we don not manage the disposal, this waste will pollute the environment. Waste management is become a problem for concrete plan's owner. All this time, waste management is not optimal yet. CSW was used to close the hole in broken road or thrown away. Waste management that can applied are mixing concrete by the use of return (Reuse) material that is proper to use, and reprocessing (Recycle) are the remaining material. In this research we use CSW as fine aggregate substitute. Beside CSW, we also use rice husk ash (RHA) as cement substitute. Rice husk ash is product of rice husk burning that has useful elements to increase the quality of concrete. Because RHA is a pozzolanic materials and containing the large amount of silika. If silika mixed with cement, will producing higher strength.

This research aims to know physical and mechanical properties of mortar that containing CSW and RHA and to meet the optimum mix design

## 2. MATERIAL and METHODS

The research was conducted at the Department of Civil Materials Testing Laboratory, University of Indonesia. Methods The study was conducted by laboratory testing in accordance with the data from the literature study both SK SNI Standard Indonesia and foreign standards such as ASTM.

### 2.1 Materials And Methods

#### 2.1.1 Cement

Type-I Portland cement (PCC) was used, which was manufactured by tiga roda. and its physical and chemical properties met the ASTM C150 specification.

#### 2.1.2 Fine Aggregate

The sand was obtained from the Cimangkok, West Java.

*Table 1. Fine Aggregate Test*

No.	Physis and Mechanics	Result Test	Spec
1	Specific Gravity	2,090	-
2	Specific Gravity (SSD)	2,179	-
3	Water Absorption (%)	4,280	3
4	Bulk Density( $\text{gr}/\text{cm}^3$ )	1,422	Min 1,2
5	Loose Bulk Density ( $\text{gr}/\text{cm}^3$ )	1,304	Min 1,2
6	Voids (%)	34,64	-
7	Water Content (%)	13,64	-
8	Silt Content (%)	3,30	Max 5%
9	Fineness Modulus (%)	2,66	Zone 2

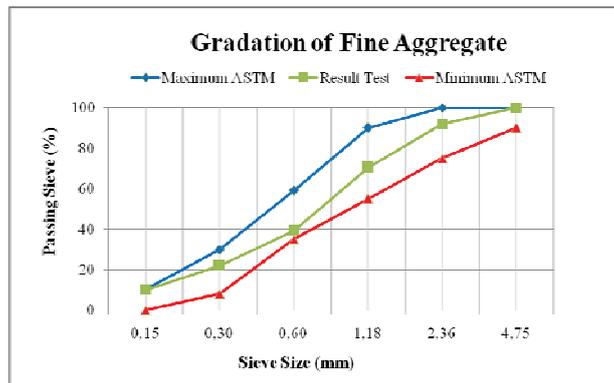

Figure 1. Gradation of Fine Aggregate

### 2.1.3 Rice Husk Ash (RHA)

Rice husk ash is product of rice husk burning that has useful elements to increase the quality of concrete. Because RHA is a pozzolanic materials and containing the large amount of silika. If silika mixed with cement, will producing higher strength. Though there are in the rice husk  $\text{SiO}_2$  reactive element that can be used as an ingredient made Pozolan concrete quality improvement (Priyosulistyo, 2001). ashes that was done burning, then crushed again to escape kesaringan 200-400 Mesh. As a whole from the ashes in the can of rice alone was only 5% or about 20% of the burning husks. Chemical analysis performed on the combustion of rice husk ash content of silica oxide showed a fairly high, as shown in the following table.

Table 2. Composition of Chemical Compounds RHA

Chemical Compounds	Amount (% Weight)
$\text{SiO}_2$	93.4408
$\text{Al}_2\text{O}_3$	0.1031
$\text{P}_2\text{O}_5$	1.0129
S	0.2227
$\text{K}_2\text{O}$	3.4808
CaO	0.7193
$\text{TiO}_2$	0.0946
$\text{MnO}_2$	0.2285
$\text{Fe}_2\text{O}_3$	0.6800
ZnO	0.0173

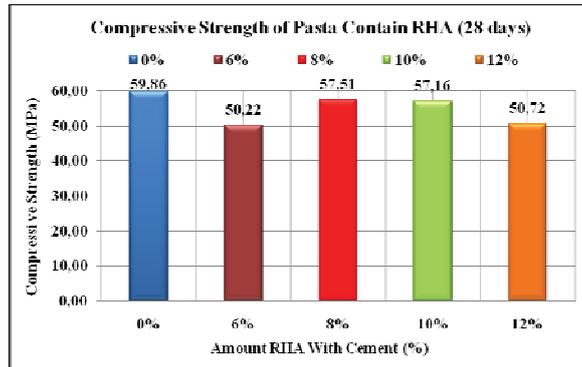

Figure 2. Histogram charts Strong Preliminary Research Findings Press CRHA (a mixture of cement + RHA) at 28th day.

Based on preliminary research results graph CRHA compressive strength that containing RHA, the CRHA compressive strength obtained at 28th day with the most optimal composition of 92% cement and 8% is 57.51 MPa. From the results of this preliminary study we used the optimal composition of RHA 8% of cement content for concrete mixtures containing RHA and CSW.

### 2.1.4 Concrete Sludge Waste (CSW)

Concrete Sludge Waste or CSW is the waste generated from washing truck mixer at the batching plant after producing and sending mixed concrete to construction sites. At the time of washing, the CSW to be like sludge which will then harden to form lumps. CSW is used in this research as fine aggregate substitute, so we can reduce use fine aggregate.

Figure 3. Process of Taking CSW

Chemical analysis of the CSW can be viewed through by PSA testing (Particle Size Analysis) dan XRF (X-Rays fluorescence), as follows :

Table 3. PSA Analysis of CSW

No.	Particle Diameter (µm)	Statistics		
		Volume (%)	Surface Area (%)	Number (%)
1	< 20	100	100	100
2	< 10	98.500	99.700	99.998

8	Cr <sub>2</sub> O <sub>3</sub>	0.1169	0.0612
9	MnO <sub>2</sub>	0.1927	0.1763
10	Fe <sub>2</sub> O <sub>3</sub>	4.7531	2.3644

CSW did not directly used but must be done further research and treatment The treatment process of CSW to be used:

- CSW is usually still in a wet or humid conditions, so it have to be drained naturally by sun or with oven.
- After CSW dried, crushed and polished slabs CSW by milled or ground.
- After CSW crushed, then sieved with a sieve size of 4.75 mm (3/16 in) which is a standard sieve for fine aggregate.
- After CSW has been sifted, stored in a dry place and already can be used.

Figure 4. Processing of CSW

## 2.2 Mortar Composition

This research made five diferent compositions of fine aggregate and CSW, where the composition of cement and RHA is fixed. The five composition of fine aggregate and CSW are :

- CHWM-121 containing 30% CSW and 60% fine aggregate.
- CHWM-122 containing 40% CSW and 60% fine aggregate.
- CHWM-123 containing 50% CSW and 60% fine aggregate.
- CHWM-124 containing 60% CSW and 40% fine aggregate.
- CHWM-125 containing 70% CSW and 30% fine aggregate.

## 2.3 Fresh Mortar Tests

### 2.3.1 Consistency Test

Consistency test were performed according to ASTM C-305-82 to measure water cement rasio.

### 2.3.2 Setting Time

The measurements were conducted according to ASTM-1117-89.

## 2.4 Hardened Mortar Tests

### 2.4.1 Compressive Strength

Compressive strength testing was use a test specimen cube size 50 x 50 x 50 mm, testing were prepared according to ASTM C 579-01and the specimens were cured for 1–90 days. At each curing age, five cube specimens were tested for compressive strength.

### 2.4.2 Absorption

Absorption test was based on ASTM C 1403-00. The specimens is cube size 50 x 50 x 50 mm. The specimens were cured until 28 days before tested.

### 2.4.3 Shrinkage

Shrinkage test was based on ASTM C490-04 and use test specimen beam size 25 x 25 x 300 mm. Right after removed from mold, measured the shrinkage of the specimens until 28 days.

### 2.3.4 Density

Based on ASTM C-905-01 and use cube specimens size 50 x 50 x 50 mm. Specimens were cured in 28 days before tested.

## 3. RESULTS And ANALYSIS

### 3.1 Test Results for Fresh Concrete

#### 3.1.1 Consistency Test

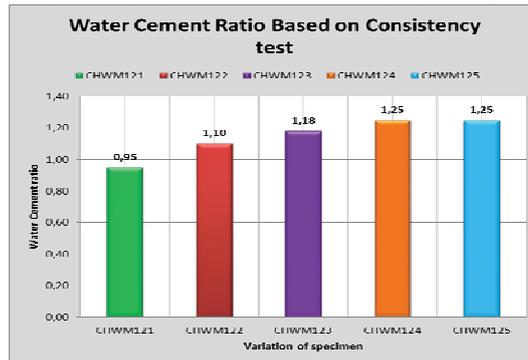

Figure 5. Graph of water cement ratio

Based on the results of consistency test, water cement ratio for CHWM-121 is 0,95 , CHWM-122 is 1,10 , CHWM-123 is 1,18 , CHWM-124 is 1,25 and CHWM-125 is 1,25 . The test result shows that CSW makes water cement ratio bigger.

#### 3.1.2 Setting Time Test

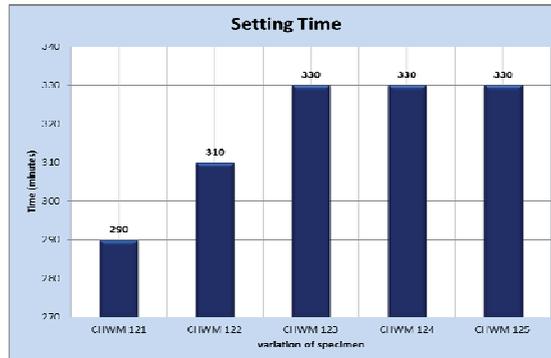

Figure 6. Graph of setting time

From the test result above, it shows that more CSW will make setting time longer.

### 3.2 Hardened Mortar Test

#### 3.2.1 Compressive Strength

Test of compressive strength used specimen cube size 50x50x50 mm, and tested when specimens reach age 3, 7, 14, 21, 28, 56 and 90 days.

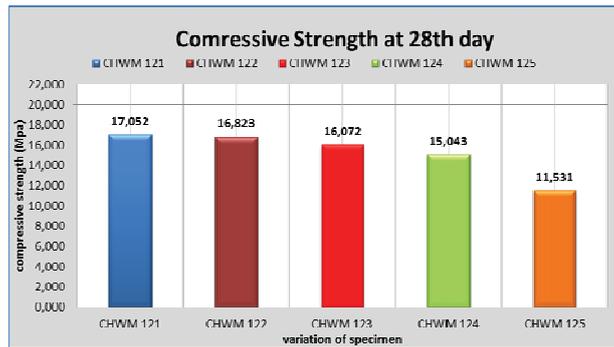

Figure 7. Histogram of Compressive Strength at 28th day

From the test result above, it shows that more CSW will decrease compressive strength.

### 3.2.2 Absorption

Absorption test used cube specimen size 50x50x50 mm and tested at 28th day.

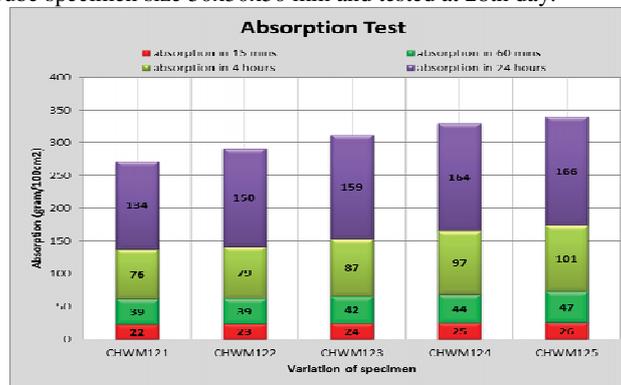

Figure 8. Graph of absorpt

From the test result above, concluded that mortar with more CSW will absorb more water.

### 3.2.3 Shrinkage

Shrinkage test used beam specimen with size 25x25x300 mm. And tested right after specimen removed from mold until 28th day.

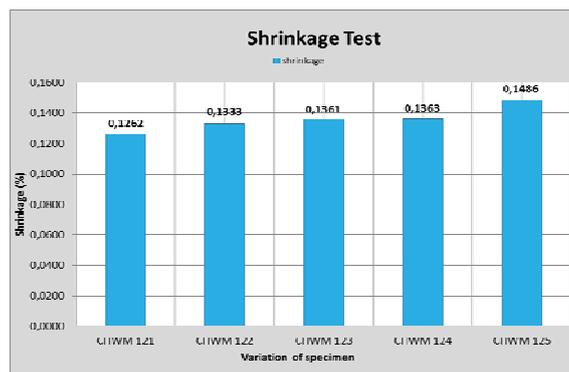

Figure 9. Graph of shrinkage

### 3.2.4 Density

Density test used cube specimen with size 50x50x50 mm and tested at 28th day.

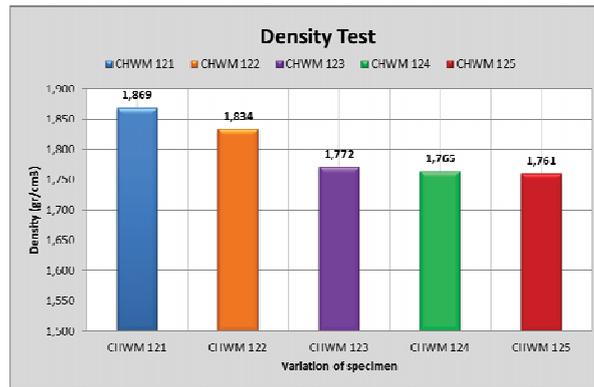

Figure 9. Graph of shrinkage

### 3.3 Application of Mortar With CSW and RHA for Construction materials.

From the test results of mortar with CSW and RHA, and compared with SNI 03 – 0691 – 1996 about specifics of paving block, concluded that mortar with composition 30% CSW and 70% fine aggregate can used to make paving block type C.

Table 5. Quality of paving block based on SNI 03 – 0691 – 1996

Quality	Compressive Strength (Mpa)		Wear resistance (mm/mins)		absorption max
	average	min	average	min	%
A	40	35	0.090	0.103	3
B	20	17	0.103	0.149	6
C	15	12.5	0.160	0.184	8
D	10	8.5	0.219	0.251	10

- A Quality Concrete bricks are used for road.
- B Quality concrete bricks are used for parking lot
- C Quality concrete bricks are used for pedestrian walk
- D Quality concrete bricks are used for park land and another function for non structural concrete.

## 4. CONCLUSIONS And RECOMENDATIONS

### 4.1 Conclusions

In this study, RHA and CSW used to partially substitute cement and fine aggregate. Based on analysis from test. The following conclusions can be drawn:

- a. Using CSW as a Partially replace of fine aggregate in mortar give effects on mortar. Mortar with more CSW need more water (based on consistency test result) and it made mortar reached setting time longer and produced more air cavity.
- b. Mortar containing 30% CSW and 70% fine aggregate made the highest compressive strength between the other compositions. Composition strength of this mortar at 28th day is 17,052 MPa.
- c. And mortar with 70% CSW and 30% fine aggregate has the smallest compressive strength, 11,531 MPa.
- d. So it can be concluded that more CSW composition in mortar will decrease compressive strength.
- e. From absorption test result, CHWC-121 could absorb 134 gram/100cm<sup>2</sup> and CHWC-125 could absorb water until 166 gram/100cm<sup>2</sup>. It can be concluded that more CSW composition in mortar will make mortar absorb more water.
- f. From shrinkage test, CHWC-121 has the smallest shrinkage, 0,1262%. And CHWC-125 has the highest shrinkage, 0,146%. It can be conclude that CSW will make mortar shrinks longer.
- g. From density test, CHWC-121 has the highest density value, 1,896 gram/cm<sup>3</sup>. And CHWC-125 has the smallest density value, 1,761 gram/cm<sup>3</sup>. So CSW decreases density value of mortar.
- h. Mortar with CSW can be used in industry as a non-structural material. Based on SNI 03 – 0691 – 1996 mortar with 30% CSW and 70% fine aggregate can be used to make paving block type C.
- i. Using of CSW in industry will reduce environmental pollution.

### 4.2 Recommendations

The following suggestions may be related to the research conducted are:

- a. Further research needs to be done on the use of CSW, in order to use the maximum percentage value of the mechanical properties of concrete.
- b. Use of CSW so great in the concrete mix, will decrease the compressive strength of concrete, so that further research is recommended to use must be adjusted to the amount of sand on the concrete.

- c. In this study the treatment of CSW proceed by manually, so that further research needs to be done on a good method to produce a CSW in standart.
- d. Need to use chemical ingredients added to the RHA and CSW mix concrete, in order to water cement ratio accordance with the composition of normal concrete.
- e. Use of CSW was able to be used as a complementary mixture of fine aggregate sand, it is necessary to do research on the economics of the use of CSW. So its use can be commercially exploited by the industry and can reduce the impact of pollution on the environment.

There are a lot of concrete sludge waste from each batching plan it so variated in Indonesia, so further research is needed on how much the use of CSW can offer.

## ABSTRACT

*Reworks, un-well-suited works of construction process with schedule, additional cost of unnecessary works, mistakes, lead time and delays, are some problems which are often met in construction process. Those problems are appeared related to bad or unexpected design. Design is fundamental due to the construction process. Building is built through the construction process of design, in which it is resulted from design process. In supporting the construction process, stakeholders (clients, project manager, quantity surveyors, designers, and contractors) are needed to be involved in design process. Collaborative design is needed to facilitate the integration of stakeholders in design process. Knowledge management is one important factor which supported the achievement of successful collaborative design. This research is conducted with purpose to explore the implementation of collaborative design in design process to support construction process, by using literature study and awareness research. Based from research, it is found that there is contradiction finding between result gained from literature study and awareness research based on the understanding of knowledge management which is caused the appearance of doubt in the role of collaborative design. Result gained from this research will be used to develop conceptual definition of dissertation.*

## Keywords

*Collaborative design, knowledge management, project performance*

## 1. INTRODUCTION

Problems are often met in construction process, in which it impacts to unsuitable works in construction process with schedule that has been planned before. This condition will lead to the failure of building objectification from design through construction process. Rework is one of problem which is met in construction process [1], in which it often appears related to the failure or incompatibility of building component design with building system design, whereas if the design is well designed, it will consider all aspect as whole system in building. Rework in construction process will cause additional cost [2, 3] and time [4]. Based from review, it can be concluded that there is a causal linkage between design and construction process. As in [5], problems which are appeared in construction process are related with bad or unexpected design which resulted from design process.

Based from identification of problems in construction process above, it can be discovered that the appearance of problems are related with design. Design is fundamental due to construction process, because design is used as guidance in construction process to build building [6]. Related with this statement, [7] stated that building is built not from trial and error, so the building should construct from best design. Best design can be achieved through the involvement of stakeholders and multiple experts in design process [8], as best solution which gained from multiple alternatives [1], or as an effort to share expertise, idea, responsibilities and source [9]. The need to involve stakeholders in design process is increasing based on the emerging of globalization and complexities of the building itself. Collaborative design is needed as an approach in design process to facilitate the integration of stakeholders and experts whom have different backgrounds in creating design. The achievement of well construction process is gained from successful collaborative design. Knowledge management is one of key success factor, in which it gives important role in collaborative design.

## 2. CONCEPTUAL BACKGROUND

Collaborative design is an approach which is used to facilitate the integration of participants with different background in design process; whereas the participants can work together simultaneously in producing best design as integrated shared solution [10]. Due to facilitate the integration of participants with different backgrounds, issues are appeared and emerging, which cause difficulties in achieving collaborative design goals. Different time and place availabilities of participants [14],

difficulties in achieving shared understanding [18], conflicts [19], and also different personality and attitude of participants [1] are some problems which appeared in collaborative design process. Researches in the area of collaborative design are developed based on the development of issues, in which researchers are finding solution that can be used to reduce or face the appearance of issues that can caused failure in achieving successful collaborative design. Based from literature review, Authors found that collaborative design is a settled knowledge in which it is proofed through researches that collaborative design is able to support the achievement of optimum design [11, 12]. Authors also found that there are three important factors that need to be considered in conducting successful collaborative design, which consist of physical, technical, and social factors. Physical factors are related with issues of difficulties in conducting meeting and doing collaborative design, which are caused by different time and place availabilities of participants whom involved in design process [10]. Solutions which can be used to solve the issue is creating system and tools based on information and communication technology (ICT) that can facilitate information sharing activities between participants whom dispersed located [13, 14, 15].

Conflicts, difficulties in negotiating alternatives, and limitation of media for integrating design objects are some emerging issue that appeared in collaborative design process, especially which facilitated by ICT. The emerging of issues in collaborative design is caused by difficulties in achieving shared understanding between participants [16]. Some solutions that invented through researches in solving the issues are related to technical factors, in which it includes knowledge management [17]. The knowledge management consists of facilities in storing the design process development [18], the use of similar software or media in processing design [19], the use of agent system [2], and also bordering the design development through criteria of design [20]. Issues in collaborative design process are then emerging to the social issues, which related with the personality of participants [1] and social relationship between participants [21]. The appearance of social issues is lead to difficulties in achieving best or optimum design [1], in which it is found that solutions related with social issues consist of personality and attitude consideration, and also the use of teamwork which has experience in working together in collaborative design process [21].

### **3. AWARENESS RESEARCH**

Awareness research is conducted with purpose reveal awareness of participants in design process about collaborative design's concept, to verify supported factors in collaborative design which is gained from literature study, and also to explore current practice of design process and implementation of collaborative design in design process. Respondents of awareness research are 36 experts whom consist of academician and stakeholders in Surabaya and have experience in design process. The research is done by using structured interviews in collecting data. Respondents were firstly asked about the current practice of design process by identifying criteria of collaborative design which were found in design process in order to explore the implementation of collaborative design, they were also asked about their understanding and viewpoints of collaborative design, and also the influence of factors which are gained from literature review in supporting the collaborative design process. Factors which are used in awareness research are representing each factor of physical factors, technical factors, and also social factors. Physical factors are representing by ICT support in conducting collaborative design process, in this paper called technology. Technical factors are representing by the use of similar software and shared understanding between participants, which are called software and perspective in this paper. And the last factor, social factors, are representing by personality of participants and also social relationship between participants, which are called personality and social in this paper. The awareness research results of participants' understandings and viewpoints of collaborative design's concept will be analyzed descriptively. The influenced factors of collaborative design will also analyzed descriptively by using score of mean and standard deviation comparison, in which the result will be plot in scatter plot diagram to analyze the importance of each factor in supporting collaborative design process.

### **4. RESULT AND DISCUSSION**

The main purpose of conducting awareness research is to explore current practice of design process, whether it was implementing collaborative design or not. The research is also conducted with purpose to reveal and identified the awareness of designers and stakeholders whom involved in design process about the implementation of collaborative design concept in supporting design process effectively and efficiently, in which according to findings revealed from awareness research, the role of knowledge management will be described as one important factor in supporting the achievement of successful collaborative design.

#### **4.1 CURRENT PRACTICES OF DESIGN PROCESS**

In order to explore the current practice of design process in Indonesia, whether it implemented concept of collaborative design or not, Authors identified criteria of collaborative design which found in design process. The criteria that asked through respondents consisted of the involvement of multiple stakeholders [8], effort to accomplish design together and simultaneously [10], and also the task interdependencies in design process [26]. Based from the findings which presented on Figure 1, Figure

2, and Figure 3; it can be found that mostly of design processes were implementing collaborative design concept, in which it can be concluded by using criteria of collaborative design attained from past researches; where it is concluded based on finding of all collaborative design criteria in design process, and none (0%) of respondents never find those criteria in design process. Based on this finding, respondents were then asked about their understanding related to concept of collaborative design through its definition and role. The level of understanding about collaborative design concept will influence the implementation in design process.

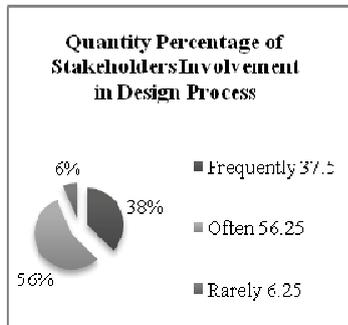

Figure 1: Quantity Percentage of Stakeholders Involvement in Design Process

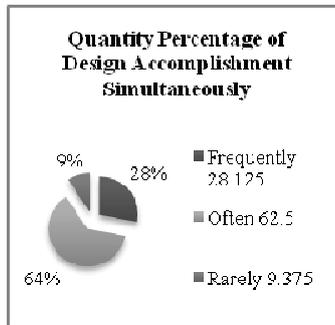

Figure 2: Quantity Percentage of Design Accomplishment Simultaneously

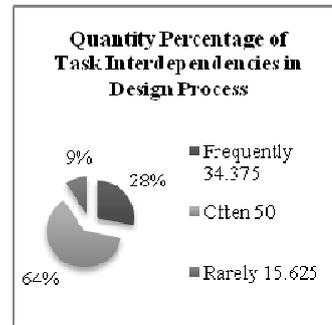

Figure 3: Quantity Percentage of Task Interdependency in Design Process

Figure 4 presents the percentage result of respondents' understandings and viewpoints about the concept of

collaborative design. Based on result it can be seen that there are some respondents (5,56%) whom do not understand yet about the concept of collaborative design, although actually they had experiences in collaborative design process. The lack understanding of collaborative design concept made them have negative viewpoints of the collaborative design role in supporting design process. As [10] stated that design resulted from collaborative design process need to be finished together by participants simultaneously, some respondents were argued about the role of collaborative design because of the essence of working together simultaneously will lead to support design process effectively. Some respondents are defining collaborative design as a collective work of design from participants involved. Collaborative design is not a collective work in design, where design should be finished together simultaneously, and the appearance of misunderstanding about collaborative design will affect to the design process and design resulted from the process [22].

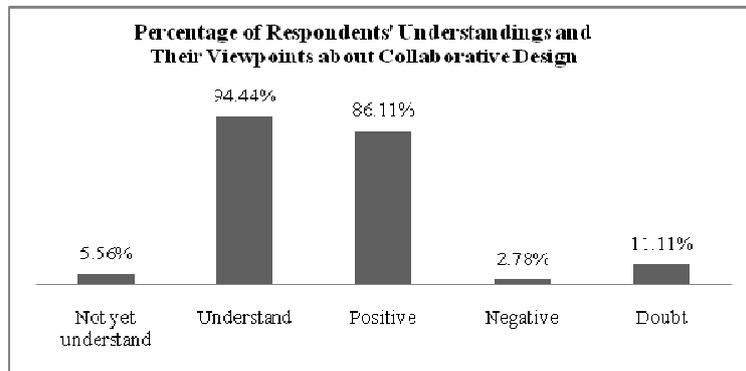

Figure 4: Awareness Research Result of Respondents' Understandings and Viewpoints

According to those finding it can be stated that the concept of collaborative design is mostly applied in current design practices, but main problem appeared due to perspectives of designers about the role of collaborative design in supporting the efficiency and effectiveness achievement in design process. Based on this finding, respondents were then interviewed about factors which made them had doubt in collaborative design role, in which it was found that problems related with knowledge management were main factor that caused respondents doubt about collaborative design role. It was also found that respondent had lack under-standing about factors related with knowledge management which able to support the achievement of successful collaborative design.

## 4.2 THE ROLE OF KNOWLEDGE MANAGEMENT

Due to awareness research, it was found that some respondents whom understand about the concept of collaborative design had doubt about the role of collaborative design in supporting design process. There are some problems which cause some of respondents had doubt about the concept of collaborative design, in which based on the interview it is found that the problems consist of difficulties in modifying design, difficulties in managing design which resulted from each participant, difficulties in achieving shared understanding between participants, and difficulties in making decision through multiple alternatives which are gained from participants. According to literatures, those problems related with knowledge management role in collaborative design [18, 20, 23]. As in [24], collaborative design process should be facilitated with tools or system that capable to facilitate each participant in modifying design, whereas transformation of design and design development as knowledge in design need to be stored [17] and classified [25]. Knowledge that has been stored can be traced by participants to know the process of design transformation and development, in which this activities support the achievement of shared understanding between participants. Knowledge in collaborative design need to be managed [18], beside the facilities of storing and modifying design [24], facilities in classifying knowledge is also needed to support the process of design development and decision making in collaborative design [2]. Based from review to researches in the area of collaborative design, it is found that knowledge management plays important role in the achievement of successful collaborative design [8, 9, 20].

Knowledge management is needed in supporting the achievement of successful collaborative design. The existence of lack understanding about knowledge management supports the appearance of doubt in the role of collaborative design in supporting collaborative design process. Based on literature study it can be found that the use of collaborative design which supported by knowledge management can be used as an approach to facilitate design process that involves participants with different backgrounds. But this finding was argued by respondents, because of their lack understanding about knowledge management in collaborative design. Related with findings found before, it is also found that factor of shared understanding (perspective) which is classified into technical factors in which it also related with knowledge management is factor which has the lowest score of importance in supporting collaborative design, in which the results can be seen in Figure 5 and Table 1. From interview to respondents, it was also found that problems related to technical factors are often solved with inappropriate approaches, in which it should be solved through the implementation of knowledge management but because of their lack understanding about knowledge management, the problems were then solved with social approaches, which lead to failure in achieving optimum design.

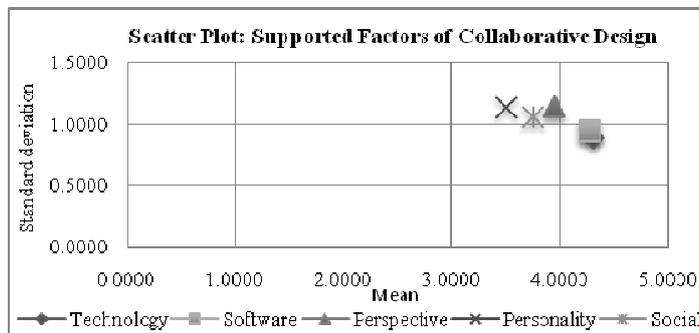

Figure 5 : Scatter Plot Diagram of Mean and Standard Deviation

Table 1 : Rank of Factors Based on Mean and Standard Deviation

Factors	Mean Score	Standard Deviation Score	Rank
Technology	4.3056	0.8886	I
Software	4.2778	0.9445	II
Social	3.7500	1.0522	III
Personality	3.5000	1.1339	IV
Perspective	3.9444	1.1450	V

One of problem that solved with inappropriate approach is conflicts which are appeared because of failure in achieving shared understanding of design development between participants. The problem should be solved through knowledge management,

whereas participants should identify the design development by tracing the storage of design process, but because of their lack understanding of knowledge management the problem was solved through social approach. Another problem that is solved using inappropriate approach is problem related with difficulties in modifying design, in which it should be solved through ICT based system and tools that applied in design software, but because of lack understanding of knowledge management the problem was also solved by using social approach. Based from findings in awareness research, it can be concluded that factor which influenced the appearance of doubt between designers and stakeholders in the role of collaborative design is their lack understanding about the concept of collaborative design itself and also knowledge management as an important factor in supporting the achievement of successful collaborative design process. This finding has contradiction with findings gained from literature review, in which the role of collaborative design is proofed through researches in facilitating design process that involved participants with different background effectively and efficiently [20], but it is argued by respondents because of their lack understanding of collaborative design and knowledge management.

## 5. CONCLUSION

There is contradiction between findings gained from literature review and awareness research, where respondents have doubt about the concept of collaborative design in facilitating design process effectively and efficiently, even that most design practices they were involved were implementing collaborative design concept. The respondents argued the finding of research in the area of collaborative design which is developed by researchers about collaborative design role in supporting design process. Based on awareness research by interviewing some respondents, it is found that the contradiction appeared because respondents has lack understanding about the concept of collaborative design itself and knowledge management as supported factor, in which it caused the appearance of doubt about collaborative design role in design process and the use of inappropriate approaches in collaborative design by applying social approaches in facing problems related with knowledge management. This situation will lead to difficulties in achieving best design which has to be accomplished in design process.

The situation will also impacted on failure in achieving optimum design as best shared solution that integrated between participants. Based from findings, it can be concluded that knowledge management plays important role in achieving successful collaborative design through the achievement of shared understanding between participants, in which it will lead to support the negotiation and decision making process in collaborative design. Successful collaborative design will contribute to support the construction process through best design that is resulted from collaborative design process. The finding gained from this research, related with contradiction finding from literature study about the lack understanding of knowledge management which caused the appearance of doubt in implementing collaborative design, will be used to develop the knowledge management model in supporting collaborative design process through dissertation research. Some factors that be used to develop the model consist of media and shared understanding as knowledge management factors, and also participants' behavior.

## ABSTRACT

*In globalization era, the more expensive construction cost and the auction transparency can cause the tightening world competition in relation to contractor service. Therefore a cost saving effort of construction is needed especially for the Singomoyo bridge upper structure in Malang regency.*

*Value Engineering method is one of the method analyses which proved effectively in saving the budget for construction projects. Value Engineering Job Plan consists of: Information, Speculation, Analysis and Proposal Phases. In order to get an optimal cost saving, we need to study the effectiveness of bridge upper structure used in the first contract. The best alternative construction selection analysis out of the several alternatives must consider cost and technical factors, and is followed up by cost calculation.*

*The finding of Value Engineering analysis shows the most effective and efficient bridge upper structure alternative by using the prestressed concrete girder. The initial cost for steel frame of upper structure was Rp. 2.615.552.816,61. After the implementation of value engineering analysis for the upper structure and the use of prestressed concrete girder for the upper structure, the cost is Rp. 1.741.886.599,65. The amount of cost that can be generated is Rp. 873,666,216.95. It is equal to 33.40% out of the initial construction cost with the use of the steel frame for bridge upper structure.*

### Keywords :

*Effective, Efficient, Cost saving*

## 1. INTRODUCTION

In globalization era when borders among countries are more opened, product and service from one place can reach another place more easily. As a result, only those who work with the principle of “doing the right things (efficient)” and “doing things right (effective)” will prevail in competition and win the market and further they will get much benefit from their efforts earlier and better” (Soeharto, 1998).

The fast development growth in Malang Regency will result in the more expensive construction cost (highway construction and maintenance department of Malang Regency, 2012). In the other side, there is higher public demand for transparency and accountability of development implementation according to Presidential Regulation no 54, 2010 on Goods and Service Provision whose funding sources are drawn from APBN (National Budget) and APBD (Regional Budget). Article 5 in the regulation mandates the principles of provision: efficient, effective, transparent, open, competitive, fair and non-discriminative and accountable. Such regulation will cause tight competition on the domain of construction executors who offer such service. One of alternative methods in an effort to tighten the budget cost is by implementing Value Engineering in construction project. Value Engineering is defined as “an organized attempt to analyze a problem with in an effort to achieve the desired functions with optimal total cost and final result”. [4].

The study will review some concerns, such as: identifying bridge upper structure construction with high cost rate in order to achieve the significant cost efficiency, finding the alternative construction type of bridge upper structure, analyzing some alternative types for bridge upper structure through the consideration of life cycle cost during planning period, carrying out comparison to study design that is supposed to follow the contract, and estimating efficiency obtained from the chosen alternative cost compared to the initial design.

Based on the concerns that have been discussed in the background section after learning information data and contractual documents thoroughly, carrying out the observation around site and analyzing the indicator fulfillment for the success of

Construction Project of Singomoyo Kebon Agung Bridge, the main problems that serve as analysis material for the study can be formulated as follows:

1. Could the construction type for the bridge upper structure implemented for the Construction Project of Singomoyo Bridge in Malang regency be considered as effective and efficient?
2. Are there any other more effective and efficient construction types?
3. How much efficiency is resulted from the implementation of value engineering?

The purpose of this study is to evaluate and analyze the efficiency and effectiveness of value effectiveness on construction of bridge upper structure for the project of Singomoyo Bridge in Malang Regency. The purpose of study can be summarized as follows:

- a. To analyze the efficient and effective bridge upper structure.
- b. To obtain the alternative bridge upper structure that is more effective and efficient through the application of value engineering on the Construction Project of Singomoyo Bridge in Malang Regency.
- c. To obtain the saved amount of bridge upper structure cost on Construction Project of Singomoyo Bridge in Malang Regency through the implementation of value engineering method and to know the amount of efficiency that can be done.

Based on the issues that have been described above, to avoid the deviation of discussion, it is important to determine the limits for present study. The following can be considered as the applied limits:

1. The analysis object is Construction Project of Singomoyo Bridge in Malang Regency.
2. The analysis and application of Value Engineering is used for bridge upper structure construction, especially for the bridge girders that must meet the characteristic and condition of the existing field.
3. The concerns that become the subject of Value Engineering analysis is beyond the issues that have relation with the policy from the owner, planner or executor of the project.
4. The price standard of basic unit for material, wage and equipment uses the price standard of highway construction and maintenance department for the year of 2011 and the price that is determined by the manufacturer of prestressed concrete and steel for bridge.
5. The analysis of unit price uses the analysis of work unit price applied in Malang Regency.

## 2. RESEARCH METHODOLOGY

The object of the study is The Construction Project of Singomoyo Bridge that is located in the border of Kecamatan Pakisaji and Kecamatan Wagir, Malang Regency. The bridge is situated in Kebonagung - Wagir Street and crosses Metro River. Traffic in the street is relatively high consisting of people and goods. The area is residential area that has high density. As one of its characteristics, Metro River has stable current because in its lower course there is dam that is controlled by irrigation department. Elevation between water surface and bridge floor is so limited while soil condition as its base is hard enough.

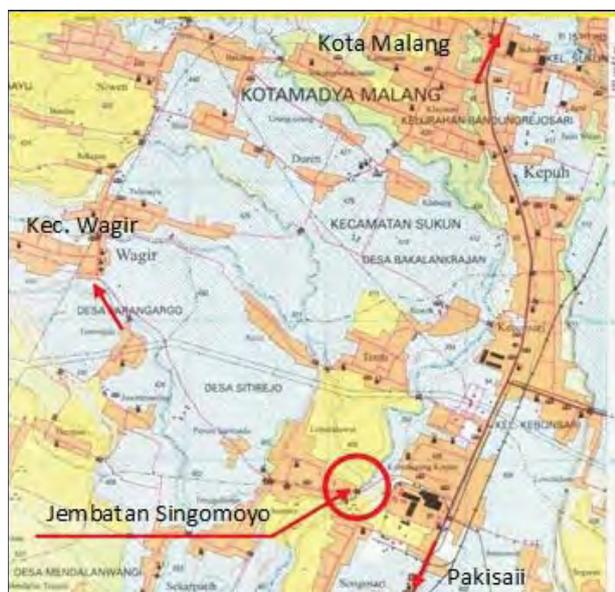

Figure 1. The Map of Singomoyo Bridge Location

Bridge structure has 1 (one) span. The design of upper structure construction uses steel frame construction. The abutment uses reinforced concrete construction and shaft foundation. The span length of the bridge is 40 m so the bridge is categorized into class A bridge. The width of the bridge is 1m + 7m + 1m.

Considering the fact that the construction planning uses steel frame construction, the cost tends to be more expensive. However after studying the field condition thoroughly, there is still possibility to apply other alternative constructions such as conventional concrete, prestressed concrete, composite girder, etc. It is assumed that cost efficiency measure must be taken without reducing the function value of the bridge. One way is to implement Value Engineering in planning construction project of Singomoyo Bridge, so the cost efficiency of construction can be estimated.

In the study the implementation of value engineering in the project uses Value Engineering Job Plan as its method or technique based on Dell'Isola theory (1975) described as value engineering job plan that comprises of information, speculation, analysis and proposal phases.

**2.1.1. Information Phase**

Information phase is carried out through the following steps:

1. Collecting project data that consists of design picture and RAB
2. Studying RAB to obtain each component and work cost
3. Determining work item cost information through the making of project model cost
4. Analyzing further in the form of function analysis.

**2.1.2. Speculation Phase**

After obtaining items to implement value engineering, the next step is to collect idea and think creatively in an effort to get the alternative design that can fulfill the basic function of the predetermined work item. In this creative phase, it is important to have creative approach toward alternative design that will meet the basic function of the predetermined work item.

**2.1.3. Analysis Phase**

Analysis phase has a purpose to select some best alternatives from the resulted alternatives during creative phase through some analysis/steps and assess those creative ideas based on the benefit and loss aspects in an attempt to obtain the cost efficiency from each evaluated idea. During the evaluation process, the some techniques can be applied such as zero one and evaluation matrix methods.

**2.1.3.1. Benefit and Loss Analysis**

Benefit and loss analysis is the roughest filtering phase among other estimation methods. Among creative ideas resulted from previous phases, the chosen ideas are Deep Galvanized Steel Frame, Reinforced Concrete Bending, Deep Galvanized Steel Girder, Prestressed Concrete Girder, and then the potential benefit and loss are put into table.

**2.1.3.2. Determining alternative rank**

One of steps in analyzing the creative ideas is to discuss the estimation subjectively because often it is difficult to obtain ideal value. Therefore, alternative rank from the potential structures is carried out.

Based on [7] , some aspects/criteria that will be reviewed and the estimation scale that will be implemented are as follows: Cost, Space Utilization, attractiveness/esthetic, implementation method, maintenance, implementation timing.

The following table shows each aspect/criteria:

Table 1. Criteria and Estimation Scale

No.	Criteria	Estimation Scale			
1	A : Cost	4 = Very Cheap	3 = Cheap	2 = Expensive	1 = Very Expensive
2	B : Space Utilization	4 = Very Proper	3 = Proper	2 = Improper	1 = Very Improper
3	C : Esthetic	4 = Very Good	3 = Good	2 = Bad	1 = Very Bad
4	D : Implementation Method	4 = Very Easy	3 = Easy	2 = Difficult	1 = Very Difficult
5	E : Maintenance	4 = Very Cheap	3 = Cheap	2 = Expensive	1 = Very Expensive
6	F : Implementation Timing	4 = Very Fast	3 = Fast	2 = Slow	1 = Very Slow

Source : analysis result

**2.1.4. Proposal Phase**

The determined alternative in analysis phase is followed up in this phase and then proposed to the project owner in the written form. The proposal must be carried out in careful and convincing way and presented with detail by using the chosen sketches and items.

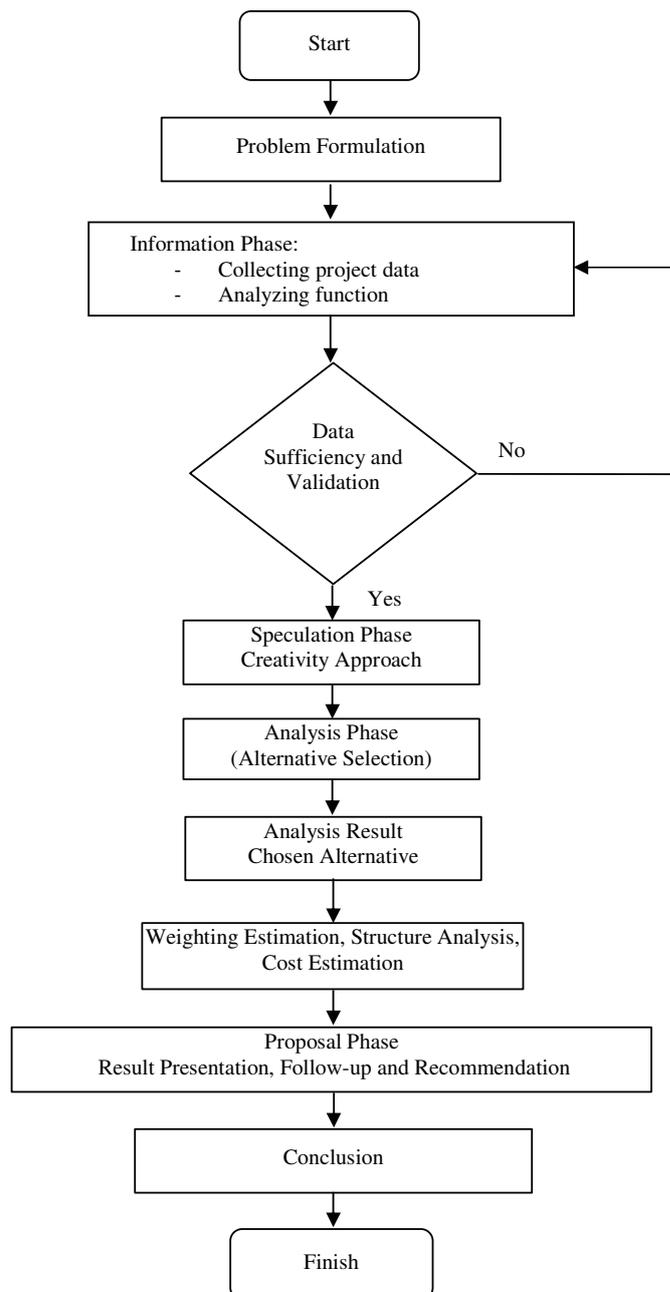

Figure 2. The flowchart of Value Engineering Job Plan

### 3. ANALYSIS AND DISCUSSION

#### 3.1. Information Phase

In the implementation of value engineering study, data about the entire planning of Singomoyo Kebonagung Bridge is required. The project information and technical data for each phase of project implementation are as follows:

The construction of upper structure

- |                     |   |
|---------------------|---|
| a. Project Name/job | : Improvement/The Construction of Singomoyo Kebonagung Bridge in Kec. Wagir |
| b. Location         | : Kecamatan Wagir   |
| c. Bridge Class     | : Class A (1m + 7m + 1m)  |
| d. Bridge Type      | : Austrian Steel Frame, the product of PT. Wagnei Biro Indonesia (WBI)      |

- e. Foundation (lower structure) : Shaft foundation with diameter of 2.5 m
- f. Bridge span : 40,0 m
- g. Project cost : Rp. 2,615,552,816.61,-

### 3.2. Analysis Phase

In this phase, input idea or alternative are analyzed so the selected idea gives more benefit seen from various aspects. The resulted alternative or idea is formulated and put into consideration in relation to their benefit and loss and then ranking is determined as a result of the estimation. The evaluation uses techniques such as zero-one method and evaluation matrix.

#### Benefit and Loss Analysis

Benefit and loss analysis is the roughest phase among the other estimation methods used in the estimation phase. Its first step is to enlist the potential benefits and losses of each alternative or idea. The following table shows the summary of benefits and losses of each alternative bridge upper structure.

Table 2. Benefit and loss analysis

No	Alternative / Idea	Benefits	Losses
1	Deep Galvanized Steel Frame	1. It is very light 2. The implementation method is very easy 3. It doesn't need maintenance 4. The implementation is very fast	1. The cost is so expensive 2. The material is difficult to obtain 3. It needs fabrication 4. The space utilization is not proper 5. The esthetic is bad 6. The construction age is 25 years
2	Reinforced Concrete Bending	1. It's easy to shape 2. Material is easy to get 3. It's durable against heat 4. The construction age is 50 years	1. The cost is expensive 2. The volume of concrete is big 3. The space utilization is not proper 4. The esthetic is bad 5. The implementation method is very difficult 6. The maintenance is very expensive 7. The implementation timing is very slow
3	Deep Galvanized Composite Steel Girder	1. The weight is light 2. The space utilization is proper 3. The esthetic is good 4. The implementation method is very easy 5. The maintenance is cheap 6. The implementation is very fast	1. The cost is expensive 2. The material is difficult to obtain 3. Fabrication is needed 4. Erection equipment is needed 5. The construction age is 25 years
4	Prestressed Concrete Girder	1. The concrete volume is small 2. The weight is light (type I) 3. The cost is cheap 4. The esthetic is very good 5. The space utilization is very proper 6. The maintenance is very cheap 7. The implementation method is easy 8. The implementation timing is fast 9. The construction age is 50 years	1. High quality concrete technology (fabrication) is needed 2. Prestressed technology is needed 3. The material is difficult to obtain 4. Erection equipment is needed

#### 3.2.1. Determining Alternative Ranking

One form of the creative idea analysis is to discuss the estimation in very objective way because it is so difficult to obtain the ideal value so ranking of each potential alternative for bridge upper structure construction must be taken into consideration. Then based on the aspects/criteria of review and estimation scale above, the following feasibility analysis for each alternative for bridge upper structure is determined:

Table 3. The Estimation Score on Criteria

No	Criteria	Criteria						Description
		A	B	C	D	E	F	
1	Deep Galvanized Steel Frame	2	1	1	2	2	2	
2	Reinforced concrete bending	1	2	2	1	1	1	
3	Deep Galvanized Composite Steel Girder	3	3	3	4	3	4	
4	Prestressed Concrete Girder	4	4	4	3	4	3	

Source: analysis result

From 4 alternatives for bridge upper structure, the best alternative is selected to be developed in the value engineering. Furthermore, the weight from each criterion is determined by using zero one method as follows:

Table 4. Zero One Method to Determine the Weight

Criteria	No.	Criteria						Total	Ranking
		A	B	C	D	E	F		
Cost	A	X	1	1	1	1	1	5	1
Space Utilization	B	0	X	1	1	1	1	4	2
Esthetic	C	0	0	X	1	1	1	3	3
Implementation method	D	0	0	0	X	0	1	1	5
Maintenance	E	0	0	0	1	X	1	2	4
Implementation timing	F	0	0	0	0	0	X	0	6

Source : analysis result

Description : 1 = more important, 0 = less important, X = same function

Table 5. Weighting

Criteria	No.	Ranking	Ranking Number	Weight
A : Cost	A	1	6	100.00
B : Space utilization	B	2	5	83.33
C : Esthetic	C	3	4	66.67
E : Maintenance	E	4	3	50.00
D : Implementation method	D	5	2	33.33
F : Implementation timing	F	6	1	16.67

Table 6. Relative Weighting for Alternative Selection

No	Alternative	Criteria						Total	Ranking	Selected
		A	B	C	E	D	F			
		<b>100</b>	<b>83.33</b>	<b>66.67</b>	<b>50.00</b>	<b>33.33</b>	<b>16.67</b>			
1	Deep Galvanized Steel Frame	2	1	1	2	2	2	549.99	3	
		200.00	83.33	66.67	100.00	66.66	33.33			
2	Reinforced concrete bending	1	2	2	1	1	1	500.00	4	
		100.00	166.67	133.33	50.00	33.33	16.67			
3	Deep Galvanized Composite Steel Girder	3	3	3	3	4	4	1,099.99	2	
		300.00	250.00	200.00	150.00	133.32	66.67			
4	Prestressed Concrete Girder	4	4	4	3	3	3	1,299.99	1	1
		400.00	333.33	266.67	150.00	99.99	50.00

### Cost and Efficiency Estimation

a. The amount of initial cost

Construction cost for upper structure (steel frame) including the work cost of reinforced concrete and steel for vehicle floor with the length of 40.0 m is Rp. 2.615.552.816,61 .

Table 7. The construction cost for upper structure (Existing)

No	Description	Unit	Volume	Unit Price	Price
<b>I Structure Work</b>					
1	K350 Concrete	m3	128.00	1,080,728.89	138,333,297.98
2	U32 Helical Reinforced Steel	kg	12,045.38	16,148.84	194,518,899.35
	<b>Sub Total</b>				<b>332,852,197.33</b>
<b>II Upper Structure Work (Steel Frame)</b>					
1	A.40 steel frame provision	kg	91,580.00	21,616.88	1,979,673,413
2	The delivery of steel frame to location (Malang)	kg	91,580.00	1,213.79	111,158,927
3	The Installation of steel frame & reaction	kg	91,580.00	2,049.81	187,721,479
4	Joint Expansion (100 ,100, 15)	M'	28.00	148,100.00	4,146,800

#### 4. PROPOSAL PHASE

This phase is the final phase of the value engineering process. The phase consists of the presentation of conclusion and recommendation of the value engineering result to the concerned parties. The following table shows the summary of the proposal about upper structure work for Singomoyo Bridge.

Table 9. The Upper Structure Work Proposal for Singomoyo Kebonagung Bridge

<b>Project Name :</b>	
Improvement/Construction of Singomoyo Kebonagung Bridge in Kec. Wagir	
<b>Plan in Initial Contract</b>	
Bridge Class	: Class A (1m+7m+1m)
Foundation (Lower Structure)	: Shaft Foundation with Diameter of 2.5 m
Distance between Abutments	: 40.0 m
Upper Structure	: Austrian Steel Frame, The product of PT. Wagnei Biro Indonesia (WBI)
<b>Proposal</b>	
<b>Alternative :</b>	
Bridge Class	: Class A (1m+7m+1m)
Foundation (Lower Structure)	: Shaft Foundation with Diameter of 2.5 m
Distance between Abutments	: 35.0 m
Upper Structure	: Prestressed Concrete Girder
After considering the alternative upper structure for more efficient and effective bridge, the following result is obtained :	
<b>Cost</b>	
Initial Contract	Alternative
Rp. 2,615,552,816.61	<b>Rp. 1,741,886,599.65</b>
<b>Cost Efficiency Percentage</b>	
<b>Alternative (Selected) :</b>	

33.40% out of the initial contract
------------------------------------

Source : analysis result

## 5. CONCLUSION

From the value engineering analysis applied for the upper construction of Singomoyo Bridge in Malang regency, the following conclusions are obtained:

1. The implemented steel frame bridge as the existing construction type of bridge upper structure for Construction Project of Singomoyo Bridge in Malang Regency is not the effective and efficient alternative after the consideration of both the used material and the cost.
2. After the implementation of value engineering analysis for bridge upper construction of Singomoyo Bridge in Malang regency, the prestressed concrete girder as the upper construction type is selected as the more effective and efficient alternative without reducing the function and the capacity of the bridge service.
3. The upper construction cost for steel frame of Singomoyo Bridge was Rp. 2,615,552,816.61. After carrying out the value engineering analysis on upper structure construction and the resulted selection of the prestressed concrete girder, the cost of prestressed concrete girder is Rp. 1,741,886,599.65. The resulted efficiency is Rp. 873,666,216.95. The value is equal to 33.40% out of the initial cost of the upper structure construction.

# Organisational Culture: The Case of Indonesian Construction Industry

Debby Willar<sup>a</sup>

<sup>a</sup>Civil Engineering Department, Manado State Polytechnic, Manado 95252  
E-mail : debby\_willar@yahoo.com

## ABSTRACT

*Despite the complexities involved in measuring culture of the construction industry, this culture is regarded as being worthy of research, especially in relation to the organisational culture needed to improve organisational performance. Questionnaire surveys were distributed to selected representative G-7 Indonesian civil engineering contractors in order to assess the organizational culture profiles of the construction companies adopting the Organizational Culture Assessment Instrument (OCAI), which is based on the Competing Values Framework. The findings from the study indicates that different culture types are emphasized in the six cultural dimensions of OCAI, reflecting various elements of cultural values that exist in an organization's operating activities. A comparison between the dominant characteristics of the organizational culture type within Indonesian construction companies, possessing a culture type similar to that of other global construction companies, shows the differences that exist with construction industries elsewhere in the world. Having different pictures of culture profiles in the construction industries suggests that the culture profiles within the construction industry might reflect the construction market demand and business environment, in each country, and the goals of each construction company.*

**Keywords:** *Competing Values Framework, organizational culture, construction industry, Indonesia.*

## 1. INTRODUCTION

Current research within the construction management area has revealed evidence that organizational culture is considered to be a determinant factor in contributing to the organization competitiveness [1], quality management systems [2], sustainability [3], performance and effectiveness [4]. The 'people' in organizations are collectively bounded by the organizational culture which in turn reflects organization characteristics [5]. In this study, the term 'organizational culture' is going to be defined as the shared values and underlying assumptions within construction organizations, which motivate and support organizations to operate effectively.

Focusing on an investigation of the link between organisational culture and effectiveness of an construction organisation, [2] provides a list of organisational culture-performance link studies which were conducted by researchers in different parts of the world, between 1990 and 2004. From the list, it can be concluded that various kinds of organisational culture dimensions have been proven to be connected with short and long-term performance, direct or indirect performance, low and high performance, and growth and profitability of an organisation.

Current research in Indonesian construction and project management has not pursued a more comprehensive study of the organizational culture profiles of Indonesian construction companies and the link to effective organizational performance. In the interviews conducted as part of a pilot survey by the author, some of the respondents, all local contractors, stated that they had never considered undertaking any organizational culture investigation and thus were unaware of what types of culture their companies possessed. They observed that, in their view, organizational culture was demonstrated by characteristics such as, commitment, loyalty, and good team work.

This current study is aimed at diagnosing the dominant culture types in the six cultural dimensions of Organizational Culture Assessment Instrument (OCAI). Further analysis was made in regard to comparing the dominant characteristics of Indonesian construction companies' culture profile with other global construction companies. The method of analysis is carried out primarily by comparing measures obtained from the OCAI of [1], in order to determine the current dominant culture types of the respondent organizations that appear to enable them to operate effective organizational and management practices, that overcome the business environment's demands and challenges, that in turn will lead to have the potential for having organization effective performance.

## 2. JUSTIFICATION FOR CHOOSING THE COMPETING VALUES FRAMEWORK

There are a number of well-established and well-recognized models and instruments, which are used for identifying and measuring organizational culture. One of the most widely used theoretical models is the Competing Values Framework (CVF),

which was developed in [6]. It has the aim of helping organizations in understanding themselves and supporting the development of effective organizational phenomena. Indeed, the CVF “has been shown empirically to reflect the current thinking of organizational theorists on organizational values and resulting in organizational effectiveness” [7].

The CVF was eventually selected as being the most suitable organizational culture model to use in the context of this study, due to its suitability in identifying the profiles or types of organizational culture of construction companies, together with providing a measure of the strength of the individual characteristics that make up those profiles. The research is considered timely as many Indonesian construction companies do not perceive the importance of organizational culture, and therefore, a model is needed, which is easy to assimilate and which allows better visualization of how this complex phenomenon operates within their companies and of how a deeper understanding of corporate culture can assist business and process improvement within their organizations.

The CVF consists of four major culture types (clan, adhocracy, hierarchy, market) that are theorized to compose cultural profiles within various kinds of organizational contexts [8]. These authors further explain that an organization can possess either a predominant internal or external focus, and may either be wishing to achieve flexibility and discretion, or stability and control. This combination of factors creates four potential cultural categories, each representing a distinct set of cultural values. The four major culture types that emerge from the framework (Figure 1) are briefly described by [1] as follows:

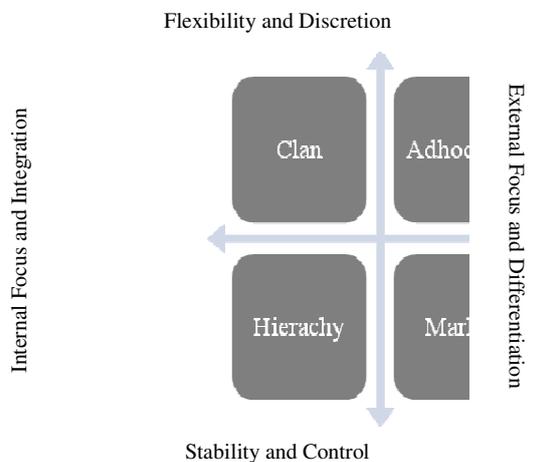

Figure 1: The Competing Values Framework

In construction research on organizational culture profiles, [9], [10], [11], [12], and [2] used the Organisational Culture Assessment Instrument (OCAI), which is based on the CVF, to identify the culture profiles of construction companies in each country of their research domain. They found that the tool is helpful in providing a comprehensive picture of a company’s organisational culture and the values that characterize each culture, as well as providing a comparison standard for culture profile interpretation. The six cultural dimensions of OCAI represent the culture climate in an organisation which forms a cumulative representation of an organisational culture [13]. The cultural dimensions with associated cultural types of the OCAI are presented in Table 1.

Table 1: OCAI traits and typologies

Cultural Dimensions	Culture Types			
	Clan Culture	Adhocracy Culture	Market Culture	Hierarchy Culture
Dominant Characteristics	It is a very personal place. It is like an extended family. People seem to share a lot of themselves.	It is a very dynamic and entrepreneurial place. People are willing to stick their necks out and take risks.	It is very results-oriented. A major concern is with getting the job done. People are very competitive and achievement-oriented.	It is a very controlled and structured place. Formal procedures generally govern what people do.
Organisational Leadership	The leader is generally considered to exemplify	The leader is generally considered to exemplify entrepreneurship,	The leader is generally considered to exemplify a no-nonsense, aggressive,	The leader is generally considered to exemplify

	mentoring, facilitating, and nurturing.	innovation, or risk taking.	results-oriented focus.	coordinating, organising, or smooth-running efficiency.
Management of Employees	The management style is characterised by teamwork, consensus, and participation.	The management style is characterised by individual risk taking, innovation, freedom, and uniqueness.	The management style is characterised by hard-driving competitiveness, high demands, and achievement.	The management style is characterised by security employment, conformity, predictability, and stability in relationships.
Organisation Glue	The glue that holds the organisation together is loyalty and mutual trust. Commitment to this organisation runs high.	The glue that holds the organisation together is commitment to innovation and development. There is an emphasis on being on the cutting edge.	The glue that holds the organisation together is the emphasis on achievement and goal accomplishment.	The glue that holds the organisation together is formal rules and policies. Maintaining a smooth-running organisation is important.
Strategic Emphases	It emphasizes human development. High trust, openness, and participation persist.	It emphasizes acquiring new resources and creating new challenges. Trying new things and prospecting for opportunities are valued.	It emphasizes competitive actions and achievement. Hitting stretch targets and winning in the marketplace are dominant.	It emphasizes permanence and stability. Efficiency, control, and smooth operations are important.
Criteria of Success	Success is on the basis of the development of human resources, teamwork, employee commitment, and concern for people.	Success is on the basis of having the most unique or newest products. It is a product leader and innovator.	Success is on the basis of winning in the marketplace and outpacing the competition. Competitive market leadership is key.	Success is on the basis of efficiency. Dependable delivery, smooth scheduling, and low-cost production are critical.

### 3. RESEARCH METHODOLOGY

The respondents to the questionnaire for this study were drawn from 74 construction companies listed as grade 7 (G-7) contractors - the highest grade of Indonesian contractor qualification. A minimum of three responses and a maximum nine responses in each company involved in the questionnaire giving a total of 403 respondents: 67 Quality Management Representatives (QMRs), 215 Managers (Ms) and 121 Project and Site Engineers (Es). These groups of respondents represented the following levels of seniority (high - QMR), (middle - M), and (low - E) in the organizational structure.

Using the OCAI questionnaire developed by [1], a respondent rated a set of statements that relate to six cultural dimensions, i.e., dominant characteristics (DC), organisational leadership (OL), management of employees (ME), organisational 'glue' (OG), strategic emphasis (SE), and criteria of success (CS); the rating level is based on whether these dimensions are similar (or not) with the current situation in a respondent's company. This instrument is used to identify the most closely fitting type of culture for the company, i.e., whether it is predominantly a Hierarchy (H), Market (M), Clan (C), or Adhocracy (A) culture.

### 4. RESULTS AND ANALYSIS

#### 4.1 Results of Construction Companies' Culture Profiles

By individually plotting each of the questions under the six cultural dimensions on the Organizational Culture Assessment Instrument (OCAI) worksheet, the analysis of the companies six cultural dimensions was focused on indicating types of culture that most dominant in the six dimensions.

Figure 2 presents an example of the OCAI results of the dominant culture type for ‘strategic emphasis’ dimension from one of the company respondents. The dominant Market type (33) was emphasized in this dimension, followed by Clan type (24), and a slightly balanced of Hierarchy (22) and Adhocracy (21) types.

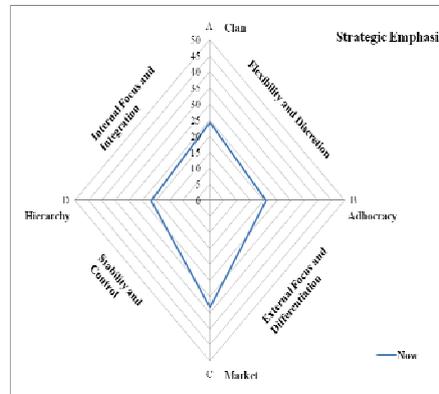

Figure 2: Dominant ‘Market’ type in the dimension of strategic emphasis

Table 2 summarises the dominant culture types of the six cultural dimensions possessed by most of the 74 construction companies. Overall, respondents perceived that the dominant characteristics or the core values of the construction companies is most represented by the ‘Clan culture’ (41.9%). The core values of ‘Clan type’ in this first dimension is the sense of ‘family’ and the importance of ‘sharing’. In reference to the style of the organization leader, most of the construction companies are strongly Hierarchy oriented (29.7%), with the leaders being hard drivers, producers, and competitors. The management style used to manage employees is strongly Clan oriented (56.8%) which is characterized by the value of team work, consensus, and participation. The organization glue that holds companies together is also the Clan culture (66.25%); loyalty and mutual trust are key norms of this Clan type in this fourth cultural dimension. The companies’ strategic emphasis is strongly Market oriented (35.1%), the Market culture having a competitive and achievement focus. Success criteria of companies as perceived by employees as the Clan culture (45.9%) that believes that their success lies on the development of human resources, commitment, and concern for people.

Table 2: Dominant culture types of six cultural dimensions

Cultural dimensions	‘C’ type		‘A’ type		‘M’ type		‘H’ type		***	
	n	%	n	%	n	%	n	%	n	%
1 <sup>st</sup> Dominant characteristics (DC)	31	41.9	11	14.9	22	29.7	5	6.8	5	6.8
2 <sup>nd</sup> Organisational leadership (OL)	18	24.3	8	10.8	21	28.4	22	29.7	5	6.8
3 <sup>rd</sup> Management of employees (ME)	42	56.8	4	5.4	11	14.9	13	17.6	4	5.4
4 <sup>th</sup> Organisational glue (OG)	49	66.2	3	4.1	7	9.5	5	6.8	10	13.5
5 <sup>th</sup> Strategic emphasis (SE)	13	17.6	6	8.1	26	35.1	15	20.3	14	18.9
6 <sup>th</sup> Criteria of success (CS)	34	45.9	-	-	11	14.9	23	31.1	6	8.1

Note: ‘C’ = Clan, ‘A’ = Adhocracy, ‘M’ = Market, ‘H’ = Hierarchy, \*\*\*= no dominant type;  
 [shaded cells] = most prevalent culture types possessed by respondents in each cultural dimension.

#### 4.2 Analysis of the Results

The findings from the study of the identification of dominant culture types within Indonesian construction companies indicates that the organisational culture within most Indonesian construction companies is predominantly of the Clan type, where the

company is focused on internal maintenance with flexibility, family-like relationships having a concern for people, and sensitivity towards its customers. This predominant culture type is also emphasized most in the cultural dimension related to how employees are managed, how the organisation is held together, and how the organisation's success in its achievements is defined. This finding is fundamental to the perspective of organisational culture within Indonesian construction companies. With the rapid and remarkable growth rate in the construction industry, it is important for this sector to recognise its individual and collective cultural patterns, in order that they can be used to evaluate companies current operational activities, achievements, and future successes. In addition, it needs to be recognised that adoption of the predominant company cultural profile allows companies to adapt and respond to challenges, and hence later set up appropriate cultural changes or maintain and strengthen the existing fundamental culture profile.

The dimension labeled 'organisational leaderships' is related to the dominant leadership style and approach used by leaders and managers in those companies which are more hierarchy-focused than the other three culture types. This indicates that the leaders and managers are generally considered to exemplify coordinating, organising, and smooth-running efficiency. For the surveyed companies, this finding confirms that the role of leaders and managers is to set an example in the day-to-day operational activities of the companies [14], [15] and [16], to become the focal points within the organisation in which the operational activities are largely governed by standardized procedures.

The dimension labelled as 'strategic emphasis', the area of emphasis that drives the organisation's strategy, in this study is 'Market type dominant', wherein the company emphasizes permanence and stability; efficiency, control and smooth operations, as the important company strategies. This finding suggests that current form of Indonesian construction strategy is focused more on profit and goal accomplishment, due to high competitiveness in both domestic and international markets. Contractors' focus on profit and market-orientation, in fact, is in line with of The Ministry of Public Work's policy to enforce Indonesian construction to take a role in global markets, as the industry can no longer just depend on the domestic market [17].

A comparison between the dominant characteristics of organisational culture type within Indonesian construction companies, possessing a culture type similar to that of other global construction companies, shows the differences that exist with construction industries elsewhere in the world. Hong Kong construction companies appear to emphasize the strong Clan type [18], while the Hierarchy type dominates the construction industry in Thailand [19]. From surveys conducted by [1], they found that, on average, the Market type was the predominant culture profile in the construction sector. A similar finding was reported by [10] for Finnish construction companies. In the case of the construction industry in China, a mixture of culture types exists, with Hierarchy – Market culture dominance being reported by [11] and Hierarchy – Clan culture dominance reported by [20]; the culture profiles of Chinese contractors varieties between geographical regions [20]. The Turkish construction industry has a mixture of Clan and Hierarchy cultures [12]. Having different pictures of culture profiles in the construction industries suggests that the construction industry has not yet been able to define 'a typical' culture profile, such as those based on Cameron and Quinn's culture typologies. The culture profiles within the construction industry might reflect the construction market demand and business environment, in each country, and the goals of each construction company. Reference [11] state that the understanding of organisational cultures (overlaid with national cultures) is an important element of any business enterprise.

## 5. CONCLUSIONS

The finding of this study is that Clan culture is most dominant within the highest grade of Indonesian construction companies qualification, while the style of organisational leadership is a hierarchical dominance. As common for an organisation in doing business, Indonesian construction companies emphasize Market type in their strategy settings. The identified organisational culture profiles most emphasized within Indonesian construction companies contributes to the recognition of the current contractor's cultural pattern, and this can be a basis for a company to consider further measures for matching the current culture profiles with the future demands of its environment, including future challenges and opportunities to be faced by the company. This will then advantage the company in setting up appropriate culture changes and/or strengthening its current culture profile in order to possess the most adaptable organisational culture; that culture will, in turn, help the company to successfully deal with the complexities of construction business entities.

Different countries have different and specific national cultures, different market demand and business environments, and as well as the goals of each construction company, which might influence a company's culture.

## ACKNOWLEDGMENT

This research project is funded by DIKTI Scholarships on behalf of The Ministry of Education and Culture of The Republic of Indonesia.

### ABSTRACT

*Pricing is one of the most important aspects in marketing concept, including in the construction industry. Up until today, there is only one pricing strategy predominantly used in construction: cost-based pricing. There are two problems with this pricing logic: underpricing or overpricing a bid offer. Considering problems with a cost-based strategy, alternate pricing strategies in construction using market-based approach are proposed. The heart of these models is intelligence functions in a company. This paper reviews and explores pricing strategy and intelligence functions in construction. First, it explores a new marketing concept, including alternate pricing strategies. Second, marketing intelligence systems developed and used in manufacturing industries are explored, including marketing research, marketing information systems, and decision supports systems. It also explores the current developments and practices of intelligence functions in construction. Third, findings of a survey administered to contractors to investigate intelligence functions are presented. In conclusion, "marketing intelligence systems" in construction is a subject that is seldom discussed by researchers. It is found that contractors use mostly traditional intelligence activities. It is recommended that contractors should develop particularly computers related intelligence activities such as using the Internet and developing MISs/DSSs.*

**Keywords:** *marketing, pricing, contractors, intelligence system, decision support system*

## **1. INTRODUCTION**

The construction industry in most countries in the world is one of extreme competitiveness, with high risks, and generally low profit margins when compared to other areas of the economy. Consequently, pricing is one of the most important aspects of marketing in construction. But unlike in other industries, transactions and contracting in construction are conducted through the competitive bidding process, so that pricing mostly takes place in the bidding process. Consequently, up until today, there has been only one pricing strategy predominantly used in construction: cost-based pricing. The typical procedure in cost-based pricing involves estimating the project cost, then applying a markup for profit. There are two problems with this pricing strategy. Since the price is set based on internal cost and margin requirements, the price that results could be too high or too low relative to offers made by competing organizations with comparable reputation. First, it is possible to grossly underprice a project using cost-based pricing and not only forgo high levels of profitability but also risk incurring great losses that can threaten the survival of the company. The second possible consequence of cost-based pricing is overpricing. What generally happens in these situations is that the project is overpriced relative to the owner's estimated cost and the offers of competing bidders, resulting in losing the bid.

## **2. NEW MARKETING CONCEPT**

The new concept of marketing stresses the importance of the market orientation of a firm's activities. A market orientation is made manifest by the development of firm skills. They include acquiring knowledge about customers and other market participants, sharing that knowledge widely throughout the organization, achieving consensus on its meaning, and taking action to deliver superior customer value [1, 2, 3]. Managers [4, 5] and scholars [2, 6, 7] are in broad agreement that a superior learning capability is an important contributor to competitive advantage, one of the most important marketing principles. An important distinction is that the objective is to learn about customers, not just to learn from them. Beside the customer needs, one of the most important marketing intelligence functions is to learn about competitors by identifying their strategies, determining their objectives, assessing their strengths and weaknesses, and finally estimating their reaction patterns [8]. Finally, the firm can learn from experience, continuously making improvements in the way it does repetitive tasks [9]. A recent study [10] suggests that each of these learning styles make a unique contribution to organizational effectiveness. All these studies support the need for marketing intelligence activities within a firm.

### **2.1. Alternate Pricing Strategies in Construction**

Considering the problems with a cost-based strategy and the benefits of new concepts of marketing, a series of "market-based pricing" models in construction are developed [12]. First, a hybrid-pricing model, a variation of the current cost-based pricing approach, that includes additional market information. Second is a more market-based hybrid pricing model with the main information of market data collected through marketing intelligence so that a cost target can be set. Third, a market-based pricing model with the main information used of market data collected through marketing intelligence. The big assumption of third model is the belief that the company is always able to find ways and methods to construct the project below the market price with a reasonable profit. The heart of these models is market intelligence functions in a company.

## **3. MARKETING INTELLIGENCE SYSTEMS**

A definition of marketing intelligence system is the system for capturing the necessary information for business marketing decision-making [13]. The fundamental purpose of marketing intelligence is to help marketing managers make decisions they face each day in their various areas of responsibility. As directors of their firms' marketing activities, marketing managers have an urgent need for information or marketing intelligence. They might need to know about the changes that could be expected in customer purchasing patterns, the shape of the firms' demand curve, or any of a number of other issues. These issues could affect the way they plan, solve problems, or evaluate and control the marketing effort, most importantly pricing policies [14].

According to Kotler [8] marketing managers often carry out marketing intelligence by reading books, newspapers, and trade publications; talking to customers, suppliers, distributors, and other outsiders; and talking with other managers and personnel within the company. According to Safford [15], there is a need for competitive intelligence in all business- large and small- regardless of the product or the industry. Consequently, four steps are involved in competitive price information: collection of competitive price information through intelligence activities, careful analysis of this information, development of strategy based upon the above, and finally action. Furthermore, there are 12 valuable sources of information on pricing in terms of developing competitive intelligence: the firm's own salesmen and other field representatives, printed price lists, rumors, especially rumors of change, friendly customers particularly if found reliable over the years, distributor and other advisory groups, bids and quotations made by governmental bodies, newspapers/journals and advisory services, annual and other financial reports containing interesting data on competitive capital and research programs, government and other publications, direct inquiry to competitors and contacts with counterparts among them, tangible proof from customers, and finally marketing survey/research [15]. Hutt and Speh [13] claim that a comprehensive business marketing intelligence system might include formal marketing research studies, market potential and sales forecasting, financial and accounting performance analysis, new product research, and secondary data files. Marketing intelligence is clearly a broad and complex function whose effectiveness will dramatically affect the quality of marketing decisions, including pricing decisions.

### 3.1. Marketing Research

Marketing research involves certain basic elements that apply generally. In any context, the research study must be planned, a data-gathering instrument designed, and a sampling plan designed. The data must then be gathered, processed, analyzed, and reported [13]. Traditionally, marketing research is responsible for this intelligence function. Marketing research is the firm's formal communication link with the environment. It generates, transmits, and interprets feedback information originating in the environment relating to the success of the firm's marketing plans and the strategies employed in implementing those plans [14]. The findings of a survey of marketing research executive conducted by the American Marketing Association indicate that companies use marketing research in pricing activities, including cost analysis, profit analysis, price elasticity, demand analysis, and competitive pricing analysis [16]. The marketing research function within a firm has no single form of organization and it is dynamic and ever changing. Small firms are likely to have a one-person market research operation, while large firms are more likely to have either a research department with some personnel or both a corporate marketing research unit and smaller-scale divisional marketing units. It could be centralized or decentralized, depending on the organizational structure of the firm itself. Large firms are likely to spend a larger proportion of the marketing budget on research, approximately 3.5% of the average marketing budget, than are small firms (only 1.5% of the average marketing budget) [17].

### 3.2. Marketing Information Systems and Decision Support Systems

Marketing information systems (MISs) and decision support systems (DSSs) are not competitive mechanisms for marketing research projects in gathering marketing intelligence but, rather, complementary ones. MIS is a set of procedures and methods for the regular, planned collection, analysis, and presentation of information for use in making marketing decisions [18, 19, 20]. The key word in the definition is "regular", since the emphasis in MIS is the establishment of systems that produce information needed for decision making on a recurring basis rather than for one-time research studies such as most marketing research projects. In designing an MIS, the thrust is a detailed analysis of each decision maker who might use the system in order to secure an accurate, objective assessment of each manager's decision making responsibilities, capabilities, and style. It considers not only the types of information but also the form in which the decision-makers like to receive it. Then designers attempt to specify, get approval for, and subsequently generate a series of reports that go to the various decision-makers [21].

However, there are problems with MIS: many decision-makers are reluctant to disclose to others what factors they use and how they combine these factors when making a decision in a particular issue, different managers typically emphasize different things and have different data needs, the systems do not lend themselves to the solution of ill-structured problems [14]. As these problems with MIS became more apparent, the emphasis in supplying marketing intelligence on a more regular basis changed from the production of preformatted, batch reports to decision support system (DSS) mode. DSS is a coordinated collection of data, systems, tools, and techniques with supporting

software and hardware by which an organization gathers and interprets relevant information from business and the environment and turns it into a basis for marketing action [22]. According to Sprague and Carlson [23], a DSS concentrates on the design of data systems, model systems, and dialog systems that can be used interactively by managers. The data system in a DSS includes the processes used to capture and the methods used to store data coming from marketing, finance, and manufacturing, as well as information coming from any number of external or internal sources. One of the important trends in the development of DSS is the explosion in the last few years in databases. There are thousands of databases that can be accessed on line via computer. The model system includes all the routines that allow the user to manipulate the data to conduct the kind of analyses the individual desires. Whenever managers look at data, they have a preconceived idea of how something works and what is interesting and worthwhile in the data [24]. Furthermore, with the advent of neural network technology, marketing and sales professionals can now access the knowledge of experts with only a few taps on their computer keyboard.

### **3.3. Marketing Intelligence in Construction**

According to Diamant [25], it is important to know whom you are bidding against. Services giving the information are available by subscription, such as Dodge Reports and Brown Letters, in areas where the bid project is. For special cases, such as in overseas marketing strategy, Kelley and Kohne [26] stress the importance of local representatives for furnishing marketing intelligence and advice in local customs, and legal and tax implications. This is also true for companies who enter a new local market area.

According to Groob et al. [27], effective marketing in construction begins with marketing intelligence and strategic planning and moves through management, to sales follow-up. A plan based on thorough marketing intelligence allows the company to anticipate and take full advantage of new business opportunities [28]. Other researchers like Gladden and Ollitt [29] and Preece and Male [30] also stress the importance of effective marketing research and selling techniques to strengthen the useful application of the marketing plan.

There are several interesting findings concerning the marketing intelligence practices of top U.S. construction contractors in a survey conducted by Arditi and Davis [31]. This finding indicates that most contractors are already practicing a market-oriented approach, rather than a sales-oriented or production-oriented approach in their daily business practices. It seems that the belief that construction business enterprises are left behind in marketing practices, especially in market orientation and marketing intelligence, is not totally true.

Information technology is developing rapidly with major impact on the industry and the life styles of people. It can no longer be viewed as an enhancement to traditional business procedures, but rather as an innovative agent that enables new and different alternatives to organizing and operating business enterprises, including construction businesses [32]. Andi [33] claims that it is easy to find construction company websites that include information on the strengths of the company, such as a list of services offered, experience of field staff, financial stability, innovative methods used, and others. An Internet site dedicated to the construction industry, The Global Construction Network (GCN), is also available nowadays. It offers anyone connected to the Internet a place to start when seeking information and services involving construction.

Bidding decision, including the estimation of optimum markup, represent major decision problems for contractors formulating successful business strategies [34]. For example, in a study attempting to uncover the underlying factors that characterize the bidding decision making process, Ahmad and Minkarah [35] found that bidding decisions are greatly influenced by subjectively evaluated criteria, such as type of job, location, size of job, need for work, owner, subcontractors, degree of hazard, and degree of difficulty. The usual practice is to make bid decisions on the basis of intuition, derived from a mixture of gut feeling, experience, and guesses [36]. The problem, as such, lends itself more to analogy-based solutions, for which neural networks could provide a more suitable and practical solution [37]. Very few DSSs are based on this approach in construction. For example, Moselhi et al. [34] developed an analogy-based DSS for bidding in construction coded in user-friendly software, called DBID.

## **4. SURVEY FINDINGS**

As part of this research, a mail survey was conducted to 100 Asosiasi Kontraktor Indonesia (AKI) contractors in 2011 regarding intelligence functions in construction [12] with 30 data responses processed . Findings are presented in this section.

In one question, contractors are asked to describe the current marketing intelligence practices used by their company in the last one year for each intelligence action (see Table 1). The choices (with the scoring used) are never (1), sometimes (2), often (3), and always (4). Table 1 presents data that concerns respondent companies' marketing intelligence practices, both in terms of percent of respondents, and average scores of each type of action. Table 1 indicates that the three most popular types of intelligence actions are "talking to current and prospective clients", "talking to managers within the company", and "reading trade publications" with average scores of 3.55, 3.28, and 3.14 respectively. Information about clients, key competitors, and the environment allows managers to base price decisions more on the realities rather than on guess and intuition. One way to do this is by talking to current and prospective clients which is the most popular intelligence practice. It appears that the culture that puts clients as the highest priority is already in place in construction. By acquiring information about a client such as the services that the client highly appreciates, a contractor can deliver superior value, a key to success in marketing. The objective of communicating with clients should stress not only learning from clients, but also learning about them. It could be done in a formal meeting in the bidding process or after project completion for input in future projects. It could also be done in informal meetings in the negotiation process or after project completion for future projects.

As mentioned above, delivering of superior value alone is not sufficient in effective marketing; information about key competitors and knowledge about the market environment are part of the formula for success. There are many ways to acquire information about competitors and the market environment as discussed in previous sections. It appears that talking to managers within the company is very often practiced in construction so that it is the second most popular intelligence action. This finding is in line with Safford's [15] and Kotler's [8] belief discussed in previous sections that managers and other personnel within the company constitute one of the most valuable sources of information in terms of advancing competitive intelligence even though alerts must be in place to avoid invalid information. One possibility that makes this practice popular is that it is relatively easy and cost-free; this information can be retrieved in periodic formal meetings or in informal conversations such as in the morning before managers get busy with their routine daily tasks, or when they have lunch or dinner together.

Table 1. Marketing Intelligence Practices Characteristics

Types of Action	Respondents as Percentage	Average Scores
Reading newspapers/journals		3.08
never	3.3	
sometimes	20.9	
often	40.7	
always	35.2	
Reading trade publications		3.14
never	2.2	
sometimes	18.7	
often	41.8	
always	37.4	
Talking to current and prospective clients		3.55
never	0.0	
sometimes	6.6	
often	31.9	
always	61.5	
Talking to subcontractors/suppliers		2.97
never	2.2	
sometimes	26.4	
often	44.0	
always	27.5	
Talking to managers within the company		3.27
never	0.0	
sometimes	13.2	

often	46.2	
always	40.7	
Conducting marketing research project		2.08
never	27.5	
sometimes	42.9	
often	22.0	
always	6.6	
Establishing internal marketing information/decision support systems		2.87
never	6.6	
sometimes	27.5	
often	38.5	
always	27.5	
Purchasing information from research agency		1.68
never	49.5	
sometimes	37.4	
often	8.8	
always	4.4	
Monitoring and analyzing rumors		2.18
never	16.5	
sometimes	56.0	
often	20.9	
always	6.6	
Collecting and analyzing competitors' bids		2.14
never	22.0	
sometimes	48.4	
often	23.1	
always	6.6	
Training company's staff in marketing/sales issues		2.66
never	7.7	
sometimes	31.9	
often	47.3	
always	13.2	

Note: 1=never; 2=sometimes; 3=often; 4=always

Table 1. (Continued)

Parameters	Respondents as percentage	Average Scores
Searching market information through the Internet		2.27
never	14.3	
sometimes	50.5	
often	27.5	
always	6.6	
Searching and analyzing owners' and competitors' information during bid preparation		2.76
never	7.7	
sometimes	29.7	
often	41.8	
always	20.9	

Note: 1=never; 2=sometimes; 3=often; 4=always

The third most popular intelligence practice is reading trade publications. Trade publications such as *Dodge Reports* and *Brown Letters* are available by subscription. General information regarding past bids and future project bids is available in such publications. Even though more detailed investigation is needed, this information can be used as a preliminary guideline to the subsequent actions in marketing intelligence. Because they are relatively

cheap and easily obtainable, most contractors subscribe to trade publications to help them make marketing and pricing decisions.

Table 1 also indicates that the three least popular types of intelligence action are "purchasing information from research agency", "conducting marketing research project", and "collecting and analyzing competitors' bids" with average scores 1.68, 2.08, and 2.14 respectively. The least popular action is purchasing information from a research agency, an action that is categorized by Kotler [8] as one way to improve the quality and quantity of marketing intelligence. Even though research agencies could gather data for a much lower cost than if a company has done it on its own, it seems that there are problems in making use of outside marketing research organizations. One possible problem may be that there are not many research agencies offering such services in construction: it may therefore be difficult to find such an agency that can deliver a company's information needs. Another possible problem may be that the cost of purchasing such information is an important burden, considering that profit margins in construction are one of the lowest compared to other industries.

The second least popular intelligence action is conducting marketing research projects, generally undertaken for unique projects with specific objectives. The nature of the marketing research project process is a long and costly because it includes problem determination, planning, sampling design, data gathering, data analysis, and finally reporting. It seems that it is inappropriate in the construction industry's environment where the majority of the clients are one time buyers, where each construction project has unique needs, and where the time between determining project needs and bidding is very short. Consequently, conducting a marketing research project may be difficult and inefficient if implemented in construction. On the other hand, establishing internal marketing information/decision support systems (MIS/DSS) is quite popular (average score 2.87; ranked 6<sup>th</sup> out of 13 actions) particularly compared to marketing research project practices (average score 2.08; rank 12<sup>th</sup> out of 13 actions). The majority of contractors (66%) claims they often or always establish such MIS/DSS systems. As mentioned in previous sections, MIS/DSS provides continuous monitoring of new trends in market changes, while marketing research for individual projects is not able to generate that kind of information. Establishing MIS/DSS is also simpler than the complex and lengthy marketing research procedures. It appears that MIS/DSS fits construction industry characteristics better.

The third least popular action is collecting and analyzing competitors' bids. Even though many bidding strategy models require information about competitors' bids, it seems that only few contractors (29.7%) often or always seek this information. There might be three reasons that can explain this finding. The first reason might be that it requires many hours of work to collect and analyze competitors' bids, while contractors are already busy with their daily tasks. The second reason might be that most contractors do not know about the existence of these models, because they do not or rarely read scholarly journals. Even though the average score of "reading newspapers/journals" is relatively high (3.08; rank 4<sup>th</sup> out of 13), it is difficult to differentiate between those who read newspapers and trade magazines and those who read scholarly journals. More investigation is needed to clarify this issue. The third reason why contractors do not often collect and analyze competitors' bids might be that the bidding models are too complex and unreliable.

It is interesting to note that despite the rapid development of Internet and associated information technologies as discussed in previous sections, the majority of contractors (64.8%) claim they never or only sometimes search for market information through this technology, resulting in an average score of 2.27 (rank 9<sup>th</sup> out of 13 actions investigated). More workshops seem to be highly needed on how contractors can use effectively thousands of free databases and web-sites related to information that can be used for marketing purposes, particularly pricing.

## 5. CONCLUSION

Marketing intelligence systems are highly developed in the manufacturing industry as the result of the new concepts of marketing that stress the importance of the market orientation of a firm's activities. Marketing intelligence systems include marketing research, marketing information systems, and decision support systems. With the rapid development of computer technology and the frequent occurring problems with marketing information systems

implementation, decision support systems have become the most popular marketing intelligence system in manufacturing industries.

In construction, there is only one pricing strategy predominantly used: cost-based pricing, because of the belief that it is the most appropriate approach in bidding system in construction transactions. Consequently, a marketing intelligence system is a subject that is seldom discussed by researchers. The importance of marketing intelligence becomes clear as proposed alternate pricing strategies that use a market-based approach become available because market based pricing strategies highly depend on marketing intelligence functions.

In a survey of top Indonesian AKI contractors, it was found that marketing intelligence practices currently used by contractors include mostly traditional activities such as "talking to current and prospective clients", "talking to managers within the company", and "reading trade publications". More involved intelligence gathering methods such as "conducting marketing research project", "developing MISs/DSSs", and "using the Internet" are not used extensively. The possibilities of conducting marketing research projects in the construction environment must be explored. On the other hand, the development of databases in a company that contain information about owners and competitors is one important starting step; given the anticipated rapid breakthrough developments in computer and information technologies in the future, the Internet and MISs/DSSs will become two most important intelligence tools in making pricing decisions.

## ABSTRACT

*As the adoption of project financing is gaining momentum, there is a concurrent need of innovation in project financing scheme in order to accelerate infrastructure assets provision in Indonesia. As the largest Muslim population in the world, sharia-compliant financing offers tremendous potential as a source for infrastructure financing for Indonesia. To realize this potential, there is a need of a framework to guide its adoption. Hence this paper discusses the potential implementation of Islamic finance to fund infrastructure projects in Indonesia. Through comparative analysis, this paper illustrates how Islamic principles can be incorporated into Indonesian infrastructure project financing.*

### Keywords

*Sharia-compliant financing, infrastructure financing, project financing*

## 1. INTRODUCTION

Infrastructure plays an important role in supporting a nation's economic growth and competitiveness. Accelerating infrastructure provision is one of the main priorities in Indonesia's national development. In order to fulfill infrastructure needs, a huge amount of funding would be required and the government cannot rely solely on the national budget. Therefore, funding sources from private sectors should be created in a mode of infrastructure investment and project financing scheme.

Infrastructure investment has flowed steadily into Indonesia infrastructure development. Before the financial crisis in 1990s, in fact Indonesia was one of East Asia's private infrastructure success stories with majority of investments were concentrated respectively in energy, telecommunication, transport, water and sanitation sectors. However, the crisis has resulted in a huge plunged in the investment flow. Hence, investment in infrastructure should be expanded once more.

In 2005, the government of Indonesia (GOI) embarked on a comprehensive program of infrastructure reforms, and issued the first Infrastructure Policy Package. In the same year, the GOI also established the Policy Committee for Accelerating the Provision of Infrastructure (KKPPI). The GOI also started to organize annual events associated with infrastructure investment or infrastructure summit to attract more infrastructure investors. Several laws and regulations on the subject of private sectors participation in infrastructure provision had been enacted after a thorough reform.

In Indonesia, the concept of project financing for the provision of public infrastructure is still developing. As the adoption of project financing is gaining momentum, there is a concurrent need of innovation in project financing scheme in order to accelerate infrastructure assets provision. One area of recent innovation is Islamic financing. In particular, the scheme of *sharia*-compliant project financing (or Islamic project financing) is expected to be one of the best alternatives in Indonesia infrastructure financing.

This paper proposes a model that can be used as a framework for implementing Islamic project financing in the provision of infrastructures in Indonesia. The paper begins with the discussion on infrastructure financing need and project financing in infrastructure development. It then examines the principles of *sharia*-compliant financing and how they can be incorporated into project financing. Finally, the paper proposes a project financing model, which is in compliant with Islamic principles that can be used to finance infrastructure projects.

## 2. INFRASTRUCTURE FINANCING DEMAND

Infrastructure investment is a complex and multifaceted aspect of the national economies. Benefits of infrastructure can be maximized by formulating the respond of private sector in infrastructure policies. Such policies should not result in wasteful

duplication of infrastructure facilities. They should enhance complementarities and synergisms between public and private infrastructure providers. Infrastructure project financing involves combination of project promoters (sponsors and investors), lenders, government, contractors, suppliers and customers [1]. The funding includes loans, bond issuances, and equipment leasing. Infrastructure funding can be divided as a shared services, public private partnership (PPP), and outsourcing in accordance with the main responsibility which are taken such as public sector, public and private sector, and private sector respectively [2].

The use of private participation in infrastructure (PPI) projects can potentially improve efficiency in infrastructure projects transactions [3]. Within PPI, management in infrastructure project is also more effective [1]. PPI project also associates with societal benefits achievements as it may improve infrastructure efficiency [4]. Project financing, as a scheme of PPI implementation, then becomes important in infrastructure investment not only because of the financial scheme, but also to address institutional problems [1].

Project financing is a structured financing that needs a Special Purpose Vehicle (SPV) in the form of a company to run the project and sponsors to contribute equity and debt. An SPV can consist of sponsors, equity investors, off-take purchasers, bondholders, lenders, government, constructors, suppliers and operator. All the stakeholders are managed through contracts and arrangements. Mostly, major portion of project financing is the long-term debt financing. The projected cash flow is the primary source to reimburse the loan when the asset acts as only the collateral [5]. Therefore the payback depends on detailed evaluation of cash flow. It also needs contractual and arrangement among sponsors. Project financing is usually implemented in a green field project which tends to be a non-recourse or limited recourse.

The success of project financing implementation in infrastructure provision can be influenced by several factors, which include investment policy clarity; credibility and financial viability of the infrastructure agency; transparency and competitive bidding; and restructuring and improvement in fiscal environment. Good credit enhancement mechanism, sustainable capital markets, efficient and effective bureaucratic process, and legally enforceable and fair contracts are also the factors that could affect infrastructure project financing [6].

In order to attract more investment in Indonesia infrastructure development, there are some challenges that need to be addressed. Good governance and regulatory framework are considered the major challenges [7, 8]. Poor governance and inadequate legal system and institutional framework undermine service provision, which could keep investors away. Lack of clear policy indicates that the program is not integrated with the infrastructure needs. Strengthening the regulatory framework could remove obstacles in private sector involvement in infrastructure sector.

### 3. SHARIAH-COMPLIANT PROJECT FINANCING

Infrastructure investment is suitable to be financed with Islamic financing scheme, because infrastructure is an asset and it does not contain any activities that are prohibited in Islamic law. The use of Islamic finance in infrastructure project has been noted in some Islamic countries especially in energy and housing projects [9, 10, 11, 12, 13, 14]. Some types of Islamic financial instrument that might be suitable in infrastructure investment are:

- *Mudarabah*: cooperation between two parties which the first party gave 100% equity to the second party as the executor and profit will be shared based on agreement. In *mudarabah*, the second party is not liable for loss unless the loss occur due to mismanagement or negligence of second party. Therefore *mudarabah* is also called as trusty financing.
- *Musyarakah*: also known as partnership or joint venture, is the cooperation among two or more parties that each party shares equity with covenant that profit and losses will be shared together.
- *Ijara*: also known as leasing, is a hiring or renting of an asset to gain benefit of its usufruct.
- *Istisna*: is an order to a manufacturer to produce a specific asset for the purchaser (manufacture-sale). The payment term can be arranged in advanced or in credit.
- *Sukuk*: the Islamic investment certificate/bond.
- *Murabaha*: also known as mark-up sale, this type of finance is based on transaction cost and there is fee to compensate the service. The fee itself has been determined and agreed by both parties and written in the contract (*aqd*). In *murabaha*, the asset should be real although it is not necessarily tangible. Therefore the seller must state the original price and the additional expenses in truth. In conventional infrastructure procurement, this scheme is identical to cost plus fee contract. *Murabaha* has been implemented in real estate investment.
- *Kafalah*: is a guarantee given by insurer to a third party in order to fulfill obligation of second party or borne.

Although Indonesia is not an Islamic state, the total Muslim population in this country is the largest in the world. It is, therefore, conceivable that Indonesia can also implement Islamic principles for financing its infrastructure provision. To facilitate this, there is a need for a framework to guide its adoption.

Islamic finance has become prevalent in financial matter. *Sukuk*, for example, is one of the most innovative amongst Islamic investment. It attracts Islamic banks, Islamic insurance companies and *shariah* managed funds that cannot invest in conventional securities [15]. *Sukuk* is a tradable asset-backed, therefore it must be supported by real asset such as land, building or equipment. It is also issued for a fixed period of time which varies from short-term (three months) to medium-term (five or ten years) [15, 16]. Although most of *sukuk* structures are based on *murabaha* or *ijarah*, there are several forms that have been implemented such as *salam sukuk* structure and *musyarakah sukuk* structure.

Islamic finance has several advantages compared to the conventional finance. Islamic finance is observed as financial intermediation competitiveness [17], therefore it is now considered as one of the fastest growing financial segments in the world. The business area of Islamic finance has been broadening in many aspects such as private equity, project finance, *sukuk*, or other wealth management movement. The regulatory and legal frameworks recently have been evolved. Islamic finance nowadays has been internationally recognized and will contribute to global financial integration. Since Islamic intermediation is an asset-based and risk-centered sharing, it is more closely related to real economic sector [18].

#### 4. THE IMPLEMENTATION OF SHARIA-COMPLIANT PROJECT FINANCING IN INFRASTRUCTURE

Several papers started discussing Islamic project financing in infrastructure in the late 1990s. The financial model and contract agreement of Western project financing was modified by integrating Islamic financing in power plant project. Therefore it allows Islamic and Western financiers to finance the project without compromising any religious principles or financial interest [19]. Then it continued with *istisna* scheme to finance light railway and power plant projects developed using the build own operate (BOO) and build own operate transfer (BOOT) arrangement [20]. In 1999, an integrated model of Islamic and Western project financing was proposed by synthesizing *mudarah* security. It combined *murabahah* facility and call option to derive profit sharing ratio endogenously [21].

An innovative way to gain capital in infrastructure projects is by combining Islamic and Western finance (co-financing), which lead to a creation of a new structure of financing, or finding other ways to mitigate risks [22]. The Equate Petrochemical project is an example of project successfully delivered using this financing model. The project used *ijara*, *istisna* and *murabaha* structures [23]. Since then, there had been several more co-financed deals in infrastructure projects, such as the Kuala Lumpur Light Rail Transit 2 project, Thuraya Space Telecommunications project, Shuaiba power plant project, the TAG and Mersin Motorways project, and the Kuala Lumpur International Airport. However, the number of projects which used co-financed structures is not plenteous. There are factors that need to be considered such as improving understanding in Islamic finance and Islamic project financing.

There are potential sources of problem when projects with Islamic scheme attempt to suit Western financing. The first source of problem is the lack of cohesive regulatory body, in this context is the *shariah* boards [13]. There is uncertainty regarding *shariah* boards' decision which somehow unpredictable and subjective. The *Shariah* board needs to ensure that every transaction acknowledges the cultural, moral, ethical and religious principles. The board will examine the investment structure and documentation to approve an Islamic investment. The *Shariah* board will make a decision whether the project can be implemented based on *fiqh*, *shariah* principles as well as the decision on the duration of financing [9]. Although the board will consider similar transactions, there is no guarantee the decision will be the same because a fatwa is only valid for one specific case. Those situations make *shariah* board holds a significant decision in project endorsement. Typically, Islamic financing is utilized in a short term or medium term finance. Therefore the *shariah* board should also understand and analyze infrastructure project condition in term of financial duration. The second source of problem is that Islamic finance scheme requires lender to share project risks in contrast with Western finance scheme which lender reluctant to share the risks [13]. This circumstance may cause risk enhancement from Western lenders perspective. The third source of problem is institutional problem which can increase financial cost [22]. However, it can be diminished by establishing an *adl* (trustee), a uniform Islamic finance body and accounting practices.

Government guarantees are less needed when the profit sharing is high and sponsor's own capital is big. However, government financial guarantees are still necessitated in order to increase the creditworthiness and to raise the debt capacity of the project [24]. Government can provide financial guarantee by first analyzing project risks and then determining the type of government support given.

Based on the above discussion, Figure 1 describes a concept model of Islamic project financing in Indonesian infrastructure. The model is developed based on two categories which are infrastructure project financing scheme and Islamic financing concept. The model is influenced by *shariah* board decision, the contracts, investment method, risks and financial guarantee. Co-financing and off-takers will both reciprocally influence the implementation of Islamic project financing in infrastructure.

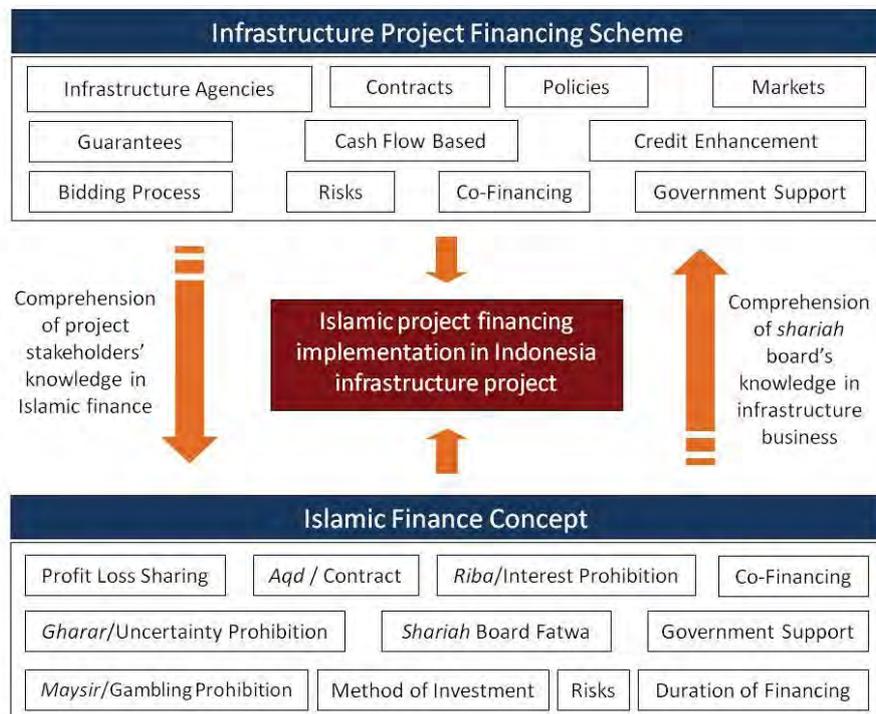

Figure 1: The concept model to implement Islamic project financing in infrastructure

## 5. SUMMARY

Within the scheme of Islamic finance and infrastructure characteristics, infrastructure investment is suitable to be financed with Islamic financing scheme because infrastructure is an asset and it does not contain any activities that are prohibited in the *shariah law*. However, as shown in Figure 1, there are factors that can influence Islamic project financing implementation. The factors are related to infrastructure project financing scheme and Islamic finance concept. Both knowledge on infrastructure business and Islamic finance should be well-known by all stakeholders. Without knowing both concepts comprehensively, the implementation of Islamic project financing in Indonesian infrastructure can be hindered, for example, by project stakeholders' acceptance of Islamic finance or the *shariah* board's decision on Islamic financing transaction. Additionally, every factor in each category should not stand alone, rather should somehow correlate and influence each other.

## ABSTRACT

*Product quality control is an important factor in industrial field. Continuous quality control enables company to detect abnormality in haste and anticipate them. PT Semen Padang always control their product quality in order to keep their product meet consumer's need. The fluctuation of cement compressive strength for the last few periods urge the company to evaluate, improve and sustainable quality standard. Research was done to indentify mandatory factors influencing cement compressive strength. Data processing was done using SPSS and Minitab 15. This reseach give recomendation to PT Semen Padang, it should control composition of C<sub>3</sub>S, H Pijar dan SO<sub>3</sub> in order to keep cement compressive strength standard. Besides, workshop about Statistical Process Control by using Minitab and SPSS is needed to be presented by the company for quality control process in future.*

**Keyword:** quality, cement compressive strength, linear regressions

## 1. INTRODUCTION

Product quality control in the production process is a very important factor for industry, because of good quality control and done continuously will able to detect abnormalities quickly that can be taken anticipation. Low qualities products can cause company lose customers. PT Semen Padang always try to maintain the quality of the product in order to meet market demand. Cement quality required by the customer is bonding time, compressive strength, heat hydrasi, expansion / contraction of cement, and resistance of cement to environmental influences such as acid / sulfuric (durability). Compressive strength is an indicator of quality most preferred by PT Semen Padang in line with consumer demand.

Primarily related to quality of cement compressive strength there is a need of PT Semen Padang to determine mandatory factors affecting it. Knowing the most significant factors PT Semen Padang can optimize both in terms of methods, materials, and also reduce costs optimally.

This research is carried out to identify factors that influence the compressive strength of cement by evaluating it at some recent time period. This research also compare between actual evaluation and standards specified compressive strength (SNI and internal standard) in order to determine deviations (gap analysis); determining the mandatory factors affecting the compressive strength of cement includes: a) identification of variables that affect the compressive strength, b ) statistical data processing and c) conduct an analysis of the mandatory factors affecting the compressive strength of cement; obtaining follow-up recommendations for improvement in the form of a work program based on the evaluation results.

Scope of this research are; 1) statistical analysis to look at the factors that affect mandatory focused on the compressive strength of cement contained cement mill cement mill Indarung V ie X (CM X) XI and cement mill (CM XI), 2) cement product observed are the product of cement type I and PCC; 3) data compression strength for 2 years (2010-2011).

## 2. RESEARCH METODOLOGY

This research is explanatory quantitatively using linear regression. Measuring the influence of independent variables on the dependent variable, and predict the dependent variable using the independent variables. Gujarati (2006) defines a regression analysis as the study of the relationship of explained variable with one or two variables that explain (the explanatory). The first variable is also known as the dependent variable and the second variable is also called independent variable. If more than one independent variable, the regression analysis is called multiple linear regression. Because influence several variables will apply to dependent variable.

This research used free CaO; C3S; insoluble part (BTL); SO<sub>3</sub>; Missing incandescent; sieve on 45, and blaine as independent variables and Cement Compressive Strength as the dependent variable.

Steps being taken in this research are :

1. Understanding current practice

At this stage of understanding of the cement production process in detail, and the things that affect the quality of the cement itself.

2. Formulation of the problem

The problem formulation in this research is how to determine the most significant factors affecting the compressive strength of cement and PT Semen Padang to optimize both in terms of methods, materials, cement makers to reduce the cost of optimally

3. Research Objectives

The objectives of this research were:

- a. Identifying the factors that influence the compressive strength of cement
- b. Determining the dominant factor affecting the compressive strength of cement
- c. Get recommendations for improvement follow

4. Literature Review

Literature review conducted to find the most appropriate method is used to solve the problem

5. Dependent and independent variables

Variables in this study were divided into dependent and independent variables.

- a. Independent variables are : free CaO; C3S; insoluble part (BTL); SO<sub>3</sub>; Missing incandescent; sieve on 45, and blaine.
- b. Dependent variables are : Compressive Strength Cement

6. Verification of data

Data verification is done by studying, organizing and sorting data associated with semen quality, especially compressive strength.

7. Data processing

Data processing begins by testing the assumptions of the multiple linear regression model. At least there are five tests that must be conducted on the assumption of a regression model that normality test, auto-correlation, multikolinieritas test, heteroscedasticity test and linearity test. The next stage is to determine the equation of the linear regression between the independent variables and the dependent variable. Of free and bound variable relation calculated the P-value and VIF to determine the significance of the independent variables to the dependent variable.

8. Analysis and discussion

At this stage, the analysis and interpretation of the results obtained processing.

9. Conclusion

This stage consists of the conclusion of the materials that need follow-up recommendations by PT. Semen Padang for improvement.

For clarity, the stages of this research can be seen in the figure below:

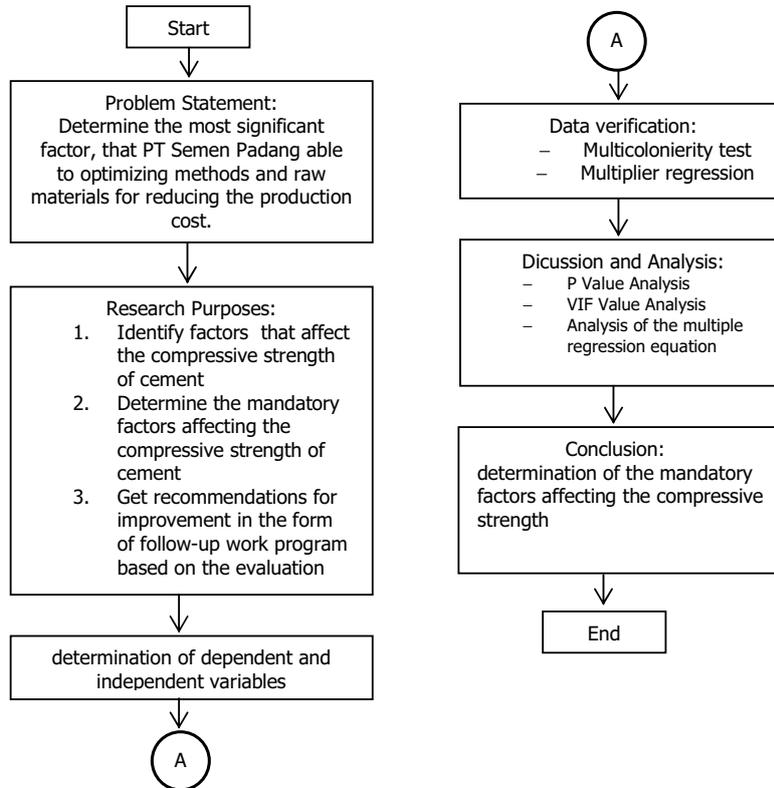

Figure 1: Research Methodology

### 3. DISCUSSION

#### 3.1. Multiple Regression Analysis of Test Requirement

Test requirements analysis is needed to determine whether the analysis of the data for testing hypotheses can be continued or not. Several data analysis techniques demanding test requirement analysis. Analysis of variance requires that data came from a normally distributed population and the groups were compared homogen. Because of that variance analysis requires test normality and data homogeneity. Regression analysis, in addition to requiring normality test also require linearity test, heterokedasitas test, autocorrelation test, and test multicollinearity test

Normality test data to show that the sample data came from a normally distributed population. There are several techniques that can be used to test normality of data, among others: with SPSS, which see the ratio of skewness and kurtosis.

Table 1. Descriptive Statistic

	Descriptive Statistics			
	Skewness		Kurtosis	
	Statistic	Std. Error	Statistic	Std. Error
Unstandardized Residual	-,020	,140	,239	,280
Valid N (listwise)				

From the above results of SPSS can be seen that the ratio of skewness and kurtosis is between -2 to +2, it can be said that data were normally distribution.

### 3.2. Linearity test

Linearity test is useful to see the linearity between dependent variable (compressive strength) with independent variable (C3S, BTL, free CaO, H Incandescent, Sieve on 45, Blaine, SO3).

Table 2. ANOVA Table

ANOVA Table			Sum of Squares	df	Mean Square	F	Sig.
KT3H * SO3	Between Groups	(Combined)	26257,187	77	341,002	1,379	,037
		Linearity	3754,246	1	3754,246	15,185	,000
		Deviation from Linearity	22502,941	76	296,091	1,198	,158
	Within Groups		55379,899	224	247,232		
	Total		81637,086	301			

The result showed that the value of F is 1.198 with a significance 0.158 (above 0.05). It means linear model regression.

### 3.3. Heteroscedacity Test

Heteroscedacity occur when the variance regression error ( $\sigma^2$ ) for some value of  $x$  change. Detection constant or not constant error variance to do with drawing the graph between the residues  $Uy$  ( $y - Uy$ ). If the line that limits the distribution of points relative error variance is constant.

If the graph looks the points spread above and below the Y axis, there is no particular pattern. It can be concluded that there is no heterokedasitas.

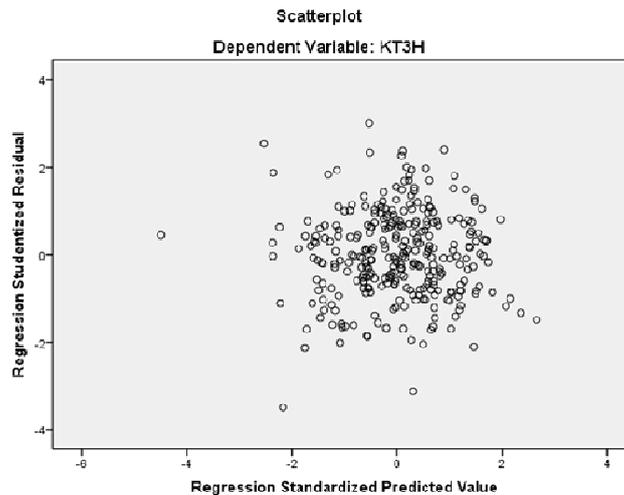

Figure 2. Scatterplot

### 3.4. Autocorrelation test

Autocorrelation is occurred when two errors in the regression  $\epsilon_t$  and  $\epsilon_{t-1}$  are not independent or  $Cov(\epsilon_t, \epsilon_{t-1}) \neq 0$ . Autocorrelation usually happened when the variable measurement is done in a specific time interval.

Table 3. Model Summary

Model Summary					
Model	R	R Square	Adjusted R Square	Std. Error of the Estimate	Durbin-Watson
1	,590 <sup>a</sup>	,348	,333	13,45346	1,375

a. Predictors: (Constant), Blaine, Sieve\_On45, C3S, H\_Pijjar, CaO\_Bebas, SO3, BTL

b. Dependent Variable: KT3H

Apparently Durbin-Watson coefficient magnitude of 1.375, nearly 2. Thus, it can be concluded that the regression between variables C3S, BTL, free CaO, H Incandescent, Sieve on 45, Blaine, SO3 not happen autocorrelation.

### 3.5. Multicollinearity test

Multicollinearity test is used to determine significant relations (correlation) between the independent variables. If there is a high correlation (significant), means that there is same aspect measured at independent variable. It is not feasible to determine the contribution of independent variable and dependent variable.

Table 4. Collinearity statistic

Model	Collinearity Statistics	
	Tolerance	VIF
1 (Constant)		
CaO_Bebas	,935	1,070
C3S	,966	1,035
BTL	,466	2,147
SO3	,719	1,390
H_Pijjar	,474	2,111
Sieve_On45	,989	1,012
Blaine	,826	1,211

a. Dependent Variable: KT3H

Multicollinearity test is done with SPSS regression test, with value of VIF (variance inflation factor) as standard and correlation coefficients between the independent variable. The criteria used are: 1) If the value of VIF around the 1 or have a tolerance close to 1, it is said there is no multicollinearity problem in the regression model, 2) If the correlation coefficient between the independent variable is less than 0.5, there is no multicollinearity problem.

Apparently VIF value close to 1 for all independent variables. Similarly, the tolerance value close to 1 for all independent variables. It can be concluded that the regression between the independent variables C3S, BTL, free CaO, H Incandescent, Sieve on 45, Blaine, SO3 not happen multicollinearity between independent variables.

### 3.6. Multiple Linear Regression

Linear regression is used to determine significant factor or mandatory factor affecting compressive strength of cement. Data processing is performed by using the software Minitab 15. P-value is the standard value (significance) so that the smallest value of the observed test statistic is still significant. P-value always compared to the value of  $\alpha$ .  $\alpha$  is 0.05 with 95% confidence level. This means that 95% of study have been considered correct, started from collecting data, and the processing and obtaining result. Comparisons with  $\alpha$  P-value:

- If  $p\text{-value} < \alpha$ , reject  $H_0$
- If  $p\text{-value} \geq \alpha$ , do not reject  $H_0$

Example: Cement Mill X PCC CS 3 DAYS, based on the results of processing software Minitab 15, it can be inferred from the P-value and VIF sorting factors that influence the compressive strength is: BTL, H Incandescent, C3S, Sieve on 45, SO3 and Blaine.

Regression equations were obtained:

$$\text{CS 3 DAYS} = 219 + 0,56 \text{ CaO Bebas} + 0,567 \text{ C3S} - 3,46 \text{ BTL} - 11,0 \text{ SO3} - 10,3 \text{ H Pijjar} - 1,61 \text{ Sieve on 45} + 0,0150 \text{ Blaine}$$

It can be concluded that the addition of C3S significantly increase the pressure, while the addition of BTL, H Incandescent significantly decrease the pressure.

#### 4. CONCLUSION

From the research it can be concluded as shown in the following table:

Cement Types	increasing compressive strength	decreasing compressive strength
CEMENT MILL X PCC CS 3 DAYS	C3S	H Pijar
CEMENT MILL X PCC CS 7 DAYS	C3S	H Pijar
CEMENT MILL X PCC CS 28 DAYS	C3S	H Pijar
CEMENT MILL XI PCC CS 3 DAYS	C3S	H Pijar
CEMENT MILL XI PCC CS 7 DAYS	C3S	H Pijar
CEMENT MILL XI PCC CS 28 DAYS	C3S	H Pijar
CEMENT MILL X TYPE I CS 3 DAYS	C3S	SO3
CEMENT MILL X TYPE I CS 7 DAYS	C3S	SO3
CEMENT MILL X TYPE I CS 28 DAYS	C3S	SO3
CEMENT MILL XI TYPE I CS 3 DAYS	C3S	SO3
CEMENT MILL XI TYPE I CS 7 DAYS	C3S	SO3
CEMENT MILL XI TYPE I CS 28 DAYS	C3S	SO3

From the table above shows that the quality of clinker C3S primarily on factors greatly influence increasing compressive strength for both types of cement. While the addition of H pijar and SO3 factor on Cement Mill effect decreasing compressive strength (CS) of PCC and Type 1 sequentially. For more details, the factors that affect the compressive strength can be seen based formulation of regression:

1. Cement Mill X PCC CS 3 days  
 Equation of multiple regression :  
 $CS\ 3\ DAYS = 219 + 0,56\ CaO\ Bebas + 0,567\ C3S - 3,46\ BTL - 11,0\ SO3 - 10,3\ H\ Pijar - 1,61\ Sieve\ on\ 45 + 0,0150\ Blaine$
2. Cement Mill X PCC CS 7 days  
 Equation of multiple regression :  
 $CS\ 7\ DAYS = 300 + 0,29\ CaO\ Bebas + 0,583\ C3S - 3,73\ BTL - 17,6\ SO3 - 14,9\ H\ Pijar - 1,96\ Sieve\ on\ 45 + 0,0218\ Blaine$
3. Cement Mill X PCC CS 28 days  
 Equation of multiple regression :  
 $CS\ 28\ DAYS = 436 - 1,79\ CaO\ Bebas + 0,439\ C3S - 3,73\ BTL - 25,9\ SO3 - 23,2\ H\ Pijar - 2,48\ Sieve\ on\ 45 + 0,0280\ Blaine$
4. Cement Mill X Type I CS 3 days  
 Equation of multiple regression :  
 $CS\ 3\ DAYS = 89,8 + 4,01\ CaO\ Bebas + 1,29\ C3S - 5,32\ BTL - 35,5\ SO3 - 3,46\ H\ Pijar - 0,125\ Sieve\ on\ 45 + 0,0365\ Blaine$
5. Cement Mill X Type I CS 7 days  
 Equation of multiple regression :  
 $CS\ 7\ DAYS = 300 + 0,29\ CaO\ Bebas + 0,583\ C3S - 3,73\ BTL - 17,6\ SO3 - 14,9\ H\ Pijar - 1,96\ Sieve\ on\ 45 + 0,0218\ Blaine$
6. Cement Mill X Type I CS 28 days  
 Equation of multiple regression :  
 $CS\ 28\ DAYS = 298 + 0,59\ CaO\ Bebas + 1,03\ C3S - 6,33\ BTL - 61,1\ SO3 - 9,63\ H\ Pijar - 0,914\ Sieve\ on\ 45 + 0,0501\ Blaine$
7. Cement Mill XI PCC CS 3 days  
 Equation of multiple regression :  
 $CS\ 3\ DAYS = 233 + 2,10\ CaO\ Bebas + 0,570\ C3S - 1,38\ BTL - 7,29\ SO3 - 7,63\ H\ Pijar - 1,85\ Sieve\ on\ 45 + 0,00250\ Blaine$
8. Cement Mill XI PCC CS 7 days  
 Equation of multiple regression :

- CS 7 DAYS = 320 + 1,36 CaO Bebas + 0,670 C3S - 0,841 BTL - 27,3 SO3 - 8,88 H Pijar - 2,32 Sieve on 45 + 0,00885 Blaine
9. Cement Mill XI PCC CS 28 days  
 Equation of multiple regression :  
 CS 28 DAYS = 470 + 0,55 CaO Bebas + 0,790 C3S - 0,16 BTL - 31,1 SO3 - 16,3 H Pijar - 3,46 Sieve on 45 + 0,0051 Blaine
10. Cement Mill XI Type I CS 3 days  
 Equation of multiple regression :  
 CS 3 DAYS = 56,4 - 0,12 CaO Bebas + 0,960 C3S - 5,06 BTL - 21,5 SO3 - 0,64 H Pijar - 1,62 Sieve on 45 + 0,0496 Blaine
11. Cement Mill XI Type I CS 7 days  
 Equation of multiple regression :  
 CS 7 DAYS = 320 + 1,36 CaO Bebas + 0,670 C3S - 0,841 BTL - 27,3 SO3 - 8,88 H Pijar - 2,32 Sieve on 45 + 0,00885 Blaine
12. Cement Mill XI Type I CS 28 days  
 Equation of multiple regression :  
 CS 28 DAYS = 260 - 5,26 CaO Bebas + 0,667 C3S - 8,59 BTL - 51,0 SO3 - 2,78 H Pijar - 2,49 Sieve on 45 + 0,0665 Blaine

## ACKNOWLEDGEMENT

The author would like to thank to Quality Assurance Department, Padang Cement Company for the reseach grant.

## ABSTRACT

Hollow round pile besides used as deep foundation of building, is also often used as a foundation of maritime building (wharf, dolphine, etc.). Pile foundation in maritime buildings have a special chaeacteristic are the free length. Fixity of pile is at certain depth below the sea-bed depend on soil parameter. Depth of sea water level to sea-bed is varies 10 - 15 metres.

When wharf or dolphine subject to eccentric lateral/hirizontal forces, the structure will be torsion/twisted. The same condition is occured for pile. The knowledge of torsional moment capacity is very important things, because will ensure strength and stability of structure. The phenomenon of torque on the hollow round section, especially on concrete, not been widely discussed and applied. The calculation method of torsional moment capacity is usually ACI 318's formulas. These formulas are developed based on theory of twisted rectangular beam.

This research is be done to know structural behavior of hollow round pile torsioned and effect of direction and spiral stirrup spacing. Samples are hollow round piles with spiral spacing varies and get torsional forces. Torsional forces were be got as the result of forces with certain distance to be the arm of moment. The rotation was got from measurement of the resultant of force arm. Relation between torsional force and rotation will be analysed to know the torsional moment capacity of sample. Spiral stirrup is studied its effect to torque moment capacity.

The result of this research will be compared to formula from concrete code.

## Keywords

*hollow round pile, torque/torsional moment, torque moment capacity, rotation, spiral stirrup*

## 1. INTRODUCTION

Hollow round piles can be twisted, mainly occurs in piles that is not entirely embedded in the ground, as the foundation of the building dock (*wharf, dolphine*). Torque moment will cause cracks on the surface of piles. Failure to crack it in daily practice is minimized by the shear strength of concrete and spiral reinforcement.

The study was done to know the behavior of hollow round piles piles having twisting and influence the direction and distance of the spiral reinforcement. The objective to reach is to understand the behavior of a hollow round piles having torsional, study the effect of spiral reinforcement dimensions and distance, and know the torque capacity with a variety of spiral reinforcement. Torque force was generated from a horizontal force that works with a certain eccentricity distance form the moment arm. Forces and rotation that occurs analyzed by creating a relationship of some parameters.

## 2. TORQUE MEMBERS HAVING A ROUND HOLLOW CROSS SECTION

### 2.1. Forces and Stiffness of Torque

Analysis of torque on a solid circular cross-section can be applied directly to a hollow circular cross section having outer radius ( $R_o$ ) and inner radius ( $R_i$ ). The equation below can be used for analysis of torque. The equation is :

$$T = \frac{\pi}{2} (R_o^4 - R_i^4) G \frac{\theta}{L} \quad (1)$$

While the polar moment of area,  $J$ , is:

$$J = \frac{\pi}{2} (R_o^4 - R_i^4) \quad (2)$$

### 2.2. Member Deformation due Twist

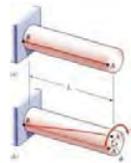

Figure 1. Deformation twisted member

Torsional angle that occurs on the member proportional to the work torque moment and the length of the member. Means more length of the twisted member round, the smaller torque moment occurs. Deformation that occurs in a twisted rod does not always change the shape (distortion). For round rod (solid or hollow) which are torsional, each slice section will remain flat and without distortion (This is because the circular cross section is Axisymmetry).

Figure 2. Illustrations of a torque rod round

For non-circular cross section (*tidak-axisymmetric*), rods will be distorted when subject to torsion.

Figure 3. Illustration of distorted rod

**2.4. Shear Stress Distribution based on Elastic Approach**

a. Round Section

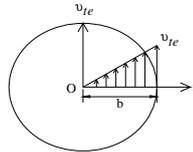

Figure 4. Torsional elastic distribution for round section

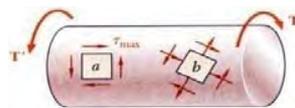

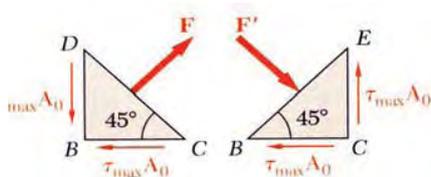

Figure 5. The difference in the element of pure shear conditions (a) and torsional shear (b)

Review of stress that occurs on the element(b) according to Figure 5 is as follows :

$$F = 2(\tau_{max} A_0) \cos 45 = \tau_{max} A_0 \sqrt{2}$$

$$\sigma_{45} = \frac{F}{A} = \frac{\tau_{max} A_0 \sqrt{2}}{A_0 \sqrt{2}} = \tau_{max}$$

Element (b) having the tensile stress at 2 sides and the compressive stress at 2 another sides. mempunyai besaran tegangan yang sama dengan elemen (a)

**2.5. Torsional Cracks**

As well as bending, twisting rod also fractured. To calculate the torsional cracks using the following formula :

Reinforcement concrete :  $T_{cr} = v_{cr} \frac{A_{cp}^2}{P_{cp}}$  (3)

$v_{cr} = f_{cr}$  (4)

Prestressed concrete :  $v_{cr} = f_{cr} \sqrt{1 + \frac{f_{pc}}{f_{cr}}}$  (5)

$f_{cr} = 0.33 \sqrt{f'_c}$  (6)

**2.6. Analysis of Torsional Moment Capacity**

Torsional moment capacity can be calculated by equation as follows :

$$\frac{A_t}{s} = \frac{T_n}{2A_{ch} f_{yv} \cot \theta} \quad (7)$$

$$A_t = \frac{A_t}{s} p h \left( \frac{f_{yv}}{f_{yt}} \right) \cot \theta^2 \quad (8)$$

$$\text{Total } \left( \frac{A_v + t}{s} \right) = \frac{A_v}{s} + 2 \frac{A_t}{s} \quad (9)$$

In this equation  $\phi T_n \geq T_u$ , so that

$T_n \geq \frac{T_u}{\phi}$  where :  $\theta =$  crack angle to the axis of the beam

$$= 45^\circ \text{ for reinforced concrete}$$

$$= 37.5^\circ \text{ for prestressed concrete}$$

$$\Phi = 0,75 \text{ (torsional reduction factor)}$$

where  $t$  is the walls thickness of hollow cross section at the location where tension is being examined.

### 3. SAMPLING METHOD AND METHODOLOGY OF RESEARCH

#### 3.1 Sampling Method

Piles specimen are modeled as a a twisted rods. Moment of torque resulting from the horizontal force acting on a certain distance to form moment arm. Piles specimen consists of 8 pieces of each 300mm diameter length  $L = 3$  m with technical details as follows:

1. Specimen number 1 with dual spiral reinforcement spaced 50 mm  $\varnothing$  4 mm by two pieces .( Rotated the direction of spiral) (BU-1).
2. Specimen number 2 with single spiral reinforcement spaced 50 mm  $\varnothing$  4 mm by two pieces .( Rotated the direction of spiral) (BU-2).
3. Specimen number 3 with single spiral reinforcement spaced 50 mm  $\varnothing$  4 mm by two pieces .( Rotated Opposite the spiral) (BU-3).
4. Specimen number 4 with single spiral reinforcement spaced 100 mm  $\varnothing$  4 mm by two pieces .( Rotated the direction of spiral) (BU-4).

#### 3.2 Set up of Equipment and Specimen

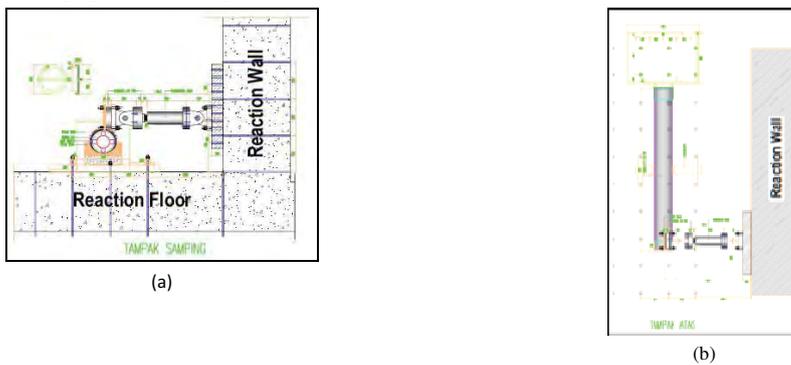

Figure 6. Testing scheme

Figure 7. Set up of Equipment and Specimen

#### 3.3 Methodology of Testing

- a. Specimens were given torque moment until crushed.
- b. Made the relationship chart between torsional moment versus rotation
- c. Torque moment is produced from the lateral force acting on a moment arm within 30 cm of the center of specimen.
- d. Rotation obtained from the transducer mounted and observed lateral movement is lateral movement, then converted into rotation.

## 5. ANALYSIS, TESTING RESULT AND DISCUSSION

### 5.1. Torsional Moment Capacity of Hollow Round Pile

The calculation of torsional moment capacity based on equation in ACI 318-11 Section 11.5.1. Torque capacity of a reinforced concrete cross-section consists of two parts, namely the torque capacity of the concrete and the torque capacity of the longitudinal and the spiral reinforcement. Torque capacity of concrete itself is :

$$T_{u,c} = \frac{\phi \sqrt{f'_c}}{3} \times \frac{A_{cp}^2}{P_{cp}} \times \sqrt{1 + \frac{3f_{ps}}{\sqrt{f'_c}}} \quad (10)$$

Transversal reinforcement :  $A_t = \frac{T_{u,s} \cdot S}{2 \cdot A_0 \cdot f_{yv} \cdot \cot \theta}$  (11)

$$T_{u,s} = \frac{A_t \cdot 2 \cdot A_0 \cdot f_{yv} \cdot \cot \theta}{S} \quad (12)$$

Longitudinal reinforcement :  $A_l = \frac{A_t}{S} \times \phi \times \frac{f_{yv}}{f_{yl}} \cot^2 \theta$  (13)

$$T_u = T_{u,c} + T_{u,s} \quad (14)$$

From equation (10), (11), (12), (13) and (14) obtained a theoretical torque moments as follows:

Tabel 1 : Momen teoritis benda uji

No.	Nama Benda Uji	Jarak Spiral (mm)	Ø Spiral (mm)	Jumlah Spiral	M <sub>torsi</sub> teoritis (t.m)
1	BU-1	50	4	2	3.445
2	BU-2	50	4	1	2.334
3	BU-3	50	4	1	2.334
4	BU-4	100	4	1	1.777

## 5.2. Discussion

### Pattern of Specimen Cracking

(a) BU-1

(b) BU-2

(c) BU-3

(d) BU-4

Figure 8. Pattern of cracked hollow circular piles had a torque moment.

From Figure 8 shows that the pattern of cracks that occur always correspond with the direction of the torque moment working. The pattern of spiral reinforcement does not affect fracture pattern forms. However, the number and spacing of the spiral reinforcement can increase the capacity of torque moment.

**BU-1**

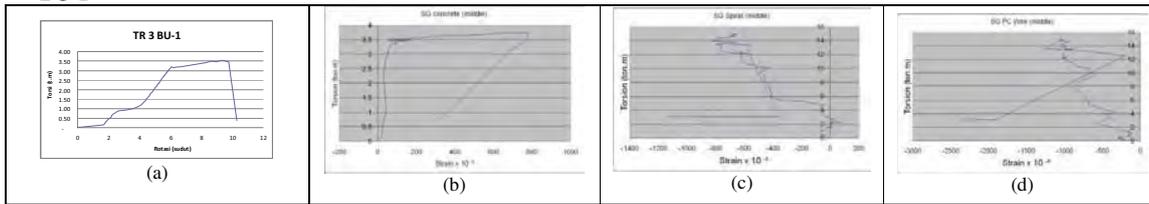

Figure 9 : (a). Relationship between torque momen vs rotation BU-1, load vs  $\epsilon_{\text{beton}}$  BU-1, load vs  $\epsilon_{\text{spiral}}$  BU-1, load vs  $\epsilon_{\text{PC wire}}$  BU-1.

Spiral installed two dual. Torque moment is working in the direction of the spiral. Exfoliation concrete occurs until look the spiral reinforcement. The pattern of crack is opposite with the directional of spiral reinforcement. Based on figure 9a cracks occur at torque moment 3.15 ton.m and  $5\sigma$  rotation. Then broken at torque moment 3.5 ton.mm and  $5\sigma$  rotation. Observations of the result of transducer correlated with strain gauge in concrete. Ratio of  $M_{t, \text{uji}}/M_{t, \text{teori}} = 0.91$ . In Table 1 shows that the the spiral is closed yield and concrete already far exceeds the allowable tensile stress. While stress in PC wire is still far below yield stress. From the results of stress that occurs torque strength is more influenced by the strength of the spiral and concrete. While PC wire is not too much effect resist torque.

**BU-2**

Figure 10 : (a). Relationship between torque momen vs rotation BU-2, load vs  $\epsilon_{\text{beton}}$  BU-2, load vs  $\epsilon_{\text{spiral}}$  BU-2, load vs  $\epsilon_{\text{PC wire}}$  BU-2.

Spiral is installed in one layer. Torque moment is working in the direction of the spiral. Exfoliation concrete occurs until look the spiral reinforcement. The pattern of crack is opposite with the directional of spiral reinforcement. The damage is more severe than the test results to the BU-1, so that there is a correlation number or sectional area the spiral or the spiral with the level of damage. At the initial torque load is rotated around the pile as far as  $0.5\sigma$  working torque moments though still small. Possible tools for turning positioning themselves so that they can work full rotating specimen. Cracks occur at torque moment 2.9 ton.m and  $2.5^\circ$  rotation. And then ultimate moment decreased until broken at torque moment 2.7 ton.m and  $3.5^\circ$  rotation. Ratio  $M_{t, \text{uji}}/M_{t, \text{teori}} = 1.26$ . Reading of strain gauge at BU-2 found similar condition with BU-1, however spiral reinforcement at BU-2 had not yield.

**BU-3**

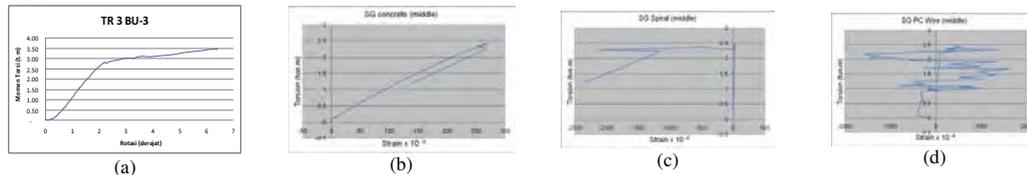

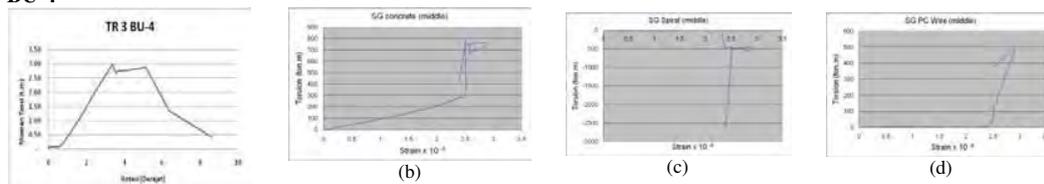

Figure 11 : (a). Relationship between torque momen vs rotation BU-3, load vs  $\epsilon_{\text{beton}}$  BU-3, load vs  $\epsilon_{\text{spiral}}$  BU-3, load vs  $\epsilon_{\text{PC wire}}$  BU-3.

Spiral is installed in one layer. Torque moment is opposite with the direction of the spiral. Exfoliation concrete occurs until look the spiral reinforcement. The pattern of crack is same with the the directional of spiral reinforcement. The damage is much less than the test results to the BU-1 and BU-1, so that there is a correlation with the directional of spiral to level of damage. At the initial torque load, the pile has rotated around the pile as far as  $0.5\sigma$  working torque moments though still small. Possible tools for turning positioning themselves so that they can work full rotating specimen. Cracks occur at torque moment 2.87 ton.m and  $2.95^\circ$  rotation. And then ultimate moment increased until broken at torque moment 3.5 ton.m and  $7^\circ$  rotation. Ratio  $M_{t, \text{uji}}/M_{t, \text{teori}} = 1.19$ . In Table 3 shows the spiral has been broken up so concrete failure occurred despite the stress in the concrete is much smaller than the BU-1 and BU-2. This possibility occurred because the load was opposite direction to the spiral. And the torque moment that happens is 2.87 t.m

**BU-4**

(a)

Figure 12 : (a). Relationship between torque momen vs rotation BU-4, load vs  $\epsilon_{\text{beton}}$  BU-4, load vs  $\epsilon_{\text{spiral}}$  BU-4, load vs  $\epsilon_{\text{PC wire}}$  BU-4.

Spiral is installed in one layer more tenuous the spiral distance 100 mm . Torque moment is working in the direction of the spiral. Exfoliation concrete occurs until look the spiral reinforcement. The pattern of crack is opposite with the the directional of spiral reinforcement. The damage is much less than the test results to the BU-1 and BU-1, so that there is a correlation with the directional of spiral to level of damage. At the initial torque load, the pile has rotated around the pile as far as  $0.5 \sigma$  working torque moments though still small. Possible tools for turning positioning themselves so that they can work full rotating specimen. Cracks occur at torque moment 2.87 ton.m and  $2.9^\circ$  rotation. And then ultimate moment increased until broken at torque moment 3.5 ton.m and  $7^\circ$  rotation. Ratio  $M_{t, uji}/M_{t, teori} = 1.66$

From the analysis above shows that the formula used ACI 318 2011 which is relatively close to the test results, so that the formula can be used. While the test specimen 2 and 3, the both of test specimen underwent the test load torque in the opposite direction. At the direction of rotation yield slightly larger than the rotation in the opposite direction, so that it can be said that the rotation can be done in both directions.

Tabel 2 : Strain and stress for material with tor momen torsi

Sample	No	Position Strain Gauge	E Material (MPa)	Strain ( $\times 10^6$ )	Stress (MPa)
BU-1	1	Spiral	2.10E+05	1141	239.61
	2	PC Wire	1.90E+05	2390	454.10
	3	Concrete	3.00E+04	782	23.46
BU-2	1	Spiral	2.10E+05	1028	215.88
	2	PC Wire	1.90E+05	2280	433.20
	3	Concrete	3.00E+04	1233	36.99
BU-3	1	Spiral	2.10E+05	2363	496.23
	2	PC Wire	1.90E+05	1552	294.88
	3	Concrete	3.00E+04	272	8.16
BU-3	1	Spiral	2.10E+05	2630	552.3
	2	PC Wire	1.90E+04	6102	1159.38
	3	Concrete	3.00E+04	781	23.43

Tabel 2 : Ratio  $M_{t, uji}$  to  $M_{t, theoretical}$  dan rotation

No.	Sample	$M_{t, teoritis}$ (t.m)	$M_{t, uji}$ (t.m)	Ratio $M_{t, uji} / M_{t, teoritis}$	Rotasi (degree)
1	BU-1	3.445	3.13	0.91	9.8
2	BU-2	2.334	2.94	1.26	3.5
3	BU-3	2.334	2.78	1.19	7.8
4	BU-4	1.777	2.95	1.66	4.5

## 6. CONCLUSION

1. The test results are close to the torque moments calculated using the formula torque moment of ACI 318-11, so that the testing method used can be accounted for.
2. Torque moment calculation procedure in hollow circular piles can also be justified scientifically.
3. Rotation in the opposite direction to the direction of the spiral is only slightly different from the direction of rotation.
4. The addition of the effective spiral reinforcement (by narrowing the distance between the spiral) increases torque capacity torque on the cross section.

### ABSTRACT

Cement production, which results in higher CO<sub>2</sub> levels, has a negative impact on environment. This phenomenon has caused the emergence of a new type of environmentally friendly cement, such as cement composites. Some previous studies have recommended the use of rice husk ash (RHA) as a partial replacement of cement. In Indonesia, Ordinary Portland Cement (OPC) has been difficult to find in the market, thus many constructions use composite cement, known as Portland Composite Cement (PCC). On the other hand, rainfall becomes high acidity level. This will be an issue in the construction of concrete, which causes concrete deterioration if value of pH is below 6. The purpose of this study is to investigate corrosion caused by acid rainfall when used PCC cement mixed with RHA. RHA replacement level of 5%, by weight of cement was used in this study. The compressive strength design was 30 MPa. The simulated acid rain solution was prepared by mixing pure chemical reagents such as H<sub>2</sub>SO<sub>4</sub> and HNO<sub>3</sub> to reach value pH of 4. The deterioration was measured by the number of corrosion product using SEM test. The results indicate a decrease in the number of component corrosion that occurs by using ASP.

## ABSTRACT

*The use of concrete as construction materials in Indonesia is increasing, especially in ready mix concrete industry (Ready Mix Concrete). One of the problems that arise in the ready mix concrete industry, is to collect and dispose of the rest resulting from washing concrete mixer truck concrete after the concrete mix, produce and deliver to construction sites. On the basis of this, the purpose of this study was to determine the physical and mechanical properties of concrete containing waste slurry ready mix concrete (Concrete Sludge Waste) or collectively, CSW is also ditambahkan with rice husk ash (Rice Husk Ash) or also known as RHA . RHA and CSW function is as a partial replacement of cement and fine aggregate. Physical and mechanical properties to be tested that include concrete compressive strength, modulus of elasticity with the Pundit, permeability, and density. Based on test results obtained from the optimum compressive strength is the composition of the mixture of 92% cement, 8% RHA, 70% sand and 30% CSW of 32.12 MPa at 28 days. Similarly, the test characteristics of concrete such as modulus of elasticity of the other hard to come by using a Pundit 32133.33 MPa, penetration testing on the permeability of 19.67 mm, and for the density of 2.056 g/cm<sup>3</sup>. From the results of such testing according to SNI for non-structural concrete, can be used as paving blocks, kanstin, parking lot and other non-structural concrete.*

## Keywords

*Rice Husk Ash, Concrete Sludge Waste, compressive strength, modulus of elasticity, permeability, density.*

## 1. INTRODUCTION

currently is to collect and dispose of the remainder resulting from washing concrete mixer truck concrete after the concrete mix, produce and deliver to the construction site, which eventually removed and piled on vacant land just like that. Waste disposal can harm the environment and reduce the aesthetic value of the location - the location of disposal. Reduction in residual waste solution is mixing concrete by the use of return (Reuse) material that is proper to use, and reprocessing (Recycle) are the remaining material. In order to be utilized as a construction material other material that is friendly to the environment. The goal is to achieve sustainable development (sustainable construction) that can be used and carried by the community. In this research, in addition to the concrete mix of cement, fine aggregate, coarse aggregate and water, the addition of Rice Husk Ash (Rice Husk Ash) or called the RHA, the burning of rice husk waste which has elements that are useful for improving the quality of concrete, have a nature Pozolan and contain silica which is very prominent, if the element is mixed with cement will result in a higher power. Ready mix concrete waste (Waste Concrete Sludge) is the rest of the concrete resulting from the leaching process of concrete mixer truck which is also called CSW. CSW is taken from the accumulation in the batching plant with varying compressive strength that has been mixed. RHA and CSW utilized to partially substitute cement and fine aggregate. So in this study aims to determine the nature of the RHA and CSW Fisk to be used, Knowing the composition of the CSW is effective and can meet the target of the desired strength, Knowing the behavior of nature - the physical and mechanical properties of concrete containing RHA and CSW.

## 2. MATERIAL And METHODS

The research was conducted at the Department of Civil Materials Testing Laboratory, University of Indonesia. Methods The study was conducted by laboratory testing in accordance with the data from the literature study both SK SNI Standard Indonesia and foreign standards are ASTM and DIN.

### 2.1 Materials And Methods

#### 2.1.1 Cement

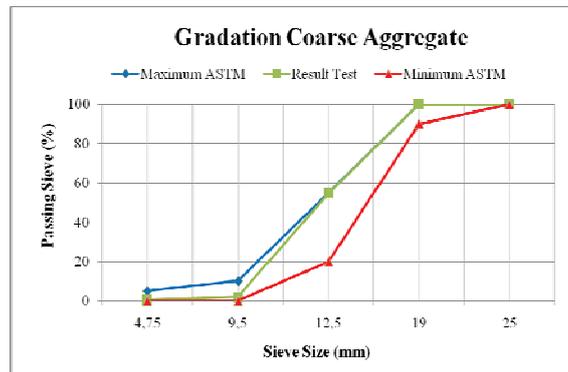

Type-I Portland cement (PCC) was used, which was manufactured by tiga roda. and its physical and chemical properties met the ASTM C150 specification.

#### 2.1.2 Coarse Aggregate

The large stones were crushed first; those with screened split 10 – 15 mm a mixed ratio were used as the coarse aggregate. The fineness modulus was 7,44%.

**Table 1. Coarse Aggregate Test**

No.	Physis and Mechanics	Result Test	Spec
1	Spesific Gravity	2,540	-
2	Spesific Gravity (SSD)	2,560	-
3	Water Absorpstion (%)	0,880	3
4	Bulk Density(gr/cm <sup>3</sup> )	1,425	Min 1,2
5	Loose Bulk Density (gr/cm <sup>3</sup> )	1,331	Min 1,2
6	Voids (%)	45,59	-
7	Water Content (%)	1,47	-
8	Fineness Modulus (%)	7,44	-

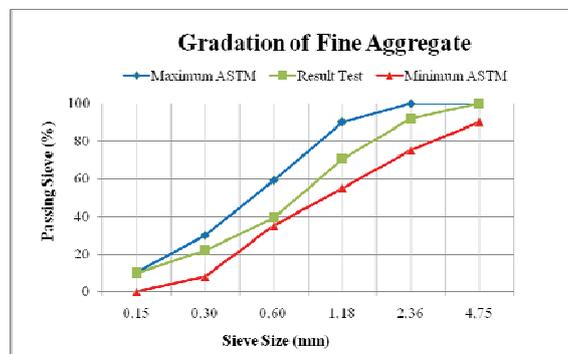

**Figure 1.** Gradation of Coarse Aggregate

### 2.1.3 Fine Aggregate

The sand was obtained from the Cimangkok, West Java and had a fineness modulus of 2,66%.

**Table 2. Fine Aggregate Test**

No.	Physis and Mechanics	Result Test	Spec
1	Spesific Gravity	2,090	-
2	Spesific Gravity (SSD)	2,179	-
3	Water Absorpstion (%)	4,280	3
4	Bulk Density(gr/cm <sup>3</sup> )	1,422	Min 1,2
5	Loose Bulk Density (gr/cm <sup>3</sup> )	1,304	Min 1,2
6	Voids (%)	34,64	-
7	Water Content (%)	13,64	-
8	Silt Content (%)	3,30	Max 5%
9	Fineness Modulus (%)	2,66	Zone 2

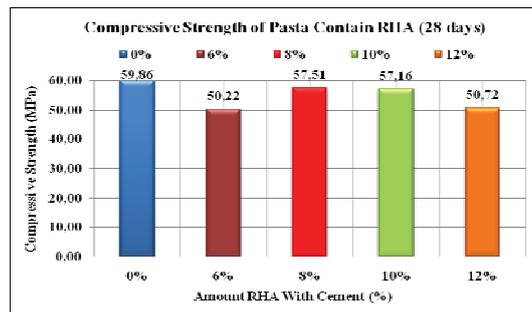

**Figure 2.** Gradation of Fine Aggregate

### 2.1.4 Rice Husk Ash (RHA)

Rice bran is the outer portion of the grain, which is a byproduct of rice milling process when done. While the ash or Rice Husk Rice Husk Ash called RHA is a waste burning rice husk has elements that are useful for improving the quality of concrete, has Pozolan nature and contain silica which is very prominent, if the element is mixed with cement will result in a higher power. Though there are in the rice husk SiO<sub>2</sub> reactive element that can be used as an ingredient made Pozolan concrete quality improvement (Priyosulistyo, 2001). chaff that was done burning, then crushed again to escape kesaringan 200-400 Mesh. As a whole from the chaff in the can of rice alone was only 5% or about 20% of the burning husks. Chemical analysis performed on the combustion of rice husk ash content of silica oxide showed a fairly high, as shown in the following table.

**Table 3.** Composition of Chemical Compounds RHA

Chemical Compounds	Amount (% Weight)
SiO <sub>2</sub>	93.4408
Al <sub>2</sub> O <sub>3</sub>	0.1031
P <sub>2</sub> O <sub>5</sub>	1.0129
S	0.2227
K <sub>2</sub> O	3.4808
CaO	0.7193
TiO <sub>2</sub>	0.0946
MnO <sub>2</sub>	0.2285
Fe <sub>2</sub> O <sub>3</sub>	0.6800
ZnO	0.0173

**Figure 3.** Histogram charts Strong Preliminary Research Findings Press CRHA (a mixture of cement + RHA) at 28 days

Based on preliminary research results graph CRHA compressive strength and cement mixtures containing RHA, the CRHA compressive strength obtained at 28 days with the most optimal composition of 92% cement and 8% at 57.51 MPa RHA. From the results of this preliminary study we used the optimal composition of RHA 8% of cement content for concrete mixtures containing RHA da CSW fit the normal concrete mix design plans based on SNI 03-2834 - 2000.

### 2.1.5 Concrete Sludge Waste (CSW)

Concrete Sludge Waste or CSW is the waste generated from washing truck mixer at the batching plant after producing and sending mixed concrete to construction sites. At the time of washing, the CSW to be like sludge which will then harden to form lumps. CSW function in this study aims to conserve the use of sand and own a maximum compressive strength and can also be used will be environmentally friendly building materials, appropriate such as paving blocks, bricks.

Figure 4. Process of Taking CSW

Chemical analysis of the CSW can be viewed through by PSA testing (Particle Size Analysis) dan XRF (X-Rays fluorescence), as follows :

Table 4. PSA Analysis of CSW

No.	Particle Diameter (µm)	Statistics		
		Volume (%)	Surface Area (%)	Number (%)
1	< 20	100	100	100
2	< 10	98.500	99.700	99.998
3	< 8	92.300	98.400	99.990
4	< 6	79.600	94.900	99.900
5	< 4	60.500	87.600	99.700
6	< 2	36.000	71.500	98.000
7	< 1	16.200	44.800	86.700
8	< 0.4	0.220	1.040	4.930

Table 5. XRF Analysis of CSW

No.	Chemical Compounds	Prosentase	
		Weight (%)	Atom/ Molecul (%)
1	MgO	1.8284	3.6062
2	Al <sub>2</sub> O <sub>3</sub>	7.5603	5.8951
3	SiO <sub>2</sub>	<b>35.5793</b>	47.0789
4	S	0.5744	1.4243
5	K <sub>2</sub> O	0.7181	0.6061
6	CaCO <sub>3</sub>	<b>48.0781</b>	38.1902
7	TiO <sub>2</sub>	0.5984	0.5955
8	Cr <sub>2</sub> O <sub>3</sub>	0.1169	0.0612
9	MnO <sub>2</sub>	0.1927	0.1763
10	Fe <sub>2</sub> O <sub>3</sub>	4.7531	2.3644

From the results of the PSA test, CSW has the smallest particle size of 0.4 µm and the number of particles that measure between 0.4 CSW - 1 µm as much as 16.42% of the total samples tested. While the test results of XRF, CSW to own most of the chemical composition containing SiO<sub>2</sub> and CaCO<sub>3</sub>.

CSW in this study did not directly used but must be done further research and treatment so as expected, here's how the processing of CSW to be used:

- CSW is usually still in a wet or humid conditions, it must first be dried by drying using the sun or can also be roasted.
- After CSW dried, crushed and polished slabs CSW by milled or ground.
- After CSW crushed, then sieved with a sieve size of 4.75 mm (3/16 in) which is a standard sieve for fine aggregate.
- After CSW has been sifted, stored in a dry place and already can be used

Figure 5. Processing of CSW

## 2.2 Design of Concrete Proportion

The concrete mixing proportions were for moderate strengths of 35 MPa, whereas the slump was 6 - 18 cm. The constituent contents of RHA and CSW are shown in Table 5.

Table 6. Material Composition

Sample Code	MATERIAL COMPOSITION				
	PC + RHA		Fine Aggregate		Coarse Aggregate
	PC	RHA	Sand	CSW	
CHWC-131	92%	8%	70%	30%	100%
CHWC-132	92%	8%	60%	40%	100%
CHWC-133	92%	8%	50%	50%	100%
CHWC-134	92%	8%	40%	60%	100%
CHWC-135	92%	8%	30%	70%	100%

## 2.3 Fresh Concrete Tests

### 2.3.1 Slump Test

Slump tests were performed according to ASTM 143 to measure the slumps for concrete containing RHA and CSW.

### 2.3.2 Unit Weight of Concrete

The unit weight of the fresh concrete was measured according to ASTM C138.

### 2.3.3 Initial Setting Time Test

The measurements were conducted according to ASTM C403.

## 2.4 Hardened Concrete Test

### 2.4.1 Compressive Strength

Compressive strength testing using a test specimen cube 100 x 100 x 100 mm, testing were prepared according to ASTM C39 and were cured for 1–56 days. At each curing age, five cube specimens were tested for compressive strength. the cube compressive strength of test specimens are converted into compressive strength of cylindrical specimens are shown in table 6.

**Table 7.** Conversion of compressive strength based on shape of sample tests

NO	Shape of sample test	Konversion Value (A.M. Neville)
1	Cube 10x10x10 (cm)	1,04
2	Cube 15x15x15 (cm)	1,00
3	Cylinder d=10, t=20 (cm)	0,86
4	Cylinder d=15, t=30 (cm)	0,83

### 2.3.2 Modulus of Elasticity

Modulus of elasticity is a measure of material stiffness or resistance to deformation. Modulus of elasticity is determined voltage change of strain in the elastic limit. Elastic region in concrete according to ASTM constrained between 0.00005 strain with 40% voltage at the maximum voltage. But in this study the elastic modulus testing using non-destructive testing device that is Pundit (Portable Ultrasonic Non-Destructive Digital Indicating Tester) that uses ultrasonic waves. The ability of this tool, besides knowing the quality of concrete, can also detect a thick layer of concrete that is damaged, or it cracks in the concrete. The relationship between modulus of elasticity and compressive strength of concrete according to SKSNI 1991 which were used by ACI are:  $E_c = 4700 \sqrt{f_c}$

The equation above shows that the magnitude of the modulus of elasticity of the concrete increases with increasing compressive strength of concrete.

### 2.3.3 Permeability

Permeability is the nature of the ease of escape of water or similar substances to penetrate the concrete surface. Rate of water passing ability of a material is expressed by the coefficient of permeability (k), which depends on the concrete surface area, water pressure, and duration of time. Concrete permeability testing to determine the effect of variations in cement and aggregates, or influences many kinds of concrete mixing operation, printing and maintenance, taking into account the basic information on the inside of the relative porosity of concrete is directly related to absorption, capillary channel, the resistance to freezing, preparation, lift and other so on. Factors affecting the quality kekedapan material, method of preparation of concrete, and concrete maintenance (Brook K.M, Murdock L.J, 1991).

### 2.3.4 Density

Based on ASTM C 642-97, this method involves the determination of density. This test is useful in developing the data needed for the conversion between mass and volume for the concrete. It can be used to determine compliance with spesifikasiuntuk concrete and to show the differences from place to place in mass concrete. The amount of density can be measured as follows:

$$[A/(C-D)].\rho = (\text{g/cm}^3)$$

Where :

- A = mass of oven-dried sample in air, (g)
- C = mass of surface dry sample (g)
- D = apparent mass of sample in water (g)
- $\rho$  = density of water (1 g/cm<sup>3</sup>)

### 3. RESULTS And ANALYSIS

#### 3.1 Test Results for Fresh Concrete

##### 3.1.1 Slump test

Based on the results of such testing, the average slump for normal concrete, CHWC131, CHWC132, CHWC133, CHWC134, CHWC135 is 80 mm, 66.67 mm, 61.67 mm, 70mm, 74.33 mm, 78.33 mm. Obtained that the value of the entire mixture into the slump slump plan is 60-180 mm.

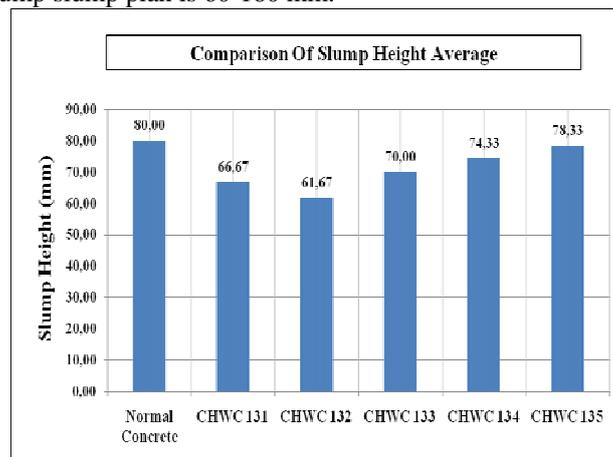

Figure 6. Graph of Slump

##### 3.1.2 Unit Weight of Concrete

Table 8. Result Test of Unit Weight Fresh Concrete

No	Measurement	Unit	Mixed Code					
			Normal	CHWC131	CHWC132	CHWC133	CHWC134	CHWC135
1	Weight of Cylinder (W1)	Kg	4,998	4,998	4,998	4,998	4,998	4,998
2	Weight of Cylinder + Water (W2)	Kg	14,75	14,75	14,75	14,75	14,75	14,75
3	Weight of Cylinder + Concrete (W3)	Kg	26,2	26,1	25,5	25,3	25,25	24,8
4	Weight of Concrete (W3 - W1)	Kg	21,20	21,10	20,50	20,30	20,25	19,80
5	Unit Weight of Concrete (W4) = ((W3-W1)/(W2-W1)) x 1000	Kg/m <sup>3</sup>	2174	2164	2102	2082	2077	2031
6	Purpose of Unit Weight of Concrete (W5)	Kg/m <sup>3</sup>	2190					
7	Yield (W5/W4)		1,0073	1,0121	1,0417	1,051	1,0546	1,0785
8	Voids [(Y-1)/Y] x 100 %	%	0,73	1,19	4,00	4,94	5,17	7,28

Based from table 10, More and more using csw, then water content is high. Large air content which is also caused due to a lack of good compaction at the time of testing.

##### 3.1.3 Initial Setting Time Test

Table 9. Results of Initial Setting Time Test

Test	Normal Concrete	CHWC 131	CHWC 132	CHWC 133	CHWC 134	CHWC 135
Initial Setting Time (Minutes)	117,4	134,3	135,2	142,4	145,2	146,8

Result of setting time for normal concrete is 117,4 minutes, then shown from table 11 more using CSW, more longer setting time.

### 3.2 Hardened Concrete Test

#### 3.2.1 Compressive Strength

Test of compressive strength using sample shaped a cubed size of 100x100x100 mm. The result obtained from cubed sized 100mm, converted to  $fc'$  cube size of 150x150x150 mm that ( $fc'$  cube 100mm / 1,04), then converted again to  $fc'$  shaped cylinder 150mm x 300mm of ( $fc'$  cube 150mm x 0,83). Tests performed at the age of 3, 7, 14, 21, 28, and 56 days of the results can be shown in the picture 7.

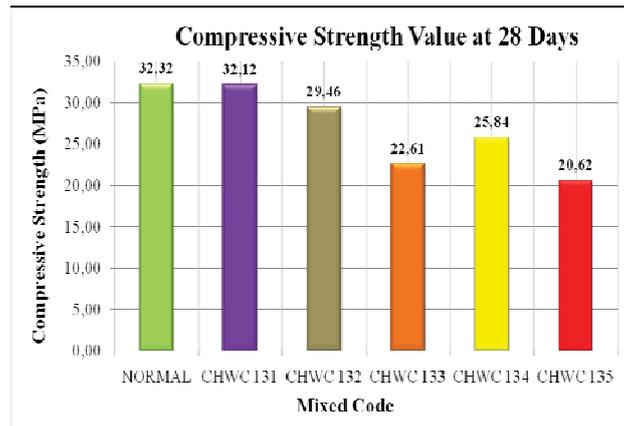

Figure 7. Histogram of Compressive Strength at 28 days

#### 3.2.2 Modulus of Elasticity with (PUNDIT)

Test of Modulus of elasticity for this study using non destructive equipment that is PUNDIT (*Portable Ultrasonik Non-Destructive Digital Indicating Tester*), that work is carried out using ultrasonic waves at concrete 28 days old. From the test results on PUNDIT test doing compare with the value modulus of elasticity from compressive strength of concrete at 28 days according to SKSNI 1991, using the formula:

$$Ec = 4700\sqrt{fc'}$$

Table 10. Result Test of Modulus Elasticity With PUNDIT

Mixed Code	Poisson Ratio	Compressive Strength (MPa)	ME PUNDIT (MPa)	Ec SKSNI (MPa)	Comparison
CHWC131	0,22	32,12	32.133,33	26.638,10	1,206
CHWC132	0,22	29,46	31.150,00	25.511,23	1,221
CHWC133	0,22	22,61	29.966,67	22.349,56	1,341
CHWC134	0,22	25,84	31.037,50	23.890,49	1,229
CHWC135	0,22	20,62	25.268,75	21.340,79	1,184
Average					1,250

Shown from table. 10 the comparation average value between modulus of elasticity ratio testing with PUNDIT, with the theoretical value according SNI is 1.25.

Comparison between the modulus elatisitas with compressive strength by the equation  $Ec = 4700\sqrt{fc'}$  not valid again for concrete that contain RHA and CSW. To obtain a new equation of the elastic modulus relationship with compressive strength used equation  $Ec = C\sqrt{fc'}$ . Where C is a constant of modulus of elasticity results for testing with the square root of compressive strength obtained from the research. C values of the test results can be seen in the table 11.

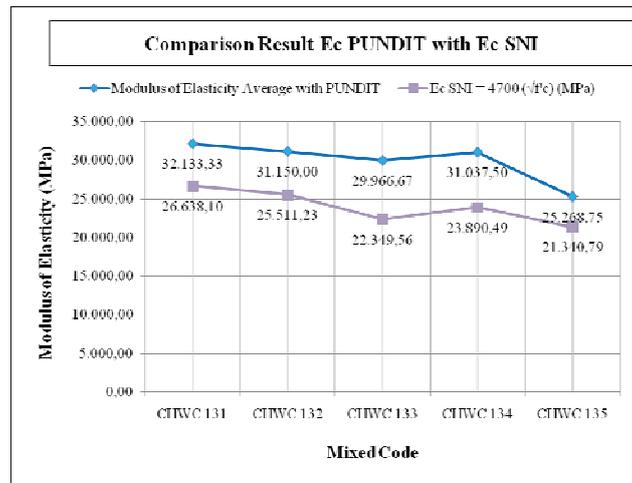

Figure 8. Graph of Modulus of Elasticity

Table 11. Value of New Constanta Modulus of Elasticity with Compressive Strength

Mixed Code	ME PUNDIT (MPa)	√fc (MPa)	Value of Constanta
CHWC 131	32.133,33	5,67	5667
CHWC 132	31.150,00	5,43	5737
CHWC 133	29.966,67	4,76	6296
CHWC 134	31.037,50	5,08	6110
CHWC 135	25.268,75	4,54	5566
			<b>5875</b>

Based on the table it can be determined the relationship between the modulus of elasticity equations with the compressive strength of concrete contain RHA and CSW at 28 days is  $E_c = 5875 \sqrt{f_c'}$ .

### 3.2.3 Permeability

Test of permeability performed at 28 days by using a cylindrical test with diameter 15 cm and length of 15 cm. Tests carried out with water pressure of 0.5 N / mm<sup>2</sup> at 72 hours or 3 days after the split and measured values of the incoming water penetration.

Table 12. Result of Average Penetration

Mixed Code	Pressure (MPa)	Time (Hours)	Compression Strength at 28 days (MPa)	Average of Penetration (mm)
CHWC131	0,5	72	32,12	19,67
CHWC132	0,5	72	29,46	21,33
CHWC133	0,5	72	22,61	23,44
CHWC134	0,5	72	25,84	17,22
CHWC135	0,5	72	20,62	25,56

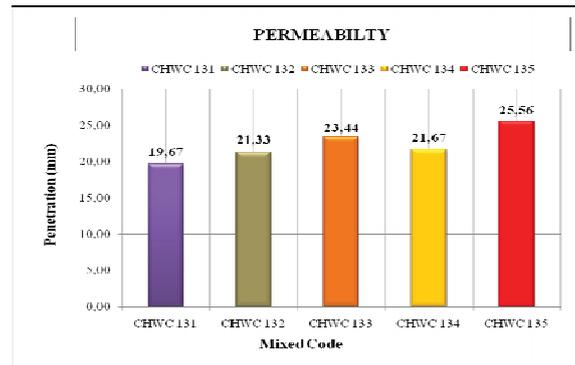

Figure 10. Histogram of Permeability

Shown on graph the value of greatest penetration is in from mixed code CHWC135 that is equal to 25.56mm, while the smallest penetration value is in from mixed code CHWC131 that is equal to 19.67 mm. CSW CHWC135 to own composition more than the other mixture of 70%. Then it can be analyzed that more using CSW it can be a higher penetration occurs.

### 3.2.4 Density

Test of density performed at 28 days by using a cube specimen size 100 x 100 x 100 mm. Result test of density can be shown at table 13.

Table 13. Result Test of Density

NO	Mixed Code	Age of Test (Days)	Water Density ( $\rho$ ) ( $\text{g}/\text{cm}^3$ )	Compressive Strength at 28 days (Mpa)	Density (Average) ( $\text{g}/\text{cm}^3$ )
1	NORMAL	28	1	32,32	2,286
2	CHWC131	28	1	32,12	2,056
3	CHWC132	28	1	29,46	2,047
4	CHWC133	28	1	22,61	1,918
5	CHWC134	28	1	25,84	1,934
6	CHWC135	28	1	20,62	1,865

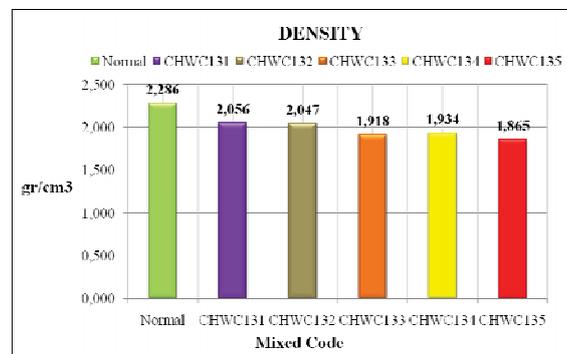

Figure 11. Histogram of Density

Shown at picture. 10, showed that the average density value the largest average occurs in CHWC131 mixture, while the average density value is the smallest average CHWC135 mixture. Then it can be analyzed that more using of CSW, the greater density obtained.

### 3.3 Using CSW Into Material of Construction

From the research, that the benefits from CSW can be used by the industry. In this study, the composition of the five concrete mixtures CHWC131, CHWC132, CHWC133, CHWC134, CHWC135 at 28 days reached the compressive strength of 32.12 MPa, 29.46 MPa, 22.61 MPa, 25.84 MPa and 20.62 MPa . Based from requirements of concrete brick (paving blocks) according to SNI 03-0691-1996 on quality requirements and classification of concrete brick, concrete contained RHA and CSW can being :

- A Quality Concrete bricks are used for road.
- B Quality concrete bricks are used for parking lot
- C Quality concrete bricks are used for pedestrian walk
- D Quality concrete bricks are used for park land and another function for non structural concrete..

Table 14. Terms of Quality Paving Blocks According to SNI

Mutu	Kuat Tekan (MPa)		Ketahanan Aus (mm/menit)		Penyerapan air rata-rata maks
	Rata-rata	min	Rata-rata	min	%
A	40	35	0.090	0.103	3
B	20	17.0	0.130	0.149	6
C	15	12.5	0.160	0.184	8
D	10	8.5	0.219	0.251	10

## 4. CONCLUSIONS And RECOMENDATIONS

### 4.1 Conclusions

In this study, RHA and CSW utilized to partially substitute cement and fine aggregate. Based on analysis from test. The following conclusions can be drawn:

- Using CSW as a Partially replace of fine aggregate in concrete, effect on the reduction in workability of fresh concrete is characterized by a decline in the value of slump, so it should be added to water at the time of stirring so the mixture does not dry quickly
- More used of CSW, more water to cement ratio resulting in a decreased value of compressive strength.
- The greater percentage using of CSW, that the unit weight of concrete it so small and so that the levels of air (voids) in the fresh concrete increases. Weight content of the smallest mixed it is in mixed code CHWC135 with percentage of 30% sand and 70% CSW in the amount of 2031 kg / m<sup>3</sup> with the air content of 7.28%. When compared with normal concrete is equal to 2174 kg / m<sup>3</sup> with the air content of 0.73%.
- The greater use of CSW, that the longer initial setting time occurring, so that process of cement hydration reaction had a long time. Caused CSW has a very high water absorption compared to the sand.
- At mixed code CHWC131 had a very high value of Compressive strength of 32,12 MPa at 28 days compare that another mixed code. So that CHWC131 with 92% cement, 8% RHA, 70% sand, and 30% CSW, it is a effective mixed for concrete Contain RHA and CSW.
- From modulus of elasticity test, the EC value acording SNI not applicable for concrete contain RHA and CSW, so that from test result value of EC be avowed by the formulation is  $EC = 5875 \sqrt{f_c}$ .
- The benefit of CSW can be used by industry as a material manufacture of paving block, according from SNI 03-0691-1996.
- Waste generated by batching plan can be recovered into a building material products can also be an environment that would minimize the environmental impact around the batching plan.

### 4.2 Recommendations

The following suggestions may be related to the research conducted are:

- Further research needs to be done on the use of CSW, in order to use the maximum percentage value of the mechanical properties of concrete.
- Use of CSW so great in the concrete mix, will decrease the compressive strength of concrete, so that further research is recommended to use must be adjusted to the amount of sand on the concrete.
- In this study the treatment of CSW proceed by manually, so that further research needs to be done on a good method to produce a CSW in standart.
- Need to use chemical ingredients added to the RHA and CSW mix concrete, in order to water cement ratio accordance with the composition of normal concrete.
- Use of CSW was able to be used as a complementary mixture of fine aggregate sand, it is necessary to do research on the economics of the use of CSW. So its use can be commercially exploited by the industry and can reduce the impact of pollution on the environment.
- Amount of concrete sludge waste from each batching plan it so variated in Indonesia, so further research is needed on how much the use of CSW can offer.

## ABSTRACT

*The adoption of smartphones, which is the result of the convergence of Information and Communication Technology (ICT), grow rapidly in mobile professionals, i.e. segment who spend 20 per cent or more of their total working time to work away from their office. The type of work of mobile professional, with the greater unpredictability and heterogeneity than fixed node-worker, need additional support in order to decrease the contextual constraints encountered while mobile, and smart phone may fulfil such needs. Smart phone potentially allow the restructuring of activity patterns of individual during work and in turn can influence their travel pattern. To understand it, this study theoretically discussed how individuals of mobile professionals adopt and use smartphones, and how its implications on the work activities and travel pattern by using a concept: mobile interaction based coordination. To provide the first insight, the results of the initial interview conducted on 20 mobile professionals in Indonesia are given. As the result, there are indications of change of the way of the coordination of mobile professionals and leads to changes in the dynamics of the mobile work-travel pattern. In aggregate, it will have large impacts on the use and configuration of urban transport network.*

**Keywords:** Smartphone, Professional Mobile, Mobile Interaction based Coordination, Work Activity, Travel Pattern

## → 1. INTRODUCTION

Information and Communication Technology (ICT) plays an increasingly important role in human life. For instance, as shown by the data at the end of 2011, which states that there are approximately six billion mobile phone subscribers in the world, with global penetration reaches 87%, and 79% in developing countries [1] and 89 per cent of users use it throughout the day [2]. Adoption is increasing due to the convergence of ICT has facilitated the transmission of large amounts of information with high speed and accuracy with a relatively low cost. It is then further strengthened with the advent of smartphones, which is a contemporary type of mobile phone that integrates a number of technologies for computing capabilities and advanced internet connectivity [3]. This phone is built in with applications and internet access, digital voice, text messaging, e-mail, browser (browsing) web, and multimedia devices, so users can do many things on the go, anytime, with direct access and multi-function. Technological and social characteristics of this device make them potential to change the behaviour of the users, more than the previous ICT.

Smartphone market started out in the business segment [4][5]. Especially so-called mobile professionals are important beneficiaries here. Mobile professionals could be characterized as individuals over age 20, employed full time in a professional occupation, who spend 20 per cent or more of their total working time away from their work environment [6][7]. The nature of work of mobile professional differs in many ways from desk work or fixed-node worker, because of the greater unpredictability and heterogeneity of the work caused by contextual constraints [8]. Mobile professional have less control over the configuration of their environment, therefore, they need additional support/information in order to decrease the uncertainty associated with the contextual constraints encountered while being mobile [9]. Thus, smartphone may fulfil such needs.

The issue of the interaction between the developments of ICT in individual travel behaviour is not a new thing. ICT-transport interaction is often expressed in function substitution, complementary, modification, and neutrality [10][11][12]. The main concern in many studies is whether ICT increase or decrease the amount of travel demand, and it seems that complementary concept (ICT increase transport demand) still dominates today, stronger than the interaction substitution [13]. Still in order to investigate the interaction, this study is a little different because it uses the 'activity system' as an intermediary interaction.

Because the interaction between ICT-transport is very complex, then to be more focused, objects are selected only one product technology (i.e. smart phone) and only the individual effects (i.e. the individual mobile professional), the purpose of the trip (i.e. travel to work) and then considering only one dimensional travel (i.e. use of smart phones in the coordination of activities performed while out of the office). This paper explores the impact of the use of smart phone technology on how the implications for the way individuals from mobile professionals organize activities and movement during work. Indonesia is used as a case, because the adoption of smart phones in Indonesia nearly 56 million and will continue to increase its penetration of the overall mobile phone subscribers in Indonesia, which has reached more than 240 million [4][14]. The rapid move towards the adoption and use of smart phone has provided people and organizations with the ability to work in novel and previously unpredictable ways. Thus, it is alleged that urban transport Indonesia will certainly dealing with the consequences of the transformation behaviour due to the use of smartphone.

This paper explores the use of smart phone mobile professionals and potential implications on the activities of their daily work, by reviewing relevant research that has been conducted before. To complete the review and obtain the first insight, it is given the results of a preliminary survey analysis of the semi-structured interviews with 20 smartphone users from mobile professionals in Indonesia. With this first insight, it is expected to gain a better understanding, and can be developed in subsequent phases of the study. The outline of the paper is as follows. The early part is an introduction, followed by a section that describes the theoretical background, which contains how smart phone technology, and the increasing number of mobile professional and nature of mobile work and how this use of ICT as well as the concept of the coordination of activities. In the section 3, the research methodology is presented which is contains the research design and expected outcomes, followed by section 4, the first insight as a result of the preliminary survey. The paper ends with a conclusion.

## → 2. THEORETICAL BACKGROUND AND HYPOTHESIS

### 2.1. Technology of Smartphone and Mobile Interaction

Recent Information and Communication Technology has the potential to transform everyday life: how to interact, privacy, social networking, economics, education, and urban transport [15]. Taking into account that smartphone is evolution of mobile phone, it is first necessary to review the research that has been done on the mobile phone. Over the past two decades, there are so many studies that focus on the use of mobile phones (e.g. [16][17][18][19]). Most of studies have tried to understand and explore how mobile adoption and potential changes in behaviour due to the use of mobile phones, from the perspective of sociology, for example [20] who focused at how mobile phones change the way a person interacts socially.

In the first phase of the development of mobile phones, users use the phone as a function of supplement, which is only for receiving and making calls or messages outside the home, office or other workplace. Mobile phone gives the possibility of new ways of doing activities and allows one to interact and carry out activities in a new way [21], and this results in (1) increasing the spatial and temporal flexibility, (2) the impact on travel behaviour and the decision to make the trip (3) to encourage users to spend their free time outside of the home, (4) the emergence of changes in the function and role of the existing nodes in the urban transport system, (5) a new mode of mobility that can improve accessibility to opportunities, services and social networks a person, even for individuals with limited physical mobility. After the convergence of ICT, the motive for adopting smartphones more powerful and causing consumers of mobile phones are quickly shifting to smart phones.

### 2.2. Mobile Professional and Mobile Work

Nature of work and location of work is undergoing a shift. Work is diversified, along with its increasingly mobile workers and the use of ICT equipment [22]. There is a tendency that the workforce has to deal with an increasingly complex job. With the expansion and globalization of business activities is rapidly increasing with higher consumer demand, the organization felt the need to better adapt the turbulent business environment. This trend led to a growing demand for highly skilled labour and a consequent increase in the number of mobile professional.

Technologies such as mobile phones and e-mail allows for workers and employers to keep in touch without the always present physically and led professional 'post-modern', the mobile nature, in the sense of operational, locational and interactional [22][23]. In operational terms, as a professional working in a flexible organizational structure, for example, in project teams, task forces, and virtual organizations, and in a different location and not always in the office. ICT helps them in organizing work in different locations, with continuous interaction with a large number of different people both inside and outside of formal organizations in a wide geographical area. List of tasks of a mobile professional work are planning, acquiring, searching, analysing, organizing, storing, organizing programs, distribute, and market information [24], . Mobile professional activities include creating, capturing, communicating, collaborating, seeking processes, and review the results and save them. With the advent of the function and connectivity to internet e.g. ability to send and receive email on a smart phone, which is not presented by earlier technology of mobile phone, the usage of smartphone during working is increasing. This is in line with statement that most interactions with mobile phones occur at working time/when a person is working [25].

Mobile work can be conceptualized in three types: travelling, visiting and wandering [8]. Travelling is essential for mobile work and it is important for transport study because it affects the performance of the transport network. Ref [26] call work related travelling as business trip, i.e. work related trip to a place that is not fixed, e.g., work to visit clients, participate in a conference or a meeting with business relations. Looking at the nature of their work, there are no strict boundaries whether inside or outside the office, because of where it could be their office, they penetrate the "regional" and "network." For mobile workers, work can be done not only in their formal office but at various locations such as home, a client's office, hotel, cafe, moving vehicles, and so on. Seeing the nature of their work, there is no rigid boundary between inside or outside the office, because of every place could be their office, they penetrate the "regional" and "network." In this sense, mobile work seems as working in the fluid mode.

### 2.3. Mobile Interaction based Coordination and Its Impact on Mobile Work

Coordination is a common everyday activity for mobile professionals. In practice, people often make an appointment, to arrange a visit, manage schedules and synchronize activities. The need to coordinate the activities is the basic social function, especially in contemporary society, which is characterized by distributed residential location, car-based transport, and complex activity patterns [27]. For mobile professionals, coordination means that the extension of the control [25]. He argued that interaction with mobile phones allow the coordination to do the movements, so that the meeting can be designed and people can be found. He calls a form of coordination that arise as a result of the use of mobile phones as a "coordination-based mobile interaction" and identifies three ways occurrence, namely (1) midcourse adjustment, which refers to the transfer of the journey has started and setting details of the meeting which had previously been agreed upon, (2) interactive coordination, which refers to the progressively setting of the meeting that is certain, (3) softening the schedule, which refers to the potential for increasing the flexibility of schedule compared to occurrence coordination based on fixed time [28].

It is undeniable that for mobile professionals working outside the office, smart phones useful in providing access to resources and result in improved efficiency and connectivity with the company. Smart phones are smaller in size than a laptop or notebook and easily grasped nature makes them ideal for mobile workers in mobile interaction. Allegedly providing mobile interactions change in the nature of the work itself, the time and place of work, as well as in the employment relationship. With the availability connectivity between the mobile workforce and its headquarters will mean greater efficiency for mobile workers, as well as they can be empowered and supported from a distance. Mobile professional still stay connected on holidays and they still work whereas they are travelling or relaxing.

Another aspect of the changes observed in the mobile work activities is the emergence of 'effects like jazz' to continue to align not only some of the activities, some of which are directly observable and some are not, but also to harmonize the activities planned improvisation activities. One view is that the basis of our research has been thorough mixing between planning and improvisation in everyday life, and especially in the middle of doing the movement [29]. Apparently terminology "mixture of planning and improvisation activities" is similar to "rescheduling of activities" [30].

Generally the activities rescheduled the agenda is at the core of many changes in travel behaviour. An agenda activity consists of a list of specific activities that would potentially be implemented, including a rare activity in spare time [31]. Activity schedule refers to a continuous pattern of activities and trips over time and space, including the observed choices of what activities to participate in, where, for how long, in what sequence, coupled with mode and route choices. The key components of this dynamic and continuous process include preplanning, impulsive and dynamic, and adaptive scheduling behaviours. Every activity on the agenda have unique attributes that affect scheduling, including the duration (min, max, average), the frequency, the time, the people involved, cost, location of people involved, the costs, the preferred location, and others. Process dynamic scheduling begins premises preplanning activities selected from the agenda, followed by re-planning and scheduling of continuous time, and ends with the pattern implementation of activities-travel schedule that can be observed. If it is true that mobile phones cause the mixing of planning the form of rescheduling, plus a shift towards coordinating with mobile interaction based coordination and potentially rescheduling, while rescheduling logically impact on aspects of space and time of movement through the space and sequence of events, it is alleged that mobile interaction based-coordination has the potential to have an impact on the travel behaviour through the concept of rescheduling. If mobile interaction based coordination using a mobile phone really has influence on one's behaviour in the conduct of activities and travelling, then issues related to how the attitude and the subjective role in it should be taken into account.

### 2.4. Hypothesis

Based on the literature review, it is developed the hypothesis that there are effects arising from the interaction using a mobile smart phone on travel pattern of mobile professionals through the change of activity pattern. Mobile interaction based coordination using smartphone increase the dynamic of activity scheduling. The dynamic of scheduling include adding/inserting, modification, and deleting activity on planned agenda. Decision to execute activity as a planned, or add, or modify and or delete is the respond of information received via smartphone. Types of information (content, from whom,

timing, service used) and situation (context of current activity performing and coming up activity, i.e. timing, urgency, flexibility activities) greatly affects the response given.

### 3. RESEARCH METHOD

The study consists of two stages, preliminary and main study. The current research is the initial part of the main study, thus this paper was not designed to provide a comprehensive study of mobile professional behaviour, but rather was intended to be interpretive. Thus we will not discuss statistics data here, but we will explore experience use-practices of mobile work from mobile professional.

Preliminary survey was conducted first to get the first insight about the phenomena. Considering that there is great diversity in the nature of work of mobile professional and their characteristic of technology use. Therefore, it is important to recruit the interviewees: 20 mobile professionals from Jakarta Great Area, Indonesia from a range of different professions, who were representative of those differences. Participant were also pre-screened to represent various level of mobility in term of frequency of mobile, the flexibility of time, flexibility of place of work. Occupation includes a variety professional from a range of consultant, project management, lawyer, veterinarian, obstetric-gynaecologic, marketing, sales, customer service, managing partner, real estate developer, government officer.

Semi-structured interviews conducted in this stage with the aim of obtaining information on the context surrounding the mobile professional activities, why they travel, with whom they visit, what will they do with them, what they do with their mobile phones while travelling, and at a third location, how they use their phones, especially for work purposes, what has changed in their mobile work, as the implications of the use of smart phones. Semi-structured interviews helped to inform us about the context surrounding the mobile professional activities. We wanted to understand the variety of ways they used their Smartphone, especially for work purposes, why they make a trip, who they would visit and what they would do with them, what they do with the smartphone during the trip and at the third location, how they plan and make an activity-travel schedule, and how they execute the agenda (include how they reschedule the agenda).

Surveys consist mostly of free response questions. In the free response surveys we found typical day of nature work, purpose of usage, characteristic of usage and what have been changed in their mobile work as implication of their smartphone usage. All of interviews are conducted in Indonesian, and the quotes have been translated to English. Interviews were transcribed and analyzed for the identification and sorting of themes and core concepts at several levels of specificity. (We translated the quotes used here from Indonesian into English). Data obtained from an initial interview indications are used as a basis to create the next step of the study.

The main survey, which is the next stage of this study, will be conducted using questionnaire with a larger number of mobile professionals, representing proportional pursued gender, profession proportion grouped by similar properties of mobile work (e.g. mobile based field work includes project consultants, city planners, contractors, distinguished group with mobile work which its location cannot be predicted, e.g. journalists, lawyers, sales, account representative, veterinarian). Clustering should be done in a more detailed classification. Participant were provided with a specific scenario to know the respond if they face the specific situation during the execution of activity-travel agenda. The study applies situational approach to understand the phenomena. Ideally we have to observed all of detailed information received from interaction using smartphone (e.g. forms, type of service, content, with whom, timing of interaction) and the attribute of activity at that moment (e.g. people involved, fixity, temporal attribute, spatial attribute, characteristic of joint the activity). Considering that every mobile professional have a unique agenda and have abroad spectrum, situational approach is chosen. The purpose of this approach is a simplification to compose the basic patterns of activity change due to the interaction using smartphones. In this approach, it is generated some scenario of situation on the storyboard that contain with “most probably information gained” from smartphone, that require immediate attention for re-scheduling decision (impulsion), as shown at figure 1.

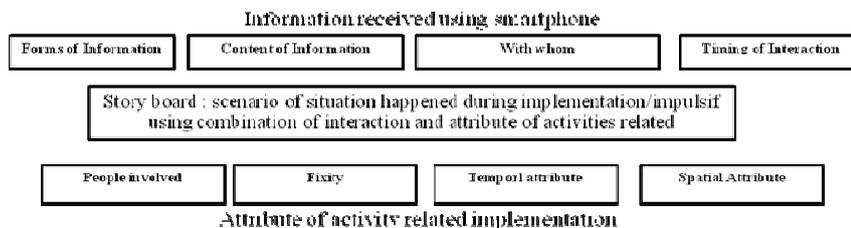

Figure. 1. Storyboard with scenario

The behavioural response to such a situation is recorded (whether addition/inserting, modification, deletion) and the basic pattern of activity execution is then analyzed. Agenda of mobile professional is assumed consist of two mandatory activity, one optional activity and one repertoire activity, with time window. During implementation, some situations might be happened, dealing with smartphone usage (access to real time information via interaction using smartphone) and it is assumed that a mobile professional make a decision whether reschedule his/her agenda or not, and what respond he/he will choose. Storyboards are prepared based on the experience of mobile professionals as told in the initial survey, i.e. results of the preliminary interviews. As the consequence of the chose, it will be noticed the pattern of activity executed and it is compared with the pre-planned activity pattern of agenda. This is accomplished also to the trip that attached to them. With the addition, subtraction or modification of activities conducted, it is logically viewed the impact on the travel pattern, whether it will potentially increase the number of trip, reducing the amount of trip, or change the destination and timing of the trip. Thus, the better understanding of phenomena of smartphone usage effect, by compare with and without using smartphone could be gained.

#### 4. RESULT OF PRELIMINARY SURVEY AND DISCUSSION

##### 4.1. Profile of Respondents

The survey was conducted on 20 respondents from professional mobile-smart phone users in the Greater Jakarta Area, with a variety of professions. Profession selected based on pre-screening that respondents actually is the target of research, i.e. more than 20% of the working time is out of the office (e.g. consultants, city planners, contractors, journalists, lawyers, sales, account representative, veterinarian, CEO). Profile of the respondents is given in Table 1.

Table 1. Profile of Respondents

Item	Profile Respondent
Number of hours working outside the office	> 20% of working hours
Age range	35-55 years
Type of smartphones user	Early adopter of smart phone users and use it all the time
Income range	3 million IDR - >25 million IDR
Gender	Male and Female
Education	Bachelor (minimum)
Managerial Position	Middle – CEO
Expenditure for smartphone operation	300,000 IDR – 3.5 million / month
Type of working time	8-4; 9-5; flexible (24 hrs)
Transport Mode	Public transport, motor cycle, private car
Travel distance range	30 – 100 km, (not include the flight)

Generally, the activities which carried out by the mobile professionals in the office are internal management functions (such as planning and organizing) and administrative work. The typical daily activities outside the office are very diverse. For example, for the CEO and GM, activities outside the office consists mainly of planning meetings, attending meetings and making decisions at the meeting. Mobile professionals from professional lawyer, insurance agent, sales agent, and account representative engaged extensively to meet with their clients, both existing and which are prospective/potential clients. Similar to them, veterinarians and obstetricians work mobile mainly to visit and treat patients, and they are often faced with an emergency situation. Consultants and Contractors, not only need mobile work to visit their client's office to present their plans and explain the progress of their work, but also need to meet with colleagues involved in the project at different locations such as members of the project from construction companies, architects, government offices, administrative, and others. From the interview, CEO, GM, Sales Agent, and journalist are highly mobile.

The utility of their smart phones is high averagely, characterized by high monthly expenses (ranged from IDR 300 thousand to IDR 3.5 million) and a higher frequency of daily use, such as the size of the calls made, emails sent/received/read, messages sent and received, with five of the most commonly used features are the instant messaging, voice calls (dialler), short message (SMS), electronic mail (e-mail) and browser.

Because of its multi-function, all respondents said that they always turn on their smartphones throughout the day and anywhere. Some reasons why they always turn on their phones throughout the day are: (1) to avoid the frustration of the people who contacted him (HD, urban planner), (2) to avoid accusations of 'irresponsible', and to provide security to something urgent and need immediate response (EMD, IT Programmer). During the trip, all of the respondents admitted that this was the most important moment they can always be connected. "Feeling more secure" and "feel comfortable" are other reasons they need to use smartphone during activity out of office. It is because when they were in the office, an alternative device of communication is still possible (e.g. landlines phone, computer).

#### 4.2. Mobile Interaction using Smartphone during Mobile

During planning a business meeting, the smart phone is used to make an appointment and determine whether or not the meeting is done, if the interaction is not too complicated, then communication with a smart phone can replace face-to-face, according to the role of a smart phone as a function of equivalent. The most frequently mentioned word, often repeated by all respondents was the word "coordination" as the intended use of smart phones, both internal and external coordination. Before a business trip, smart phones serve as verification of pre-trip. During a trip for business, mobile phones are used for traffic conditions investigate travel and to monitor the work and often also useful for gathering rearrangement, in the third and during the visit, most respondents use smart phones to coordinate, collect information about work and monitor the work of subordinates in the office during the time of waiting and also use it for personal gain, in order to balance personal life and work.

#### 4.3. Implications of Mobile Interaction using Smartphone on Work Related Movement

Some respondents felt the direct impact in the form of a reduction in the number of trips, such as NKL (GM mining company, 40). Equality interaction functions cause the occurrence of substitution. Some respondents claimed a relationship between cell phone use and the way it works is an indirect relationship, such as (EMD, IT Programmers, 40). For PJR (journalist, 44), the use of cell phones impact changes on the way to work and this then affects to the number of trips he can subtract to achieve the target word. EDP (CEO, 40) is quite different with him, who saw a more dominant complementary interaction with said, "The total trip seems to increase. Because the more information, the opportunity is also more and more. If the opportunity was taken, it appears the addition of new activities, and the edges are increasing the number of my daily trip."

According to the DHD (account representative, 39), "Smartphones really a coordination support, usually if there is an immediately change, then I use a smartphone to match the client's agenda and my activities. Activities and trips can be adjusted". It is shows that the smart phone is a coordination tool that helps in modifying travel in the event of a change of activities and design adjustments in the form of rescheduling. This is consistent with the concept that will be revealed through this research that the phenomenon of mobile interaction based coordination from Ling (2002).

One case for example is Experience of ARD (Lawyer, 55) i.e. "For the plan of the house in the morning I first went to the office, arriving at the office at 8:30, I monitor all the activities of my men, and it was much interrupted by communication with clients, my office 1.5 hours from home, as I monitor the entire work of my taskforce, where he was, who to an extent, then I check whether there is a need administrative approval, again I see my smartphone, whether there are another appointments. I have made schedule for tomorrow. Take a lunch at 12. I have a lunch date with Bank (A) directors at Pacific Place, after I finished my lunch there external meetings around Kelapa Gading, related to business clients in Cargo. I also have appointments with existing clients and he wants me to meet him in his house. I have already known where I will do my activities tomorrow, I already consider travel time". During implementation of his agenda, he use smartphone and make a conversation while mobile with another client. "On the way there was an impromptu incident, "Sir, the man was arrested today". He is a new client. We cannot say "tomorrow", it is not allowed to delay, we cannot delay it. It has to be done at the same day".

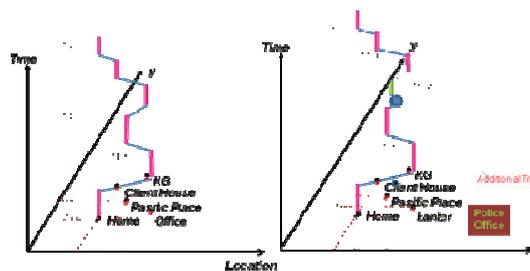

Figure 2. Case for example: adjustment of agenda as implication of mobile interaction and its impact to the total number of trip and travel distance

Based on the experience of the respondents can be described spatial-temporal graph agenda the day's activities and the implementation of the agenda, after the mobile interaction using a smartphone, as presented in Figure 2. It shows that, the number of trip is increasing as well as travel distance, because he inserted an unplanned activity to his agenda during execution, at once he receive the information via smartphone. In this case, indirect effect of smartphone effect to trip is complementary.

Another case is shown from RTP (Lecturer, Consultant, 49), “Yesterday afternoon I was not able to lunch out, because there were so many guests. I had to delay 13-hr meeting appointment to 14.30. They agree. I can leave the office at 14.20, and can conduct meetings with business partners from other company. We're so easy to adjust for any changes. I cannot imagine if I do not use smartphone”. In this case, she did not delete or insert an activity, but modified the attribute of activity, i.e. duration of prior activity and changed the start time of the next activity. Implication of those change, she had to modify timing of trip execution to the second activity. In this situation, smartphone indirectly modify her travel pattern.

Based on the results of the initial survey, although done on a very limited number of samples and a variety of professions, can still reflect a step forward in examining the relationship between the smart phone and the movement, which is an indication that there are more indirect influence, through the process of change in the pattern activities first. Taking into account the results of the interviews it was a real experience mobile professionals, developed situations that may occur and potentially to coordinate-based mobile interaction and how the responses will be analysed. This would then invoke a scheduling respond and subsequent changes in activity and travel pattern. Research paradigm is shown in figure 3.

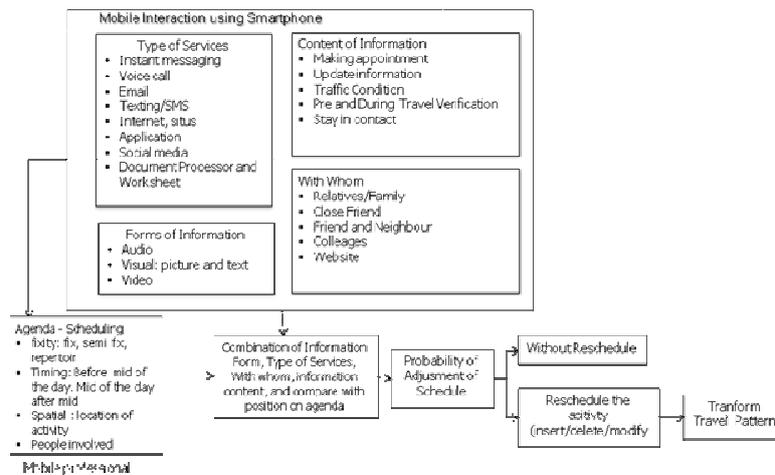

Figure 3. Research Paradigm

Probability of adjustment of schedule (rescheduling) due to mobile interaction based coordination is shown by the respond of combination type of services used, content of Information, Information form, and with whom, to evaluate whether they need to adjust or not by consider position of activity on agenda (fixity, people involved, temporal attribute, and spatial attribute). It need to be examined using main survey (the next stage of research), how the mechanism and when adjustment tend to be done (in what extent of information, which combination of information and activity), how significant the changing to number of trip, travel distance and travel time, and how the change in accessibility that will lead to make addition, modification or deletion of activity, and in turn will affect the increasing, reducing trip number or modification on destination and timing of trip execution.

The next step is to configure the basic pattern changes that occur in the activities as well as on the travel pattern. Illustrations can be made using space-time graph, or by using the comparison between the pattern of pre-planned activities with execution. Using data from a variety of responses to various scenarios situation developed, it is expected to be compiled basic typology of the phenomenon of changes in activity-travel pattern, as the impact when a mobile professional intensively uses smartphone.

## 5. CONCLUSION

This paper is a part of on-going research and will continue to evolve to the next research steps. First insight gained from the preliminary survey shows that: there is a change in the nature of professional work as an implication of the use of mobile smart phones. Smart phones fulfil to meet their needs for support information in order to reduce the uncertainty associated with the contextual constraints faced while being mobile. Smartphone influence when planning activities, before the trip, during the trip and upon arrival at the third location. Mobile Interaction based coordination using smart phone changes in the way of coordination, and potentially led to rescheduling agenda of mobile professional and in turn changes the trip pattern (e.g. travel distance, number of trip). Agenda of mobile professional is more dynamic and flexible. Some professionals feel the direct impact on the reduction or increase in the movement, and on the other have a look at the impact of indirect impact, through their impact on work activities in advance, especially through mobile interaction in nature is coordination.

For the next step, which is to stage collecting of main data to uncover patterns of communication and work practices of mobile professionals to answer questions include: how the patterns of usage of smart phones on a variety of different mobile professional group? How interaction patterns formed by mobile professionals to use a smart phone? How mobile professionals can work positively influenced and how these mechanisms affect their decision to adjust the schedule and changing their attribute business trip? These questions can be answered through an analysis by completion of the next step of this study.

### ABSTRACT

*This paper discusses the selection of transportation modes which plays important role in the growth of economics, politics, social, culture, and defense and security. Urban mobility which has been more varied than the sustainable transport system, will be required to support their activities. MRT (Mass Rapid Transit) is the mass transportation system mode which is based on road or rail (subway/elevated) ranging locally. This mode is generally operated on dedicated lines or potential common pathway, which is used separately and exclusively on schedule and routes that have been designed for the destination of a particular station. MRT can be operated in a variety of traffic conditions, in particular; the MRT is designed to be able to move the large numbers of the people on the same time.*

*Monorail is one of the MRT modes based single rail; the rail/track function is a guide-way of trains, that is usually, installed at elevated more positions from the road surface. That only takes a small area in vertical and horizontal space. The track/rail width is merely as wide as the cabin supported by the several columns along with its track. The body of a train is made more "lightweight" than the conventional train, the elevated rail position that only covered up a small area of the road surface. The noise can be reduced, because the bogie uses rubber tire that runs over a concrete/steel track as its trajectories. The monorail has the uphill and downhill, and small turning radius capability with movement faster than the conventional trains. The designs of a monorail have a high safety level; the bogies have holding design of the rail, so that the risk of the tumble, is much smaller. The noise can be reduced, because the bogie use rubber tire that runs over a concrete/steel track as its trajectories. Risks of bumping against the crossing of rail are very impossible because the rail is positioned on the elevated position instead the road surface. From the funding and investing, selection of this mode will be more interesting and affordable, the construction and maintenance is much easier than the other types of train modes.*

*Constructions of monorail facilities are as an alternative of MRT in Indonesia, to be balanced with the development of another infrastructure, including the human resources development and strengthening of the local industry as its supporters. Involvement of the local industry in the provision of facilities of the monorail considering the costs, quality, capacity, efficiency, and technologies is expected to reduce the cost required and increases the independence of the technology in transportation technology. Since 2006, BPPT in cooperation with PT. INKA (PT. Industri Kereta Api) in Madiun, has begun the activity of design and manufacturing a monorail prototype. This activity is part of the process in strengthening the local industries for support of the design and manufacturing of the national monorail. PT. Pindad in Bandung has the ability in designing and manufacturing an electric motor drive for the train. For a long time, these products have been used by PT. KAI (PT. Kereta Api Indonesia Persero). Moreover, the active participation from the national private company such as PT. MBW in Bekasi, needs to get the support of government, because, they have developed a monorail design of the prototype phase which is ready to be tested (gamma prototype) for multiple projects planning in Indonesia.*

**Keywords:** Monorail, Sustainable Transportation Modes, Mass Rapid Transit

### 1. INTRODUCTION

In some major cities, public transport has become a primary requirement for its inhabitants, so are in Indonesia. Public transportations in Indonesia are very diverse, from such unofficial modes like Ojek, Becak, and Andong to licensed public transport, such as taxi, bus, busway, and train. All of them aimed to serve the needs of the mass public transport which should operate with safe, convenient and inexpensive. The typology of public transportation in Indonesia is grouped based on the mass transit and individual shuttles [1].

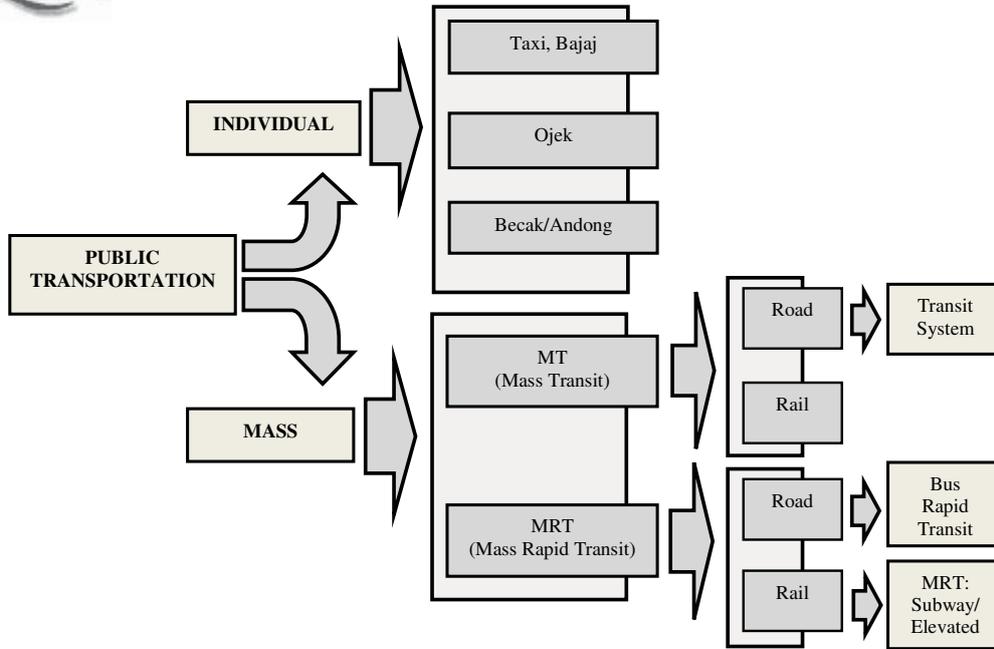

Figure 1: The typology urban public transportation in Indonesia [1]

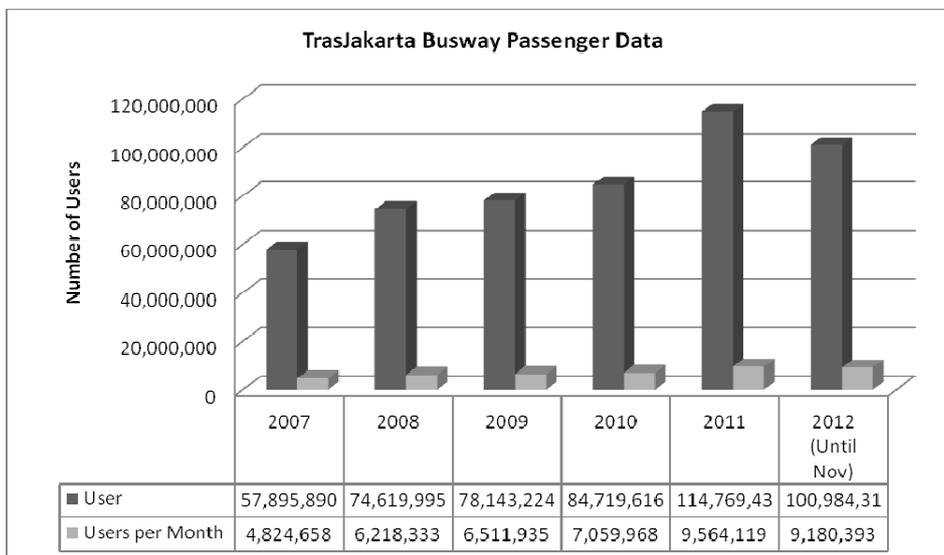

Currently, public transportation in Indonesia has not been able to address the demands of the public in terms of security, comfort, and timeliness to come and arrive on destination. As a result, the people prefer to use individual transportation modes, which have the impact in more increased traffic volume on the road. The survey result of “*The Study on Integrated Transportation Master Plan (SITRAMP)*” in 2004, shows that the economic losses due to congestion in Jabotabek traffic are Rp. 3,0 trillion for operating costs of vehicles; Rp. 2,5 trillion for a loss of time; Rp. 2,8 trillion for the loss of health impact. The same information from the Transportation Agency of Jakarta says that the losses due to congestion if assessed in monetary terms are equal to 12.8 trillion per annum [2].

The need for a safe, convenient, and inexpensive mass public transportation in several major cities in Indonesia is very reasonable, if seen from statistical data, the user of the means of that transportation in Jabodetabek area within last five years kept increasing both the based of roads and rail. Graph growth of the mass-transit users shown in figure 2 and 3.

To answer the problems above, the Jakarta regional government has made the breakthrough by offering to the private to build the mass-transit system in the capital within the package of developments the *Macro Transportation Programs (PTM)* in Jakarta. The pattern will integrate four public transportation system in Jakarta in the form bus priority includes *Bus-way*, *Light Rail Transit (LRT)*, *MRT* and the transportation of lake river and the crossing (in Indonesian: *ASDP/Angkutan Sungai Danau dan Penyeberangan*).

Monorail is one type a mass-transit system offered to the private in 2004. The project is divided into two paths, green line, circular route - *Casablanca - Kuningan - Semanggi* and blue line, the pathways connecting *Kampung Melayu - Casablanca - Tanah Abang - Roxy*. The implementation of this project has been offered into three stages, the first stage, Jakarta corridor with the length of  $\pm 27$  km, for the construction of the Green Line ( $\pm 14$  km) and the path of the blue line ( $\pm 13$  km), the second phase, Jakarta - Bekasi - Cikarang ( $\pm 18-30$  km), and the third phase Jakarta - Tangerang - Karawaci ( $\pm 16-25$  km). However, the project was eventually ended on 20 September 2011.

DataKRLJabodetabek(Source: PT. KAICommuterJabodetabek)

The breakthrough conducted by Jakarta Government at that time was considered against the law Number 13 of 1992 regarding the railway as the bylaw does not enable the private sector as a train operator. The law of that was eventually repaired and replaced by Law Number 23,2007 which provides opportunities to the private entrance as the operator of a train [3].

The construction plan of monorail in Indonesia continues to run, on July 25, 2011, conducted by the signing of a memoranda of understanding among the Government of Makassar, Maros regency and Gowa regency with Kalla Group, to construct a mass transportation systems in Makassar. The construction implementation began in early 2012 and the completion is targeted to be finished no later than 2015. The monorail with more than 30 kilometers length of track will connect between the Hassanudin airport, Karebosi and Gowa.

Another issue was proposed by Kalla Group on August 5, 2011 in Bandung. They plan to build a monorail facility in Bandung with a +30km length path way, the rail will be operated inside and outside the city of Bandung, among the city of Bandung regency of Bandung and City of Cimahi.

Besides Kallagroup, The Mayorality of Surabaya has planned to construct a monorail facility with the +22 kilometers length, connecting the station Sidotopo, Gubeng, Wonokromo, Waru, Sedati and veered toward Juanda. The project is planned to be realized in 2015, in collaboration with the Societe Nationale des Chemins de Fer France (SNCF).

The plan of monorail construction for the mass transportation in Jakarta, was re-launched by the Governor of Jakarta at the beginning of 2013. The construction of the monorail facility will be continuing with the master plans that have been defined in the previous monorail project. This is to keep with the previous master plan for the development of the national railway network and train services the urban Jakarta year 2020 [3].

## 2. MONORAIL AS AN ALTERNATIVE MRT

The public transportation, classified by Joewono and Kubota (2005) [4] is shown in Table 1. The monorail itself is classified into rapid transit. The first application of a monorail for the mass rapid was proposed by Edward H. Anson (1954) [5], and Hermann (1957) [6], who made the feasibility study of monorail implementation as a mass rapid transport for community.

Table 1. Public Transportation Classification by Mode [4]

Public Transportation Class	Type of Mode
Paratransit Street Transit	Ojek, Bajaj, Becak, Angkutan Kota, Taxi Metromini, Reguler Bus, Rapid Bus, Trolleybus, Streetcar, Trem

Semirapid Transit	Light Rail Transit, Semirapid buses
Rapid Transit	Light Rail Rapid Transit, Rubber-tired Monorail, Rubber-tired rapid Transit, Rail Rapid Transit

MRT is a mode of transportation with the most efficient energy consumption in terms of the number of passengers which can be transported. When compared with other modes of land transportation, MRT energy consumption is only about 16% and 10% from the bus and private cars (Table 2).

Table 2: Comparison of energy consumption per km passenger [3]

Transportation Mode	Volume of Transport (persons)	Energy Consumption per km (litre)	Energy Usage (per km passenger)	Rates per Passenger Fuel Price Assumptions Rp 4500/litre (Rp)
MRT	1500	3	0,002	9,00
Bus	40	0,5	0,0125	56,25
Private Car	5	0,1	0,02	90,00

As a MRT, monorail has the following advantages as:

- generally constructed above the road, so it only needs small area to install the supported beam.
- more "lightweight," if compared to the conventional railway, with the elevated rail position, so that only the cover a small surface,
- reducing in total noise, because monorail uses rubber tire to run on the track concrete/steel (pathway),
- running on uphill, downhill, and turning with a radius smaller and faster than the conventional railway,
- more secure, because the train set that holds the rail is not a lot. Risks of bumping against the crossing of railway are very rarely,
- more reliable in construction investment and maintenance operation cost.

Meanwhile the disadvantages are:

- compared with the subway, monorail look take a greater space and hide the panoramic of the city because the monorail is usually built above the ground,
- the passengers could not be evacuated immediately in case of emergency, because they are only excluded at the station,
- the total capacity is still questionable due to the manufacturer design specification which is usually customized with the demand requirement.

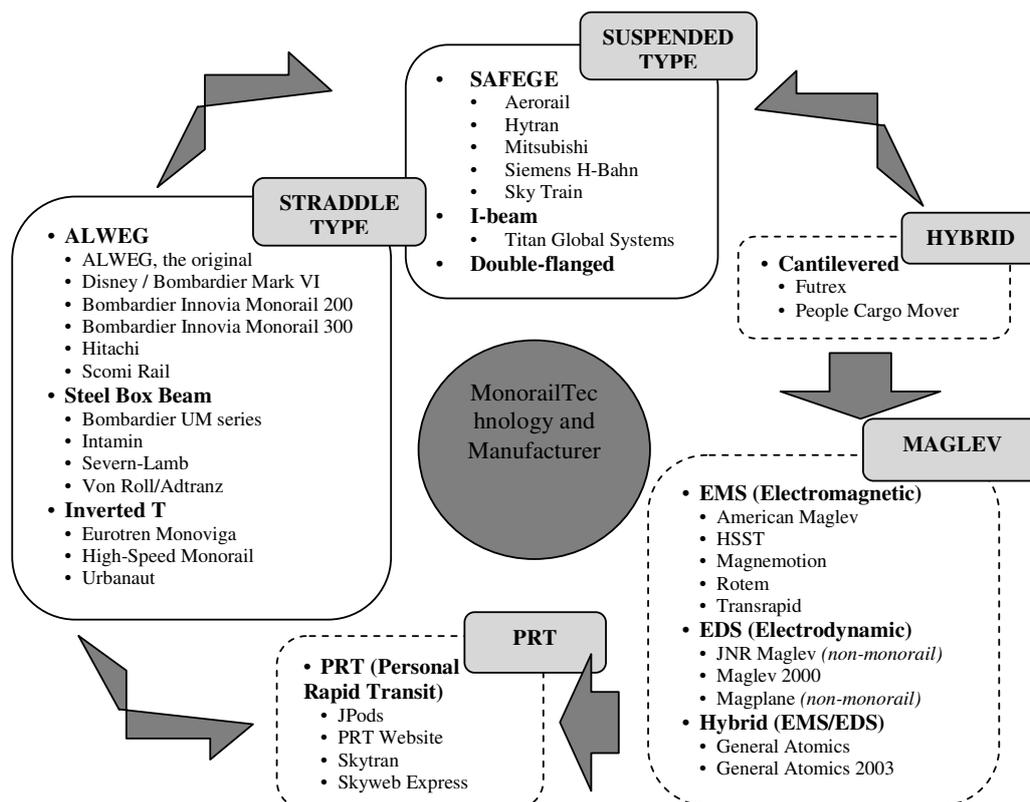

Figure 4: The blockclassificationof the monorailtechnology(source: <http://www.monorail.org>)

### 3. MONORAIL TECHNOLOGY

The monorail is a single rail-based transportation which serves as a pathway. This term is used to describe the system or vehicle that travels over a beam or pathway track. This term is derived from the combination of words mono and rails. The term has been used since 1897, and was often called monorail. The vehicles run on single track first patented by *Henry Robinson Palmer* in the UK with the number 4618 on 22 November 1821[6].

The monorail society defines as follow: "A single rail serving as a track for passenger or freight vehicles. Usually, rail is elevated, but monorails can also run at grade, below grade or in subway tunnels." This definition is somewhat confusing because it does not cover the whole development of the monorail technology. Monorail if classified according to the technology and its manufacturer can be seen in the schematic in Figure 4.

The straddle type of monorail is the most widely applied type because this type has more advantages than others. *Ishikawa* (1999) [7], has made a prediction with various considerations and reasons, that monorail system would lead the mass-transit system in the future. It is based on the possibility of this monorail type to be applied in various types of sizes, adjusted with their needs. This statement was confirmed by his partner, *Kubawara* (2001) [8], who proposed the straddle monorail type with small type for medium distance and for urban transport's solution, with the reasons and advantages in terms of environmental improvements. This concept has been reinforced by *Siu* (2007) [9]. He has proposed analysis of the light weight transit system innovations for the urban mobility in the perspective of the development and planning of sustainable transportation systems.

### 4. MONORAIL DESIGN AND MANUFACTUR, DOMESTIC TECHNOLOGY

The of Existence the plan to build a monorail as a facility system for mass transportation in several major cities in Indonesia must be balanced by the development of its infrastructure, including human resources development and strengthening of the local industry as its supports. Some of the important variables in the process of improving the ability local industries are:

- Cost of manufacturer.
- Quality of product.
- Capacity and productivity.
- Efficiency.
- Technology and skill.

With the involvement of local industries in the provision facility a monorail system which integrate the five variables above in the construction of the monorail system facilities, it is expected that the cost required can be reduced as low as possible, both in the construction and operation phase, especially in a procurement the spare parts supporters at the operation phase.

Figure5: The prototypemonorail bogie developed atBPPTandPT. INKA.

Figure6: The prototypemonorail bogie developed atPT. MBW.

The process of the reinforcement of local industries in upgrading design competency of the monorail system, has been running since 2006. BPPT in cooperation with PT. INKA in Madiun, has been pioneering in design activities of the monorail. The other national private company, PT. MBW has developed a monorail system design. Currently the prototype is ready for testing (unscaled prototyping test). This design will be used in Makassar, which will connect between the *Hasanuddin Airport, Karebosi, and Gowa*.

The design capabilities of local industries of Indonesia in the monorail system design, is the initial capital in the construction of a monorail system which is planned. This is a phase in supports the development of national sustainable transport systems. It is already shown by *PT. Pindad*, with its ability in design and manufacturing an electric motor. It has been currently a supplier of PT.KAI in the procurement of it's driving the electric train (in Indonesian; *KRL/Kereta Rel Listrik*).

The design of a monorail system which is done by the local industry should be accepted and usable by the public, without violating the design criterion, which will become the basis in proving of productfeasibility for a regulator to issue permits road worthy. Currently, these are fundamental problems faced by the local industry in defining that theirproduct design should be proven safe. To answer these problems faced by the local industries, it needs to do an academic study which strengthen its design safely and feasible to use. The results of those studies will be the basis for a regulator to provide the road worthy license for that product.

## 5. CONCLUSION

Construction of the monorail facility is expected to be able to answer problems of urban transport which has an important part of the driving force to the national economy.

Construction of the monorail facility which integrates with other modes of transport will improve efficiency of the national economy.

The Law Number 23 of 2007 on Railways has encouraged the participation of local governments in the implementation of railway transportation in the area. For that, the local government should be able to use this momentum to build transport facilities in the areas many as possible to accelerate the pace of economic growth in the region.

In the framework of encouraging participation of the local government in the administration of the mass transportation, a few things that need to be prepared are as follows:

- The involvement of the local government, in the planning process with the spatial structure plan and the availability of land.
- The involvement of the local government, in the investments, constructions, and operations, both of intercity and urban services.
- Strengthening the local industry as its supporter, in the form of technological support, regulations, which can strengthen its involvement.

## ACKNOWLEDGEMENTS

This research was fully supported financially by research grants from DRPM-UI (*Directorate of Research and Community Services, Universitas Indonesia*) and *PT. MeluBangunWiweka*. The authors also express sincere thanks to Mr. Didi for their kind assistance with the manuscript of this paper.

## ABSTRACT

*In RTRW Banyumas, Purwokerto develop as a strategic area for economic growth and urban development southerly direction to reduce pressure woke cultivation in the north Purwokerto. Teluk housing in South Purwokerto built in 1985 with changes of land use is residential to business units by 10.17%. Trip generation are light vehicle 149 vehicle, 1250 motorcycles and 87 slow vehicles and people 1710 occur at 6-7 Am. Classification of regional development are large-scale and the traffic impact analysis considered class III. Trip distributions from Perumnas Street to Sultan Agung Street are 69% and Suwatiao Street 31%. The purpose of travel is work by 10-20 km travel distance and the average travel time of 10-20 minutes. Mode used is 63% motorcycles, cars 27%, 8% public transport and "becak" 4%. Traffic assignment in 1984, housing road around have VCR very low. In 2012 VCR increased but Suwatiao Street up to 0.67. After housing in 2012 VCR are be increased but Suwatiao Street decreased. Teluk intersection VCR 0.74 with an average delay 55.17 second per smp with length of queue 57 meters at the Perumnas Street so as to reduce the impact of traffic need management and traffic engineering.*

**Key words:** *Traffic impact, Development, Housing*

## 1. INTRODUCTION

Easiness of investor in investment and the needs of livable homes are encouraging investors to invest in housing development. The change of land use is field into housing that will be increase the demand of trip in the fulfillment of their needs, such as work, school or campus, and into the shopping center to meet their needs. Varies trip generation housing will be affect the traffic assignment around the road especially with the fluctuation in peak hour that varies every day. This movement, if left to the rate of accumulation will be cause changes in the road performance. Besides that the high level of vehicle ownership and support facilities poor performance can be traffic jump. Based on research are use vehicle on the road in Purwokerto of motorcycles reaches 87.75%, light vehicles 11.99%, and medium weight vehicle of 0.25%. (Juanita, 2011).

Inconsistency in the development of land use on urban spatial system of the plan is not followed by changes in the transport network plan will result in the network is not able to accommodate the movement by the system activity, causing problems such as congestion, delays and queues of vehicles that safety and fluency traffic is reduced. Therefore, the development of land must be accompanied by an increase in good transport facilities so that land use changes are beneficial and efficient as optimal as possible. Under these conditions, the traffic impact analysis is required to save the conflicts of land use changes and transportation interests.

## 2. BASIC THEORY

### 2.1. Traffic Impact Analysis

Government Regulation No 32 in 2011 stated that traffic impact analysis is a series of studies on the traffic impact from the development center, residential, and infrastructure that aims to determine traffic impact that will be cause of security, safety, discipline and traffic fluency and road transport.

Department of Public Works stated that the development of criteria that must traffic impact analysis as follows: a) Development of the planned direct access to arterial road. b) If the planned development of the area does not have access to the arterial road, then apply the following criteria: 1) the scale of activities and / or planned effort is greater or equal than the minimum size of development set. 2) The development of area is expected to trip generation greater than or equal to 100

persons per hour trips. 3) There are some areas development plan that access to the road same, so the cumulative criteria in point a, b. 4) The development of area direct access to the road which has degree of saturation greater than or equal 0.75 and / or if the junction nearest to location of development area has degree of saturation greater than or equal 0.75. While of the expected trip generation caused of development area to classified four that are; 1) the development area of small scale, expected will result trip generation less than 500 trip persons per hour. 2) The development area of medium scale, expected will result trip generation between 500 to 1000 trip persons per hour. 3) The development area of big scale, expected will result trip generation greater than 1000 trip persons per hour. 4) The development area of medium or big scale, that done step by step with the implementation in a few years.

## 2.2. Transportation Planning

Transportation planning consist of four step are trip generation, trip distribution, modal choice and traffic assignment. Trip generation is step of expected some of generate and attraction to land use of zone. Trip generation is dependent of two aspects that is type of land use, amount of activity and intensity of land use. The higher of level of land use then will more higher traffic resulted. Trip distribution is the function of land use and transportation. The pattern of trip distribution between origin and destination of zone is from two aspect that occured simultaneously between location or intensity of land use that result of traffic and spatial separation. The interaction of two land use can be result movement persons and / or goods. Modal choice exist because of the interaction two land use then occur of traffic. For meet this conditions, there will be a step to determine whether modes using. The first of modal choice is walk or using car. If using car must be choice private or public transportation. Traffic assignment for people who use private transportation will be concern travel time and other factors such as security, safety and cost. But people use public transportation will be choose the shortest route and the consideration of cost, safety and security.

## 3. METHODOLOGY

The methodology of research is done assesment of literature to gain approaches and regulations concerning traffic impact analysis. The collection of data divided two data are secondary and primary data. Secondary data are map of land use study area, residential data is covering a land area and the number of housing units, The General Plan of City, road and traffic data and population. Primary data are through a direct survey that is road geometric data, traffic volume data of roads and intersections, trip geberation and attraction data. Than make an analysis trip generation, trip distribution, modal choice, traffic assignment and conduct traffic impact analysis before and after of housing.

## 4. RESULTS AND DISCUSSION

### 4.1. Characteristics of Study Area

Banyumas district is located direct border with four districts that are East with Purbalingga, Banjarnegara, and Kebumen District, West with Cilacap and Brebes Districts, North with Tegal and Pemalang Districts. The area study of research is Teluk Housing that located in South Purwokerto since 1985 which is intended for residential area of development area V. Regulation of Banyumas District in No 18 in 2005 about Spatial Plan of Banyumas is a guideline in utilization of space that stated Purwokerto into a strategic area of growth economical and Sub Regional Development I. In Spatial Central Java Province, Purwokerto will be plan to urban areas serving as provincial scale of activity or some cities / districts in southern and west part of Central Java. The reviewing of rapid population growth, then development policy of Purwokerto is southerly direction which aims to reduce the pressure in the wake cultivations in North Purwokerto which is a water catchment and conservation buffer of Slamet Mount. Besides that development of south is aim to distribution of urban development evenly.

### 4.2. Trip Generation Teluk Housing

Total of trip generation and trip attraction based on survey in 9-10 May 2012, the result of survey is Table1. From Table 1, the condition peak hour is 6 – 7 AM with total vehicle 1399 per hour and 1710 persons per hour. The resulting trip rate in peak hour is 6.995 vehicle per hour each 100 square meters total area.

### 4.3. Determination of Class Traffic Impact and Area Study

Total trip generation of 1710 persons per hour are classified the development area of big scale and traffic impact analysis class III. Then limitation of area study is minimal intersection between the collector to collector roads either signal or not, while the road is a road accessed by the development area within a radius of 2 km from the outer development site. Conclusion of intersection and road study is Teluk intersection that is a node of Sultan Agung Street, Suwatio Street and Perumnas Street, while roads surveyed are Sultan Agung Street and Suwatio Street are primary collector road functions; Lesanpura Street and Perumnas Street are primary local road functions.

Table 1 Total of trip generation Teluk Housing

Time	Heavy Vehicle	Light Vehicle	Motor Cycle	Total (vehicle/hour)	Vehicle Slow	Person
6-7 am	0	149	1250	1399	87	1710
7-8 am	4	158	1187	1349	117	1699
8-9 am	7	116	923	1046	80	1293
11-12 pm	21	95	598	714	25	861
12-1 pm	4	112	678	794	69	1027
1-2 pm	11	84	732	827	51	993
4-5 pm	6	128	905	1039	75	1300
5-6 pm	0	93	815	908	43	1091
6-7 pm	0	62	659	721	24	838

Source: Survey, 9 – 10 May 2012

#### 4.4. Trip Distribution

Trip distribution from Perumnas Street to Sultan Agung Street total is 69 % and to Suwatio Street is 31 %. The purpose routines are to work 55 %, business 25 %, to school or campus 12 % and to market 9 %. Travel distance to routine less than 10 km reaches 55%, between 11 km-20 km by 25%, between 21-30 km by 13% and more than 30 km by 9%. Travel time average is 10-20 minutes by 65%, between 20-30 minutes by 20% and between 30-40 minutes by 15%.

#### 4.5. Modal Choice

Modal choice based on survey using motorcycle 63 %, cars 27 %, public transport 8 % and rickshaw 4 %. The ownership of motorcycles one vehicle 46%, two vehicles 44%, more than three vehicles 2 % and do not have a motorcycle 3 %. While car ownership is 34 % one car, two cars by 14 %, more than two cars 2 % and 50% did not have a car.

#### 4.6. Traffic Impact Analysis

##### 4.6.1. Traffic condition before and after housing

Traffic condition before and after housing are based on primary and secondary survey presented in Table 2 which shows the VCR after the development is less than the critical VCR (Volume Capacity Ratio).

Table 2 Road VCR before and after housing

Access Road	Before Housing		After Housing 2012		VCR Critical
	1984	2012	Nothing trip generation	With trip generation	
Lesanpura	0.198	0.323	0.405	0.49	< 0.75
Sultan Agung	0.126	0.207	0.431	0.531	<0.75
Suwatio	0.409	0.667	0.395	0.443	<0.75
Perumnas	0.246	0.400	0.441	0.643	<0.75

Source: data analysis 2012

Teluk intersection have three phases, phase 1 and 2 are green time 14 second with inter green 2 second, while phase 3 is green time 11 second and inter green 8 second. Intersection performance in 2012 is shown in Table 3.

Table 3 Intersection performance in 2012

Access Road	Volume (pcu/hour)	Capacity (pcu/hour)	Degree of Saturation	Intersection Delay (second/pcu)	The Average Intersection Delay (second/pcu)
Suwatio (N)	206.1	277.61	0.74	53.26	55.17
Perumnas (S)	241.7	325.56	0.74	53.33	
Sultan Agung (E)	403.7	543.77	0.74	55.11	
Sultan Agung (W)	630.4	849.13	0.74	56.53	

Source: data analysis 2012

##### 4.6.2. Evaluation Traffic Impact Analysis

From Table 2, the traffic condition after the housing is still below the critical VCR. The category level of service B is Lesanpura Street, Sultan Agung Street and Suwatio Street, while Perumnas Street in category C. For Teluk intersection by VCR 0.74 is nearing the critical VCR 0.75 with the average intersection delay approaches one minute so need resetting time of traffic light to be a long queue from Perumnas Street and Sultan Agung Street. The resetting times are all phases in green time 14 second, with inter green 3 second but in the phase 3 by 5 second. So that performance intersection is shown Table 4.

Table 4 Intersection performance resetting

Access Road	Volume (pcu/hour)	Capacity (pcu/hour)	Degree of Saturation	Intersection Delay (second/pcu)	The Average Intersection Delay (second/pcu)
Suwatio (N)	206.1	317.65	0.65	20.79	21.89
Perumnas (S)	241.7	372.52	0.65	20.64	
Sultan Agung (E)	403.7	622.19	0.65	21.86	
Sultan Agung (W)	630.4	971.59	0.65	22.76	

Source: analysis 2012

## 5. CONCLUSIONS

Based on the analysis it can be concluded as follows:

1. Teluk Housing in view of urban spatial of land was appropriate functions.
2. Teluk Housing entry into the development area of large scale and traffic impact analysis class III.
3. The resulting of trip rate generation is 6.995 vehicles every 100 meter square at peak hour.
4. The impact of housing development will be increase on traffic assignment on the surrounding road network but still below the critical VCR. While the Teluk intersection required of resetting time of traffic light.

## ABSTRACT

*The development of environmental friendly road need to be considered at recent years, given the material used for the construction of a road largely derived from natural resources that can not be renewable. Sustainable practices can be used as the basis of assessment of environmental friendly road design and construction. Therefore, there should be a research that discussed the aspects of sustainability as an example case is Cemoro Sewu Road Construction Project. The research was carried out by conducting field studies at the location of case study, dissemination of technical questionnaire, the data collection and documents relating to the Cemoro Sewu Road Project. Data related to the road project, divided into a number of assessment criteria based on the categories that exist in Greenroads Rating System. The end result of this assessment in the form of mock certification from the Cemoro Sewu Road Project that can serve as input to the local government to plan a sustainable development. Based on the analysis of the assessment of each criterion, total earned credit for Cemoro Sewu Road Project by 36 points from 8 of the 11 criteria in the categories of Project Requirements that meets the criteria. This suggests that the non-fulfillment of all the requirements of existing projects on Project Requirements category, indicated that Cemoro Sewu Road Project can not be certified according to the provisions of Greenroads Rating. If all project requirements are met, then the Cemoro Sewu Road Project can obtain certification level that is "Certified".*

## Keywords

*Greenroads Rating System, Sustainability, Mock Certification*

## 1. INTRODUCTION

Sustainable development of the system becomes an important topic in the field of engineering and construction, road work being substantial part for further follow-up. Sustainable practices can be used as the basis of assessment of the environmentally friendly design and construction. Greenroads Rating System provides parameters that can be used to consider the sustainability of the design and construction of a road project. Greenroads first introduced in 2007 as an original concept in the form of credit linked to the six preliminary case study. Since then, the scoring system has undergone significant revisions in the opinion of professional stakeholders with empirical evidence on the field. Basically, this assessment system can be used to help people and agencies in making decisions on planning better sustainable way. Government as regulator that plays a role in the development and the construction industry must think of ways to reduce the consumption of materials used in construction projects. Cemoro Sewu. Road as the road connecting the region of Karanganyar and Magetan in Java Island, Indonesia selected on this research in order to give a little overview assessment of road projects in Indonesia by mock application of Greenroads Rating System v.1.5.

## 2. LITERATURE REVIEW

Clark [1], explaining that the design and construction of the road is a complex process that requires experienced professionals to work in it. Environmental assessment process is an important part of decision making in the construction of a road. Decisions will be made to describe the project as a whole with an effective way to determine the expectations and needs of decision-makers based on the limits of space and time. In addition, the feasibility of environmental impacts can also be made based on the most reasonable choice or based on the total cost of the necessary and meaningful and comprehensive benefits. According to Caldwell [2], road construction and maintenance activities get a tremendous demand on a national scope, especially financial resources. But in fact, the practice of design and construction of the current path is not always systematic or holistic manner to address the environmental impact or the quality of the environment occurs. The concept of environmental impacts or effects caused by road construction on the surrounding conditions are often ignored. It can be caused by three

common problems, namely: (i) Decision makers do not understand the complexities of ecosystems and how human-made highway context of sustainable roads. (ii) Decisions are often taken sometimes transcend conventional wisdom or existing traditional assumptions. (iii). Decision makers fail to understand that humans have limited control in the management of ecosystem resources [3]. Muench, et al. [4,5], defines Greenroads Rating System as an assessment system based road project award points system for approval as an option of sustainable practices and can be used to certify projects based on the total value of criteria that are certified.

### 3. RESEARCH METHOD

The method used in this research is to conduct a field study in the form of directly to the location of research survey, dissemination of technical questionnaire and the data collection and documents relating to the Cemoro Sewu Road Project. Distribution of questionnaires carried out to the two parties related to the Directorate General of Highways Central Java as Owner and PT. Pancadarma Puspawira as the General Contractor. All data related to the road project, divided into a number of assessment criteria based on the categories that exist in Greenroads Rating System. Based on the technical and data processing surveys and questionnaires, then the ranking will be obtained for mock certification from the Cemoro Sewu. If the results of research on the mock assessment of Greenroads Rating System at the Cemoro Sewu deemed applicable, the assessment results can be used as input to the government and the contractor to plan more sustainable road construction project.

### 4. ANALYSIS

#### 4.1 Criteria categorized by Greenroads

##### 4.1.1 Project Requirements

Based on the calculation and analysis on each of the criteria in this category, obtained 8 of 11 criteria that meet the requirements. 3 criteria that do not meet the requirements are:(i) Noise Mitigation Plan, (ii) Waste Management Plan, (iii) Educational Outreach. As an example, the calculation of energy requirements and CO<sub>2</sub> emissions in road construction projects of Cemoro Sewu using Software "Palate v.2-2" as listed in Table 1.

Table 1. Energy requirement and CO<sub>2</sub> emission of Cemoro Sewu Road

Palate V.2-2		Energy required [GJ]	CO <sub>2</sub> Emission [kg] = GWP
<b>Initial Construction</b>	Materials Production	267.096,5	18.297.543
	Materials Transportation	337.635,2	23.292.953
	Equipment	12.890,0	889.263
<b>Maintenance</b>	Materials Production	26,7	1.931
	Materials Transportation	7,0	482
	Equipment	0,3	18
<b>Total</b>	Materials Production	267.123,3	18.299.474
	Materials Transportation	337.642,2	23.293.435
	Equipment	12.890,3	889.280
<b>Total</b>		617.655,7	42.482.190

Figure 1 shown the need for energy consumption during construction activities, that is very high as calculated of 617,621.70 GJ compare to at the maintenance period which is only 34 GJ.

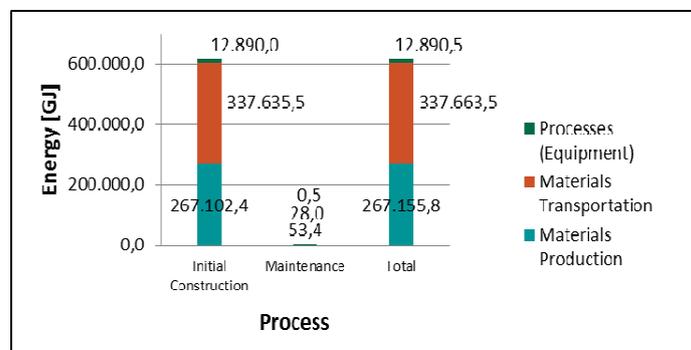

Figure 1. life Cycle Energy Consumption

Figure 2 indicated that the CO<sub>2</sub> emissions during the construction period is very high, that is 42,479,759.00 kg when compared to the maintenance period which is only 2,431.00 Kg.

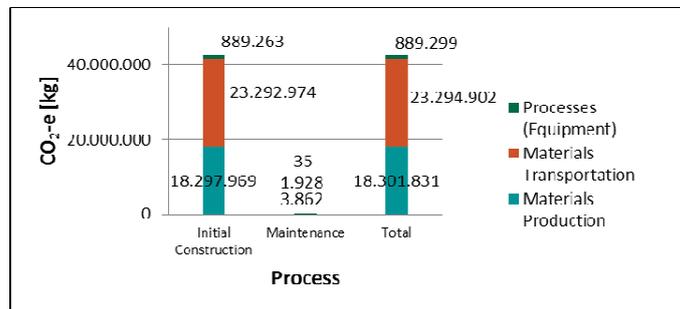

Figure 2. Life Cycle CO<sub>2</sub>-e Emissions

#### 4.1.2 Environment and Water

Based on calculations, Vegetation Site is only the criteria that can be processed for the assessment of the 8 criteria available on this category. A total of 3 points earned by Cemoro Sewu Road Project for this category. Cemoro Sewu Road Project has met the requirements for applying the criteria of site vegetation with 3 elements of the following requirements: (i) Using non-invasive plants as the site vegetation. (ii) Does not require additional irrigation water supply after the construction is completed. (iii) Using native plant species that previously existed in the project.

#### 4.1.3 Access and Equity

Fulfillment 5 of 9 criteria presented in this category, making Cemoro Sewu Road project gets big enough additional points which is 16 points. As an example the calculation of Pedestrian Access. The supporting infrastructure needs such as roads (sidewalks) and pedestrian bridges rated very important existence. It allows residents to enter and exit the area. Cemoro Sewu road project gives access to the pedestrian bridge located on Dawuhan Bridge I and II as well as in places such as at the Km. 1 +600, 1 +700, 2 +100, 2 +250, 2 +900, 3 +000, 3 +260, 3 +300 and some other places. The amount of the credit for this criterion is 2 points.

Figure 3. Site vegetation

#### 4.1.4 Construction Activities

There are three criteria from 8 criteria of construction activities category such as Quality Management System, Paving Emissions Reduction, and Warranty Contractor that meet the requirements. A total of 6 points to additional value for Cemoro Sewu Road Project of this category.. As an example the requirement of Quality Management System. PT. Pancadarma Puspawira as the General Contractor which is the respondent of this research has been certified for the Quality Management

System in accordance to the International Standards Organization (ISO) 9001:2008 with the following Standard: BS-EN-ISO 9001:2009 Certificate Number: AJA04/7859 Validity: August 3, 2011 to August 9, 2014. Based on the presence of ISO documentation, then the amount of credit for this category is 3 points.

Figure 4. Pedestrian Access

#### 4.1.5 Materials and Resources

Based on the calculation, only the category of Regional Material that can be processed for assessment. Total points earned is 5 for Cemoro Sewu Road Project for this category. Example for calculation of points from this criterion is for using regional materials. The crush stone material taken from the district of Sentolo at Yogyakarta province. The distance between project and material quarry sources is  $\pm 130$  km or about 81 miles from the project site, thus meeting the qualification requirements of 5 points.

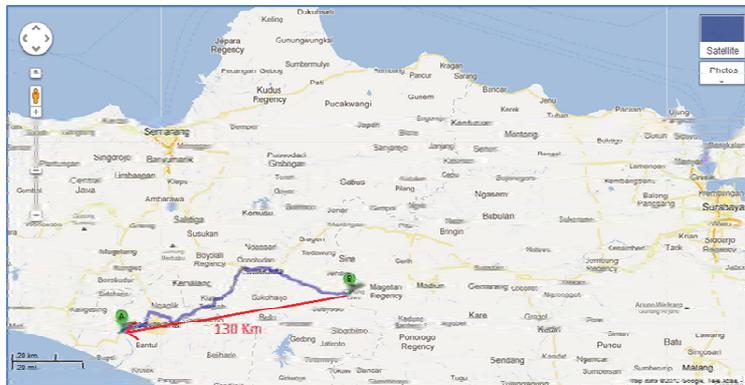

Figure 5. The location of materials quarry

#### 4.1.6 Pavement Technology

Based on the analysis and calculations, only the criteria of Long-Life Pavement and Pavement Performance Tracking are eligible. A total of 6 points to additional value for Cemoro Sewu Road Project of this category. The example of points determination for pavement Performance Tracking is the documentation manage by Directorate General of Highways as a service user Sewu Cemoro Road construction that has held the documentation about the performance of the road.. The documentation consist of documentation of the construction period, the maintenance period until the documentation of repairs of the road. One example of this form of documentation as indicated on the document Provisional Hand Over (PHO) No: 55/BA/BKGG/XII/2009.

Table 2. Total point of Greenroad Certification

No.	Criteria	Point
-----	----------	-------

EW-Site	Site Vegetation	3
AE-1	Safety Audit	2
AE-3	Context Sensitive Solutions	5
AE-4	Traffic Emissions Reduction	5
AE-5	Pedestrian Access	2
AE-8	Scenic Views	2
CA-1	Quality Management System	2
CA-6	Paving Emissions Reduction	1
CA-8	Contractor Warranty	3
MR-5	Regional Materials	5
PT-1	Long-Long life pavement Life Pavement	5
PT-6	Pavement Performance Tracking	1
Total		36

## 4.2 Certification

Based on the analysis they are only 8 of 11 criteria that meet the requirements. So it is concluded that Cemoro Sewu Road Project has not met the requirements to be certified. To obtain the real certification from Greenroads, Cemoro Sewu road projects should review and consider to met all the criteria based on the results of the assessment on each criterion. Table 2 shows the point of each criterion that met the requirements. However, if all the criteria met and based on the total points gain by Cemoro Sewu road project with a points total of 36 points, it could be categorized as "Certified".

## 5. CONCLUSION

1. Cemoro Sewu Road Project does not meet the requirements to be certified according to Greenroads rating system because there are only 8 of the 11 criteria that met the project requirements.
2. This project has fulfilled some criteria as follow:
  - a) Environment and Water: 3 Points
  - b) Access and Equity: 16 Points
  - c) Construction Activities: 6 Points
  - d) Materials and Resources: 5 Points
  - e) Pavement Technology: 6 Points

The total points earned by Cemoro Sewu Road project is 36 points. If all criteria in the category Project Requirement have been met, then the Road Cemoro Sewu entitled to certification standard as certified.

### ABSTRACT

*The material commonly used for flexible pavement surface layer is asphaltic concrete with various compositions and procedures. This research aim is to know Hot Mix Asphaltic Concrete behavior on surface pavement with compares the performance of both kinds of aggregate gradation, Superpave and Bina Marga fine gradation mixtures. Performance evaluation conducted on the characteristics of Marshall, dynamic stability using wheel tracking devices and roughness of mixture using British Pendulum Tester. Conclusions after analyzing data obtained that fine gradations of Bina Marga needs more asphalt to covered a whole surface because it has more fine grain. Flow smaller and stability is greater than the Superpave with a majority of coarse aggregate. However, this difference was not significant. Resistance to permanent deformation of asphalt concrete mixture with Superpave gradation is much larger, but the roughness is smaller, which means the Superpave surface rougher than Bina Marga. With the advantages of each mixture, it is recommended to choose the mixture that really fit with the field characteristics of the traffic and climate.*

**Keywords:** *Bina Marga, Marshall characteristic, permanent deformation, roughness, Superpave.*

### 1. INTRODUCTION

The commonly used method for flexible thick pavement design in Indonesia is based on design methods empirically developed by the AASHTO. The material commonly used for flexible pavement surface layer is asphaltic concrete with various compositions and procedures. In the case of asphalt concrete, road construction projects in Indonesia usually utilize specific asphalt concrete layer (*laston*) for AC-WC (Asphalt Concrete – Wearing Course) surface layer in accordance with the General Specifications of Bina Marga, Sixth Division, Asphalt Pavement, 2010.

On the other hand, the United States (through State Highway Research Program, SHRP) has developed specifications intended to fix the performance of pavement serving heavy traffic load, known as the **Superior Performing Asphalt Pavement** (Superpave). As it is focused on the enhancing of resistance, both the amount of fine aggregate and the use of asphalt decrease; consequently, it is more economical whereas in Indonesia, the Bina Marga provides two kinds of mixture for surface layer (Wearing Course) with both fine and coarse gradation. In comparison with the Superpave gradation, the amount of fine grain is higher, hence, the mixture is more dense and flexible; however it needs more asphalt.

Superpave is created in accordance with the performance of asphaltic mixture and the condition of the environment in order to improve the mixture's resistance to rutting, fatigue, thermal crack at low temperature, humidity, and material fatigue. The SHRP Program research on asphaltic Superpave carries three goals: investigating the reason why some kinds of pavements have good performance while some others don't; developing tests and specifications for superior material that is more durable than the current pavements there are; giving new alternative specifications (TRB Superpave Committee, 2005). Determining the resistance of superpave mixture comes from series of compaction that gives a more vibrating effect (gyratory) compared to compaction, so that it is closer to the conditions on the field as a representation of the vibration of vehicle wheels.

The design of the mixture is based on the Marshall Method, invented by Bruce Marshall in 1939 and standardized by both the ASTM and the AASHTO through various modifications; the ASTM D 6927-06 or the AASHTO T-245-90. The basic principle on the Marshall Method mixture design consists of choosing the optimal asphalt intensity that is in accordance with stability and flow testing with analyzing the density and pores of solid mixture that is form (Sukirman, 2003). The Marshall Test intends to measure the stability of asphaltic and aggregate mixture to plastic flow. The stability of the mixture is measured by the sample's resistance to a certain amount of compaction as a representation of traffic load planned to go through the pavement. Nowadays the Marshall Test is the most commonly used test in Indonesia. This is due to the simplicity of the equipment and the practicality of mobilization.

Finding the resistance of the mixture to permanent deformation is tested using Wheel Tracking Machine in laboratorium. This test is intended to measure the ability of asphalt concrete withstanding traffic load repetitions. Deformation values obtained from the depth of the specimen surface is formed due to load repetitions

This research aim is to know Hot Mix Asphaltic Concrete (HMA) behavior on surface pavement with compares the performance of both kinds of aggregate gradation, Superpave and Bina Marga fine gradation mixtures, which are made by the Marshall Method. Traditional compaction through the Marshall Method is more widely known compared to gyratory compaction; therefore, the availability of the equipment is more possible. After going through initial testing by the Marshall Test, it is then continued by measuring the values of deformation speed and dynamic stability using wheel tracking device and the roughness of the mixture using the British Pendulum Tester.

The research was carried out to the effort of designing an efficient, flexible pavement resistant to the effects of loading and climatic influences. The almost –always- jammed traffic conditions in Jakarta, coupled with the extreme heat as well as days-long floods submerging roads, and the overloading that always occurs on the main road, cause roads to be more easily deteriorated despite still being in its service life. It prompted the start of this research in an effort to contribute to the development of applied science and solutions to infrastructure problems.

## 2. METHODOLOGY

Research on the performance of two kinds of asphalt concrete aggregate gradation is done by using Marshall method as preliminary data. The values of deformation speed and stability are obtained with the wheel tracking as a destructive test and roughness value by British Pendulum Tester. In different ways, both initial tests simulate the resistance of mixtures to repeated loading. All of tests are performed in the laboratory. It is begins from Marshall test to obtain mechanical properties of two kinds of hot mix asphalt, which uses stone dust 7% with optimum asphalt percentage 5,90% for Bina Marga, and for Superpave 5,65%.

Samples are made according to the best mixture of asphalt optimum percentage with Marshall's method before. Wheel tracking test is done with 30 cm x 30 cm x 5 cm samples, which are passed repeatedly by the examiner wheel made of hard rubber that has a 20 cm diameter by wide wheel tread 5 cm ± 0.1 cm and loaded 20 N ± 5 N.

Measuring the value of roghness in the laboratory is done using the British Pendulum Tester (BPT) based on ISO 4427 (2008). With a simulated vehicle speed of 60 km/h, the skidding value is obtained from the result of friction between the rubber of the pendulum with the surface of the mixture. BPT will indicate the British Pendulum Number (BPN) that converted using the formula  $MuN = 1,017BPN - 20,9$  based on ISO 6748: 2008. The roughness values obtained by the unit μm.

## 3. DISCUSSION

### 3.1 The physical properties of aggregate

Table 1 and 2 shows the results of testing the physical properties of coarse and fine aggregate. Aggregate characteristics are in accordance with the requirements. Test results with specific gravity greater than 2.5 indicate that the aggregate can be used on roads with large volumes of traffic and high temperature.

*Table 1. Coarse Aggregate Testing tabulation*

No	Test	Results	Requirements
1	Apparent Relative density	2,596	Min 2,5
2	Bulking relative density	2,549	Min 2,5
3	Moisture content, %	1,812	Min 3
4	Unit weight without voids kg/m <sup>3</sup>	1508,52	Min 1200

5	Unit weight with voids kg/m <sup>3</sup>	1465,75	Min 1200
6	Material finer than 200 µm, %	1,75	-

*Table 2. Fine Aggregate Testing tabulation*

No	Test	Results	Requirements
1	Apparent Relative density	2,546	Min 2,5
2	Bulking relative density	2,518	Min 2,5
3	Moisture content, %	2,73	Min 3
4	Unit weight without voids kg/m <sup>3</sup>	1577,49	Min 1200
5	Unit weight with voids kg/m <sup>3</sup>	1503,10	Min 1200
6	Material finer than 200 µm, %	2,60	Min 8

The equation to obtain the percentage of each aggregate is done as follows:

$$Y = Y_a \frac{a}{100} + Y_b \frac{b}{100} + Y_c \frac{c}{100} \quad (1)$$

$$a + b + c = 100 \% \quad (2)$$

Where,

Y : percentage of each aggregate from the definitive hole of the curve that uses aggregate

Ya : ordinate of the curve aggregate A on the same hole with sieve Y

Yb : ordinate of the curve aggregate B on the same hole with sieve Y

a,b,c : percentage of each aggregate on the same hole with Y

Results from equation (1) and (2) listed in table 3, table 4, and figure 1 and figure 2 below

### 3.2 The physical properties of asphalt

Tests on physical properties of asphalt are needed to determine whether the characteristics of asphalt match field conditions where the mixture will spread out, and as preliminary data for the design of asphalt concrete. Asphalt specific gravity, penetration, softening point, ductility and flash point value are a description of the asphaltene and maltene composition which determines its adhesiveness, generally tested at a temperature of 25<sup>0</sup>C, except for softening point at a temperature of 5<sup>0</sup>C and the flash point is obtained in accordance with its resistance when heated until it ignites and then burns. Table 5 shows the results of testing the physical properties of asphalt in accordance with the requirements of Highways Department of Public Works, 2010 Edition. According results of the testing, it is obtained that asphalt is included in the group with a 60/70 penetration and minimum 48<sup>0</sup> C softening point; suitable for roads with large traffic volumes and high temperature of road surface.

Table 5 Asphalt testing tabulation

No.	Laboratory Test	Specification		Result	Information
		Min	Max		

1	Penetration	60	70	64	Qualified
2	Specify Gravity	1	-	1	Qualified
3	Softening Point (°C)	48	58	49	Qualified
4	Burning Point (°C)	232	-	310	Qualified
5	Loss on Heating (TFOT) (%)	-	0,8	0,145	Qualified
6	Solubility (%)	99	-	99,59	Qualified
7	Ductility (cm)	100	-	130,5	Qualified

### 3.3. Designing mixture

From the aggregate blending data estimation, asphalt percentage is calculated. In preliminary tests to determine the characteristics of the mixture, the obtained optimum bitumen percentage is 5.9 % for Bina Marga Specification, and 5.65% for Superpave Specification, obtained through the following equation:

$$P_b = 0.035 (\%CA) + 0.045 (\%FA) + 0.13 (\%filler) + K \quad (3)$$

Where,

P<sub>b</sub> : percentage of binder

CA : % coarse of aggregate retained no 8

FA : % fine of aggregate passed no 8

K : constants from type of hot mixed asphalt

The same mixtures with various aggregate filler are then used on this test. Trial mix formula is applied to get a precise optimum asphalt percentage of asphaltic concrete mixture which is then determined based on a number of different asphalt percentages to certain aggregate graded by trial and error.

### 3.4. Marshall Stability Test

Figure 3 and 4 shows that Marshall Stability and Void In Mixture of Bina Marga are higher than Superpave's. However, Superpave's Void Filled with Binder, Flow and Marshall Quotient are higher than Bina Marga. Bina Marga has lower void filled explained that because of higher fine aggregate content. So, surface area covering with same amount of asphalt larger and affects higher asphalt void in mixture

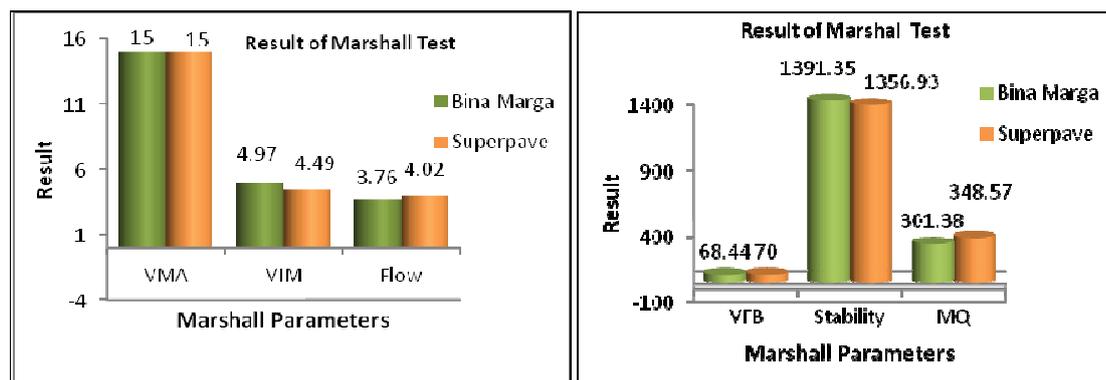

Figure 3 and 4 result of Marshall Test

### 3.4 Dynamic Stability Test

The results of this test, at two gradations, Bina Marga and Superpave, are presented in Figure 5. It is shown that the Dynamic Stability (DS) of Superpave gradation is higher than Bina Marga's. Hence it referred that the use of Superpave gradation would increase its resistance to permanent deformation.

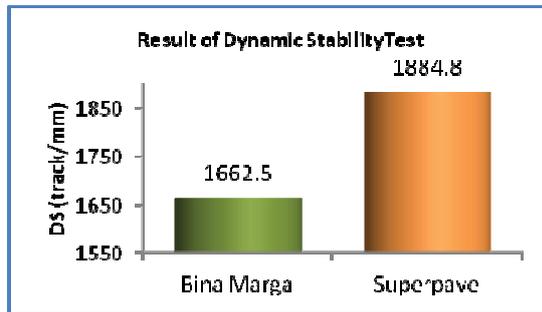

Figure 5 result of dynamic stability test

### 3.5 Roughness Test

Figure 6 is shown because of higher amount of fine aggregate, roughness value of Bina Marga is higher than Superpave but both are qualified the minimum specifications, which is 0.33  $\mu\text{m}$ . The more abrasive the surface of the pavement, it will reducing the accident rate more caused by the slippery road surface. However, it will also speed up the wear of vehicle tires. The values of roughness is obtained from the following formula:

$$MuN = 1,017BPN - 20,9 \quad (4)$$

Where,

MuN : *Mu Number*

BPN : *British Pendulum (Tester) Number*

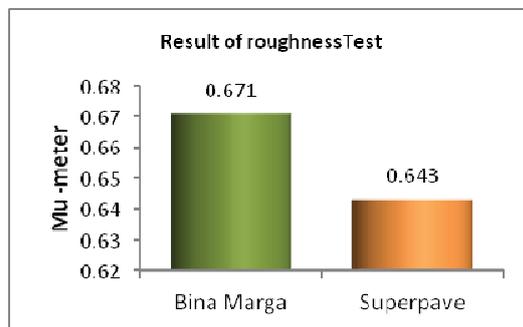

Figure 6. Result of roughness test

## 4. CONCLUSION

Based on research aim that comparing performance of both mixtures Superpave aggregate gradation and Bina Marga fine gradation, the conclusion are:

- Preliminary test with Marshall method, Bina marga mixture produce higher void in mixture and Marshall stability. The difference is not significant.
- Dynamic stability of the mixture obtained from the wheel tracking test shows enough significant difference. The ability of Bina Marga mixture to permanent deformation lower than the Superpave
- Bina Marga mixture has higher roughness value than superpave.
- The results of this research is expected to contribute to the efforts to find a solution of asphalt concrete mix design that meets the conditions the big cities of Indonesia, but remains economical. The results of this research are expected to contribute to the efforts to find a solution of asphalt concrete mix design that meets the conditions the existing in big cities in Indonesia, while remaining economical.

With the said advantages and disadvantages of each of the mixtures, they can be selected to be used in accordance with the actual condition in the field

## ABSTRACT

*Over the recent years, many researches and experiments have been conducted in order to obtain a solution of soft soils problems. Soft soils can be commonly found in most of Indonesian regions. Basically, it provides small bearing capacity and can be extremely deformed due to massive and cyclic loads, especially on railway track. However, track sub-structure layer plays significant roles on railways performance. This paper provides an alternative of settlement problems in railway system lied on soft soils subgrade. By using reduced scale model of railway track with soft soils subgrade, this laboratory experiment was carried out to observe its settlements behaviour under repetitive loading with and without reinforcements. On this research, wooden pile was chosen as an alternative to settlement problems in laboratory model. The results showed that the wooden pile used in laboratory model subjected to cyclic load can significantly reduce settlement because of its friction capacity which could increase model bearing capacity on soft soils. According to this condition, applying wooden pile reinforcement would be necessary to overcome the problems.*

**Keywords :** bearing capacity, railway track, settlement, soft soils, wooden pile

## 1. INTRODUCTION

Several train accidents have been reported during year 2012 in Indonesia and mostly because of the track subgrade failures. It means that the track subgrade should be properly well-designed to keep the whole structure remains safe. However, there is an issue which is popularly known called soft soil. The existence of large soft soil deposits in railway subgrade can induce large settlements. Applying some reinforcement would be necessary in order to increase its bearing capacity to preserve the railway structure against the loading from passing train over the railway structure.

The main indicator that maintenance and improvement are needed are usually defects in geometry, as well as the deformation on the railway subgrade. Furthermore, as an integral part of railway structure, it is governed by two factors, strength and deformation. The strength itself refers to soils shear strength which governs bearing capacity and considered to be the general indicator of strength. Whereas the deformation refers to the subgrade settlement influenced by stiffness (soil modulus) [1].

Wooden pile was chosen to be an appropriate solution of this condition based on several consideration including economical one which needs less cost than replacing the existing subgrade. Assuming the wooden pile as a pile fondation, its resistance comes from two aspects, there are friction resistance and point resistance. But in this research, this pile will act as a friction pile because it doesn't reach the rock layer at the bottom so then it is called floating fondation.

Based on the case that has been described above, a reduced laboratory model of railway structure in soft soils subgrade with and without reinforcements are made to observe its behaviour during the loading phase. To obtain the effectiveness of using wooden pile reinforcements in terms of reducing the settlement caused by train loads, the deformation for both condition will be analysed and compared.

## 2. SOFT SOILS CHARACTERISTIC

Soft soil is one of problematic soils which is categorized as cohesive and high-compressibility soils. In fact, it will be harmful for the construction above. Under the load, large settlements will occur and damage the structure. Moreover, the deterioration caused by soft soil also needs high cost to overcome. These soils which generally comprise soft clay and peat, are widespread in Indonesia, specifically in area where so much infrastructures have to be constructed (Figure 1).

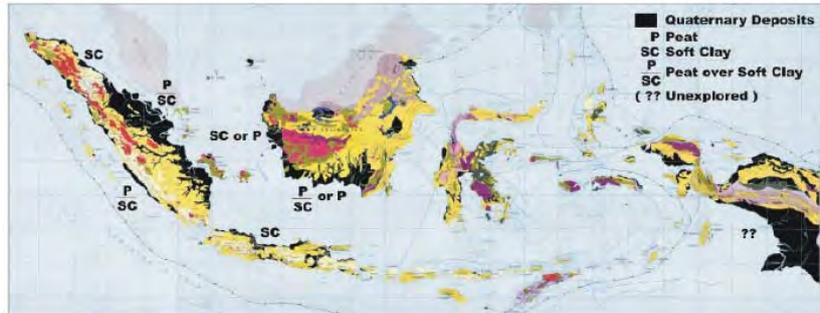

Figure 1: Soft soils deposit in Indonesia [2]

The identification of soft soils can be easily performed by either field test or laboratory test which have been developed by many experts. Firstly, simple field method that usually uses to identify the soft soils is by squeezing the soil. If it is formed easily using the fingers, then it is categorized as soft soil. In addition to this method, if the soil is suddenly came out between fingers when squeezed by hand, then it is very soft soil. Secondly, laboratory method takes into account high natural water content ( $\geq 40\%$ ), medium-high index of plasticity ( $>20\%$ ), and  $S_u$  value of  $<25$  kPa [3]. An additional indicator is described by table below.

Table 1: Shear strenght of soft clay [2].

Consistency	Shear Strenght (kN/m <sup>2</sup> )
Soft	12,5 – 25
Very Soft	< 12,5

## 3. SUBGRADE BEHAVIOUR APPROACHES

As a platform upon which the railway structure is lied above, the subgrade which is known as substructure must provide a stable condition. Literally, any other soil existing locally is uneconomical to use for the subgrade, besides it will be used without disturbance as much as possible. On the other hand, the substructure design needs better understanding of track forced that beared by railway structure. The classification of track forces that the structure must restrain involve mechanical (static and dynamic) and thermal. Figure 2 below describes load distribution from passing train into the subgrade layers [4].

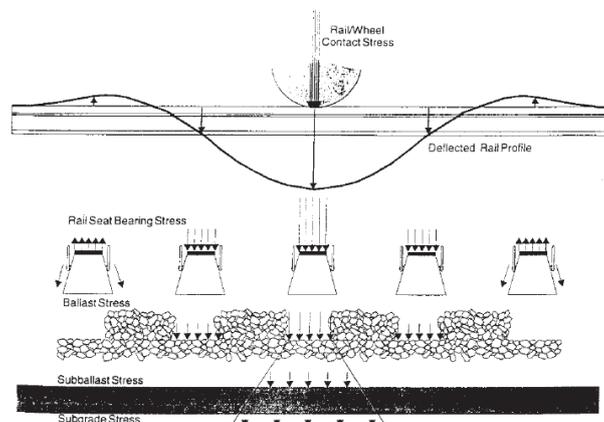

Figure 2: Typical wheel load distribution into the track structure [4].

On the both stable and unstable site test under axle load, the settlement which occurred in the test can be described through the figure 3. Each site has three settlement categories which are maximum, average, and minimum. According to the figure, unstable site definitely has bigger range of settlement than stable site which tend to retain track forces with its settlement below 10 mm. Since, there are so many factor that influences site condition, the charts below are only approaching result.

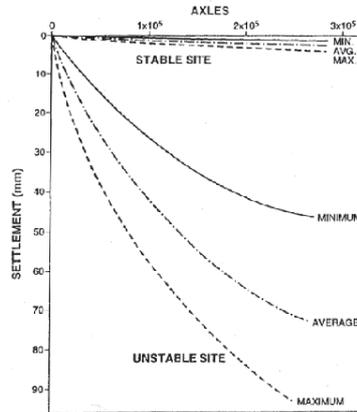

Figure 3: Comparison of settlement rates at stable and unstable sites [4].

#### 4. DESIGN OF LABORATORY MODEL

In this paper, reduced-scale model of railway structure (laboratory model) is proposed instead of field scale model. Although using field scale of railway structure gives real result, the cost will be very expensive and need long time. Thus, laboratory model is used to represent the real condition in the field. As a consequence, boundary condition is also carried out. Figure 4 shows the cross section of laboratory model reinforced by wooden pile.

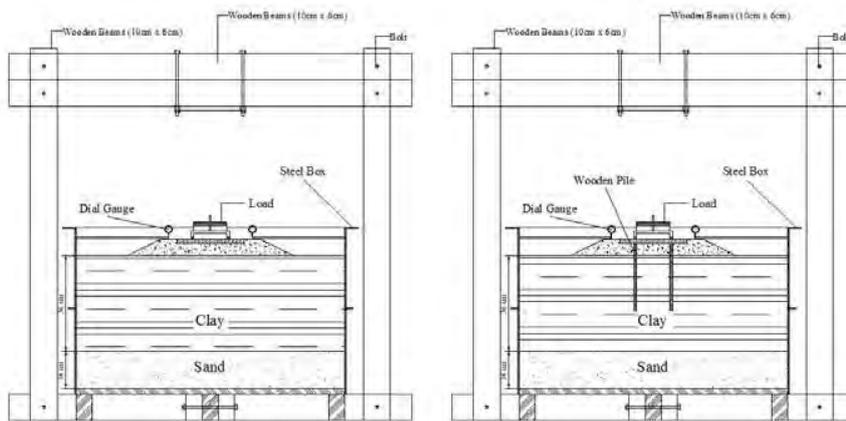

Figure 4: Cross section of laboratory model

Firstly, two different subgrades are sequentially used in this experiment, those are soft soil subgrade and soft soil subgrade with reinforcements embedded to the sleeper in both edges. The wooden pile which proposed as the reinforcement has 1 cm diameter and 25 cm length as shown in figure 3. Secondly, loading variations which comprise size, position, and cycle, are also applied to the reduced model. Size loading variations used to generate the settlement are 16 kg, 32 kg, 48 kg, 64 kg, and 80 kg. Similarly, the position and cycle variations with total loading cycles of 10 will be explained more by figure 6. With these variations, using the laboratory model is roughly assumed as a representation of real condition of railway structure.

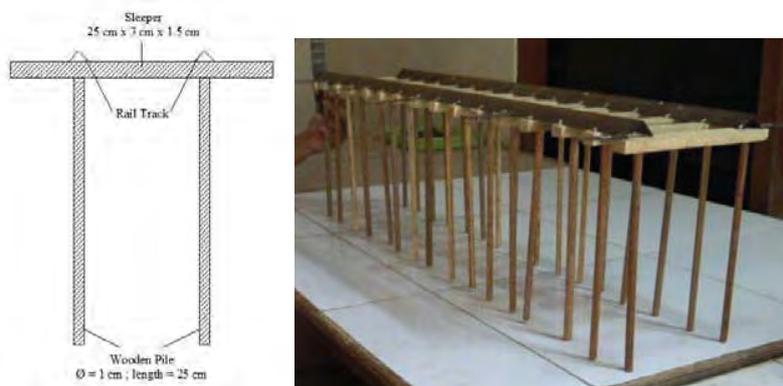

Figure 5: Wooden pile reinforcement

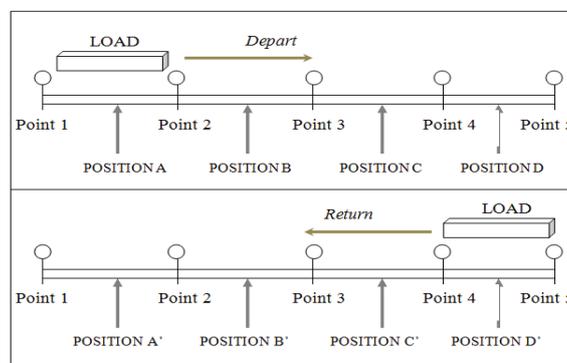

Figure 6: Variations of position and cycle loading

All of the reduced scale of railway structure and subgrade are set inside steel box. During the loading phase, the deformation of the railway structure are recorded by reading the dial gauge placed in the right and left side of railway track which only focused on position B and position C each cycle. The main reason is to approach the real condition in which as continuous structure, it has no end or rarely be found. The set-up of laboratory model is shown by figure 7.

Figure 7: Set up of laboratory model

## 5. RESULTS AND ANALYSIS

### 5.1. Soil Properties

As shown by table 2 below, laboratory test of soil subgrade is summarized. Several laboratory test subjected to soil sample cover moisture content test (ASTM D 2216) [5], direct shear test (ASTM D3080) [6], particle size analysis of soil (ASTM D422), hydrometer analysis of soil (ASTM D422) [7], unconfined compressive strength test (ASTM D2166) [8], liquid limit, plastic limit, and plasticity index of cohesive soil (ASTM D 4318) [9]. Compared to the parameter of soft soil identification which has been described in sections 2, soil subgrade that will be used as a platform of reduced model of railway structure can be categorized as soft soil. Two main consideration of this identification lied on both index properties and engineering properties.

Table 2: Soil Properties.

Parameter	Unit	Soil Sample
Moisture content	%	57,83
Cohesion (direct shear)	kg/cm <sup>2</sup>	0,081
Φ (direct shear)	...°	4,63
Cohesion (triaxial)	kg/cm <sup>2</sup>	0,133
Φ (triaxial)	...°	2,177
Gravel Proportion	%	0
Sand Proportion	%	16,93
Silt Proportion	%	36,72
Clay Proportion	%	46,35
Liquid Limit	%	41,32
Plastic Limit	%	12,45
Plasticity Index	%	28,87
Su	kPa	15,406

### 5.2. Deformation Behaviour

The vertical deformation were measured and plotted against cycle through figures below which is divided into two conditions of models subgrade. First part explains results of settlements recorded in soft soils subgrade without wooden pile reinforcement. This condition refers to unstable condition with excessive settlement occurred in it. Conversely, small settlements were recorded in soft soil with wooden pile reinforcement. However, to investigate the overall performance of reinforced laboratory model, comparison of both subgrade conditions must be considered.

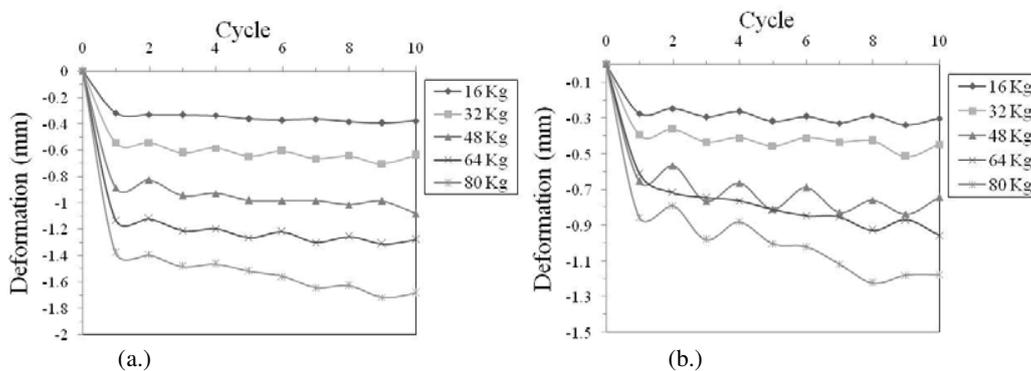

Figure 8: Measured deformation under loading variation in laboratory model without wooden pile reinforcement. (a.) Position B (b.) Position C.

Referring to the figure 8.a which represents deformation caused by cyclic loading, the minimum settlement was about -0.3 mm during the loading phase of 16 kg. The settlements kept rising through the increasing of load until reach about -1.7 mm of settlement which was assumed as the maximum settlement due to 80 kg loading. Similar to this condition, the loading phase of position C with 16 kg load induced minimum settlement of about -0.3 mm, while the maximum settlement of about -1.2 mm was measured due to 80 kg load. However, at the end of loading cycle, the deformation trends of 64 kg and 80 kg were still increasing while the other loads shows constant settlement values. Another result, as shown by figure 8.b, there are some oscillation of measured settlement, specifically caused by load 48 kg and 80 kg. This condition happened because the soil compaction did not evenly spread from one area to another within the steel box. Thus, for the next model of reinforced railway structure, the compaction process prior to the loading test were carefully carried out to avoid these condition.

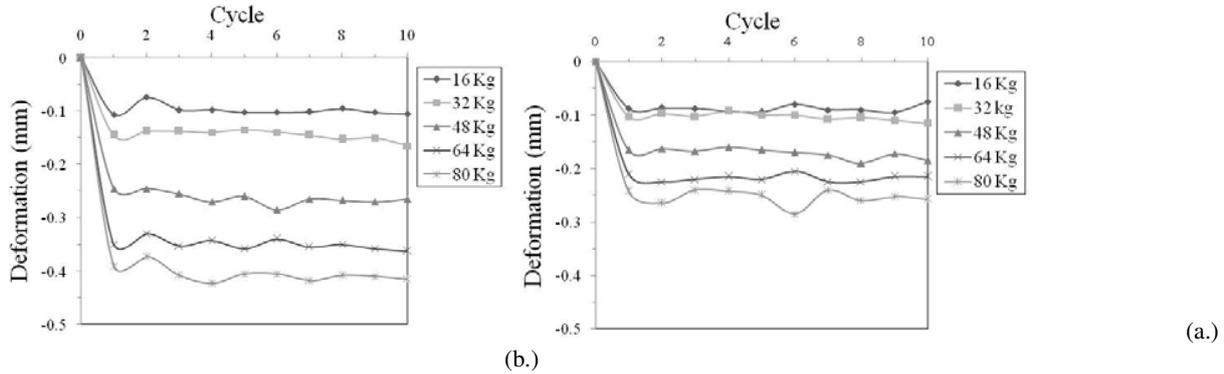

Figure 9: Measured deformation under loading variation in laboratory model with wooden pile reinforcement. (a.) Position B (b.) Position C.

For the reduced model of railway structure with wooden pile reinforcements, the settlement occurred in this model were much less than model without reinforcement. The measured settlement because of loading variation in position B was about -0.1 mm which is known as minimum settlement, then the maximum settlement was about -0.4 mm as shown in figure 9.a. The result of loading in position C was slightly different than position B, which measured minimum and maximum settlement were about -0.1 mm and -0.25 mm, respectively. Overall, the range of settlement each load was small and not exceed -0.5 mm. Furthermore, until the end of loading cycle, the settlement trends shown by figure 9 reach constant value.

### 5. FEM VALIDATION

Finite element method was used in this research to validate the laboratory results, particularly on its final settlement (last loading cycle). By using Plaxis 3D Foundation, a finite element software, the model was created similar to the laboratory model with their parameters including soils and structural parameters. Figure 10 and figure 11 illustrate the result comparison between laboratory model and FEM model which are focused on the induced settlement on the last cycle. It can be concluded that there are very small discrepancies from those two models. On the other hand, FEM models produce more conservative results than that of laboratory models.

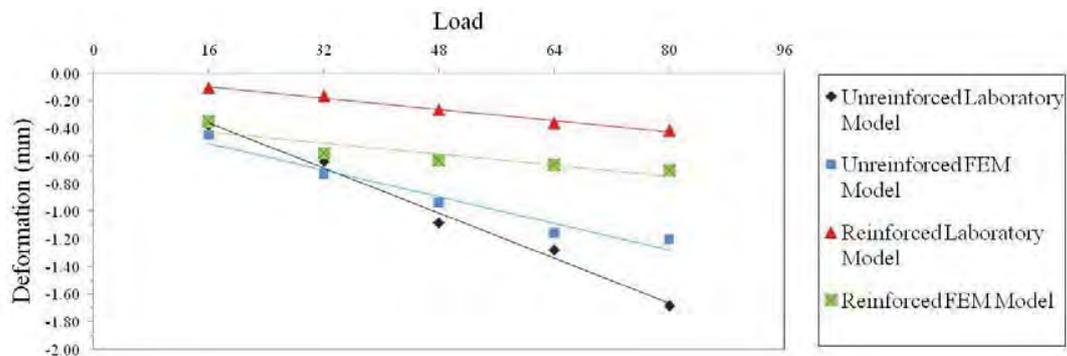

Figure 10: Settlement comparison between laboratory model and FEM model in position B.

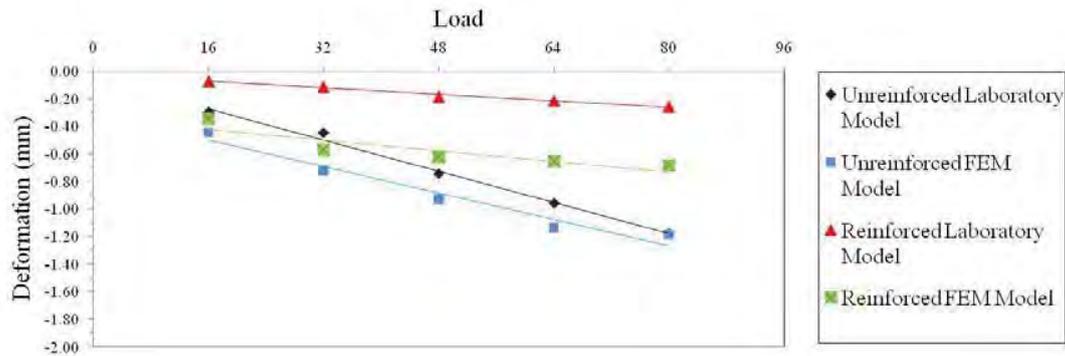

Figure 11: Settlement comparison between laboratory model and FEM model in position C

## 6. CONCLUSION

According to the results, the reinforced model tend to produce less settlements compared to the unreinforced model. Excessive settlement which occurred in both laboratory and FEM model without reinforcement generally was caused by small strength of soft soils which could not restrain the loading. In contrast, small settlement in reinforced model indicate that wooden pile used in the model provided support against the loading. This is due to capability of the reinforcement to reduce the excessive settlement into minimum through its friction which demonstrate the potential benefits of using wooden pile.

The effectiveness of applying wooden pile to reduce the settlement also has been calculated with consideration took into account the comparison of deformation between both models. The comparison of deformation was conducted each loads in each models. Therefore, it can be concluded that using wooden pile reinforcement can reduce the settlement with ranged from 70.09 % to 76.70 %.

### **ABSTRACT**

*The development of the airport always causes the noise impact to the surrounding environment.<sup>1</sup> Housing close to the airport will be annoyed by the aircraft noise, especially if the building is not added by absorber building materials. Housing lay out towards the runways as noise sources is also an aspect that should be considered. This research resulted building models equipped by simple material compositions that had capability in reducing the airport noise optimally. The decrease of the noise level found out from the research is caused by the value of Sound Transmission Loss (STL) of the building materials composition. The models of housing are laid out with a number of specific orientation angles towards the runway and resulted values of the highest noise level reduction.*

### ABSTRACT

Road safety barriers are used to shield pedestrians and workers from oncoming traffic at roadsides. When filled with water, these barriers are able to withstand low to moderate impact speeds up to 50km/h. Despite this feature, Portable Water Filled Barriers (PWFBs) face challenges with large deflections, tear and breakage during impact, especially at higher speeds. This study explores the use of composite material to enhance the safety of these PWFBs and enable their use at higher speeds. Energy absorption capability of PWFBs is first investigated. Then, composite action of the PWFB with the introduction of foam and a steel frame is considered to evaluate its enhanced impact performance. Findings of the present study show that the initial height of the impact must be lower than the free surface level of water in a PWFB in order for the water to provide significant crash energy absorption. In general, an impact at 0.8 of the barrier height seems to be a good estimation. Furthermore, the addition of a composite structure greatly reduces the probability of tearing by decreasing the strain and impact energy transferred to the shell container. This allows the water to remain longer in the barrier to absorb energy via inertial and sloshing response. Information from this research will aid in the design of new generation roadside safety hardware that will cater to the modern roadways with enhanced safety to motorists and persons at roadsides.

### **ABSTRACT**

*This paper introduces the managed motorway research that was recently performed by the Smart Transport Research Centre at Queensland University of Technology, Brisbane, Australia. The aim of the managed motorways research is to develop smart motorway traffic control and management solutions to cost-effectively alleviate congestion pressure, and thereby to reduce its negative impacts on travel time reliability, traffic throughput, and safety. Research was conducted to develop enhanced algorithms for motorway ramp metering and variable speed limits. This paper introduces those two algorithms highlighting the fundamental concepts, control principles, and evaluation results.*

# Modified Buton Granular Asphalt with SBS as binder of hot-mix asphalt

Heddy R Agah

Faculty of Engineering, University of Indonesia, Depok 16424  
 E-mail : agah@eng.ui.ac.id

## ABSTRACT

*Buton Asphalt (Butas) is naturally occurring bitumen and categorized as natural asphalt which is found in Buton Island – Indonesia. It contained of mineral and 10-30% bitumen of the total weight and can be used as materials for asphalt concrete mixture. Butas has shown it is function as materials for asphalt concrete both for hot mix and cold mix asphalt concrete. Number of researches aimed at improving Butas due to its relatively low bitumen content and low penetration. This paper assessed the empirical rheological properties of Butas in a form of Buton Granular Aggregate (BGA) as binder of hot-mix asphalt concrete. It is laboratory research work, and Marshall method of testing and preparation of sample is used. Two type of asphalts are use which are genuine asphalt of 60-70 pen and SBS polymer modified asphalt as binder, and BGA is treated as fine aggregate. Extraction of sample mixtures after Marshall test is undertaken to evaluate the physical characteristic of materials composition includes aggregate gradation and asphalt properties. The finding shows that BGA contributed to the increase of fine aggregate percentage and asphalt content. The optimum combination is 5% of BGA and with 2% of polymer modified asphalt.*

**Keywords:** *Buton asphalt, Marshall method, modules resilient, polymer modified asphalt, physical properties*

## 1. INTRODUCTION

Asphalt based materials for road construction remains the primary choice for pavement industries. Asphalt can be obtained as oil based materials, several natural bitumen with various content composition and mineral are also found. The types of natural asphalt in Buton-Sulawesi can be classified into two categories: hard asphalt found in the Kabungka area and soft asphalt mined in the Lawele area [1]. The area of the rock asphalt mine in Buton located at 5 longitude and 123 latitude, has an asphalt content that varies from 10% to 40%. Using a number of mined materials, the data suggests that the average level of asphalt ranges roughly 21.8%.

The deposit of this material is predicted at the amount of 62.5-350 million tonnes. This material is available at a the depth of about 1.5meter, spreading at approximately 70.000acres. Buton asphalt has been used as asphalt construction based materials as its quality improvise through extraction or division (splitting into parts) of its forming component, and as primary binding material or additive. Conventional Asbuton particle in the form of Asbuton aggregate with maximum size of 12.5mm distributed in the bulk is a type used in Indonesia [2]. Requirements for buton particles are presented in Table 1. Buton Granular Asphalt (BGA) is the research product of Asbuton which is broken by a suitable crusher to certain desirable size particle.

The usage of asbuton is expanded through raw material modification in order to be used both as an additive in the form of granular and also as modified asphalt. [3]. The nature of the aggregate asbuton agglomerates becomes altered during the process of storage due to the migration from hydrocarbon phase, from interion component to the granular surface [4]. The other negative result can occur because of Indonesian humidity which may cause result in more sticky material. The asphalt content varies from 20% to 30%, and the test result for penetration value varies significantly between 4 to 36. Penetration is higher for the Lawele area compared to the one mined at Kabungka. The softening point of the material at the two areas is around 59<sup>0</sup>C, and the flash point is 198<sup>0</sup>C. The test result of the softening point of BGA base material is 67.5C, (SNI 06-2432-1991 – Indonesia National Standard - standard is 60<sup>0</sup>C). The results implicate that this material is suitable to use with the weather condition of typical tropical areas.

Table 1 Asbuton specification

Parameter	Type *)			
	5/20	15/20	15/25	20/25

No.16 (min)	95	95	95	75

Water content (%) max	2	2	2	2
Penetration (25°C, 100gr, 5sec, 0,1mm)	≤ 10	10-18	10-18	19-22

The usage of asbuton started (during 1929) with bitumen content of 18-22% max size 12,7mm, further, fine asbuton with 6.35 diameter was developed. In 1993 Asbuton Micro plus with maximum size of no.8 was developed, with bitumen content of 25%, water content less than 2%. Butonite Mastic Asphalt was developed in 1995 with bitumen content of 50%, in 1997 added by liquid asphalt and Extracted Buton asphalt resulted in Retona type. In this study, the BGA used was resulted in max size 1.16mm and <2% water content which was initially developed in 2003. In 1995 Issacson and Lu introduced polymer, along with the finding of various types and derivatives of polymer, which are elastomeric and thermoplastic types to modify asphalt. Polymer can be used both as admixture and binders [5], [6], [7], [8]. This research is conducted to assess the characteristics of gradation and the influence of asphalt content based on BGA composition. Polymer modified asphalt is introduced to strengthen binding influence for BGA mineral deposit

## 2. METHODOLOGY

The materials are asphalt cement, BGA, and asphalt modified polymer. The gradation composition conforms with Bina Marga continuous gradation specification, Indonesia. Asphalt mixtures are designed as a combination between BGA and polymer in each composition of 5-7% and 2-4% respectively. This results in one combination without additive and four type combinations with BGA and polymer asphalt..

The test is carried out using indirect tensile strength and Marshall methods. The indirect tensile strength test is used to determine the tensile properties of the asphalt concrete which can be related to the cracking properties of the pavement. [9]. After tested using indirect tensile strength and Marshall methods, the sample is extracted to analyse the aggregate gradation. Extraction test is aimed to evaluate the gradation resulted from BGA material.

## 3. MATERIAL AND TESTING

Based on the composition of aggregate and BGA, gradation is designed to comply with the percentage of BGA addition. (Table 2). BGA gradation is tested in two ways: before and after extraction. Table 3 and 4 shows test result of asphalt and aggregate.

Table 2 Gradation BGA before and after extraction

Sieve	Before	After
3/8"	100,00	100,00
4	88,19	100,00
8	68,77	99,75
30	42,94	98,24
50	15,42	85,53
100	3,10	60,38
200	0,20	39,87

Table 3 Test result of aggregate per fraction

Type	Coarse	Medium	Fine

No 200	4.49	4.0	4.13

#### 4. ANALYSIS

##### 4.1 Mixture performance

BGA addition in the mixture is able to increase performance measured from the Marshall test. The result shows an increase of mixture with BGA of 1,45 and 1,63 times compared to the mixture without BGA. Stability increases significantly for the addition of 2% and 4% polymer to the mixture with 5% BGA. However, influence of combination of 7% BGA and polymer produced lesser value compared to 5% BGA. Marshall quotient varies between 320 to 385, in which the higher is reached at combination of 5%BGA and 2% polymer (B5P2) with 385kg/mm, showing that the mixture is relatively rigid. All combinations with 4% polymer seem more flexible with moderate high value of stability (Figure1).

##### 4.2 Modulus of Resilient

UMATTA set is used as a tool to analyse MR in two scenarios: (i) normal temperature, and (ii) preheating at 40°C for 24 hours with variation of rise time and pulse. Optimum value is reached for all combination of the mixture at asphalt content of 5.5%. BGA addition and BGA in combination with polymer increase MR value, each amounts to 1.33 and 0,99 times for BGA mixture of 5% BGA and 2,4% polymer; and 1.07 increase for concrete mixture with 7% BGA and 4% polymer compared to the mixture without polymer. (Figure 2 and 3)

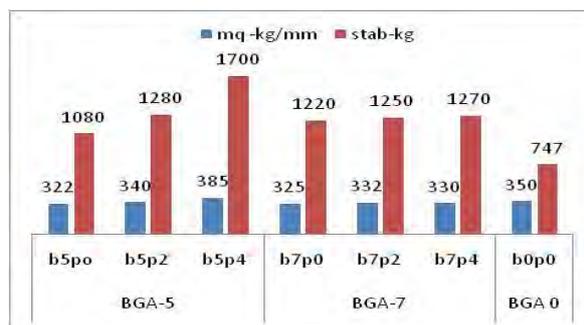

Figure 1 Stability and Marshall Quotient

The value of MR for 7% BGA mixture is higher than 5%BGA estimated from rise time and pulse variation of 80-3000 and 40-1000. However the mixture with polymer content, causes MR value to decrease, indicating impact of polymer to mixtures stiffness (see Figure 4).

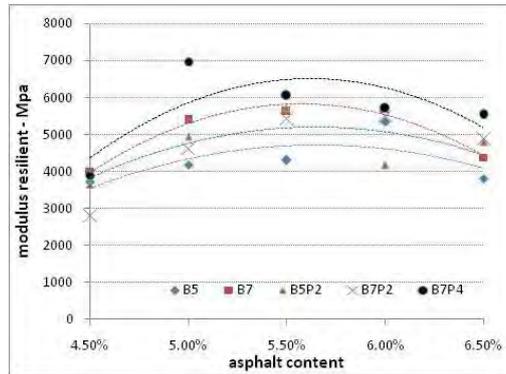

Figure 2 Modulus resilient for BGA 5%

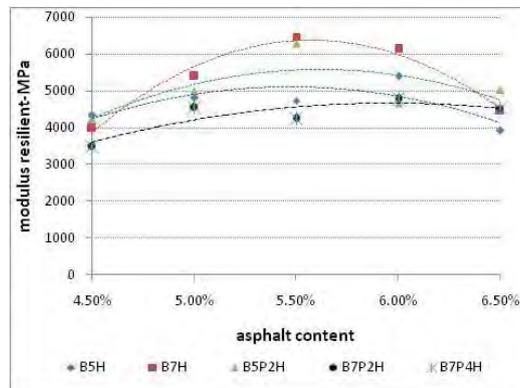

Figure 3 Modulus resilient for BGA 7%

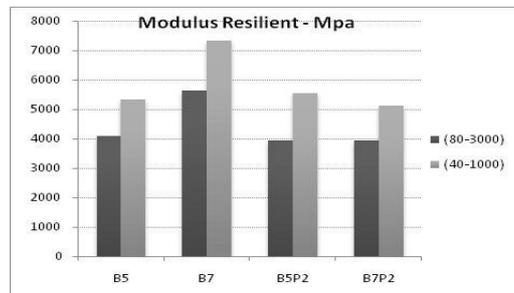

Figure 4 Modulus resilient for BGA 5% for different raise time and pulse

### 4.3 Gradation

It was found that [11] potential degradation or aggregate is caused by compaction, and Marshall compaction create more aggregate degradation. BGA addition changes initial gradation because a part of the fine fraction portion is substituted by BGA. BGA which comprised of mineral and asphalt will separate to its components during mixing time. The addition occurs for fine granule (no.50, 100 and 200), and it tends to reach maximum level, while the highest is at sieve no.100. Fine granule percentage is increase 21.02%, 71,89% and 105.74% respectively for sieve sizes of no. 50, 100 and 200 estimated from design and extracted gradation. The small fraction comprised of 7% BGA mixture is for the three aggregate sizes is 16.48, 67.8 and 107.9%. For the two types of BGA mixture, the addition of fine granule of no 200 almost doubles the initial percentage. The result is presented at Figure 5, 6, and Table 5. Polymer addition minimizes fine granule addition so that initial design gradation can be maintained.

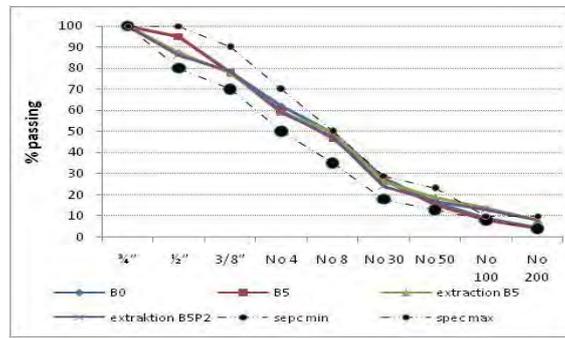

Figure 5 Comparison of aggregate gradation with BGA 5% polymer 2%, (B5P2) before and after extraction

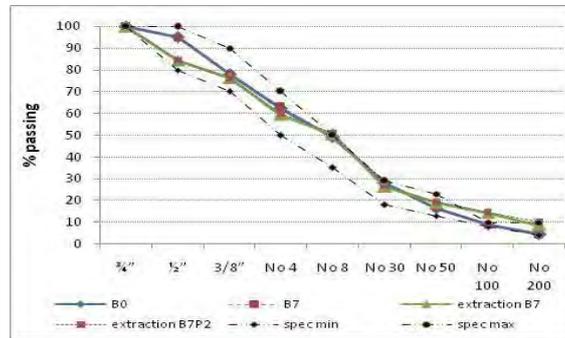

Figure 6 Comparison of aggregate gradation with BGA 7% polymer 2%, (B7P2) before and after extraction

Table 6 Aggregate gradation for various mix after extraction

Sieve size	Spec	Basic	B5P0	B5P2	B5P4	B7P0	B7P2	B7P4
3/4"	100	99.81	100	100.0	100.0	100	100	100
1/2"	80-100	94.98	87.3	86.1	85.7	84.4	85.0	84.2
3/8"	70-90	77.92	77.4	78.6	76.4	76.2	73.2	74.9
No 4	50-70	62.25	59.2	59.2	60.7	59.4	58.2	59.4
No 8	35-50	49.07	49.8	47.6	50.4	50.3	48.1	46.6
No 30	18-29	28.14	26.1	23.9	27.6	26.3	26.3	24.7
No 50	13-23	16.44	18.5	17.0	19.9	18.9	20.0	18.6
No 100	8-10	9.04	13.9	12.9	15.1	14.3	12.9	12.1
No 200	4-10	4.49	8.2	7.9	9.0	8.6	8.1	7.8

## 5. CONCLUSION

- 1) Buton asphalt has role in increasing the quality of concrete asphalt mixture and simultaneously utilizes great amount of natural asphalt avails in Sulawesi island. Mineral and asphalt content contributes to the composition of both aggregate and mixed concrete asphalt content
- 2) The use of BGA influences the composition and fine granular content, especially after mixing process, it increases at the mixing because mineral content changes to be finer sizes.
- 3) The amount of 5% BGA addition trends to better result compared to BGA high content. The mixture of Marshall properties increases with the addition of BGA. Polymer role gives better bond on fine granule addition as a result of BGA physical change and has improved the mixture performance.
- 4) UMATTA test proves that the mixture can overcome speed and load frequency for medium to high traffic amount.

# The Urban Transportation System and Fuel Consumption of Metropolitan and Large Cities In Java

Dr. Ir. Mudjiastuti Handajani, M.T

Civil Engineering, Semarang University, Semarang 50196  
E-mail : hmudjiastuti@yahoo.co.id

## ABSTRACT

*The urban transportation system includes the number of private passenger cars, private buses and motor cycles, public buses and public passenger cars, goods transportation vehicles, road length, and route length. The fuel consumption is greatly influenced by the city typology (land use management, population size, population density, RGDP). Both transportation and fuel consumption are very strategic because they are related with the local, national, and global-scale economy and environment.*

*The data were analyzed by using a multivariate-multivariable analysis, including a co-relational analysis, Biplot and a multivariable regression analysis. Metropolitan and large cities in Java have the following characteristic: city typology, transportation system, bigger fuel consumption than medium cities. The effect of the population on the fuel consumption is very great.*

*The urban transportation that can make efficient fuel consumption: small percentage and number of vehicles (private and goods vehicles), route efficiency, the public transportation services with a large capacity, grid road network, land use management (compact). The fuel consumption is influenced by the urban transportation system and city typology. All integrated influential variables can reduce fuel consumption, can reduce subsidy on the fuel consumption, can increase health, and increase state economy.*

### Keywords:

*city typology, fuel consumption, Java, transportation system, urban transportation.*

## 1. INTRODUCTION

State that the concept of sustainable transportation becomes both a foundation and challenge for effective development and implementation [18]. One of the challenges of *sustainable transportation* is the *urban resource conserving mobility* [4], [5] or by developing a transportation mobility strategy in the country [24].

Improving the city transportation system, especially that is triggered by the increase of private vehicle ownership and usage negatively has some impacts on the city, like traffic jams and accidents, space usage, environmental preservation (exhaust gas emission, air pollution, energy resource exploitation, etc.). This occurs in large cities of both developed and developing countries, like Rio de Janeiro, Mexico City, Jakarta, New Delhi, and Bangkok.

States that sustainable transportation is related to collective and integrated management of fossil fuel consumption, vehicle exhaust gas emission, safety, traffic jams and social economy towards future sustainability without causing problems for future generations around the world [23]. Therefore, an environment-based transportation is needed by taking potential environmental implications and impacts into consideration, especially air pollution, noise pollution and energy consumption. These impacts trigger the *sustainable urban city transportation system*, which is a concept involving several systems and is cross-disciplinary and requires a holistic analysis.

Biplot is a *multivariate multivariable* statistics technique which can be displayed visually to simultaneously demonstrate the  $n$  observed object and the  $p$  variable on a two dimensional space for the variable and observed object characteristics and the relative position between observed objects with the analyzable variable. So, the Biplot can show the relationship between variables, the relative similarities between observed objects, as well as the relative position between the observed object and the variable [13].

The objective of this study is to investigate the effect of city typologi and urban transportation system on the fuel consumption of Metro and Large Cities in Java.

## 2. LITERATURE REVIEW

According to [6], with respect to fossil fuel consumption in the United States, 80% of the transportation sector is taken up by land transportation, 20-30 % uses truck and buses. [9] Considers trucks carrying goods consume up to 30-40% of the transportation fossil fuel consumption. In Indonesia, the national economy growth has increased the number of private vehicle ownership and usage in the city area. Private vehicle ownership has increased significantly compared to public transportation, therefore also increasing fossil fuel consumption. According to [12], to reduce fossil fuel consumption, we need to reduce the number of private vehicles. In reality, the number of private vehicles in Indonesia actually rises each year. The number of vehicles and fossil fuel consumption in Indonesia during 1983-2003 can be seen in Figure 1[8].

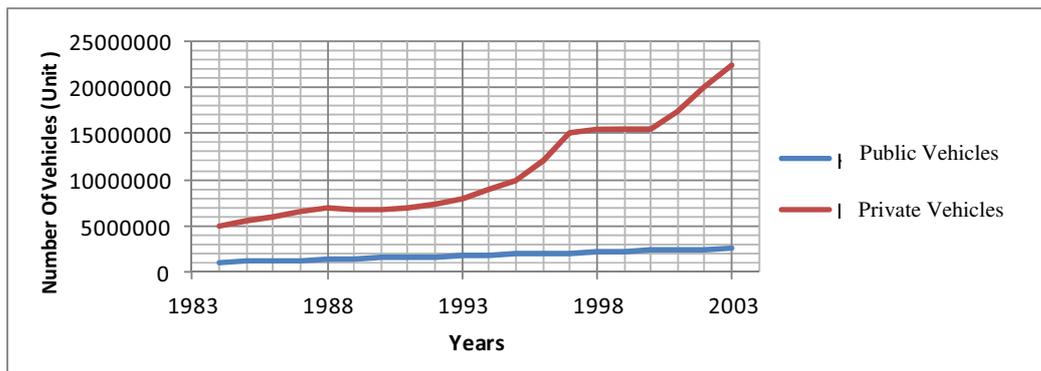

Figure 1. Number of Vehicles in Indonesia 1983-2003

In the United States, between 1970 and 1995, there was a large gap between the supply or production of fossil fuel and the need for fossil fuel for transportation. This fact is considered worrying because the transportation sector is currently heavily reliant on unrenrenewable fossil fuel that is rare and decreasing. Declining supplies affect the rising price of fossil fuel, impacting the creation of wide external factors towards the national social-economy condition. In Indonesia, the growth of fossil fuel need is bigger than the government's capability in providing subsidies [21]. Some developing country governments are forced to provide subsidies for the people to be able to access the rising prices of fossil fuels. Figure 2 shows energy consumption in Indonesia based on their resources [8].

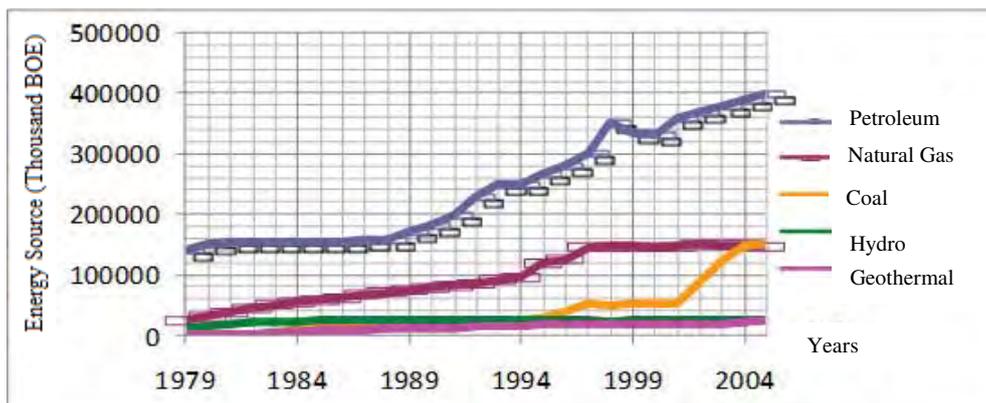

Figure 2. Energy Consumption in Indonesia Based on Resources

Because road transportation consumes fossil fuel the most, reaching 70 % (for developing countries) [15], and even in Australia energy needs for transportation reaches 80% [17], this transportation sub-sector requires attention in several policies, planning and research. According to [1], the fossil fuel consumption for each vehicle's transportation needs is different. The calculation for each vehicle's fossil fuel consumption can be seen in Table 1.

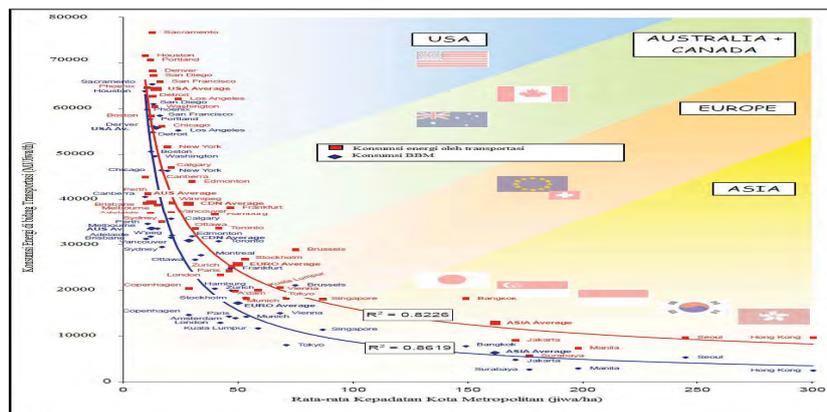

Table 1. Fossil Fuel Consumption Intensity Calculation

Type of Vehicle	energy intensity				
	km / l	liters / km	km / day	liters / day	liters / year

### The Impact of Land Use (LU)

According to [10], the effect of city growth developing through a concentric typology or a single city center saves fossil fuel consumption more than a city typology with several city centers. This is in accordance with [12], and [11], the city form influences energy use. There is a conservative view stating that the current land use will not change much even if there is a change in the public transportation system. According to [22], the empirical reality always proves that land use has a strong correlation to city transportation because the land use determines the size and distribution of movement, influencing travel movement, transportation modes used and fossil fuel consumption.

The impact of land use on fossil fuel consumption is not only caused by the type of land use, but also the influence of the intensity in using the land of which can be demonstrated through population density. Rising population density allows higher possibility for *mixed use* to happen. Areas with lower population density have higher per capita fossil fuel use, on the contrary, areas with high population density have lower per capita fossil fuel use. The land use and transportation cycle can be seen in Figure 3.

Source: [16]

Figure 3. The Relation between Per Capita Energy Use and Density in Cities

Figure 3 shows the relation between fossil fuel/capita and population density in cities, by sampling 84 cities in the world [16]. The study conducted by [2],[3], shows that rising population density in West Europe does not always lower vehicle ownership which would lower fossil fuel consumption, but the people or population's travel route in the city is more determining. Likewise, according to [7], studying cities in Asia (including Indonesia), fossil fuel consumption has a low correlation with population density. Research in Indonesia shows that fossil fuel consumption is influenced by travel patterns, meanwhile travel patterns are influenced by the location of activity centers (residences, shopping centers, offices, schools, hospitals, etc.) [20].

### 3. METHODOLOGY RESEARCH

Fuel consumption data is taken from the gas station to purchase Pertamina 2007-2008. The data analysis will involve many variables and indicators, so a multivariate multivariable analysis, that is an application method that deals with large number of measurement (more than one independent variable and one dependent variable) of the objects simultaneously conducted. Analysis of the characteristics of the fuel consumption, the typology of cities and the transport system using biplot The proposed analysis of the relationship between transportation system and fuel consumption of the cities in Java is made in accordance with the theoretical framework as illustrated in Figure 4.

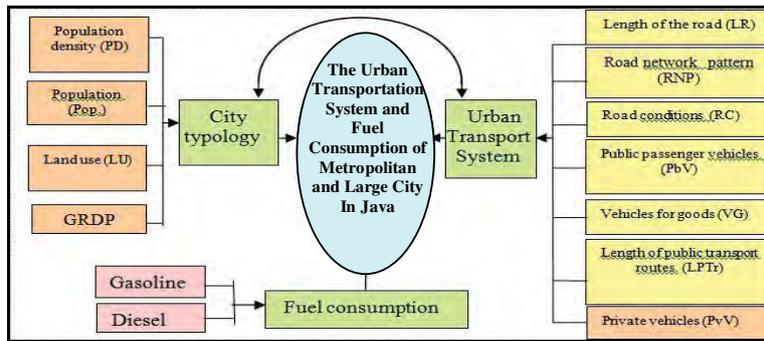

Figure 4. Theoretical Framework for Urban Transportation Model System and Fuel Consumption Of Metropolitan and Large City In Java

### 4. ANALYSIS

#### 4.1. Fossil Fuel Consumption Characteristics in Cities in Java

The analysis results show that large and medium-sized cities can be grouped together and are positioned opposite of the direction of the line, meaning that large and medium-sized cities share similarities in fossil fuel consumption (petrol, diesel oil and both), in that they have low consumption of petrol fuel, diesel oil and both, whereas metropolitan cities (Semarang, Tangerang, Surabaya, Bekasi and Bandung) are spread out, meaning that each city is different in its fossil fuel consumption. Bandung has the highest petrol fuel consumption. Tangerang and Semarang has the highest diesel fuel consumption, the highest two types of fuel consumption is Surabaya, with almost equal percentages of petrol and diesel fuel consumption. The Biplot fossil fuel consumption analysis results can be seen in Figure 5 below.

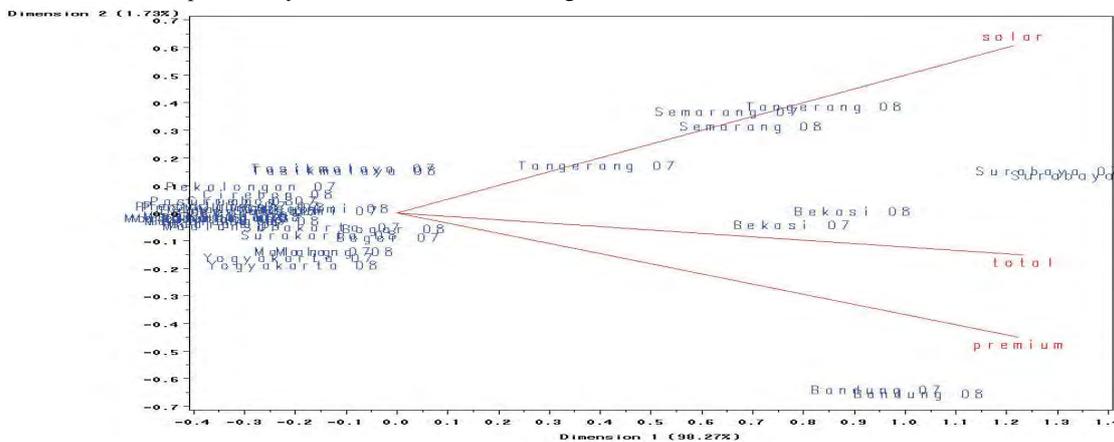

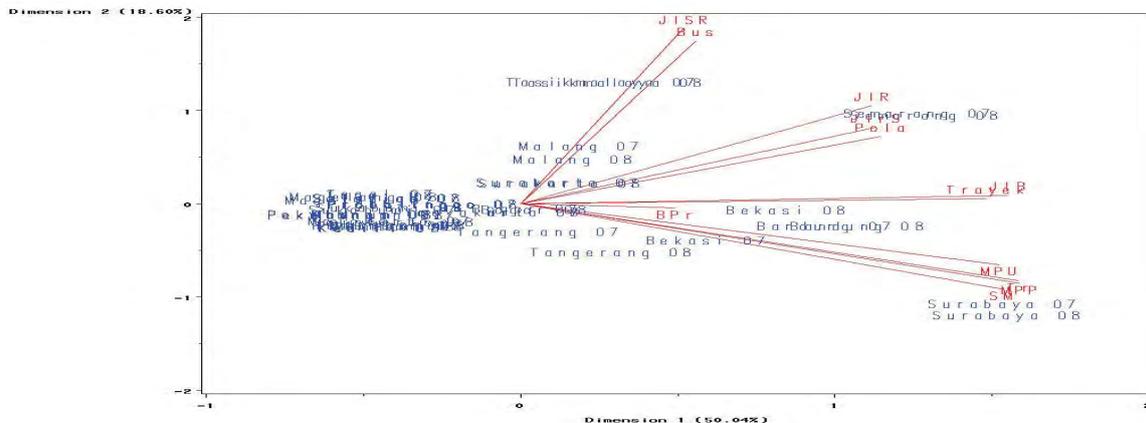

Figure 5. Biplot Fossil Fuel Consumption Analysis Results

#### 4.2. City Transportation System Characteristics in Java

Large cities are within the middle group. This shows that large cities have the following transportation system characteristics: a) road length, b) road condition (good, fair, damaged, very damaged), c) goods vehicles (trucks), d) public transportation vehicles (buses and public passenger cars), e) route length of public transportations, f) personal vehicles (buses, passenger cars, motorcycles) are not too apparent when compared to metropolitan cities. The Biplot city transportation system analysis results can be seen in Figure 6 below. Metropolitan cities consisting of: Semarang, Surabaya, Bandung, Bekasi and Tangerang have different prominent transportation system characteristics. This is evident from their spread out positions. Semarang has the

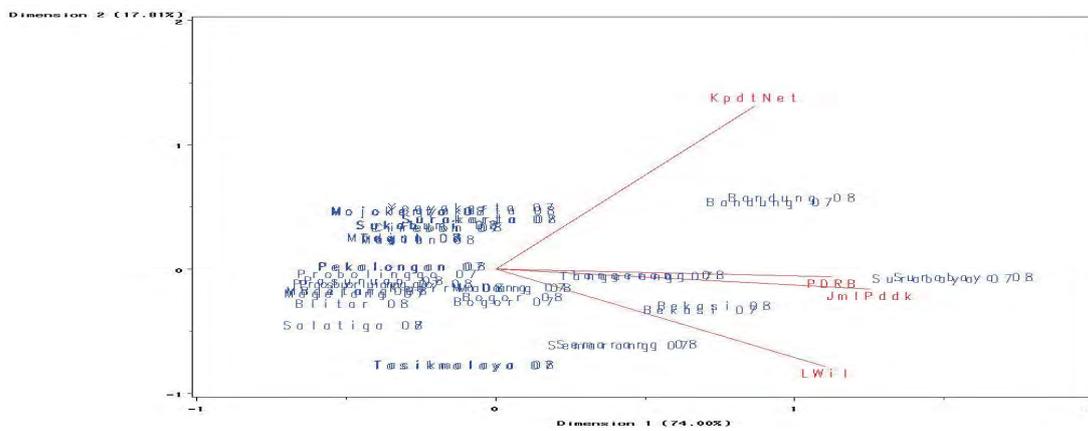

longest road length. Surabaya has the largest number of public passenger cars, motorcycles and trucks. Bekasi has a prominent number of private passenger cars. Bandung has prominent public passenger cars, truck and motorcycles.

Source: [14], 2010  
 Figure 6 Biplot City Transportation System Analysis Results, All Cities

### 4.3. City Typology Characteristics in Java

The variables of city typology consists of the number of population, the nett area (area based on the width of developed areas), population density (based on developed areas), and RGDP (based on current prices). Analysis results show that there is grouping of the position and proximity between objects of city typology in Java. This shows that there are resemblances or similarities, meaning the cities have a relatively similar city typology. Cities grouped together are medium-sized and large cities. These cities have similar city typology, which is a low population number, low population density, low PRDB and low developed area. Metropolitan cities are widely spread or not grouped together, meaning each city has a different prominent city typology. Bandung has a high population density nett, Surabaya has the highest number of population and RGDP, and Semarang has the largest area. The Biplot city typology analysis results can be seen in Figure 7 below.

Source: [15], 2010  
 Figure 7 Biplot City Typology Analysis Results

### 4.4. Fossil Fuel Consumption Model of Metropolitan and Large Cities in Java

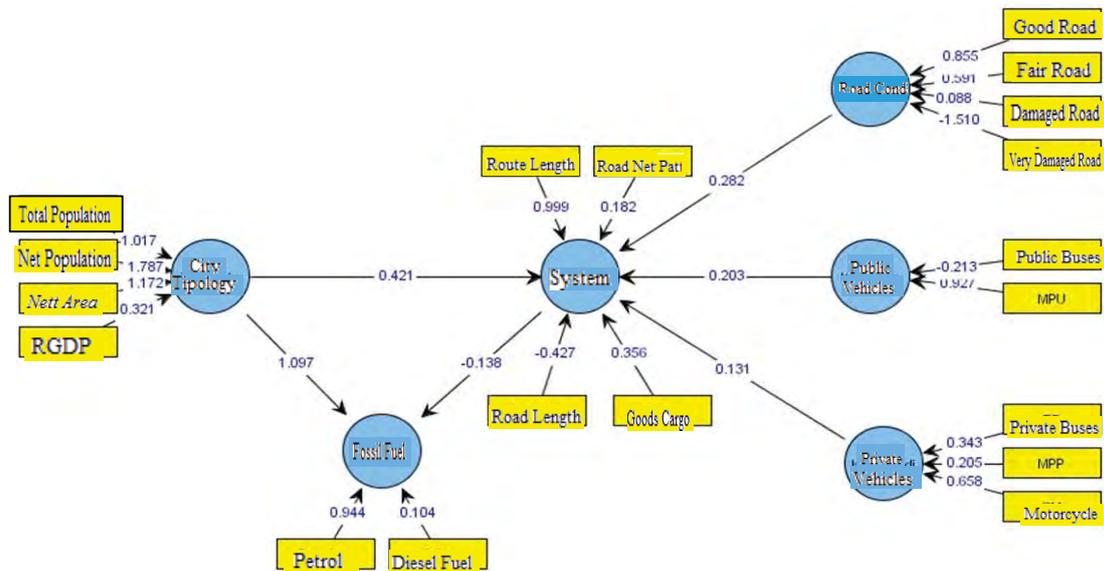

Petrol fuel consumption highly influences total fuel consumption, yet not so for diesel fuel. Diesel fuel has a low and negative effect on total fossil fuel consumption. The higher the petrol fuel consumption, the higher the total fossil fuel consumption, but the higher the value of diesel fuel, the lower the value of fossil fuel consumption. City typology influences the city transportation system. The effect of the city typology on fossil fuel consumption for metropolitan cities are far bigger compared to the effect of the city transportation system on fossil fuel consumption. The higher the value of city typology is, the higher the fossil fuel consumption will be. The higher the value of the city transportation system is, the lower the fossil fuel consumption will be. The metropolitan city population density nett and developed areas variables have the biggest impact on

city typology. The same applies for the transportation system variable: route length, good condition of roads, public passenger cars and motorcycles have a big impact on the city transportation system.

The population size in metropolitan cities is much higher than large and medium-sized cities, so fossil fuel consumption in metropolitan cities is much higher compared to large cities and medium-sized cities. Rising fossil fuel consumption in metropolitan cities is influenced more by the rise of RGDP rather than the rise of population. The higher the population, the higher the value of city typology, and this will raise fossil fuel consumption. The same applies for a rise in RGDP in metropolitan cities, where the higher the RGDP is, the higher the fossil fuel consumption will be. Population density in metropolitan cities has a big effect on city typology, so the higher the population density is, the higher the fossil fuel consumption will be.

The rise of the value of city typology is influenced more by the population number, population density nett and developed area as well as RGDP. So if the population size, population density nett and developed area as well as RGDP rise, the value of city typology also rises, therefore increasing fossil fuel consumption. In reality on the field, metropolitan cities have a higher population density nett, a wider developed area and a higher RGDP compared to large cities and medium-sized cities. Metropolitan cities generally have a wider administrative area than other cities but also a higher population density, so fossil fuel consumption, if viewed from the number of vehicles by the length of the road and population density nett divided by the city's branches, has a smaller angle. The longer the roads is, the lower the value of the transportation system will be. This will increase fossil fuel consumption.

The number of motorcycles in metropolitan cities is higher than any other private vehicles. Although the fossil fuel consumption, especially petrol fuel, per motorcycle is smaller than for passenger cars, but the impact of motorcycles toward private vehicles is high, therefore, increasing petrol fuel consumption with the increasing number of motorcycles. The number of private passenger cars vehicles greatly affect private vehicles, meaning the higher the MPP vehicles are, the higher the value of private vehicles and the higher the value of the transportation system will be, which will eventually reduce fossil fuel consumption. The data analysis using Structural Equation Modelling PLS (Partial Least Square) has produced *Bootstrapping*, and has produced an impact model of the city transportation system on fossil fuel consumption which can be seen in Figure 8 below.

Source: [14] 2011

Figure 8. Metropolitan and Large Cities Fossil Fuel Consumption Model

The metropolitan cities in Java fossil fuel consumption model can be explained as below:

If the length of the road increases in value by 1 unit, the system's value will decrease 0.427. If trucks increase in value by 1 unit, the system's value will increase 0.356. If the route length increases in value by 1 unit, the system's value will increase 0.999. If the road network patten increases in value by 1 unit, the system's value will increase 0.182.

The road condition is classified into good roads, fair roads, damaged roads and non-damaged roads. If the road condition increases in value by 1 unit, the system's value will increase by 0.282. If the good road condition increases in value by 1 unit, the road condition value will increase by 0.855. If the fair road condition increases in value by 1 unit, the road condition value will increase by 0.591. If the damaged road condition increases in value by 1 unit, the road condition value will increase by 0.088. If the very damaged road condition increases in value by 1 unit, the road condition value will decrease by 1.510.

will increase by 0.591. If the damaged road condition increases in value by 1 unit, the road condition value will increase by 0.088. If the very damaged road condition increases in value by 1 unit, the road condition value will decrease by 1.510. A good road condition greatly impacts the road condition value.

The public vehicle value is formed from public buses and public passenger cars. If public buses increase by 1 unit, the public vehicle value will decrease by 0.213. If public passenger cars increase by 1 unit, the public vehicle value will increase by 0.927. The private vehicle value is formed from private buses, private passenger cars and motorcycles. If private buses increase by 1 unit, the private vehicle value will increase 0.343. If private passenger cars increases by 1 unit, the private vehicle value will increase by 0.205. If motorcycles increase by 1 unit, the private vehicle value will increase by 0.658.

If the population increases by 1 unit, the typology value will increase by 1.017. If the population density increases by 1 unit, the typology value will increase by 1.787. If developed area increase by 1 unit, the typology value will increase by 1.172. If RGDP increases by 1 unit, the typology value will increase by 0.321.

Fossil fuel consumption in cities in Java can be explained as follows: if the typology increases by 1 unit, fossil fuel consumption will rise up to 1.097 kilo liters per year, but if the system increases by 1 unit, fossil fuel consumption will decrease 0.138 kilo liters per year. So the above explanation can be put into the following equation:

$$\text{Road Condition} = 0,855*\text{Good Road} + 0,591*\text{Fair Road} + 0,088*\text{Damaged Road} - 1,510*\text{Very Damaged Road} \quad (1)$$

$$\text{Public Vehicles} = -0,213*\text{Public Buses} + 0,927*\text{MPU} \quad (2)$$

$$\text{Private Vehicles} = 0,343*\text{Private Buses} + 0,205*\text{MPP} + 0,658 * \text{Motorcycles} \quad (3)$$

$$\begin{aligned} \text{System} = & -0,427*\text{Road Length} + 0,182*\text{Road Network Pattern} + 0,282* \text{Road Condition} \\ & + 0,203*\text{Public Vehicles} - 0,131* \text{Private Vehicles} + 0,999* \text{Route Length} + 0,356 * \text{Goods Cargo} \\ & + 0,421 * \text{City Typology} \end{aligned} \quad (4)$$

$$\text{City Typology} = 1,017*\text{Population} + 3,378* \text{Net Population Density} + 1,172* \text{Nett Area} + 0,321*\text{RGDP} \quad (5)$$

$$\text{Fossil Fuel (outer)} = 0,944*\text{Petrol} + 0,104*\text{Diesel Fuel} \quad (6)$$

$$\text{Fossil Fuel (inner)} = 1,097*\text{City Typlogy} - 0,944*\text{System} \quad (7)$$

The number of public passenger cars strongly influences public vehicles, the more public passenger cars are, the higher the value of public vehicles and the higher the value of the transportation system will be. This will eventually lower fossil fuel consumption. Public transport buses have a relative (negative) effect on the metropolitan cities transportation system. The more buses are, the lower the value of public vehicles will be, and also the lower the transportation system value is, therefore increasing fossil fuel consumption. This is caused by the number of public transport buses that is lower than the required amount.

The route length in metropolitan cities greatly affects the city's transportation system. The longer the route length of city public transportation (wider service area of public transportation) is, the higher the transportation system value will be, which will lower the fossil fuel consumption. Good road conditions in metropolitan cities greatly affects the city transportation system, the longer the good road condition is, the higher the transportation system value will be, which will lower fossil fuel consumption. Goods transportation has a fair effect on the city transportation system.

The dependent variable is fossil fuel consumption (petrol and diesel oil) and the independent variables are city typology (population size, nett area, population density nett, RGDP) and transportation system (road length, road network pattern, number of public vehicles, number of private vehicles, number of goods vehicles, road length based on road condition (good, fair, damaged, and very damaged).

## 5. CONCLUSION

The city transportation system and city typology have reciprocal effects. Fossil fuel consumption in metropolitan cities are more influenced by the city typology (population size, nett area, nett population density, RGDP) than by the city transportation system. This is because the currently available transportation system has not been provided well and the management of land use has not been implemented well.

The city transportation system consuming fossil fuel efficiently is a city transportation system with public transportation services using large capacity vehicles, efficient routes, low percentage and number of vehicles (private and goods), road network pattern using *grid*, and a compact *land use*. The transportation system consuming a lot of fossil fuel is the city transportation system providing small capacity public transportation services, inefficient routes, high percentage and number of vehicles (private and goods), a radial road network pattern, and a *land use* that is not compact (for example: Semarang, Bandung, Tangerang).

## ABSTRACT

*Grouted Macadam*s are manufactured by producing a very open porous asphalt skeleton and filling the voids with selected cementitious grouts, the final product is combination of the flexibility of the bituminous component with the strength and rigidity of the cementitious component. A range of cementitious grouts was formulated using a variety of binders including ordinary Portland cement, silica fume and fly ash. The grouts were designed to provide improved strength and performance characteristics with reduced water/binder ratios, whilst maintaining high workability. This was achieved with the aid of chemical admixtures that allowed the grouts to penetrate the porous asphalt skeleton by gravitational. The formulated cementitious grouts attained high strength characteristics (90-120 MPa at 28days), with the pozzolanic materials silica fume and fly ash, providing improved permeability and shrinkage properties. This paper is discussing the influence of grout properties containing fly ash especially on the indirect tensile properties of grouted macadam. It is concluded that the indirect tensile strength of grouted macadam were greatly affected by the cementitious grout type, in general the higher the compressive strength of the cementitious grout, the higher the tensile properties of the hydrated grouted macadam.

## Keywords

*Grouted macadam, fly ash, indirect tensile strength*

## 1. INTRODUCTION

The tensile properties of materials govern the cracking behaviour and affect other properties such as stiffness and fatigue behaviour of the materials. Tensile strength can be determined either by direct tensile tests or by indirect tensile tests such as flexural or split cylinder tests. Due to the difficulty in testing, only limited and often conflicting data are available on direct tensile tests. It is often assumed that the direct tensile strength of concrete is about 10% of its compressive strength [1].

The indirect tensile test was introduced to measure the tensile properties of pavement materials due to its many practical advantages as summarised by Kennedy [2]:

- (1) the test is relatively simple to carry out,
- (2) the type of specimen and the equipment are the same as those used for other testing, for instance using cylindrical specimens,
- (3) failure is not seriously affected by surface conditions and is initiated in a region of relatively uniform tensile stress,
- (4) the test can be conducted under static or repeated loading conditions, and provides information on:
  - a. the tensile strength, modulus of elasticity, and Poisson's ratio for both static and repeated loads,
  - b. fatigue characteristics,
  - c. permanent deformation characteristics of pavement materials.

The indirect tensile test is carried out on a cylindrical specimen by loading it with a single or repeated compressive load which acts parallel to and along the vertical diametrical plane of the specimen. This loading system develops a relatively uniform stress perpendicular to the direction of the applied load and along the vertical diametrical plane, thus ultimately causing failure of the specimen by splitting along the vertical diameter. The stress state in the surroundings of the centre of the circular face of an indirect tension specimen is similar to the stress state that occurs at the underside of a bituminous road layers.

Grouted macadam have visco-elastic properties similar to flexible pavements. The tensile properties of grouted macadam covered in this investigation were mainly the indirect tensile strength (ITS), the indirect tensile stiffness modulus (ITSM) and the indirect tensile fatigue test (ITFT) [4]. These tests were conducted at several temperatures and at a range of curing ages. Flexural strength testing was additionally carried out to enable a direct comparison to be carried out between the flexural

strength of grouted macadams and those of a typical concrete at 28 days curing. Grouted macadam test results were thus compared to the properties of bituminous mixtures and concrete.

## 2. RESEARCH METHOD

### 2.1 Materials preparation

#### 2.1.1. Materials for cementitious grouts

The cement used through out this investigation was ordinary Portland cement (OPC) supplied by Castle Cement Limited. The OPC complied with requirements of BS 12 (BS 1996). The properties of OPC are presented in Table 3.7. Quartzitic sand obtained from Tyhram Hall Quarry supplied by Tarmac Northern Ltd. was sieved, and the material passing 300µm was used as fine sand for the cementitious mortar. The water used in this investigation was tap drinking water from Yorkshire Water. The fly ash used in this investigation was produced at Drax Power Station and supplied by National Power plc. U.K. The ash conforms to BS 3892: Part 1 (BSI 1997). Table 3.6 gives the chemical composition of the Fly Ash use. Powdered silica fume was supplied by Elkem Chemical. The chemical composition is also presented in Table 1.

Table 1: Chemical composition of OPC, fly ash (FA) and silica fume (SF).

	<i>Ordinary Portland cement %</i>	<i>Fly ash %</i>	<i>Silica fume %</i>
SiO <sub>2</sub>	21.03	49.9	90.0
Al <sub>2</sub> O <sub>3</sub>	4.73	26.5	1.21
Fe <sub>2</sub> O <sub>3</sub>	2.93	8.1	3.87
CaO	63.63	1.7	0.34
MgO	2.67	1.3	1.43
SO <sub>3</sub>	3.00	0.9	0.31
K <sub>2</sub> O	0.65	3.6	1.49
Na <sub>2</sub> O	0.30	1.5	0.46
Loss on Ignition	0.97	3.8	2.17

#### 2.1.2 Superplasticizer

The use of chemical admixtures is an essential requirement for the production of flowable high performance slurries. A superplasticiser (SP) based on modified polycarboxylic ether was used with all the cementitious mixes, which complied with BS 5075: Part 3 (BSI 1985). This chemical admixture was supplied by Feb MBT Ltd. in liquid form. Technical data as supplied by supplier is presented in Table 2.

Table 2: Properties of superplasticiser

Appearance	Viscous liquid
Colour	brown
Specific gravity	1.1
pH	6
Alkali content (as Na <sub>2</sub> equivalent)	< 5g/l
Chloride Ion content	< 0.1% w/v
Hazardous ingredients	none

## 2.2 Cementitious grout mixture design

### 2.2.1 Binder compositions and fresh properties of the grouts

It is now generally accepted that mineral and chemical admixtures are essential requirements for the production of concrete. In addition to their dramatic effect of on the reduction of mortar porosity, they improve the packing capacity at the interface with the aggregates and thus create a tighter pore structure of the composite [5].

Three main cementitious binders were used in this investigation with the composition and binder/cement ratios as shown in Table 3. The first type was used as a control mixture by incorporating 100% ordinary Portland cement (OPC). The second type

was formulated by adding 5% of silica fume (SF) and the third cementitious binder was formulated by adding 30% of fly ash (FA).

Table 3: Composition and fresh grout properties of the different grouts used in this investigation

Grout	Composition	Super-plasticiser	W/B*	Workability index (seconds)	Setting time	
					initial	final
OPC	OPC 100	1%	0.28	9.50	3h. 05min.	4h. 10min.
SF	OPC: SF 95: 5	1%	0.28	9.10	3h. 35min.	4h. 30min
FA/SF	OPC: FA: SF 65: 30: 5	1%	0.28	10.32	3h. 50min	4h. 55min

W/B\* = water/binder ratio, binder is defined as blend of OPC or OPC and mineral admixtures

The proportions of mineral admixtures as cement replacement can vary from 5% to 80% by mass of cement. In normal structural concrete containing 5% silica fume addition, the water demand is normally increased to maintain the desired workability otherwise a superplasticiser is added [6]. In this investigation, the water/binder ratio was selected to produce grout flow times between 8-11 seconds as measured using the Leeds flow cone. Several initial trials indicated that by adding 1% superplasticiser by mass of binder to a grout with a water/binder ratio of 0.28 produced grouts that had satisfactory workability. Ease of impregnation was also assessed using dummy porous asphalt samples to ensure full depth penetration of the grout into the porous asphalt.

### 2.2.2. Strength properties

Both silica fume and fly ash are industrial waste by products and are very well known as mineral admixtures or supplementary cementing materials. In many cases these mineral admixtures react more slowly than OPC, giving increased strength and improved impermeability to the hardened cement paste at later ages.

The strength property of various cementitious grouts, at various curing ages is presented in Table 4. and graphically shown in Figure 1.

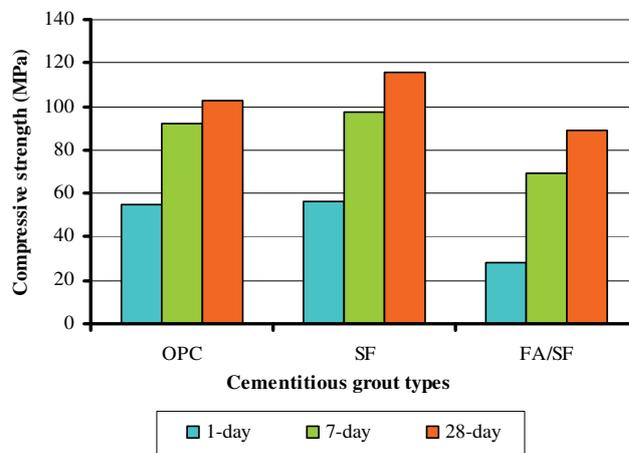

Figure 1: Compressive strength of three main types cementitious grouts

Table 4: Compressive strength of the cementitious grouts

Grout	Compressive strength (MPa)		
	1 day	7 days	28 days
OPC	55	96	102
SF	56	97	108
FA/SF	28	69	90

All the hydrated grout mixes showed little variation in bulk density (density values ranging from 1.85 to 2 g/cm<sup>3</sup>). However, the compressive strengths varied widely depending on the grout composition. As shown in Figure 1 the highest compressive strength values were found with the SF grout mixture. The 1-day compressive strength was 56 MPa, which increased to about 108 MPa at 28-days. The OPC showed similar strength to that of SF whereas fly ash grouts (FA/SF) resulted in a lower compressive strength at 1-day, but achieved a reasonably high value at 28-days. Both SF and FA are pozzolanic materials, which provide additional hydration products through their pozzolanic reaction to densify the cementitious matrix and improve the micro-structural properties [7]. Whilst Fly Ash adversely affects the strength gain at early ages, it contributes more to the strength development in the long term [8].

### 2.2.3 Performance properties

The performance properties of cementitious grouts at 28 days are presented in Table 5. Drying shrinkage results of the cementitious grouts up to 180 days are presented in Figure 2. The results, as shown in Table 5, indicate little variation within the calculated porosity values for the different cementitious binders, overall the results ranged between 29 and 31%. The effect of SF and FA replacement can be seen more clearly from the permeability and shrinkage results. Both replacement types are known to refine the pore structure of the cementitious composites and hence improve the performance properties. The pore refinement effect was reflected in the results, as both grout mixtures exhibited lower permeability and shrinkage than the OPC grout. The reduction in permeability was about 60% for the SF and 35% for the FA/SF, when compared to the OPC mix. SF and FA also reduced the drying shrinkage values by about 12-15%.

Table 5: Performance properties of the cementitious grouts measured at 28 days.

Grout	Porosity (%)	Oxygen permeability ( $10^{-17} m^2$ )	Shrinkage (micro-strain)
OPC	29.4	3.05	1803
SF	29.8	1.17	1518
FA/SF	30.9	1.95	1578

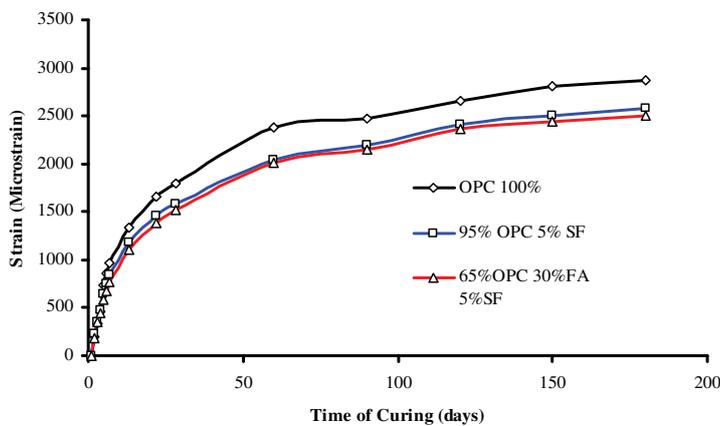

Figure 2: Drying shrinkage of the main type of cementitious grout up to 180 days

### 2.3 Indirect Tensile Strength Test

The indirect tensile strength test was conducted according to BS:99/108553 BS EN 12697-23 “Determination of the indirect tensile strength of Bituminous Specimens” (BSI 1999). The test was carried out using a Marshall loading frame fitted with a 12.5mm wide concave surface loading strip. The cylindrical specimens are subjected to compressive loads, which act parallel to and along the vertical diametrical plane. This creates uniform tensile stresses perpendicular to the direction of applied load and along the vertical diametrical plane, which ultimately causes the specimen to fail by splitting along the vertical diameter. Based upon the maximum load carried by a specimen at failure, the ITS is calculated from the following equation:

$$ITS = \frac{2 \times P_{max}}{\pi \times t \times d} \quad (1)$$

where: *ITS* = indirect tensile strength (kPa), *P<sub>max</sub>* = maximum applied load (kN),

$t$  = average height of specimen (m),  $d$  = diameter of specimen (m).

The tests were conducted at three temperatures (5, 20 and 60°C) to simulate various pavement conditions. To investigate the early strength development, the tests were also carried out at three curing ages (1, 7 and 28 days).

### 3. RESULTS AND DISCUSSION

Grouted macadam specimens produced using the same hot mix limestone porous asphalt skeleton with three types of cementitious grouts were subjected to the ITS test at three different temperatures. The tests were conducted after 28 days of curing. The results are presented in Table 6. and graphically displayed in Figure 3.

Table 6: The effect of cementitious grouts on ITS at different test temperatures

Material	Indirect tensile strength at 28 days (kPa)		
	5°C	20°C	60°C
HL/OPC-GM	1027	957	219
HL/SF-GM	1152	1050	220
HL/FA&SF-GM	943	935	206

At a test temperature of 5°C, the ITS values were approximately 110% higher than the ITS at 20°C. Increasing the test temperature from 20°C to 60°C, reduced the ITS of the specimens by approximately 80%. It was clear that the mechanical properties of grouted macadams, similar to conventional bituminous mixtures, were highly dependent on the test temperature. The visco-elastic nature of the binder in the porous asphalt skeleton was clearly reflected in the performance of the grouted macadams.

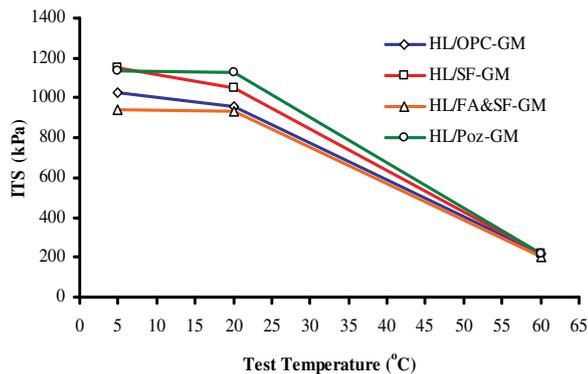

Figure 3: Effect of cementitious grout on the indirect tensile strength of grouted macadam at different test temperatures. Since all the results shown in Table 6. were of identical porous asphalt skeletons, it was clear that the properties of cementitious grouts also had a marked influence on the properties of grouted macadams. The relation between compressive strength of cementitious grouts and ITS of grouted macadam are presented in Table 7 and graphically displayed in Figure 4.

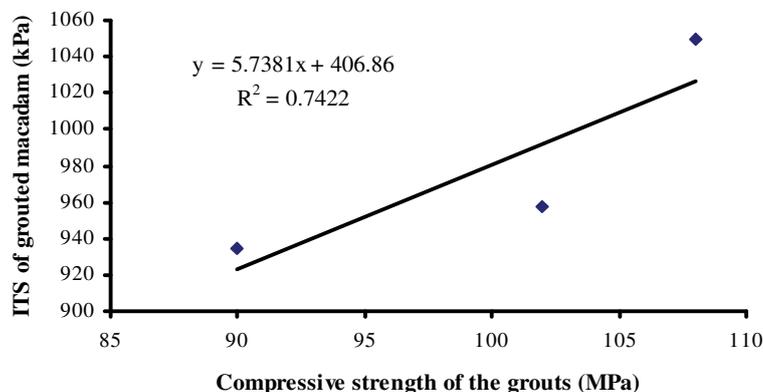

Figure 4: Relation between indirect tensile strength of grouted macadam and compressive strength of the grouts

In terms of ranking, it was clear that the strength of the hydrated cementitious grouts had a direct influence on the tensile strength of the respective grouted macadam.

Table 7: Relation between ITS and Compressive strength of cementitious grout

<i>Material</i>	<i>Compressive strength of cementitious grouts (MPa)</i>	<i>ITS of grouted macadam (kPa)</i>
HL/OPC-GM	102	957
HL/SF-GM	108	1050
HL/FA&SF-GM	90	935

#### 4. CONCLUSION

1. High workability cementitious grouts that can rapidly penetrate a porous asphalt skeleton by gravitational flow and provide adequate hydrated strength and performance properties were also successfully produced using combinations of readily available cementitious binders (including silica fume and fly ash) and chemical admixtures (superplasticizer).
2. The use of silica fume and fly ash were shown to enhance the porosity, permeability and shrinkage characteristics of the hydrated cementitious grouts
3. The indirect tensile strength of grouted macadam were greatly affected by the cementitious grout type, in general the higher the compressive strength of the cementitious grout, the higher the tensile properties of the hydrated grouted macadam.

### **ABSTRACT**

*This paper presents an evaluation of precast system structure implementation for the rehabilitation of a historical colonial building in Surakarta dated back from year 1880 hereafter called Ex Mabrigif 6 Building Block B. Due to lack of maintenance and care, one corner has collapsed and material deformation happened in some places. Rehabilitation is necessary to be done to strengthen and ensure that the building can be used again.*

*Analysis and experimental methods has been used in this research to determine the structre of the building's strength. Analysis has been done by conducting studies to existing condition of the building and precast structural system by using SAP2000 program. The step consists of field investigations, building damage assessment, evaluation and determining the solution. Experimental method is done by simulating structural model and making of concrete beam models. Structural model simulation provides some alternative for precast structural system. The deflection test has been done to 5 pieces of concrete beams with 250 mm x 350 mm x 3500 mm in size and 40 MPa compressive strength to provide the best beam model.*

*The laboratory test results showed that beam with sugar-based additive composition and confinement has the highest rupture value. The use of precast system model 2 and beam with sugar-based additive composition and confinement is the recommended for the rehabilitation of the building.*

**Keywords** : confinement, evaluation, inspection, precast, recommendation, rehabilitation.

### **I. INTRODUCTION**

Building rehabilitation is an effort to restore a building to a better condition to be used for its purpose. Building rehabilitation includes all building components that suffered damage or degradation. Quality degradation can occur because of material disorientation caused by environmental factors such as weather and aging. Failure of each sub and or super structures may cause damage to the building. Material deterioration due to aging of old buildings has a big influence in deteriorating buildings strength and structural stiffness. Similarly, structural damage might also occur during the service life of a building. Rehabilitation of each case of damage are specific and need accurate in identification of the main cause of damage.

The buildings of the former Markas Brigade Infanteri 6 (ex Mabrigif 6) building complex is a heritage building which was built during the Dutch colonial era in XVIII-XIX century as a complementary facility to Vastenburg Fort (Beteng Vastenburg). It is located at the intersection of Mayor Katamso Road and Kapten Mulyadi Road. It is an integrated part of Beteng Vastenburg which has a great historical value for Surakarta City. According to information submitted by Executive Daily Branch of "Angkatan 45" (DHC 45), the buildings in the complex were built in 1880. Building used as a Dutch internaat office until 1942. During different stages in Indonesian history, buildings in ex Mabrigif 6 complex experienced the transition of ownership and function. I was functioned as an educational facilities in 1945-1949, and then used as military base in 1949. Currently some buildings in ex Mabrigif 6 complex are used as the DHC 45 office. Presently the buildings are the property of the Department of Defence of Republic of Indonea. The building rehabilitation effort has been initiated by the government of Surakarta City and Department of Defence. However due to some administration problems this plan has not been realised. There are three mass buildings in this complex and not all are in good conditions. One mass bulding at the east side (block B) suffered from structural damage with the collapse of one of its corner.

Principles and conservation measures on historical building in Indonesia as the basic reference to the treatment of historical buildings have been set in the State Law No. 5 tahun 1992 regarding cultural and historical building preservation area, government law No. 10 year 1992 on the operationalization of State Law (UU) No. 5 year 1992, and the Cultural and Tourism Law No PM.49/UM.001/MKP/2009 on Guideline of Cultural Tangible Heritage and Sites. The Basic technical handling is stated in the State Law No. 28 year 2002 on Buildings and government law No. 36 year 2005 on the operationalisation of state law on building. Considering that most part of the Beteng Vastenburg area has a historical value, buildings of ex Mabrigif 6 complex can be categorized into cultural heritage building in accordance with the State Law No. 5 year 1992 in terms of age. The rehabilitation of ex Mabrigif 6 block B bulding is a promising step in saving the historical asset of Surakarta city which are in the verge of extinction and started to be replace by new buildings. Rehabilitation has also been done to extend the service life of buildings by increasing its strength.

Figure 1: Condition of Block B building corners.

Precast system structure is known as a method that use concrete into part of building's structural and non structural component with more practise and carefull material control quality. It is well known that precast concrete product can be installed quickly and will lead to a good quality work result. It is not only superior in terms of structure, strength and shear, but also in architectural form on exterior view. The benefits of precast concrete technology include speed of construction time, flexibility in the planning process, more simple on site job, carefully accounted concrete quality, dimensional accuracy and better quality building.

## II. STRUCTURAL ANALYSIS

Structural analysis is based on the following rules and procedures:

- SNI 03-2847-2002 on the procedure to calculate concrete structure for buildings.
- SNI 03-1726-2002 on the procedure to plan the resilience of a building towards earthquake.
- Regulation on the weighting for Indonesian building year 1983.
- Analysis and structural calculation using SAP2000.

According to article 8 of SNI 03-1726-2002 about structural performance of building, building structure must comply with the performance requirements for serviceability limit ( $\Delta s$ ) and ultimate limit ( $\Delta m$ ).

### 1. Serviceability limit performance ( $\Delta s$ )

Serviceability limit performance ( $\Delta s$ ) is determined by storey drift under seismic design. It is intended to maintain users comfortability, prevent non structural damage, limit the steel elasticity and over cracking concrete. Therefore  $\Delta s$  storey drift must not be larger than:

$$\Delta s = \frac{0.03}{R} \times h_i \quad \text{or } 30 \text{ mm} \quad (1)$$

(whichever smaller)

in which :

$h_i$  is number of storey,  $R$  is seismic reduction factor.

To calculate the serviceability limit, the performance of the inter level should consider structural deviation output based on the earth quake load.

### 2. Ultimate limit performance ( $\Delta m$ )

Ultimate limit performance ( $\Delta m$ ) is determined by the deviation and maximum storey drift due to seismic design on the verge of the collapse building condition. According to article 8.2 in SNI 03-1726-2002, deviation and storey drift should be calculate from structural deviation due to nominal quake load, multiplied by a multiplier factor  $\xi$ .

$$\Delta m = \xi \times \Delta s \quad (2)$$

Rate of multiplier factor  $\xi$  : For regular building  $\xi = 0.7 \times R$ , For irregular building  $\xi = R$ , with  $R$  is seismic reduction factor and regular building type.

## III. RESEARCH METHOD

Activities of this research are as follows:

### 1. Investigation and assessment of damage level

The first step in the on site investigation to see the existing building condition. The result of the assessment of the damage level found in the existing building leads toward a recommendation for further action towards the building rehabilitation methods. Investigation and damage level assessment step should be implemented.

An examination to determine the building status, to be used as a basic determination for the classification of the building's damage has been implemented. Subsequently further necessary actions should be evaluated to solve the problems.

### 2. Experimental Test

Planned alternative models have tested using SAP 2000 program to determine the strength level of the building. If the results are less than the standard requirements for earth quake resistant building, then we remodel the step to get the optimal result. After we obtained the optimal system structure result, we need a concrete beam models test as part of precast system structure. The quality of material used in this test is in accordance with the assumptions of material quality in structural model plan to obtain the alignment of research settings.

### 3. Laboratory Experiments

Laboratory model experiment is done by making and testing concrete beam models with aim to obtain the best composition beam model. Bending test done to 5 beam with 25 cm x 35 cm x 350 cm in dimension. Its variation is as follows:

- a. 1 (one) model of normal composition beam.
- b. 1 (one) model of sugar based additive composition beam.
- c. 2 (two) models of normal composition with confinement beam.
- d. 1 (one) model of sugar based additive composition with confinement beam.

## 4. RESULT AND DISCUSSION

### 4.1 Preliminary Building Damage Assessment Result

Result of building damage assessment of ex Mabrigif 6 blok B building shows that the wall structure of the 1st floor outer walls had a Rangk-IV damage of 42,3 m (> 20%) and Rangk-V damage of 10,65 m (> 10%). The 1st floor inner walls have no damage. Structure wall of 2nd floor outer walls had a Rangk-IV damage of 0 m (< 10%) and Rangk-V damage of 16,05 m (> 10%). Building components that have risk overturned and classified with risk level B (be careful) are the windows, stairs and ceilings. Overturned risk can be classified with risk level C (danger) on coating components, roof and walls. Recommended decision and advice on emergency inspection on ex Mabrigif 6 blok B building as follows:

- a. Building included in category of **“Danger”**.
- b. For activities around the building is categorized in **“Be careful”**.

Result of classification damage building assessment and follow-up determination, damage evaluation 1st floor shows that building suffer the damage level of **“medium”** with D (damage ratio) of 22,1589. 2nd floor structure suffered the damage level **“medium”** with D by 34,4103. Based on both conditions, identification of overall damage level the building include damage category **“medium”**. Advice given in the building damage classification assessment and follow up determination can be determined the possibility act as **“repairing or strengthening (for further investigation)”**.

### 4.2. Building Component Testing Result

Test carried out on wall component to get mass weight and compressive strength (f'c). Thus then fill into SAP 2000 program to analyse building strength. Test done in two ways: with rebound hammer test and compressive strenght test to building sample on laboratory. Average value of compressive strength result using rebound hammer test shown in Table 2. and average value building sample material test, as shown in Table 2.

Table 1. Value of Concrete Compressive Strength Testing Result in Field by Rebound Hammer Test

No.	Average Compressive Strength (MPa)	No.	Average Compressive Strength (MPa)
1	12,66	14	8,50
2	8,50	15	8,50
3	10,58	16	8,86
4	8,50	17	14,45
5	15,21	18	9,92
6	15,96	19	8,99
7	8,50	20	10,09
8	17,94	21	10,39
9	8,50	22	8,69
10	13,60	23	9,73
11	15,96	24	12,28
12	12,96	25	9,35
13	15,68	26	9,92

Table 2. Value of Concrete Compressive Strength testing Result by Universal Testing Machine.

No.	Compressive Strength (MPa)	No.	Compressive Strength (MPa)
1	3,88	8	6,49
2	3,08	9	4,31
3	3,25	10	7,19
4	3,76	11	6,30
5	4,17	12	4,45
6	3,17	13	3,36
7	3,56		

Result of average compressive strength with two ways testing showed significant differences. From testing with rebound hammer test obtained average value of 11,32 MPa, while testing with Universal Testing Machine (UTM) on cube samples found average value of 4,38 MPa. Calculation will be done is the calculation of building strength, compressive strength value set to smallest value to give calculation with greatest risk of 4,38 MPa.

Mass weight obtained by measure volume and weight of material is sample. Based on the measurement resul, we obtain average mass weight value of 1586,56 kg/m<sup>3</sup>.

### 4.3. Calculation of Building Strength

Deformation diagram as analysis result due to load combination 3 can be seen in Figure 4. Deformation diagram in Figure 4 explains that almost all joint deformed vertical and horizontal directions. That condition indicates wall structure is vulnerable to loads when less of structural stiffness. Vertical direction deformation with largest value were on upper beams that support roof truss and ceiling. Joint component in vicinity collapse corner, showed large deformation value.

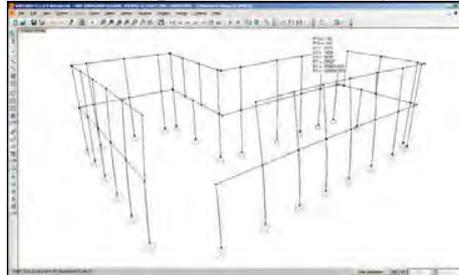

Figure 4: Deformation Diagram due to Load Combination 3 in SAP2000 program

The largest vertical deformation of Z direction were on joint number 188 at the coordinates cc, 6', 881 at 0,10961 cm due to load combination 1. The largest horizontal deformation of X direction were on joint number 140 at coordinates i, 1, 881 at 0,16945 cm due to load combination 4. The largest horizontal deformation of Y direction were on joint number 121 at coordinates i, 1, 881 at 0,075836 due to load combination 3.

The large value of vertical and horizontal deformation indicated that the wall structure critically support the dead load of 50 kg/m<sup>2</sup> live load assumption. The building's existing concrete compressive strength does not fill the quality requirement for the construction of 28 MPa. As a precaution we reduced the load of the wall, so that wall only support its own weight. The structural load and another planned load will be supported by a new system structure to be placed in the building.

Views of transferred load from wall (a) to new system structure (b) can be seen in Figure 5.

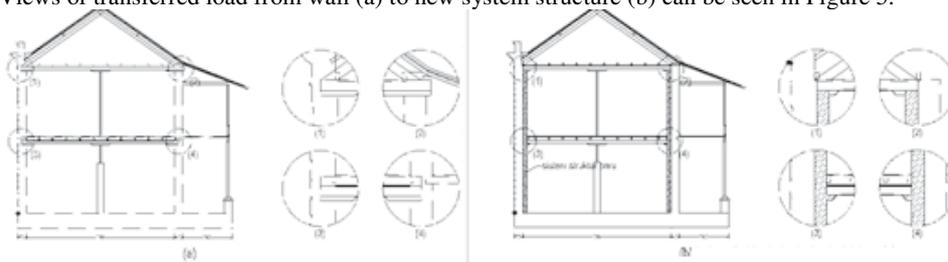

Figure 5: Transferring Load. a) Load from the truss and floor 2 beam is directly supported by the wall. b) Load from the truss and floor 2 beam is directly supported by the new structure in the building interior.

### 4.4. Handling Formulation using Precast System Structure

The strengthening alternative is determined base on strengthening identification. There are 3 (three) problems that become main issue in the strengthening identification:

- a. Effective loading distribution.
- b. Placement of structural elements that have strength and stiffness according to the load plan.
- c. Building strengthening in order to be used again refer to rules of rehabilitation of historical buildings.

Based on those main issue, we can determined the strengthening alternative by the placement of precast system structure which consist of form beams and columns in the building. There are 2 (two) alternative forms of precast system structure:

- a. Alternative 1

Alternative 1 is done by placing the form of columns at the joint of the main beams and replacement of wood main beam at the 2nd floor with precast beams. This beam is intended to eliminate the pipe's columns inside the 1st floor and the terrace column.

Figure 6: Alternative Structure Model 1.

- b. Alternative 2

Alternative 2 is conducted by placing the form of columns at joint of main beam while maintaining the wood structure of 2nd floor. The main wood beams and the pipe columns were retained. The exterior wood structure is placed to the column by the console.

**4.5. Strengthening Analysis**

Analysis result of model 1 and model 2 can be reviewed as follows:

a. Alternative 1

Based on the technical data plans, the dimension simulation input to confirm the SAP 2000 for further analysis to the planned system structure. Simulation result on structure model alternative 1 provides the optimum system structure composition data as shown in Table 3.

Deformation in model alternative 1 is due to load combination 3 can be seen in Figure 8. The larger horizontal deformation were on joint number 82 at coordinates H, 1, 891 at 0.2953 cm, while largest vertical deformation were on joint number 52 at coordinates C, 2, 457 at 0.2233 cm.

Figure 7: Alternative Structure Model 2.

Table 3. Technical Data Plan Element Model

No	Description	Dimension	Note
1	Column K-1	30 cm x 60 cm	Precast column
2	Beam B-1	25 cm x 40 cm	Main Beam
3	Beam B-1x	37.5 cm x 72.5 cm	Beam E-1/4
4	Beam B-1y	25 cm x 45 cm	Beam 2-A/E
5	Beam B-2	25 cm x 35 cm	Canopy Beam
6	Beam B-3	25 cm x 35 cm	Beam between column
7	Beam RB-1	25 cm x 40 cm	Rear Ringbalk
8	Beam RB-2	25 cm x 30 cm	Ringbalk between column
9	Height of first floor	457 cm	Distance between the floor surface and beam's surface
10	Height of second floor	424 cm	Distance between beam's surface and ringbalk

Figure 8: Deformation Model Structure Diagram Alternative 1 due to Load Combination 3.

The beam section check conducted to analyze the beam shows the favorable result, i.e.  $A_s \text{ max} > A_s \text{ analysis result}$ . The description of the beam section check analysis which evaluated some beams can be seen in Table 4.

Table 4: Beam Section Check Element Model Alternative 1.

No	Dimension (cm)	Beam	Mmax (Ton)	$A_s \text{ result}$ ( $\text{mm}^2$ )	$A_s \text{ max}$ ( $\text{mm}^2$ )	Rec
1	37.5x72.5	Beam E-1/4	23.72	1233	7745	OK
2	25 x 45	Beam 2-A/E	2.62	854	3060	OK
3	25 x 40	Beam 3-A/E	2.74	1368	2677	OK
4	25 x 40	Ringbalk 8-A/E	2.52	569	2677	OK

The performance serviceability limit ( $\Delta_s$ ) and ultimate performance limit ( $\Delta_m$ ) confirm the requirement of the maximum storey drift.  $\Delta_s$  may not exceed the value 30 mm based on calculations using Formula (1). Calculation was done with those formula, and we obtained the value of  $\Delta_s$  of 36,34 mm, maximum deviation value was set at 30 mm. The maximum  $\Delta_m$  determined by 0,02 multiplied by the height of the space between the reviewed storey. The review of  $\Delta_s$  and  $\Delta_m$  value between storey in x and y direction can be seen in Table 5, 6, 7 and 8. The review was conducted on the axis with the largest deformation.

Table 5: Review of  $\Delta_s$  x Direction

Level	$H_i$ (m)	$A_s$ (mm)	Drift $A_s$ between level (mm)	Req Drif $A_s$ (mm)	Note
2	4.24	2.95	2.68	30.00	OK
1	4.57	0.29	0.29	30.00	OK

Table 6: Review of  $\Delta s$  y Direction

Level	Hi (m)	As (mm)	Drift As between level (mm)	Req Drif As (mm)	Note
2	4.24	1.92	1.84	30.00	OK
1	4.57	0.09	0.09	30.00	OK

Table 7: Review of  $\Delta m$  x Direction

Level	Hi (m)	As (mm)	Drift As between level (mm)	Req Drif Am (mm)	Note
2	4.24	10.34	9.34	84.90	OK
1	4.57	1.00	1.00	91.40	OK

Table 8: Review of  $\Delta m$  y Direction

Level	Hi (m)	Am (mm)	Drift As between level (mm)	Req Drif Am (mm)	Note
2	4.24	6.47	6.43	84.90	OK
1	4.57	0.31	0.31	91.40	OK

$\Delta s$  and  $\Delta m$  performance of alternative model 1 according to the Table 5, 6, 7, 8 show that the model confirmed the requirement.

b. Alternative 2

Based on the technical data plans, dimension simulation input are required in SAP 2000 program for further system structure analysis. Simulation result on alternative 2 structure model provides the optimum system structure composition data as shown in Table 9.

The deformation in alternative 2 model is due to fact that the load combination 3 can be seen in Figure 9. Larger horizontal deformation were found on joint number 61 at coordinates F, 1, 891 at 1.1427 cm, while the largest vertical deformation happened on joint number 6 at the coordinate D, 8, 891 at 0.0184 cm.

Table 9: Technical Data Plan Element Model 2

No	Description	Dimension (cm)	Note
1	Column K-1	30 x 65	Precast column
2	Column K-2	35 x 65	Precast column
3	Beam B-1	25 x 44	Rear Beam
4	Beam B-2	25 x 62.5	Beam I-H/I, 4-H/I & 4-I/I
5	Beam B-3	25 x 40	Beam between column
6	Beam B-4	27.5 x 65	Beam I-A/B, I-A/C & I-I/I
7	Beam RB-1	25 x 40	Rear Ringbalk
8	Beam RB-2	25 x 30	Ringbalk between column
9	Height of first floor	457	Distance between the floor surface and beam's surface
10	Height of second floor	424	Distance between beam's surface and ringbalk

The beam section check was conducted to analyze the beam, and it confirms that  $A_s \max > A_s$  analysis result. The description of the beam section check analysis to review some beam can be found on Table 10.

Figure 9: Deformation Model Structure Diagram of Alternative 1 Due to Load Combination 3.

Table 10: Beam Section Check Element Model Alternative 2.

No	Dimen-sion (cm)	Beam Name	Mmax (Ton)	As result (mm <sup>2</sup> )	As max (mm <sup>2</sup> )	Rec
1	25 x 45	Beam J-1/4	-12.49	525.00	3060.00	OK
2	25 x 62.5	Beam I-A/B	1.40	86.60	4395.00	OK
3	25 x 40	Beam I-E/F	-1.06	27.70	2677.00	OK
4	25 x 45	Ringbalk J-1/4	-7.20	386.57	3060.00	OK
5	25 x 37.5	Ringbalk J-1/5	-0.61	14.7	2486.25	OK

In accordance with the requirements of  $\Delta s$  and  $\Delta m$  in the discussion of alternative model 1, review of  $\Delta s$  and  $\Delta m$  values between storey in x and y direction can be seen in Table 11-14.

Table 11: Review  $\Delta s$  x Direction

Level	Hi (m)	As (mm)	Drift As between level (mm)	Req Drif A (mm)	Note
2	4.24	1.89	-9.54	30.00	OK
1	4.57	11.43	11.43	30.00	OK

Table 12: Review  $\Delta s$  y Direction

Level	Hi (m)	As (mm)	Drift As between level (mm)	Req Drif As (mm)	Note
2	4.24	2.99	1.53	30.00	OK
1	4.57	1.46	1.46	30.00	OK

Table 13: Review  $\Delta m$  x Direction

Level	Hi (m)	As (mm)	Drift As between level (mm)	Req Drif Am (mm)	Note

2	4.24	6.62	-33.37	84.80	OK
1	4.57	40.00	40.00	91.40	OK

Table 14: Review  $\Delta m$  y Direction

Level	Hi (m)	As (mm)	Drift As between level (mm)	Req Drift Am(mm)	Note
2	4.24	1.39	0.01	84.80	OK
1	4.57	1.38	1.38	91.40	OK

$\Delta s$  and  $\Delta m$  performance of alternative model 2 according to the Table shown above shows that the model confirms the requirement. Model alternative 1 and model alternative 2 is in line with the structural requirement design. Both alternatives can be compared according to several variables to give consideration to the advantages and disadvantages of each alternative. Comparison summary of two model structures can be seen in Table 15.

Table 15: Comparison Structure Model Alternative 1 and Alternative 2

No	Description	Alternative 1	Alternative 1
1	Changing in space	Available	No
2	Changing in the building exterior	Available	No
3	Cost based on the volume of beton	Higher	Lower
4	Simplicity of structured system pattern	More complex	Simpler
5	Ease of execution	More complex	Easier

Based on Table 15, it can be explained that alternative 1 provided possibilities on interior space with the removal of pipe column on the 1st floor. Alternative 2 does not change the space which still retains structural wood and pipe column. Exterior view changing appears on the alternative 1 because the terrace column have been replaced by cantilever beam. Alternative 2 still gives the initial appearance because the terrace element remains as before. Based on the concrete volume required, alternative 1 is more than alternative 2. Concrete requirement is indirectly related to the construction cost. Alternative 2 provides simple system structure than system structure alternative 1 with the absence of the long span beam as cantilever. Construction of model structure alternative 1 is more complicated than alternative 2 because of the long span beam and cantilever, although technically it still can be done. Furthermore, there should be a laboratory experiment to get the best model of beam as the composer of precast system structure with compressive strength of 40 MPa.

#### 4.6. Test Beam Models

Loading test performed on 5 (five) beams give the deflection value at each loading level. Comparison of the deflection value at the same point of each beam can be seen in Figure 10, 11 and Figure 12. Point 1 and 3 are points with the distance of 100 cm from pedestal and the same point under the load point. Point 2 is the midpoint of beam (1/2 L). Deflection value shows the level of beam elasticity. The greater deviation value indicates better security level of the beam when there is an over load. In addition, the maximum load supported by each beam also shows the *maximum strength of the beam*.

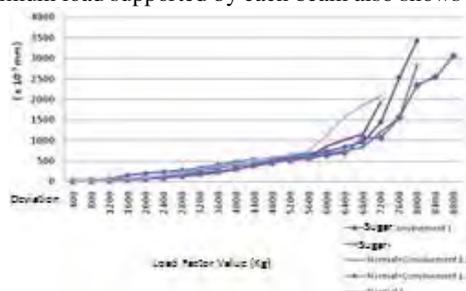

Figure 10. Comparison of Deflection at Point 1

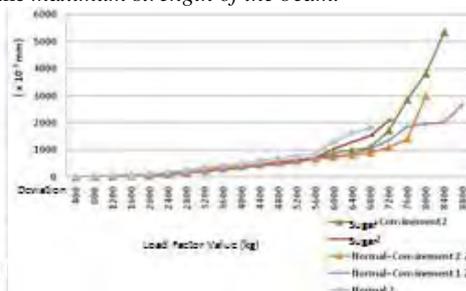

Figure 11. Comparison of Deflection at Point 2

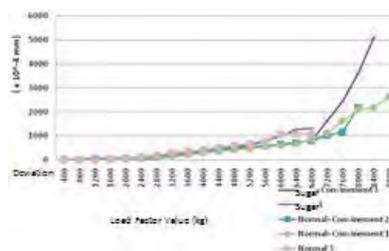

Figure 12. Comparison of Deflection at Point 3

From the figures it can be seen that the beam quality can be sorted as follows:

- Beam with the sugar based additive composition and confinement.
- Beam with the normal composition with confinement.
- Beam with the composition of sugar-based additive.
- Beam with normal composition.

## 5. CONCLUSION

Analysis of the experimental test in this research have lead to the following conclusion. Ex Mabrigif 6 block B building is included in dangerous category and require carefull act for users around the building. Advice given on the building damage classification assessment and follow up determination can determine the possibility to act as “repairing or strengthening (for further investigation)”. Rehabilitation effort by transferring load to new system structure is an alternative solution which might be chosen related to maintain the building’s historical value. Wearing out of material and deterioration of ex Mabrigif 6 block B building is caused by the condition in which structural service life requirements have not been covered. New system structure that sustain the load design is capable to support and maintain building authenticity. Two alternative of precast system structures proved that the structural capability sustain the load design. Alternative 2 has better fitness related to the rehabilitation effort compared to alternative 1. Beam model with sugar based additive composition and confinement on its bar have provided significant results. This can be conducted to increase the deflection level and the safety factor for precast construction beam.

Further research on improvement of wall construction, increasing the material wearing and strengthening foundation can be done to provide comprehensive discourse on the building rehabilitation. Beam test on samples with various composition is still limited to the deflection test. Further research on connection system and method of implementation of the use of precast structural system as an alternative method for building rehabilitation can be conducted. Building rehabilitation using precast system structure in theoretical way can be implemented to provide strengthening of old building. Further research is needed to compare the study result, and to ensure a realistic research outcome.

## **ABSTRACT**

*The construction management accomplishment on building project of manufacture industry in PT. Damai Indah Kaca Tipis – Indonesia with Analytical Hierarchy Process (AHP) and expert choice software method was analyzed. The parameters of the construction management accomplishment were the quantity of the worker, bill of quantity, time progress report, and time schedule. The quantity of the workers consists of project manager, site manager, supervisor, surveyor, mechanic, etc. The bills of quantity consist of bar chart diagram. The time progress reports consist of daily report, weekly report and monthly report. The time schedules consist of S curve. The analysis shows that the time progress report was the most important of the construction management accomplishment in PT. Damai Indah Kaca Tipis building project.*

**Keywords:** *Analytical Hierarchy Process, expert choice, construction management accomplishment, manufacture industry, building project, PT.Damai Indah Kaca Tipis.*

## **1. INTRODUCTION**

The construction industry is the uniquely industry, because every project has a different characteristic from the other project. Starting from the first step is planning process, and the second step is designing process, and the third step is an auction process and the last step is the accomplishment of the project. According to many of construction projects, the development of construction management could not separated from the development of construction service industry. In other side, the development of construction service industry is very close with the development accomplishment will be encourage in this time. Generally, the construction service industry related to all of the physically development project for human being such as high rise building, property, bridge, and so on, including the installation of each project. According to the complexity of the development accomplishment of each project, it should be followed to the good of the development of construction management, which is less cost, good quality and less time to do every project. To realize the development accomplishment

of every project that less cost, good quality and less time, we can calculate with using the parameters of the construction management accomplishment, they are the quantity of the worker that consist of project manager, site manager, supervisor, surveyor, mechanic, etc. The bills of quantity consist of bar chart diagram. The time progress reports consist of daily report, weekly report and monthly report. The time schedules consist of S curve. In Indonesia, the parameters of the construction management accomplishment have to concern for every parties of a construction contract, the owner and contractor, because, sometimes the project has time overrun and cost overrun, especially for the project that have less time (less than one year). In addition, the main goal of the parties involved in a project's construction is to have a succesful project. This is defined as a project that has been constructed in accordance with the plans and specifications, within the time and cost originally anticipated. To determine the relative importance among the parameters of the construction management accomplishment, an analytical hierarchy process (AHP) and expert choice software method is used to analysis the construction management accomplishment on building project of manufacture industry in *PT. Damai Indah Kaca Tipis*. *PT. Damai Indah Kaca Tipis* is a company that produce the sheet of glass for automotive industry such as motorcycles, cars, bus and trucks and they produce the product to sufficient for local and international demand. Besides that, *PT. Damai Indah Kaca Tipis* is a developer for manufacture industry building in Mekar Jaya Industry area in Jl. Raya Mauk Km. 7, Tangerang, Banten in 4 Hectare area, that has built a building of Indonesia 130 t/d Horizontal Drawing Glass Production Line Works. The accomplishment development of this project devided in to Combined Building Work Area, Batch House, Substation and Infra Structure for about five month (since March 1st 2010 to August 1st 2010) with cost US\$ 3.400.000,-. *PT. Damai Indah Kaca Tipis* is an owner and developer of Indonesia 130 t/d Horizontal Drawing Glass Production Line Works project and as a main contractor is *PT. Dasatria Utama* and *PT. Perkasa Adiguna Sembada* as a Sub Contractor, the two contractor lead the accomplishment of the development of this project. Whereas *PT. China Triump* as a planner and controlling consultant. There are four important point that have to concern to accomplish the development of this project, i.e: The Quantity of The Worker, The Bill of Quantity, The Time Progress Report and The Time Schedule. Based on Introduction, so we try to formulate about the poblems of this paper is how was the construction management accomplishment on building project of manufacture industry in *PT. Damai Indah Kaca Tipis* with the parameters of the construction management accomplishment (the quantity of the worker, bill of quantity, time progress report, and time schedule) using Analytical Hierarchy Process (AHP) and expert choice software methode? And the objective of this paper is to analyze about the construction management accomplishment on building project of manufacture industry in *PT. Damai Indah Kaca Tipis* with the parameters of the construction management accomplishment (the quantity of the worker, bill of quantity, time progress report, and time schedule) using Analytical Hierarchy Process (AHP) and expert choice software methode [1-8].

## 2. METHOD OF RESEARCH

The AHP is applied via three main problems solving approaches: decomposition, comparative judgements, and synthesis of priorities (Saaty 1980). Decomposition structures a complex problem into its basis elements, working from the goal objective down through various levels, from the more general to the particular and definite elements. It provides an overall view view of the complex relationship within the situation. Comparative judgements are used to determine priorities among elements of every level. This is achieved by asking the decision makers or experts to evaluate level elements pairwise with respects to elements in the next higher levels. Saaty suggested using a nine-point scale for making numerical judgments in the AHP pairwise comparisons. Using the scale, the decision makers or the experts exercise judgment about the prioritie such the factors

and the subfactors can be compared among them selves in relations of the elements of the next higher level. This leads to the construction of matrices from which relative weights of the elements with respect to each element of the level above can be determined. As for the synthesis of priorities, the constructed matrices are used for computing weighted priorities for elements of a given level over the other elements of the same level with respect to each element of the level just above. In this way, the priorities of the factors can be determined. Priorities can be calculated by a software package called *Expert Choice* (1986). And a nine point scale (1: equal importance; 3: moderate importance of one over another; 5: strong importance; 7: very strong importance; 9: extreme importance; 2,4,6 and 8: intermediate values between the two adjacent judgements) which is widely used in surveys for obtaining data for evaluation of weightings among the attributes of a complex issue through the use of AHP (e.g, in the study of Lai and Yik (2011). In short, Analytical Hierarchy Process is a technique of many criteria decision making to involve the consideration of two factors, which is objective and subjective factor to choose the best alternative. The approximation is used to get ratio – scale of cardinal rank from the alternatives that made a fool of many attributes decision making. Besides that, we have to observe about decomposition, comparative judgment, synthesis of priority and logical consistency to use the Analytical Hierarchy Process as a tool of decision making problems [4-8].

## 2.1 Measurement and Data Collection

The data collection was based on interview with five worker who have to responsible about the accomplishment of this project. They are Project Manager, Site Manager, Supervisor, Surveyor and Chief Worker. Each of this worker was asked to evaluate and assign relative scales in a pairwise fashion with respect to the subfactors of one level of hierarchy given the criteria at the next higher level of hierarchy. As a result, a set of pairwise comparison judgement matrices corresponding to the construction management accomplishment of *PT. Damai Indah Kaca Tipis* were used in all levels of the hierarchy as shown in Fig 1 below:

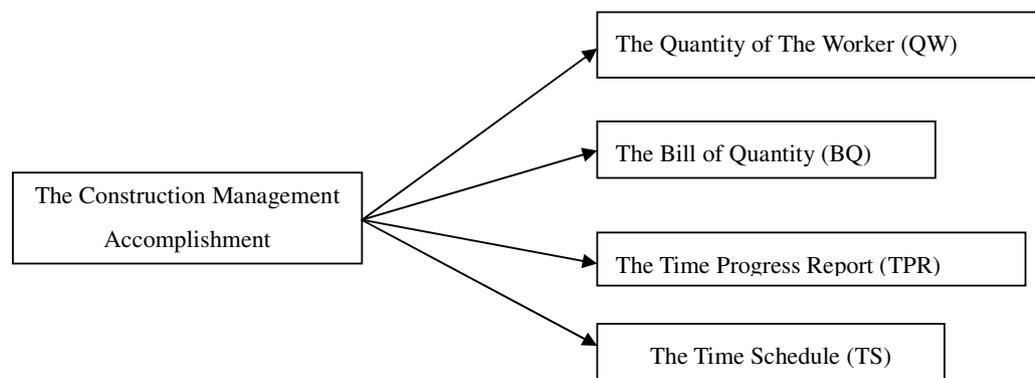

Fig 1. The Parameters of Construction Management Accomplishment in *PT. Damai Indah Kaca Tipis*

In this paper, I try to calculate about the construction management accomplishment on building project of manufacture industry in *PT. Damai Indah Kaca Tipis* with the parameters of the construction management accomplishment (the quantity of the worker, bill of quantity, time progress report, and time schedule). The first step I make comparison matrice of criteria level, the second step I calculate the criteria level in pairwise matrice to choose the alternatives and the third step I calculate about the inconsistency ratio for the criteria, if the result is smaller than 10 %, it means that the calculating of this analytical

hierarchy process is correct. Besides that, I use expert choice software to equip the analyze of the construction management accomplishment.

## 2.2 The parameters of the construction management accomplishment

### 2.2.1 The Quantity of the Worker (QW)

The quantity of the worker in this project consist of 15 qualification of the worker. They came from *PT. Dasaria Utama* as a main contractor and *PT. Perkasa Adiguna Sembada* as a main contractor, we can look at the table 1 below:

Table 1: The Quantity of The Worker

No	Qualification	Amount
1	Project Manager	1
2	Site Manager	1
3	Drafter/Technical Adm	2
4	Supervisor	4
5	Surveyor	2
6	Safetyman	1
7	Purchasing/Keeper Storage	1
8	Mechanic	2
9	Driver/Equipment Op.	4
10	Foreman	4
11	Chief Worker	4
12	Mason	23
13	Steel Bar Worker	34
14	Carpenter	58
15	Digger	68

(Source: PT. Dasaria Utama, 2010)

In this paper, I choose Project Manager, Site Manager, Supervisor, Surveyor and Chief Worker who very responsible to controll this project, to give their answer about the construction management accomplishment.

### 2.2.2 The Bill of Quantity (BQ)

The Bill of Quantity is used to make a schedule of the work accomplishment of this project using Bar Chart Diagram. It is important to do because we can make sure for how long the accomplishment of the project can finish with the existing resources

in there, such as quantity of the worker, material and machine. So, we can control about the progress of each activity every time and minimize the latest time or the failure of the project that could be done.

### 2.2.3 The Time Progress Report (TPR)

The time progress report in this project i.e. daily report, weekly report and monthly report. These all report should be joined to The Bill of quantity to get the comparison of the reality work and the planning work. Besides that, we can control about the activity in critical path without neglect the other activity.

### 2.2.4 The Time Schedule (TS)

The time schedule (for this project I use S Curve) is used to know for how long we need to finish the activity from the preparation work to acceptance work to *PT. Damai Indah Kaca Tipis* as an owner and developer .

## 3. RESULTS AND DISCUSSION

### 3.1 Calculating the analytical hierarchy process using manual methode

In order to study whether the construction management accomplishment in *PT. Damai Indah Kaca Tipis*, the explanation from the project manager, site manager, supervisor, surveyor and chief worker are very usefull as the input judgments at all levels, as shown in Table 2. According to Saaty, if the overall consistency of the input judgements was within the acceptance ratio of 0,10, this implies that the pairwise comparison judgments supplied by the project manager, site manager, supervisor, surveyor and chief worker were not bias and thus acceptable.

Table 2: Pairwise comparison for construction management accomplishment

	QW	BQ	TPR	TS
QW	1	½	1/5	1/3
BQ	2	1	1/3	½
TPR	5	3	1	2
TS	3	2	½	1
Amount	11	6,5	2	3,8

Table 2 explains about pairwise comparison for construction management accomplishment in *PT. Damai Indah Kaca Tipis*. The table made by comparative judgement based on the explanation from the worker in this project, such as project manager,

site manager, supervisor, surveyor and chief worker who lead the activity in there. After that, I try to calculate the input judgements at all levels using manual method, as shown in Table 3.

*Table 3: The input column divided to the amount*

	QW	BQ	TPR	TS	The Amount
QW	0,09	0,077	0,1	0,078	0,345
BQ	0,18	0,154	0,15	0,13	0,614
TPR	0,45	0,46	0,5	0,526	1,936
TS	0,27	0,307	0,25	0,263	1,09

Table 3 explains about the continuation of pairwise comparison. The numbers in the table 3 are from the input data divided to the amount data, such as column 1 is  $1 : 11 = 0,09$ , column 2 is  $0,5 : 6,5 = 0,077$ , and so that column 3 and column 4. If the table is completed, so every line should be sum, so that we can get the value of every alternative, such as line 1 is sum of  $0,09 + 0,077 + 0,1 + 0,078 = 0,345$ , line 2 is sum of  $0,18 + 0,154 + 0,15 + 0,13 = 0,614$ , and so that line 3 and line 4.

*Table 4: Value of the criteria of the construction management accomplishment*

QW	$0,345/4 = 0,086$
BQ	$0,614/4 = 0,153$
TPR	$1,936/4 = 0,484$
TS	$1,09 /4 = 0,272$

Table 4 explains about the value of the criteria, and we can use them to pick up the rank of the construction management accomplishment. The value of the criteria is time to the matrix pairwise comparison that made by comparative judgement (see table 2). The calculation of importance level of main criteria in comparison matrix are :

$$\begin{pmatrix} 1 & 1/2 & 1/5 & 1/3 \\ 2 & 1 & 1/3 & 1/2 \\ 5 & 3 & 1 & 2 \\ 3 & 2 & 1/2 & 1 \end{pmatrix} \times \begin{pmatrix} 0,086 \\ 0,153 \\ 0,484 \\ 0,272 \end{pmatrix} = \begin{pmatrix} 0,3409 \\ 0,6062 \\ 1,917 \\ 1,078 \end{pmatrix}$$

The result of the multiplication of the matrix shows :

$$\begin{pmatrix} 0,3409 \end{pmatrix} \rightarrow \text{The fourth rank}$$

- 0,6062 → The third rank
- 1,917 → The first rank
- 1,078 → The second rank

To get a correct calculation from pairwise comparison above, we should check them in the calculation of Inconsistency Ratio that have shown below:

$$D = \begin{pmatrix} \underline{0,3049} & \underline{0,6062} & \underline{1,917} & \underline{1,078} \\ 0,086 & 0,153 & 0,484 & 0,272 \end{pmatrix}$$

$$D = \begin{pmatrix} 3,963 & 3,962 & 3,961 & 3,963 \end{pmatrix}$$

$$\Lambda_{\max} = \frac{3,963 + 3,962 + 3,961 + 3,963}{4} = \frac{15,849}{4} = 3,96225$$

The value of Inconsistency Ratio (CR) is :

$$CR = \frac{3,96225 - 4}{2 \times 0,9} = -0,02 < 10\% \dots \text{OK}$$

The results shows that the rank of the alternatives of the construction management accomplishment are:

1. The Time Progress Report (TPR)
2. The Time Schedule (TS)
3. The Bill of Quantity (BQ)
4. The Quantity of The Worker (QW)

The first rank is the time progress report, it means that the most important thing to be consider from the contractor. It could be understand because the time to build the manufacture industry building that known Indonesia t/d Horizontal Drawing Glass Production Line Works just 5 month (from March 1st to August 1st).

### 3.2 Calculating the analytical hierarchy process using expert choice programme

In accordance with Saaty [8], the pairwise comparison for construction management accomplishment, was processed of the determination of normalized weights, and “Expert Choice” was used to transfer the pairwise comparison judgments matrices into the largest eigenvalue and then the normalized local weights was determined. Based on these normalized priority weights, the relative importance of success factors can be asseced according to the construction management accomplishment in *PT. Damai Indah kaca Tipis*.

***the construction management accomplishment***

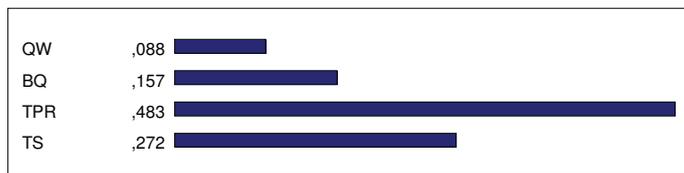

Node: 0

Compare the relative IMPORTANCE with respect to: GOAL

	BQ	TPR	TS
QW	(2,0)	(5,0)	(3,0)
BQ		(3,0)	(2,0)
TPR			2,0

Row element is \_\_\_ times more than column element unless enclosed in ()

Abbreviation	Definition
Goal	the construction management accomplishment
QW	THE QUANTITY OF THE WORKER
BQ	THE BILL OF QUANTITY
TPR	THE TIME PROGRESS REPORT
TS	THE TIME SCHEDULE

Inconsistency Ratio =0,01

***For Student Use Only***

**4. CONCLUSION**

The construction management accomplishment in PT. Damai Indah Kaca Tipis was decided in four factors. They are The Quantity of The Worker, The Bill of Quantity, The Time Progress Report and The Time Schedule. The findings from AHP and the result of the case studies have provided that The Time Progress Report is the most important thing they should be attention for this project. It should be noted that the priority weights among critical factors presented in this paper are based on the project manager, site manager, supervisor, surveyor and chief worker opinions who are very responsible leading the project.

## Plenary 1

# Architecture for People: Educating, Empowering, and Sustaining

**Dr. Yandi A. Yatmo**

*Faculty of Engineering Universitas Indonesia  
yandi@arsitektur.net*

Intervention to human living environment becomes meaningful when it is strongly grounded on the real everyday contexts and when it could offer certain benefits for the people. This presentation illustrates an idea of how the process of architectural intervention can play a significant role in enabling and empowering society. Architecture is not merely present as a physical material of building, but it embodies the process of engaging the people, promoting collective actions and celebrating localities. Research into the everydayness of the society and local knowledge forms an integral part of design method development. The making of architecture is a process of engaging the whole community. Such engagement becomes an opportunity for the community to learn what they have: existing local resources, culture and technology. The design incorporates the use of local construction methods and local materials, and celebrates local craftsmanship through the use of various craft elements and methods that are familiar to the local people. In this way, architecture becomes the process of building the community awareness of their own aspiration and strength, which is much more meaningful than just the process of building the physical materiality. It also becomes a process of generating a special form of aesthetics that represents localities and everydayness. The architecture is eventually created as a physical manifestation of the whole process of educating and empowering the people, and consequently it would be able to sustain its existence within the society.

<sup>a</sup> *Architecture Department, Faculty of Engineering, Sebelas Maret University  
 E-mail : dyah\_pradnya@yahoo.com*

## ABSTRACT

The phenomenon of commercial building, governance and social increasingly crowded urban spatial structure. Efforts over the function becomes significant with the construction of new buildings and changes ownership. Factors of accelerating the flow of traffic density, use of open space (RTH) and environmental degradation were widespread. Commercial efforts also affect the physical stability and function of *nDalem Pangeranan*. However, consideration of the existence of noble values and ownership have prompted Kasunanan Palace, to issue *Pikukuh/Palilah*. The legislation imposes a ban on building and changing conditions *nDalem Pangeranan*. Although the role of its has stimulated turning internal conflict regarding building improvements and cost limitations, but has bound existence *nDalem Pangeranan* in the original function. Then, the researcher is interested in exploring the influence of *Pikukuh* onto the physical existence *nDalem Pangeranan*, which can be used as a reference base construction efforts to control the growth of the city. This research was done using Naturalistic Qualitative method for 6 months. Sampling was used as the unit of exploration of 15 *nDalem Pangeranan* at Kampong Baluwarti. For Observation, the researcher explored every data and took information from some sources. Collecting data using Purposive Sampling technique, Snowball Sampling technique and Cross Sectional System. The result of this research showed that, generally conclusion are the buildings and environments of *nDalem Pangeranan* being stable, an nobility soul become the main force of attraction, change of functions *nDalem Pangeranan* allowed in conditional

### Keywords

*Over the function, density, renovation, stability, degradation of the normative, traditional law*

## 1. INTRODUCTION

*nDalem Pangeranan* is one of the assets of Kasunanan Palace that got the enforcement of *Pikukuh/Palilah*. The facility serves as an endorsement of the status of the building as well as to avoid the process of buying and selling of buildings of cultural heritage (BCB). Although the renovation efforts have also been undertaken in some *nDalem Pangeranan*, but the authenticity of the building forms are retained. Beside that, it also serves to seek the stability of shape and function of the building from the development efforts of the building. The effort is an example of the positive efforts that can maintain the stability of the quantity and quality of the spaces of the city. Also as a precedent to issue Act ( UU ), PP or Perda for procurement and construction complex of government buildings, social or commercial. Regarding the location of *nDalem Pangeranan*, described in the following figure:

## 2. CITATION AND REFERENCES

### 2.1. Authenticity research

In the process of collecting data, researchers have been looking for a number of studies analyzing regarding ever kind of rules in building. In several the research such are :

GRA.Koes Isbandiyah, Theses, *Kebijakan Karaton Surakarta Hadiningrat Dalam Pengelolaan Tanah Dan Bangunan Setelah Keputusan Presiden Nomor 23 Tahun 1988 Tentang Status Dan Pengelolaan Keraton Kasunanan Surakarta Di Kelurahan Baluwarti Kota Surakarta*, UNDIP, 2008. The research [1] explain about the Kasunanan Palace apply information about regarding status of land and building. Information was divided into three types namely *Palilah Griya Pasiten Anggaduh*, *Palilah Griya Pasiten Magersari*, and *Palilah Griya Pasiten Tenganan*. For *Palilah Griya Pasiten Anggaduh* and *Magersari* are rent testament while *Palilah Griya Pasiten Tenganan* is borrow-wear testament.

Lego Karjoko, Theses, *Budaya Hukum Keraton Surakarta Dalam Pengaturan Tanah Baluwarti Sebagai Kawasan Cagar Budaya*, 2005. The research [2] explain about in spite of differences of opinion regarding the status of the land of Kasunanan Palace, more people are expecting the economy to power the Palace ground in the life of society

Perda no.14/ 2011 on the amendment on Perda no. 6 / 2008 about organization and management regional taskforce the city. Regulations [3] explain about Data regional and cultural heritage the preparation of a database regional and cultural heritage labelisasi region and the preservation of cultural heritage and cultural area and heritage

Moch. Tauchid, *Masalah Agraria, Sebagai masalah Penghidupan dan Kemakmuran Rakyat Indonesia*, 2009. The study [4] explains about *Hak Tanah bagi Rakyat Indonesia ( in Kingdom era )* / Chapter 5

N. Introduction to LPKJ. The memorandum [5] explains *Penguatan Dasar Tata Kelola untuk Penguatan Ekonomi Kerakyatan dan Manifestasi Karakter Budaya Jawa/Lokal dalam Lingkungan Fisik*”

### 3. THEORIES

#### 3.1.Space

The human need for expression in the area of visual space as well as abstract. Visual space is limited by walls, partitions, furniture, while the abstract is limited by space activities, time, gender. Such a statement from Tuan (1977), [6] that is:

*Space zone changes as well as the abstract is not limited by walls, the partitions as well as limiting forms. For example: a space in the world, understood as play areas. While the site, located at a position that is more limited and fixed. For example: a place in the world of the geology of the area defined as the source of petroleum coal*

#### 3.2.House

The house is a product architecture for personal and communal activity, and reflect the personality of the owner. Same of Heidegger opinion in the Schultz (1971), [7] that:

*Dwelling is the basic principle of existence*

With regard to the process of human life, Gaston Bachelard in Schultz (1971), [8] further explained that:

*The house as “ one of the great integrative forces in man’s life*

In addition, in 1971, Bachelard Schultz ( 1971) similarly, [9] added that:

- *The image of the house, therefore, depends on the existence of differentiated places which interact among themselves and with the environment in varying ways.*
- *The character is determined by concrete ‘things’ such as the fire place, the table and the bed*

Related to the image home, Schultz (1971) , [10] explains that:

*The essence of the house as architecture, therefore, is interior space. In the city, we are still outside, although we have left the open landscape. In the house we are alone with ourselves, we have withdrawn*

### 3.3.Symbol

The symbol is a descriptive image that describes visual and non visual description about the object. Example: painting, sculpture, calligraphy, composition, time. Such explanations Argest and Gandelsonas (1996) in Nesbitt (1996), [11] that:

*A theory of symbols, describe and explain the link between society and the environment awakened from cultural differences and models produced*

On the other hand, Jenks explains (1969) in Nesbitt (1996), [12] that

*This is perhaps the most fundamental idea of semiology and meaning in architecture, the idea that any form in the environment or sign in language is motivated, of capable of being motivated*

While regarding the existence of the building as a symbol, the Handler (1970) in Nesbitt, [13] said:

- *A building is the embodiment of logic when a point on the outer side of the material and visualization form a universal principle valid, when it gives the vision of regulation in addition to the owner field, the range of a few things that have purpose and push to present back into a general concept that provides explanations and interpretations in the wider scheme*
- *The definition of the logic that is represented by the symbol does not signify the abstraction of religion, education, legal or community*
- *The logic expressed by the symbol cannot be seen because it is abstract and universal*
- *Human effort and social behavior depending on alignment with the logic of behavior*

Conceived as a symbol of an applicative forms of understanding. As explanation of Rapoport (1986), [14] that:

*The region attributes modified human action. There are divided in 3 levels , namely :*

1. *Fix feature : building*
2. *Semi fix feature :furniture*
3. *Non fix feature :behavior*

Applicative symbols as mistycal meaning, described by Eliade (1957), [15] that:

*Cosmic symbolism is found in the very structure of the habitation*

On the other hand, Morris (1938) in Nesbitt (1996) , [16] explain the symbols in the semiotic, namely:

- *Pragmatik “ deals with the origins, uses ( by those who actually make them ) and the effects of signs ( on those who interpret them ) within the ( total range of ) behaviour in which they occur*
- *Semantic “ deals with the signification of signs in all modes of signifying “ that is with the ways in which they actually “ carry “ meanings*
- *Syntactic “ deals with the combination of signs ( such as the way in wich words are put together to form sentences ) without regard to their specific significations ( meanings ) or their relation, to the behavior in which they occur “ thus ignoring the effects those meanings have on those who interpret them*

Then Eco (1968) in Nesbitt (1996), [17] providing 2 definition, namely:

- *Denotation : The meaning which a form has for all who use it*
- *Connotation : The special shades of meaning ( based on emotional or other factors ) that a form has for its individual user*

While Pierce (1974) in Nesbitt (1996), [18] explained the application symbol in sign is divided into 3 classifications, namely:

- *An icon is a sign which refers to the object that it denotes by virtue of certain characters of its own and which it possesses just the same, whether any such object actually exist or not*
- *A symbol is ‘a sign which refers to the object that it denotes by virtue of law, usually any associations of general ideas, which operates to cause that symbol to be interpreted as referring to that object’*
- *An index is a sign, or representation ‘which refers to its object not so much because of any similarity of, or analogy with it, nor because it is associated with general character which that object happens to posses, but because it is in*

*dynamical ( including spatial ) connection, both with the individual object on the one hand and with the senses or memory of the person for whom it acts as a sign*

Thus it can be understood that the sign is visible in the message that an object while a symbol is a message that is not visible in an object.

### 3.4. Typology

Engineering architecture can be a native form and development that will produce variation type. Budi A sukada ( in Eko Budiarjo ( 1991 ), [19] explained that that:

To drill beginning of the establishment of an architectural, objects to be learned through third thing, namely:

- Determine forms basic ( formal structures ) that is in every object an architectural
- Determine basic properties owned by was object an architectural, based on the fundamental forms of
- Studies the developmental process form the base until the form current

The types are explained through the display form of each work. Moneo in Rossi (1978), [20] explains that:

- *The concept of a typological series is generated by relationship among the elements that define the whole*
- *Typology views it as a frozen mechanism that denies change and emphasizes an almost automatic repetition*
- *The type is carefully avoided in favor of a generic and actual description of the current world*

Then Quatremere de Quincy in Rossi (1982) , [21] supports the explanation through types as follows:

- *Archetype is the original pattern from which copies are made*
- *Prototype is the first or primary ty of anything*
- *Stereotype is shift to something permanent and reproducible*

### 3.5. The frame of theory

As for some of the theories that support the process of research are :

- Space as the boundaries that load meaning
- House have basic function as facilities
- Symbol manifest in visualization engineering room
- Type of building is characteristic of association that is both stabl and non stable

## 4. RESEARCH METODHOLOGY

This research was done using Naturalistic Qualitative method for 6 months. Sampling was used as the unit of exploration of 15 *nDalem Pangeranan* at Kampong Baluwarti. For observation at those object , the researcher explored every data and took information from some sources. Then , researcher exploration of some themes related the problem. Some themes analized at discussion and conclusion process. Furthermore collecting data of research process using Purposive Sampling technique, Snowball Sampling technique and Cross Sectional System.

## 5. DISCUSSION

### 5. 1. The Consistency Visual Characteristics of Prototype Building

*nDalem Pangeranan* building is always in the form of buildings that remain. The efforts made to control changes to the form and the main function of the building. Although the owner of has the economy ability to build of building , but the efforts of change as well as the development of the building remain banned. In addition, Kasunanan Palace also enacted similar regulations for homes that are complex of *magersari* at *nDalem Pangeranan*. Whereas in order to improve the quality of living space, the Kasunanan Palace only allow for the renovation. Thus, the shape of the historic building remains consistent with historical value. These conditions are described in the following figure:

#### Conclusion:

The stability of the visual form of *nDalem Pangeranan* is an attempt being made to retain the original character of building. These efforts are intended to make the historical value can always be traced to inherited and hereditary. A complex environment the *nDalem Pangeranan* is also a great complement that describes the past situation. The rules that bind the existence of visual form the building has restricted the development of the situation. So even though less effective following the development of situation in modern era, but the regulation had managed to pack the traditional impression that lasts. The condition can control the acceleration of the process of development and the expansion of land degradation which affects the quality of the environment. It is described in figure 3.

Based on the image above, then the efforts made in the area of heritage buildings (BCB), referable on the development process of various government, social or commercial buildings . The development process is more appreciated and is oriented on the renovation effort and avoids the expansion of land. The balance of prosentase in the project page utilization, becoming a reference for calculating the tax of building (PBB). In addition, also in order to save on construction materials, renovation costs, traffic flow and congestion because the process of the project. It is very important for the sustainability of growth does

not mean expanding the field of maintenance and effort the project but instead a function on the natural energy into the main orientation

Figure 2: nDalem Pangeranan at kampong Baluwarti  
 Source : Personal documents and document Research Group, 2010

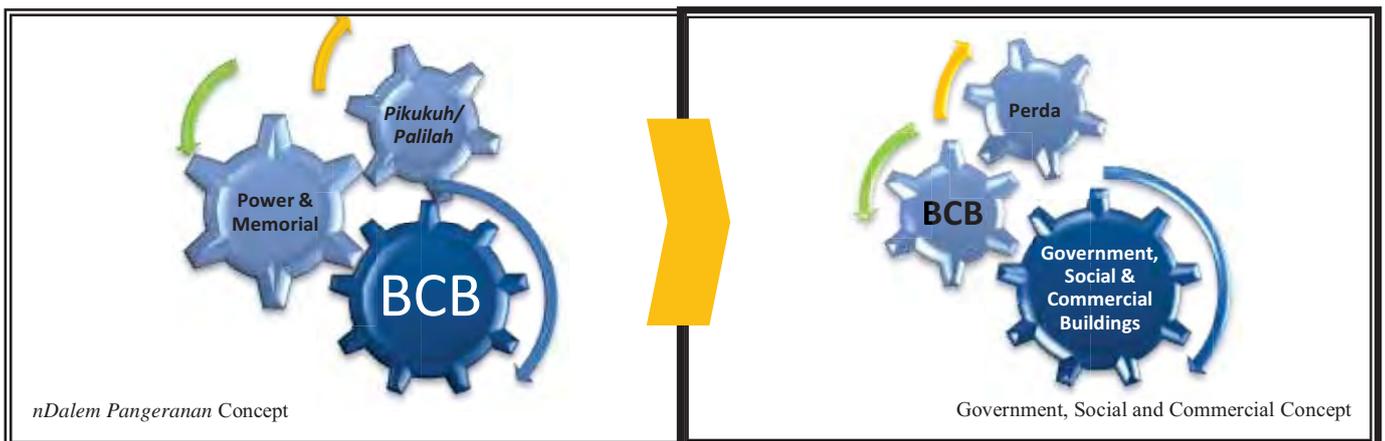

Figure 3: Contribution to the process of the construction of government, social and commercial buildings  
 Source : Personal analysis, 2013

### 5.2. The Consistency Location of *Genius Loci*

The presence of the *Genius Loci* was the location of the primary capital at the nDalem Pangeranan, because it has the ability to animate the atmosphere and situation to sacred. The *Genius Loci* are present in two forms, namely:

- Tangible : the owner (The Prince), *Krobongan*, and *Pelataran*

- Intangible: the presence of an aura of nobility that icon of location functioned as the main attraction of the *nDalem Pangeranan* and positioned as a sacred place-the mystical. Thus, among the descendants of the nobles and guests, it's easy to understand the situation of the past and be respectful of the cultural heritage. In addition, *Genius Loci* icon is also constantly being in the space that remains despite the quality of the spaces have been damaged. It is described in the following figure:

Figure 4. Interior of *nDalem Pangeranan*  
 Source : Personal documents and document Research Group, 2010

**Conclusion:**

The existence of the *Genius Loci* at the *nDalem Pangeranan* it is always preserved by the descendants of the owner and the Kasunanan Palace. Because of these efforts mean to the inner relationship with the deceased ancestors. Because inner peace become a vitality which controlled and controlling way of life. Thus, the strength and power of the memorial into something beautiful and sacred to the descendants of the nobles. Although not located on the same life period with its ancestors, but stories and ornaments in *nDalem Pangeranan* has psychic and inner binding. It is described in figure 5.

Inner bonding that occurs at the area of heritage buildings (BCB) can be used as a means of socialization to build understanding in building the space station. Efforts are being made in the area of heritage buildings (BCB), referable on the development process of various government buildings, social or commercial. The building is oriented on the preservation efforts and not change. So that the land of the magnet can be used for new buildings. Since many projects which utilize of historic buildings (e.g.: *nDalem Pangeranan*), but does not parse the *Genius Loci* of the original building from scratch. So that the efforts of the façade of the building modification efforts on the interior into a solution that often closes a location icon *Genius Loci* of the original.

### 5.3. Control-over the Building Function

*nDalem Pangeranan* not always functioned as home living (personal activity), but also enabled for communal activities. Those activities among other things for the school, where practicing of dancing, sociality, Conference Hall. Nevertheless, the complex of *nDalem Pangeranan* only functioned as a loan facility, so the activity functions are controlled by the permissions associated with it. So that there is stability of the function and a support that do not interfere with each other. Likewise *magersari* houses around the *nDalem Pangeranan*. Monitoring is also conducted through communal various related parties, e.g.: Sasana Wilapa, Stub, Wards and other social facilities. Thus, it served as the residence of each event in the *nDalem Pangeranan* can be controlled and known by the Kasunanan Palace. In order for any activities that take place in synergy with cultural activity regions. It is described in figure 6.

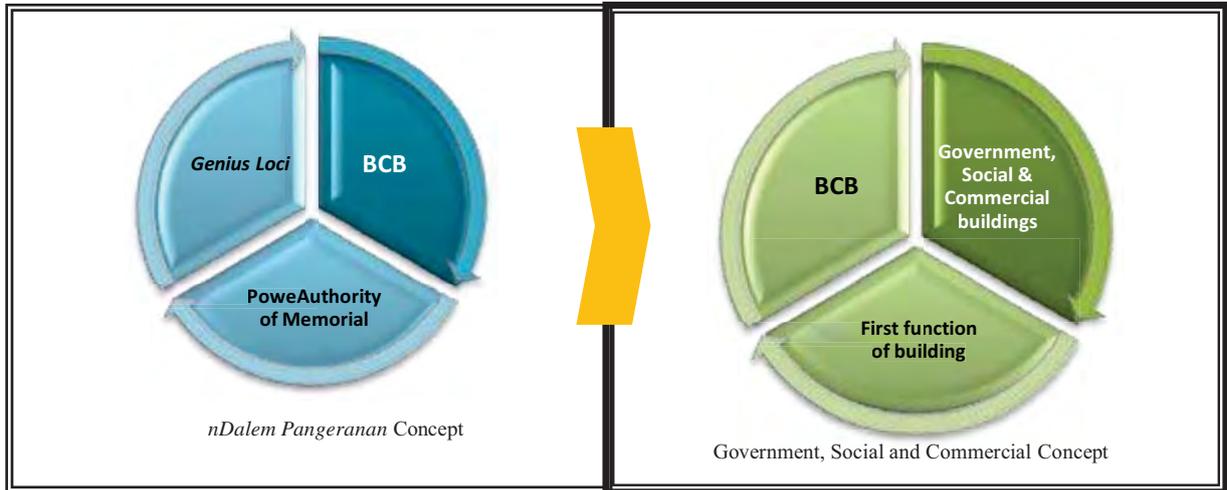

Figure 5. Contribution to the process of the construction of government, social and commercial buildings  
 Source : Personal analysis, 2013

Figure 6. Over the function of *nDalem Pangeranan*  
 Source : Personal documents and document Research Group, 2010

### Conclusion

Function changes of *nDalem Pangeranan* is oriented to meet the family economy owner. Existence facilities a great house and tend to empty has stimulation of various activities. But because it was under the supervision of family and Kasunanan Palace, then function changes be in scope culture of Java. Enactment the rule aimed the atmosphere and function *ndalem pangeranan* unchanged. So cultural identity everlastingly can be presented in a perennial manner and thorough. It was explained in a drawing the following :

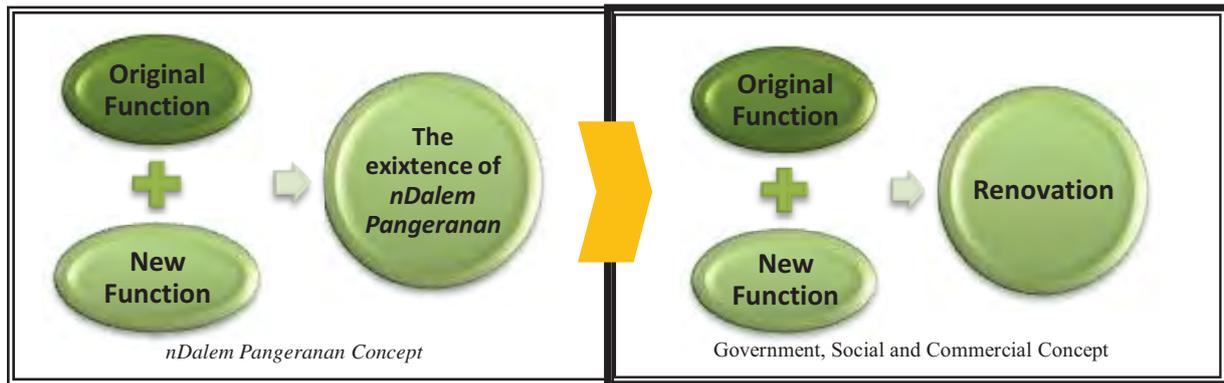

Figure 7. Contribution to the process of the construction of government, social and commercial buildings

Source : Personal analysis, 2013

Efforts are being made in the area of heritage buildings (BCB), referable on the development process of various government, social or commercial buildings. The building is oriented in an effort of renovation and not the expansion of land. The balance of prosentase in the project page utilization, be a reference counting of the tax. In addition, also in order to save on construction materials, renovation costs, traffic flow and congestion because the process of the project. It is very important For the sustainability of growth does not mean expanding the field of maintenance and effort the project but instead a function on the natural energy into the main orientation

## 6.GENERAL CONCLUSION

- Building forms and environment of the *nDalem Pangeranan* stabilized
- Aura of nobility is still the main attraction
- Transition function of the *nDalem Pangeranan* permitted by conditional

## 7.SUGGESTION

- Building construction not always have to open new land but may be conducted through renovation and refunction
- Building after habitation / after wear
- Research results can be included basic to draw up act development government buildings, social and commercial
- Limit the use of over the function and open land, so rth and reserve water stable
- Reduce traffic congestion as a result the development process new building
- Rules about area heritage buildings ( BCB ) done not only on the memorial but also to government buildings, social and commercial
- Renovation precedence more than construction process new building

### ABSTRACT

This paper reports the implementation of synergies between the design-construction partnering with health services to achieve sustainable development as system in Semarang at General Hospital-Dr. Kariadi. The main problem is how to achieve sustainable development for health care activities and development activities that are common in the same area. Where the combination of both of these activities have been considered in the design phase by the owner and designer. Development activities and the activities of health services running at the same time has achieved success, such as there is no accident for both project activities and for health service activities, without disputes and litigation.

### Keywords

*Sustainability, system, technology, partnering*

### 1. INTRODUCTION

Land development and conservation have increased significantly in many cities in Indonesia over the last three decades because of the increasing population and economic development. The concept of sustainability was raised because of growing awareness of the global links between mounting environmental problems, socio-economic issues to do with poverty and inequality, and concerns about a healthy future for humanity (Hopwood et al. 2005). On land plot there are 2 distinct areas, namely areas that allowed for the construction and conservation area. Buildings that contact life-cycle performance, durability, energy efficiency, occupant well-being and productivity are known as sustainable development. There is broad recognition that these buildings demand increased levels of optimization among architectural, structural, envelope, mechanical, and electrical systems. To quantify the benefits of delivery for sustainable of high performance buildings, that included project team characteristics, design integration, construction applications, owner commitment, contractual arrangements, procurement methods, and project delivery methods. Development by using the partnership as one method to achieve sustainable development project success through sustainable design.

Sustainability covers three interdependent and mutually reinforcing pillars, which are environmental responsibility, economic return (wealth creation), and social development (UN 2005; Ding 2008). Chan et al. (2004) describes seven main categories of critical success factors of a construction project. Those factors are support from top management, adequate resources, mutual trust, long term commitment, effective communication, efficient coordination, productive conflict resolution. All of those factors can be addressed in the delivery of the project.

Shortly speaking, physical development ahead remain oriented to the concept of organic architecture is flexible enough to be applied for and has been proven for a long time (8). The construction of the building from the side view system known as the order of the input-process-output-outcome-impact-benefit. In the system approach the boundary of the system is framed which is also meant the legal aspects in the matters of development (2, 7). Sustainable development is closely related to green: system, concept and strategy if there is a simultaneous development with very small negative impact (Low Impact Development/LID) while obtaining greater benefits known as sustainable development based on the sustainable design (4-6).

Physical development through the design of the hospital based on the master plan, so the site plan that has been in the master plan does not change the basic framework. Once the decision is made to build, start thinking of the principles of project management, design management and construction management consists of: knowledge and skills of construction, architectural, mechanical-electrical, and environmental design (7, 9). It connotes the critical success factors for the construction project, namely: Time, Quality, Cost, Meet the expectations of the owner, and small construction issues. From the Quality through performance specification of building products in the end as the terms known that the performance of buildings demonstrate the performance and leverage in the role of physical health function operated in the long term (3-6). It is therefore very important and critical for any land development in an area, particularly in the project objectives and goals of health care activities at the same time.

The objectives of the study are to determine design of the developed area; and to develop a model of system to achieve building performance.

## 2. METHODOLOGY

This paper presents case study conducted through under-construction interviews with key project team members. This case study points out important achieving project success for sustainable, mid performance buildings. The research team interviewed project participants of field office project located in Semarang. The building is 38,000 square meters and belongs to a public owner. Owner, designer and contractor (in this case a design bid build) of the project were interviewed separately. The sustainability performance of the projects was evaluated under Leadership in Energy and Environmental Design (LEED) rating system. LEED is a point based system developed by Green Building Council Indonesia (GBCI) focusing on the: sustainable site development, water savings, energy efficiency, materials selection, indoor environmental quality, and innovation in design. The interviews addressed several architectural, structural, mechanical, and electrical systems and open ended questions regarding the building design process and its relation to the performances outcomes in term of cost, time, quality (owner satisfaction) and performance achievement of the buildings.

## STUDY AREA

The study would be carried out in the developed area of GarudaII Building, Medical Rehabilitation Building, Education and Training Building, and Inpatient Building Grade 3-General Hospital Dr.Kariadi located on Dr.Soetomo, Semarang(Fig. 1).

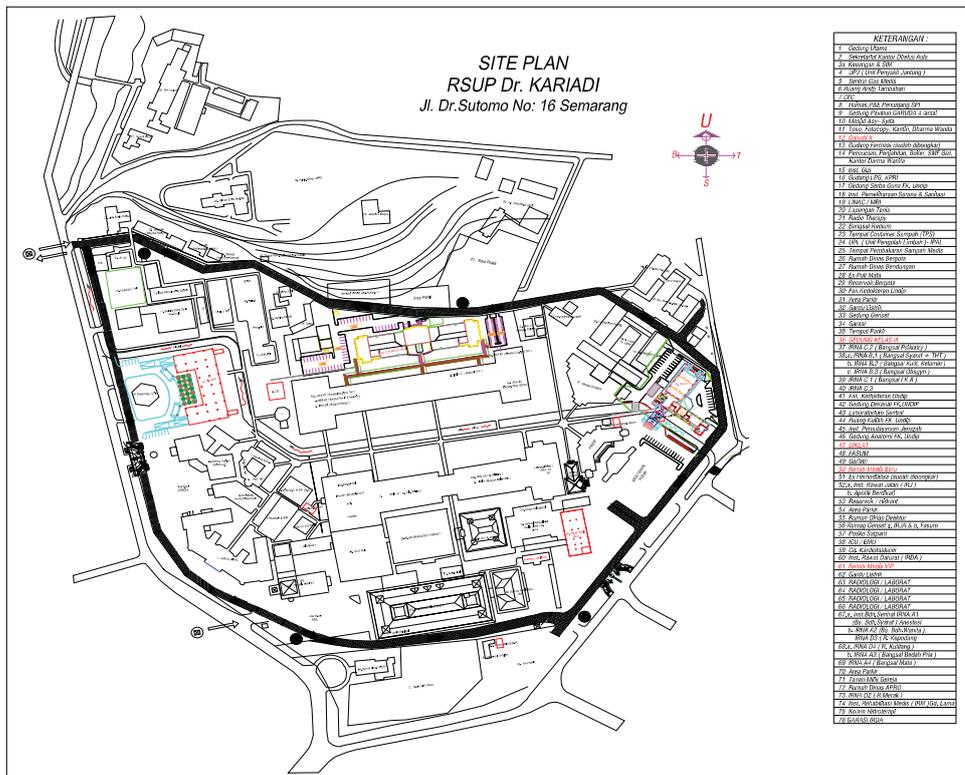

Fig. 1: Location of Study Area

This study is an observational study in the field of general hospital Dr. Kariadi during the construction of four buildings and health care at the same time. Dr. Kariadi hospital area is about 210,000 m<sup>2</sup> and the building floor area is about 190,000 M<sup>2</sup>. This condition gives a signal that has not occurred since the construction optimization building regulations stipulate Floor Area Ratio is 5 to downtown Semarang. So there is still a potential for a large area to be built in the future. Dr. Kariadi gates as access requires rethinking with regard to speed of access, safety and convenience by taking into account: the density of traffic circulation around the land, increasing the number of visitors, access to the ambulance, queuing theory.

Buildings were built in 2011-2012 consisted of Garuda II building (8 floors, 12,000 M<sup>2</sup>) with a capacity of 400 beds, Education and Training Building (3 floors, 4000 M<sup>2</sup>), Rehabilitation Medic Building (7 floors, 5600 M<sup>2</sup>), Installation Inpatient Class III Building (7 floors, 14,000 M<sup>2</sup>) with capacity of 400 beds. Thus, in 2012 RSUP Dr. Kariadi has more than 1200 beds

totally. In the present, parking capacity that uses the principle of on-street and off-street parking is full even less because every day there are 1800 cars and 2340 motorcycles taking place of parking-lot. These are demanding that the building will be constructed and parking area is already set in two places connected by the outer ring road in the general hospital area. There is flexibility for the construction industry technology options, technology tools and technology in both medical device types and in the amounts, namely: conventional, rational and industry. Implementation of building can be done by methods: cast in situ, cast in place and precast or prefab depending on circumstances. These are supported by the existence of space between buildings and the outer ring road of Dr. Kariadi hospital.

### 3. RESULTS AND DISCUSSION

The objectives identified by the different project teams show that construction projects are now considering both soft management issues and sustainable development as central to the successful delivery of construction projects. During the process of project implementation arrangements made by the contractor, as follows: physical limits of each activity, traffic project activities and activities of health services, physical security net. The result was no accident, building performance is achieved. This project has managed to cut costs up to 6%, time-saving 5% of the project, and construction claims 3%.

The concept of sustainable intended initial attention has been considered for pedestrian safety for visitors and staff, speed of ambulance services for 24 hours, the speed of other services, and physical development that has little impact for health care. Most of the rainfall water is discharged out from the land through the river. The existence of a small river not intervened so that the function of the drainage water is still running smoothly without sedimentation. The river discharge is extremely higher during rainy season, even been higher than the river capacity. The application of bio-retention is useful in order to cope with the flood and for groundwater reserves.

The orientation of new buildings facing the north and the south, thereby reducing the effect of the sun's heat directly against the glass. Planning of open space considered as an area for evacuation, green or garden, natural air flow, natural lighting, rainwater inflow into the ground, and playground or sports. In this case, the impact of land development to the runoff change would be managed by means of bio-retention system. With the LEED green building certification process buildings can achieve a certification, silver certification, gold certification or platinum certification (GBCI 2010). Main characteristic of general hospital Dr. Kariadi orientation is expressed in the design on the sides of the LID through considerations of: Planning (Master plan, Feasibility Study); System (open/closed; hard/soft; approach); Green Concepts and Grand Strategy. Sustainable design considering implementation methods either series or parallel. The substance of the design conducted design review and value engineering prior to the construction site. The view point above description is included aspects of Whole Life Costing (WLC), which has been measured so that management role can be expected.

Based on owners, users and experts of Dr. Kariadi hospital held frequent communication about the development of an appropriate scope of future requirements combined with the policy of the Ministry of Health and international rules Joint Commission International (JCI) to produce a design that supports a minimum standard of health care and Standard Operating Procedures (SOP). Discussion was also made in relation to the future problem solving and decision making and forecasting. The role of the function of these activities will lead to the need for facilities that are closely linked: Development management; Technology of construction industry; Technology of utilities and Technology of health equipment.

Within the scope of the hospital operation, on the one hand Dr. Kariadi process Eco Management Audit System (EMAS) in the system of Waste Water Treatment Plant (WWTP). Processing installation internally to maintain systems that have been built while externally conducted by the Environment Agency of Middle Java Province (BLH-Prop) with weekly-monthly evaluation reports and field investigations per semester. On the other hand, based on the policy of the Ministry of Health in accordance with the era of globalization in the Millennium Development Goals (MDGs), Dr. Kariadi follow the rules that apply in the JCI in terms of standard of health care through completion of facilities and infrastructure that meet the technical requirements and applicable law. In this case means that the use of partnering for construction projects of complex building that are in stages: planning, design, procurement, construction. At the stage of human bionomics also used partnering on operations and maintenance.

### 4. CONCLUSION

The study, however, indicate that design-construction partnering can achieve substantial sustainable development through sustainable design. Based on the above description, it can be concluded about the basics are as follows:

- a) Sustainable design has a central role toward sustainable development in the system of construction projects.
- b) Design-construction partnering consists of: owner, consultant, contractor, and supported by top management.

### ACKNOWLEDGMENT

The Authors would like to thank to the Department of Architecture, Engineering Faculty, Diponegoro University; and the General Hospital-Dr. Kariadi, Semarang.

## **Towards a Grand Scenario: Innovations in Green Architecture**

**Diane Valerie Wildsmith**

*Department of Architecture, Faculty of Engineering, University of Indonesia, Depok 16424  
E-mail: idc2003@cbn.net.id*

### **ABSTRACT**

This design research analyzes the merits of innovations in green architecture as an ecological response to meet the QIR 2013 conference objectives of 'Towards a Grand Scenario: Policy for Sustainable Growth.' Jakarta, along with Bangkok, Delhi, and Mumbai, finds itself in the unenviable category of multiple risks in five urban typologies that is related to future proofing cities against high energy use and carbon footprints, flooding, and risks to regional ecosystems and resource supply networks. High rise green architecture reduces the impact of urban sprawl, excessively high carbon footprints, and transportation costs, yet this typology increases high energy use with glass facades, high tech materials and construction costs. Greening Asian megacities is an urgently required challenge, which needs to be tackled not only with technological solutions, but also with high quality, culturally relevant design scenarios.

# Green Open Space Approach to the Building Mass Arrangement in Yogyakarta: Case Study of the Revitalization of the Tugu Rail Station

Suparwoko<sup>a</sup>

Faculty of Engineering and Planning, Islamic University of Indonesia  
E-mail: wokos2002@yahoo.com

## ABSTRACT

This paper is to analyze the green open space approach to the building mass arrangement in urban block areas. The case study is “The Project Preparation Consultant for Revitalization of Yogyakarta Rail Station and Pedestrianization of Malioboro” proposed by application of ADB Loan No. 2264-INO (SF): Infrastructure Reform Sector Development Program. Due to the building mass, the building code of the railway station area state that (1) the building coverage ratio (BCR) is 85% and the Floor Area Ratio (FAR) varies (from 3 up to 4,8) based on the Yogyakarta Municipality Building Ordinance. The Green Open Space (GOS = RTH or Ruang Terbuka Hijau) Regulation in Indonesia states that the minimum green open space in urban area is 30%. With an 85% BCR, the railway station project tends to maximize the lot for building construction. Therefore, it is difficult to wish the building ownerships providing 30% GOS from their lots. Due to such a problem concerning on the GOS regulation, how to encourage building ownerships to provide at least 30% of their lots to be GOS during their site development in central urban lot areas for the future constructions for any public services such a railway station. This paper tries to model and encourage (public and private) urban developers to provide more green open space on their lots to be replaced by more space on top of its floor area ratio based on the current building code. The method is using the case study of the Tugu rail station development of in Yogyakarta as a model of analysis. To provide more open (green) space, the model is to reduce the current BCR so that the new BCR has a more open green space. This different of a green open space will be rewarded as an incentive for the additional floor area on the top of the maximum floor area. The researcher believes that the incentive floor area to reduce the current BCR will increase green open space on urban lot areas. In this respect, the character of the building mass is determined by the BCR and representing how the green approach of its open space. This model will support the urban GOS regulation in Yogyakarta and Indonesia generally to have minimum 30% of GOS in the near future urban areas.

## 1. INTRODUCTION

The high rate of population growth is mainly because urbanization is one of the problems of cities in Indonesia. The big number of urban population is creating a high pressure on the utilization of urban space, especially the reduction of open spaces in urban areas, both green open space (GOS) and non Green Open Space [1]. In this case, GOS consists of public and private green space. Ideally, the city has a GOS least 30% of the total area of the city, referring to the Earth Summit in Rio de Janeiro, Brazil (1992), and reaffirmed at the summit Johannesburg, South Africa in 2002 [1, 2]. Regulation of the Minister of Home Affairs Decree No. 1 of 2007 on Spatial Planning can be obtained the information that the minimal of green open space in urban areas is 30%, which consists of 20% public and 10% of private GOS [3]. Based on data from the Environment Agency of Yogyakarta in 2010, the public GOS was amounted to 17.17% (557,90 hectares) of the city area of Yogyakarta. That number is still less than 20% as stipulated by the Public Work Regulation Number: 05/PRT/M/2008. Lack of the development of public GOS in urban areas caused by: 1) the limited cultivable land for green space development, 2) the rise of a variety of development projects that violates environmental rules. So the government needs to increase the number of Yogyakarta urban public green spaces. In order to increase the GOS of Yogyakarta, the Municipality Government issued regulations including the Yogyakarta Mayor Regulation No. 5 of 2007 regarding on green open spaces and the Mayor of Yogyakarta Regulation No. 6 of 2010 regarding the Provision of Private Green Open Spaces. This shows a good willingness of the city of Yogyakarta due to the provision of urban green spaces in its urban area. In order to reach the ideal size of GOS as mandated in the Spatial Planning Act, the city of Yogyakarta facilitated by the Provincial Government of the Yogyakarta Special Region (YSR or DIY) and the Directorate General of Spatial Planning - Ministry of Public Works, planned a public provision of green space in the form of increased green spaces through community initiatives that embodies the design competition for the detailed engineering design to be implemented [1]. However, there is no significant impact from the competition to the GOS growth in the Yogyakarta urban area so far. This means that the Yogyakarta government has some difficulties to increase more public GOS due to the limited budget and the number of grey land limitation. In this respect, the government should encourage any public and private development in Yogyakarta to provide more GOS by providing building volume incentive of any urban building construction. Therefore, it is crucial to create a model regarding a Green Open Space

Approach to the Building Mass Arrangement in Yogyakarta urban area. This approach will use case study of the revitalization of the Tugu Rail Station in the city of Yogyakarta.

Supporting to the Spatial Planning Act, this paper is proposing to analyze a green open space approach to the building mass arrangement by using the case study of the revitalization of the Tugu rail station in Yogyakarta. The objective this paper is to encourage public and private building development to provide more green spaces by promoting the government in providing some floor area incentive more than the existing Floor Area Ratio based on the Yogyakarta Municipality Building Code.

The method to provide some building volume incentive more than the basis Floor Area Ratio is by 1) increasing open space from the basis BCR and 2) Increases/decreases bonus floor area ratio based on the greenery ratio. To provide some incentive building volume, the site development has to provide green open spaces in their site development more than the BCR basis as seen on Figure 1. To increase/decrease the bonus building volume in the site development is to increase their greenery ratio as seen on Figure 2 including: 1) increasing bonus floor area ratio for any developments of greenery ratio more than 45% and 2) decreasing bonus floor area ratio for developments of greenery ratio below 35% [4].

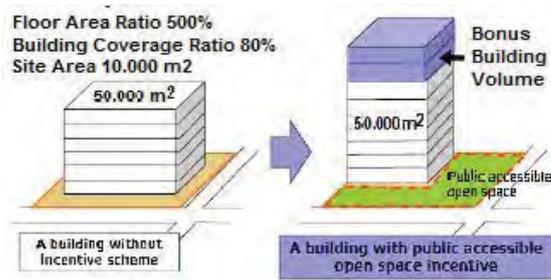

Figure 1. Three Dimension Analysis and Approach to encourage private green open space incentive in urban area [4]

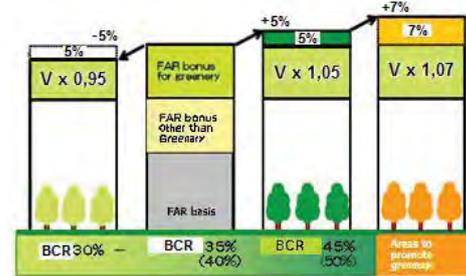

Figure 2. Increases/decreases bonus floor area ratio; [4]

## 2. GREEN OPEN SPACE APPROACH

The concept of greening of the city, or *green urbanism*, shows an important design approach to the sustainable urban development form. The urban sustainability is included on the green open space which has an ability to contribute positively to some key agendas in urban areas [5]. Urban greening approach tries to find the integration between the urban itself and natural environment as a dynamic urban of city dwellers through a diversity of open landscapes [6, 7].

The GOS is an open space area outside the building, which serves for various activities. Regulation of the Minister of Public Works No. 05/PRT/M/2008 concerning on the Guidelines for the Provision and Use of green open space (GOS) in urban areas states that the GOS in offices, shops, and places of business generally in the form of sidewalk and parking lane. Provision of green space in this area are as follows: 1) To the extent Building Coverage Ratio (BCR) 70% -90% will need to add a potted plant, 2) Offices, shops and places of business with BCR over 70%, have at least 2 (two) small tree or medium were planted on land or in pots above 60 cm in diameter, 3) tree planting requirements in offices, shops and business premises with BCR below 70%, such as the requirement applies to yards with GOS, and planted in areas outside the BCR has been determined. Spacious yard complies with BCR in urban areas, as set out in the Regional Regulation on spatial planning in each city. To facilitate classification yard in the specified category yard large, medium and small. Large courtyard is spacious yard with a larger 500 m2. Due to the case study Tugu Rail Station has lots more than 500m2 of commercial activities (shopping, office and hospitality), the appropriate rules of GOS model used for this concept is on the Big House category [8].

*Building Coverage Ratio (BCR)* and *Floor Area Ratio (FAR)* are the most commonly used to indicate for quantifying the building density at lot scale. The BCR is defined as the ratio of the building coverage area (i.e. the area of building footprint) to the size of land lot. Since the footprint represents the planimetric shape of a building, the BCR measures the building density in two-dimension (2D) space. The FAR is defined as the ratio of gross building floor area to the size of lot. The value of FAR is determined not only by the planimetric shape of the building, but also by the vertical distribution of the floors in different height and it represents the three-dimensional (3D) building density. *Open space ratio (OSR)*: is the percentage of open space to the area of the land or lot. An open-to-sky space without a roof is considered an open space. The location, size, distribution and surface nature of open spaces could change the local environment by altering the air flow, humidity and heat balance with the urban canopy layer [9]. *Green coverage ratio (GCR)*: is the percentage of the total area of all green spaces (including above green and below green coverage) to the area of the land or lot. Trees and smaller plants such as shrubs, vines, grasses, and ground cover, help cool the urban environment. Thus, *GCR* is an important parameter in describing urban surface cover, which is affects urban climate such as radiation and surface temperature through shading and evapotranspiration. Generally the sun's

energy reaches the area of trees, with the remainder being absorbed by leaves and used for photosynthesis, and some being reflected back into the atmosphere [10].

The Big House category in the Regulation of the Minister of Public Works No PU 05/PRT/M/2008 provides green space provision of the following schemes: 1) a category that includes big house is a house with a land area of over 500 m<sup>2</sup>, 2) green open space is the minimum required land area (m<sup>2</sup>) less extensive base building ( m<sup>2</sup>) in accordance with local regulations, and 3) the number of shade trees to be provided a minimum of 3 (three) combined with shade trees and shrubs as well as shrubs and ground cover or grass. Furthermore, the green space on offices, shops, and businesses, in addition to the utility, can be used also as an open parking area, carport, and a place to organize various outdoor activities such as ceremonies, fairs, sports, and others [8]. The provision of Public Open Space in Private Development (POSPD) seeks primarily to achieve better quality design, optimisation of land use, better site planning, and/or synchronising the availability of open space and the community needs arising from developments. With proper design and management, POSPD could contribute towards the provision of quality leisure and recreational space and improve urban living environment [11]. A lot of recently developed commercial and residential areas comprise higher FAR and lower Building Coverage Ratio (BCR), compared with old ones [12]. Timely and complete information about urban building density and morphology has need of the measurement of land use intensity and efficiency, design and adjustment of zoning regulations and land use policy, monitoring and enforcement of urban management policies [13, 14].

Urban designers should control some crucial variables shaping the building form and massing in the contexts of urban design including building line, setback, land use, floor area ratio (FAR), and building coverage ratio (BCR) [15]. The green building character to lower impact on local site ecology is to 1) increased green space (small building footprint, minimal surface parking), 2) provide green roofs and has highly efficient building envelopes [16]. The compact city is designed to make more efficient use of existing land resources and infrastructure, as well as reducing automobile usage as public transportation becomes more viable at higher urban densities [17]. The legislative and regulatory framework for stimulating "green" projects has been gradually taking place in Europe, particularly in France. For new residential construction, a decree relative to the Energy Policy Orientation Program authorizes the building coverage ratio up to 20% provided in all other local planning rules respectively [16].

To respond the green open space approach on the site and building scale, there are four concepts including 1) Specific block, 2) Intensive Land Use District, 3) District Planning with Redevelopment Promotion, and 4) Comprehensive Design [4]. Due to the preparation of initial design of the Tugu Rail Station, particularly on the building mass arrangement, the comprehensive design concept will be omitted on to this discussion. The analysis model of the green development approach concerning on the building form and massing of the Tugu Rail Station will use the three dimension analysis to see the schematic approach. Building Coverage Ratio (BCR) and Floor Area Ratio (FAR) are the most commonly used indicates for quantifying the building density at land parcel scale. The BCR is defined as the ratio of the building coverage area (i.e. the area of building footprint) to the size of land lot in Eq. (1), where S is the building coverage area, and S<sub>L</sub> is the area of land lot. Once the association between building footprints and land lots is determined, the BCR for each land lot can be computed using Eq. (1). Since the footprint represents the planimetric shape of a building, the BCR measures the building density in two-dimension (2D) space. The FAR is defined as the ratio of gross building floor area to the size of land lot (Eq. (2)) [12, 14]

$$BCR = \frac{S}{S_L} \dots\dots\dots Eq.(1)$$

$$FAR = \frac{\sum_{i=1}^t A_i}{S_L} \dots\dots\dots Eq.(2)$$

Where A<sub>i</sub> is the area of the first floor, and t is the total number of floors. The value of FAR is determined not only by the planimetric shape of the building, but also by the vertical distribution of the floors in different height and it represents the three-dimensional (3D) building density .

A study of a proposed project implementation is part of a development scenario. An example that the study on “*Downtown Edmonton Commercial, Office and Residential Forecasts 2009 – 2044*” examined the development growth of residential units, retail and service commercial, and office building in the Downtown. The study had two alternative approaches concerning on a „Baseline“ and „Alternate“ scenario. The „Baseline“ scenario assumed a „status quo“ or „business as usual“ scenario and the „Alternate“ scenario assumed that the vision outlined in the Plan for the Downtown would be implemented [18]. It can be seen that the „Alternate“ scenario is part of planning and development process. It can be seen that spatial and infrastructure development is always behind the economic growth resulting physical construction that is driven by social and economic activities without referring the urban spatial plan. This will be naturally growing that existing economic activities do not fit with the current urban development plan.

### 3. TUGU RAIL STATION PROJECT IN YOGYAKARTA

The Yogyakarta Special Province (Daerah Istimewa Yogyakarta, or DIY) is located in south-central Java surrounded by the province of Central Java with the Indian Ocean to the south (See Figure 3). Yogyakarta in 2009, the population and area of DIY is 3,281,000 people and 3,185.80 km<sup>2</sup> respectively with density of 1,030 people per km<sup>2</sup> and annual population growth rate is about 0.9 % per year. The Gross Regional Product (at nominal prices) is Rp. 3.5 trillion in 2000 and Rp. 4.7 trillion in 2007. Rail passengers rose from 1.7 million in 2000 to 1.9 million in 2007. Vehicular traffic has been increasing annually in the area where the proposed project is located at the Tugu rail station of the Malioboro Business District. Due to the large number of passengers and tourists visiting to this area, traffic congestion on the Malioboro road and surrounding road networks has become more acute from year to year. Moreover, since the street is rather chaotic and congested with street vendors, it is necessary to achieve the smooth traffics and to accelerate the redevelopment to the Malioboro area. On the other hand, due to the budgetary constraints, the effective solution has not been carried out in the infrastructure development scheme [19].

Figure 3. Yogyakarta in the Central Java as a Part of Indonesia

Figure 4. The Tugu Rail Station in the Malioboro Area of the Yogyakarta Municipality

Under this circumstance, the study intitle “Public-Private Partnership for Urban Infrastructure Project, Pilot Project of Yogyakarta City” with two (2) stages were conducted in 2005 and 2008 respectively. By those studies, the several examinations were implemented to solve the above issues, which are 1) selection of potential project packages, analysis of technical and 2) financial feasibility, identification of legal issues, especially in land status, analysis of social and environmental impacts by implementing the proposed project, implementation of public consultation meetings among relevant government agencies. The study of the proposed project implementation “the Project Preparation Consultant for Revitalization of Yogyakarta Rail Station and Pedestrianization of Malioboro” is proposed by application of ADB Loan No. 2264-INO (SF): Infrastructure Reform Sector Development Program. The case Study is located in Malioboro urban area in the Yogyakarta Municipality which is the capital city of DIY [19] as shown in Figure 3, Figure 4, and Figure 5.

#### 4. ANALYSIS OF THE GREEN OPEN SPACE APPROACH

The Tugu Rail Station Project is located in the Gedongtengen Sub District of Yogyakarta Municipality. The land use and the building code of the site location of the proposed project can be seen on the Figure 5 and Table 1. The site location consists of four different zones including Zone 1, Zone 2, Zone 4, and Zone 7. The description of the zones and area are clearly stated on Table 1 concerning on uses, building height, BCR, and FAR of the Tugu Rail Station area. The proposed project covers 21 sites including 15 sites accommodating commercial, office, and residential uses, and six lots accommodating parks and building conservation of the Tugu Rail Station (see Figure 5, Figure 6, and Table 1).

On the current study, the project is using the existing building code (BCR 80% with the current respecting FAR) resulting maximum floor area 624.337 m<sup>2</sup> divided on to 4 up to 6 floors (see Table 2). The following outcomes (see also Table 2) are based on the same approach:

- 1) With BCR 70%, the maximum floor area is 670.250 m<sup>2</sup> divided on to 5 up to 7 floors.
- 2) With BCR 60%, the maximum floor area is 691.999 m<sup>2</sup> divided on to 6 up to 9 floors.
- 3) With BCR 50%, the maximum floor area is 710.526 m<sup>2</sup> divided on to 6 up to 10 floors.

It can be seen that the more GOS installed the larger bonus floor area can be received (see Table 2 concerning comparative green open space to the building mass arrangement). These schemes suggest that the municipality government of Yogyakarta should encourage vertical building development in its central business district (CBD) of Malioboro without providing the budget to purchase any land to provide more greenery in urban areas. The government with the GOS incentive could privately and publicly increase GOS in urban areas, especially in the Malioboro CBD without any additional government budget. Otherwise, the City Government would spend more money to increase GOS in central urban areas of Yogyakarta.

4	: Building Setback from the Road or Pathway

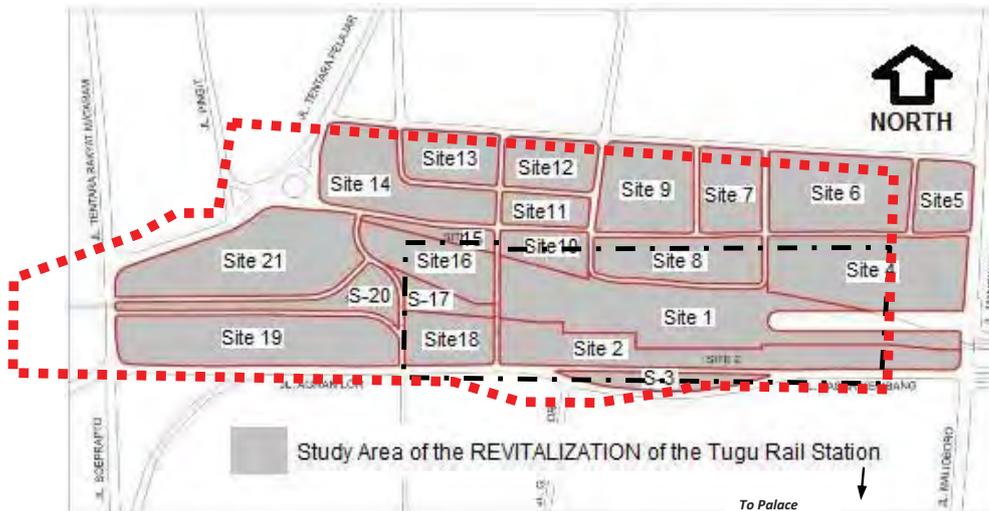

Figure 6. Site 1 up to site 20 located in the Tugu Rail Station

The 2D and 3D building mass arrangement scenario provides four different BCR base lines comparing BCR 80%, BCR 70%, BCR 60%, and BCR 50% (See Table 2, Figure 7 and Figure 8). The 2D and 3D model scenario benefit people to view spatially comparative pictures (as seen on Figure 7 and Figure 8). Figure 7 and Figure 8 showing the 2D and 3D landscapes comparatively concerning on the building mass arrangement based on BCR basis with other alternate BCR incentive affecting

different sizes of FAR bonuses (see yellow colors on Figure 7 and Figure 8). The more BCR decreased the bigger incentive FAR bonus.

Source: Analysis

The alternate BCR on Figure 7 and Figure 8 is showing the four scenarios concerning on the following schemes [4] (based on Figure 2 Formula):

- 1) the BCR 80% with no FAR bonus (the total site area is 161.101 m<sup>2</sup>)
- 2) the BCR 70% with a decreased bonus = 0,95 x 30% of the site area = 45.914 m<sup>2</sup>
- 3) the BCR 60% with an increased bonus = 1,05 x 40% of the site area = 67.662 m<sup>2</sup>
- 4) the BCR 50% with an increased bonus = 1,07 x 50% of the site area = 86.189 m<sup>2</sup>

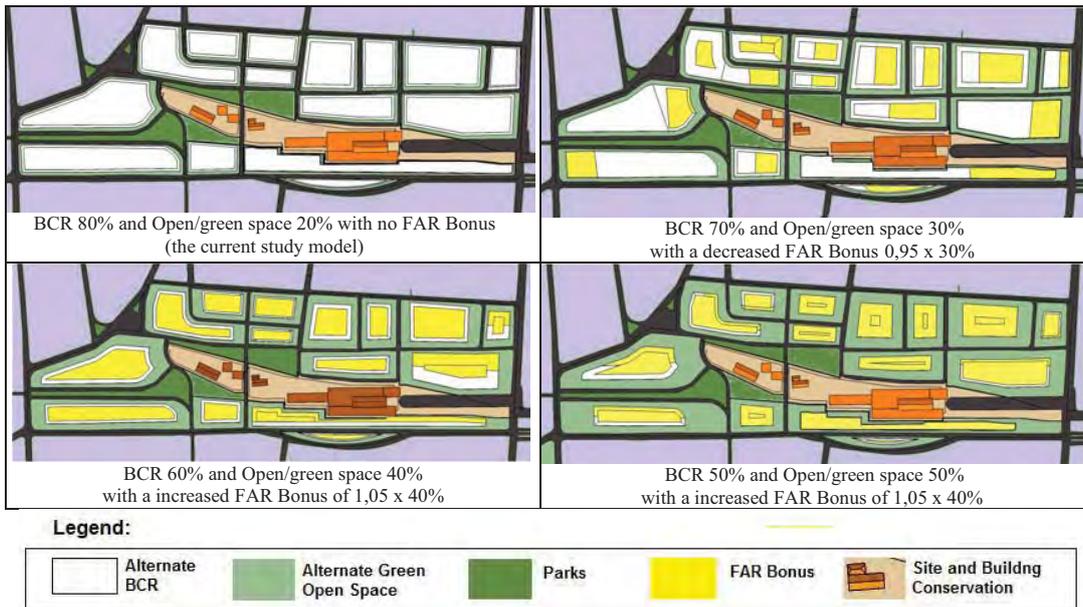

Figure 7. 2D of Green Open Space comparison concerning on FAR Basis and FAR Scenario Models

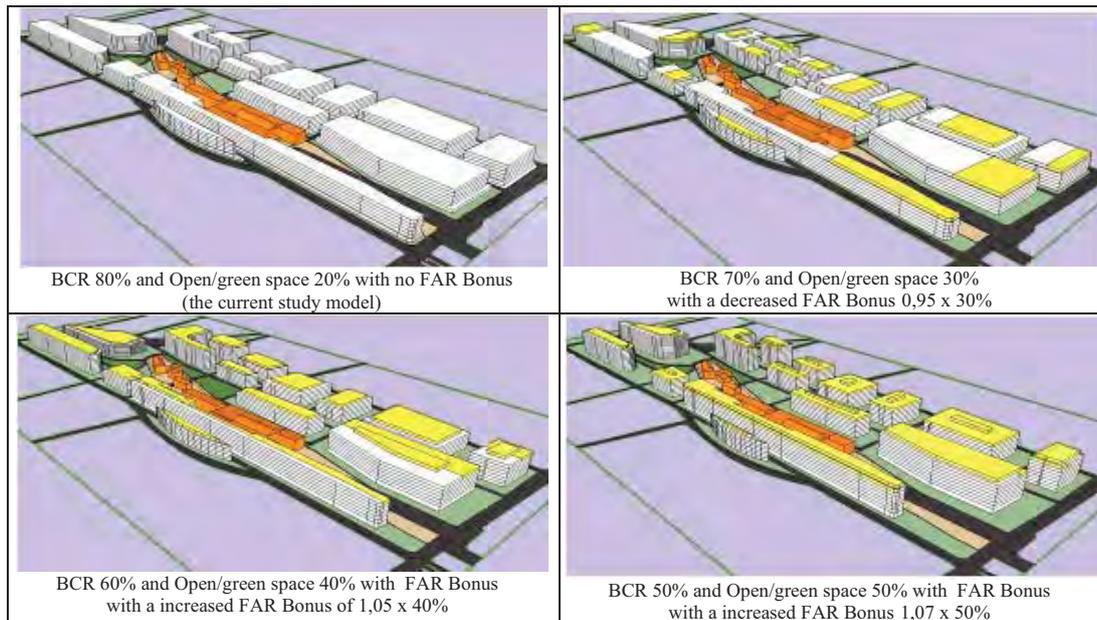

Figure 8. 3D of Green Open Space comparison concerning on FAR Basis and FAR Scenario Models

In this respect, the city government is to be sure to starting to improve its existing building code to provide some incentive floor area based on the alternate BCR as shown on Figure 7 and Figure 8. This green spatial approach also pulls and creates more opportunities for business activities and property development in central urban area concerning on commercial business growth (such as shopping, offices, hotels, apartments, etc.). Therefore, the design approach with using BCR 70% up to 50% as on Figure 7 and Figure 8 is confirmed with the concept of greening the city or green urbanism declared by Swanwick *et. al.* [5].

Therefore the Yogyakarta government should develop some key agendas in increasing GOS as part of the urban sustainability of Yogyakarta municipality. Greening more open space in the Tugu rail station is also in line with the integration between Tugu rail station area (as part of urban central area) and natural environment as a dynamic of the proposed Tugu rail station commercial and residential business activities. This also confirms with *Elkin et al* and *Jabereen's* theories concerning on diversity of open landscapes [6, 7].

This concept will also encourage more people living in central urban area because more regular people will stay in vertical housing due to easy for them to find jobs and public facilities such as retail, shopping, recreation, and vertical housing that economically fits with lower middle income. This opportunity should be captured by the city government to develop more scenario in planning the city area for the next 25 up to 50 years. This description also confirms with the master plan of the city of Edmonton [18] suggesting that the GOS approach with building mass arrangement to show its concept of sustainable vibrant well design accessible.

## 5. CONCLUSIONS

The green open space approach to the building mass arrangement in Yogyakarta urban area is a good scheme to be implemented due to the ability for the city government to increase more green open space in Yogyakarta urban area without any crucial budget to purchase land for urban greenery. The Tugu rail station project has been chosen because the project is in urban central area of Malioboro area and using the current building code that does not guarantee to provide more green open space in any construction project development in urban area. The case study of the revitalization of the Tugu rail station will be more greenary to support in sustaining Yogyakarta urban development for the future by using the floor area incentive. The FAR incentive will use two formulas including 1) increasing open space from the basis BCR and 2) Increases/decreases bonus floor area ratio based on the greenery ratio.

If this kind of approach could be implemented in urban area such as Yogyakarta. The preparation that should be conducted by the Yogyakarta government is including:

- 1) Vertical urban development zones outside airstrips and historical conservation areas.
- 2) Urban development area as a priority to increase social and economic investment gradually.
- 3) Based on the development area priority, the land consolidation to provide accessible motorized urban environment in Yogyakarta is important to be introduced.

- 4) Increasing the collaboration networks with urban business community to encourage the Public-Private Partnership for Urban Infrastructure Project to prioritize urban development areas.

This approach will promote more commercial and residential development scenarios respecting to more private investment and entrepreneur activities in Yogyakarta urban areas. If vertical urban development gradually increases due to more interesting FAR bonus schemes, it is believed that **public accessible green open space** in Yogyakarta central urban area will grow more areas without any special government budget for greenery program. Therefore, the green open space approach will support the future fresh and vibrant urban area and also promote the urban GOS regulation in Indonesia to have minimum of 30% GOS in Urban areas.

## ABSTRACT

As one of the sectors that play a role in good-governance, the private sector or the business sector is the most self-sufficient than the other two sectors, namely the government and civil society. The society gives a mandate to the government, while the government holds responsibility to the public. This gives chance for the government to play a role in facilitating cooperation and partnership between business and society. Regarding the demands for housing, particularly for self-help housing, the relation of the three sectors can be developed into a model of partnership, in which the private sector has possibility to play a bigger part. This can result in the acceleration of housing provision, particularly for the low-incomes. Through public forums / associations, they can start the partnerships with the private sector, not solely rely on the government. The forms of cooperation that already exist for this partnership are trainings, funding, provisions of building materials, etc.. This can be developed furthermore in the pattern / model and the concept of a partnership that can address the needs of the community suitably and sustainably. The aim of this article is to explain the model of the partnership for self-help housing and settlement provision in which the private sector can play bigger role, especially for the poor in urban areas. Therefore the big picture: city without slums can be achieved. The method used in this study is a literature review, secondary data analysis and review case studies of other self-help housing in neighborhoods in the city of Jakarta and Depok. Will be discussed is the private sectors that provides funding partnerships (such as CSR) and the urban poor in furtherance of the self-help housing. From the identification of the role each sector, a model of partnership can be developed. This also relates to the approach or method for the self help housing project.

*Partnership, private sector, low income, self-help housing*

## 1. INTRODUCTION

The welfare issue can be characterized by an increasing quality of life of worth and dignity, among others, through the fulfillment of housing and livable neighborhoods. Housing and settlements is one of the basic human needs, which has a strategic role as the center of family education, nurture, and improving the quality of future generations, as well as the embodiment of national identity. For the people of Indonesia, a house is a reflection of one's existence, either as individually or as a unity along with the natural environment.

One of the housing and settlements problem exists in Indonesia is due the incompatibility of the housing supply and demand. Siswono (1991) addressed these as issue related to population, finance, technology, building materials and related industries, public participation, rule of law, and business. On the other hand, the rapid population growth is not comparable to the provision of housing has led to serious problems. The unstoppable flows of migrants to urban areas due to the uneven development between urban and rural areas causes of population problems since a long time. The migrant flow is closely linked to economic activity and infrastructure development, which is still concentrated in urban areas. As an impact, the emergence of slums in urban areas become unavoidable and cannot be controlled, urbanism processes (urbanization), both physically and because of the mobilization of the population outside urban areas has led to the housing crisis (Drakakis-Smith, 1980).

Around 85% of housing in Indonesia is built and developed by the community without government assistance through the housing, private/residential developers or non-governmental organization or foundation. Aside real estate housing and housing that provided by the government, self-help housing is also one of the possibilities in meeting the need of housing in Indonesia. As a matter of fact, a large number of housing needs in Indonesia are met through this self- help housing patterns and it becomes a major asset in Indonesia. Through this pattern, the society can build and maintain the house on their initiative and effort alone, without going through a formal development procedure, either as individual or in groups/in mutual cooperation. This type of housing is often identified with the informal housing, because the construction is generally performed by low-income group, independently.<sup>1</sup> An important characteristic of the self-help housing by the low-income groups is the emphasizing the process (construction) itself rather than housing as a product. One of the factors is because the process is

---

<sup>1</sup> A. Sihombing, R. Suryantini, D. Mangiring, Sustainable Maintenance and Management in Self-Help Housing Revitalization, QIR 2011

controlled by the owner/user, which means, the initiative, the decision and the execution are made by the owner. It really depends also on the availability of the capital, not only financially, but also socially and the know-how or knowledge in constructing a house. Most of the time, the low income cannot fully maintain their house and settlement and this leads to the degradation of the house and their environment, eventually generates slums.

That kind of environmental degradation can be prevented. It seems that in most of the case in urban areas, the low income people are responsible for the quality of their housing and settlement. As the Law No. 4/1992 on Housing and Settlement Article 29 mandates that "every citizen has the same rights and opportunities to participate in the housing and settlement development", the housing and settlement is actually a responsibility of all sectors in Indonesia. Both the government and non-government, namely the civil society and private sector as well, are responsible for the provision of housing and settlement.

To understand the responsibility of the sectors involved in housing and development in Indonesia, each sector will be identified. As government institution there is the Ministry of Housing, which has the task to assist in formulating policy and coordination in the field of public housing, as decided by the President of Indonesia, PP No. 9/2005 on the Establishment of the Ministry of Housing (MENPERA/Menteri Perumahan Rakyat). Although through participatory project conducted by government or NGOs, it is not yet adequate to solve the problem. A more suitable approach or model which can accelerate the programs is required. The private sector is one sector that most self sufficient in financial, access and technology, which can be the additional force for the acceleration in solving the housing and settlement problems, mentioned above.

## **2. METHODS**

To find a suitable model of partnership in self-help housing and settlement in Indonesia, it is important to identify each sector involved, their role and possible contribution in self-help housing and patterns of relationship present in Indonesia. Based on the finding from the research using the quantitative and qualitative methods, four self-help housing communities will be involved as case study: Kampung Lio and Kampung Tambak in Depok, Kampung Wadas and Kampung Manggarai in South Jakarta. Issues related to self-help housing for the low income in urban areas, such as the availability, the maintenance and the habit of the community itself are being examine thoroughly based on observation, interviews and focus discussion group. The local government and some private sectors related to building material and technology were also discussed. Thus, pattern of partnership between each sector and their contribution in self-help housing in urban areas can be generated.

## **3. RESULT AND DISCUSSION**

Resources as financial aid, technology, building materials and related industries, public participation, conducive political will and regulation, are the issues often encountered in provision and maintenance of the self-help housing of the low income. The problems found in the maintenance and management of self-help housing, among others, is that the income level is very low, so that it is very difficult to access funds (formally), building materials, technology, and other housing resources. The difficulties in accessing the resources and its information are the obstacle for them. Their dependency on grants from the government or donator is relative high, although there are some projects that actually intended to achieve sustainability in providing and maintaining self-help housing. These were shown in the four research areas. Most of the programs conducted in the previous time by the government are consists of only physical aspects and make the sustainability of the programs questioned, because most of them are project oriented (depends on the fund from government – top down concept) and not all the problems can be solved physically. Lesson learned from those projects is that the low income housing communities need to be empowered to reach equality with other stakeholders in this housing sector, since the community empowerment method can be the key in the maintenance and development of self-help housing in order to sustain.

But it is not enough, because housing problems is necessarily only a problem for the government, but also a shared responsibility. Identified actors in housing in accordance to the function and role in housing and settlement are the government and the private sector, besides the people themselves. The role of the NGO and other institution should be developed and reckoned in the program. Most of those programs need assistance, for e.g. through competent facilitators, not only technically but also socially, psychologically and politically. Another point of view is that many of the resources are being exercised fluently by the private sector and this can be utilized as a potential attribute for the model of partnership and corporation in self-help housing.

Partnership is an agreement between both parties to achieve a mutually beneficial goal. The agreement relationship resembles a legal partnership and usually involving close cooperation between parties having specified and joint rights and responsibilities. Three principles of partnership that should be held are equity, transparency and mutual. A partnership network of interrelated schemes works together, supports each other and combines different functions, roles and responsibilities to achieve the same goals: the success of a program. Partnership in accordance with the characteristics or elements within it should be mutually supportive and mutually beneficial and based on the principle of openness and equality.

The basic scheme of the partnership is expected to build and strengthen and increase commitment among actors, in this case for example both the Central government and local government should act as a regulator and facilitator, no longer as executor in the channeling of funds and resources to improving the welfare of society. Private sector which usually acts a source of funds and other resources is expected also to be involved in selecting and determining the form of aid and where and in what manner the source of funds and resources will be channeled. The communities themselves are expected to also be able to systematically distribute both information and resources available to them for improving the welfare of the people, at least in the environment of their own.

The model of the partnerships can be very interesting, because current the approach adopted is usually the top-down approach, compared to bottom-up concept, which tries to generate action for a sustainable society, especially through the provision of information considered less. The partnership for a sustainable society will require significant attention to the transformative environment for models that are sensitive to the actions of government and the constitution of the dynamic power relations. Consideration of the political, bureaucratic, financial and all those involved in meeting the needs of low-income people need to be considered to enhance the attractiveness of the programs, which required a conducive situation for all actors.

The partnership may also have an important role in developing the operational framework of sustainable development, but unfortunately, their positive contribution can not always be guaranteed. Partnership requires to be placed on each roles and responsibilities, and greater extent of transparency in terms of the desired outcome. If the goal of the partnership is to achieve sustainable development by empowering people, then at least it would seem appropriate to involve them in the process of problem identification and definition of the program.

In the implementation process, the partnership doesn't always in the form of ideal, because the implementation is conducted based on the interests of each actors. If the partnership formed between the private sectors and the government and the community as well, they can form the third scenario, productive one. In this case, identification of actors / stakeholders, their roles and potential in the partnership needs to be done.

Several institutions have important roles in housing and settlements in Indonesia, namely central government, the provincial / district / city, businesses, donors, non-governmental organizations (NGOs), R & D institutions, Universities and Public Institutions (traditional institutions, religious institutions, and the other communities). These institutions need to cooperate and coordinate in their activities, in which one may be related another. Therefore their cooperation need to be institutionalized.

In Act No. 4 of 1992 on Housing and Settlement, every citizen has the right to occupy and or have a decent home in a healthy, safe, harmonious and orderly. It also mentions that the Government shall develop the enterprise in the field of housing and settlements in the form of regulation, guidance, assistance, convenience, development, planning, implementation, monitoring and control. The community can participate in the development of housing and settlements, by utilizing local techniques and technologies, building materials industry, construction, engineering and design of appropriate technology and environmentally friendly. According to the Act, there are three approaches in

Under the legislation, the Government should and are expected to create a conducive environment for the provision of housing and housing for the community and other agencies including the business community, associations, R & D institutions, NGOs, donor agencies, and other community agencies. Governments have a duty to facilitate the delivery of housing and settlements. There are three schemes developed to overcome slums and environmental degradation, namely restoration, revitalization, or resettlement. By using these schemes, the model of partnership can be adjusted.

Both central and local government has the authority to set policy and regulation, supervision, coaching, coordinating and providing subsidies to the public. The central government should coordinate and involve the local government to carry out the implementation of housing and settlements. Local government will directly provide services to the community in the area. Government Inter District / Municipality borders must cooperate and coordinate in the implementation of housing and settlements to be integrated and mutually beneficial. The local government together with the community should pursue the implementation measures of housing and settlements and or rejuvenation and improvement of the environment or to improve the welfare of its inhabitants.

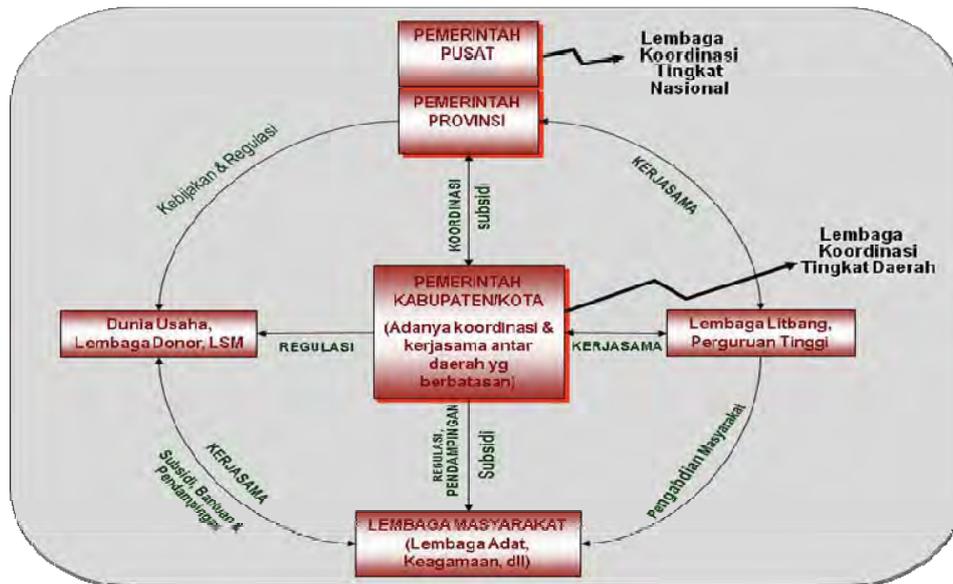

Fig 1: The Concept of Partnership in Urban Housing and Settlement  
 (A.Sihombing, et.al, 2012)

The private sector can act as a partner for the government to manage the resources, to assist the government in the business world in running the economy and leads the development, to generate income to the government, among others in the form of taxes. Private sectors, donors and NGOs can work directly with the community but should still notify the local government and obey the laws and regulations in force in the area. Forms of participation that can be done by these institutions include subsidies, support (financial and other resources) as well as assistance. In addition, these institutions can also cooperate with the government in terms of sharing of housing and settlement programs. The government both central and local governments are to facilitate the activities of these institutions through policy and regulation. Policy and regulation is certainly partial to the welfare of society.

In the last two decades, NGOs increasingly accepted as a key actors in the new partnership that allows local governments and officials' dialogue and collaboration with community organizations / civil society organizations on the issue of poverty alleviation, housing and basic services. Nevertheless, it is important for NGOs to withhold customs dominate or speak the name of community partners and is not always easy to do.

Research institutions and universities can contribute in by conducting research in form of a housing policy formulation settlement as mentioned in the previous chapter, while the government provides facilitation and regulation to support the implementation of the research. Universities can also provide service to the community as one of its functions in the form of mentoring and more. Research institutions and universities can work with government and the government should not limit with regulations in the research objective carried out by research institutions and universities. Research institutions and universities are given more freedom to innovate is responsible in carrying out its activities, for the welfare of the community.

Both the central government and local governments must coordinate with each other in the administration of housing and settlement as described in the previous. It is intended that policies, programs and activities will not overlap , but complementing each other in a synergy. Government can share program in the administration of housing and settlements. This shared program is intended as an example in the management of housing and settlement in a location where the Ministry of Housing undertake housing development or housing assistance stimulant, Ministry of Public Works provides the infrastructure development program, and the Coordinating Ministry for People's Welfare to carry out the National Program for Community Empowerment (PNPM) Mandiri.

Cooperation between central government, local governments and the central government to local governments that have been carried out starting with an agreement or Memorandum of Understanding (MoU). Cooperation agreement in the field of housing and settlements has been done by the government, in particular the cooperation agreement / MoU between Indonesia governors at the Ministry of Housing.

The community acts as a subject and as well as an object of development should be involved in the administration of housing and settlements. This is because the people who know best what their needs and wants. The intervention can be done by groups

such as traditional institutions, religious institutions and other community based organizations. Cooperation between stakeholders or stakeholder that originally accompanied the public should apply independently. The needs of the community in perpetuating social service institutions may not easy to be achieved. These needs include the need for the Budget, Facilities Support, Facilitator / Employment Assistance, Procedures Manual.

Cooperation with other institutions to do in the administration of Housing and Settlements can be done through a cooperative agreement in the form of a Memorandum of Understanding (MoU). This was already done by some of the providers of housing and settlements. From the discussion, it can be identified the role of government, society and the business community in the implementation of housing and settlements and can be described as follows:

- Government, has a leading actor, which drives, facilitates and regulates housing matter in Indonesia. This role requires the government to implement policies consistently and consequently through the realization of good governance.
- The private sector community has a role as a provider of services and driving the achievement of objectives. Idealism and good work ethic owned businesses must be maintained with the view that the profit is not everything to be achieved.
- Community as consumers, supervisors and controllers. The community has a part to play a role as well in the administration of housing and settlements with no prejudice, but also in attention to every process.
- NGO's, academics as contributor, supervisors and controllers. They serve and intervene the community through their disciplines.

Furthermore, the division of roles in the partnership relating to the slums model patterns that can be proposed are as follows:

- In the case of restoration, the partnership is expected to occur more between the Government and Society,
- In case of revitalization, a partnership may be preferred is between Entrepreneurs and Society,
- As for the case of resettlement, the partnership is expected to take place between the Government and Employers.

#### 4. CONCLUSION

From the identification of the sectors involved in the housing and settlements and the proposed partnership model, it requires further review and response. Based on the survey conducted, so far the activities and roles for each sectors was incidental and not coordinated in an integrated program or a road-map that is well planned. Scattered locations and in the form of small-scale activities resulted in positive impact on improving the quality of housing that is not always experienced by the community in particular and other stakeholders in general. This affects the sectors involved in the partnership which have less satisfaction with the results. It will have an impact on the long term, a lack of interest to participate in partnership programs and other cooperation.

Therefore it is very important to develop an appropriate road-map or model of partnership to overcome slums, taking into account environmentally, socially, economically and culturaly suitable of local communities, private sectors as well as the readiness of the Government's program (Region) in achieving sustainability partnership and cooperation. In addition, this model should be tested to see conformity and obstacles that may arise so that it can be used as a lesson-learned for the improvement of a model of partnership and cooperation and or adjustment road-map.

## ABSTRACT

Various modes of urban public transport in Indonesia have caused environmental concern as a result of the competition among them in a limited urban public space, i.e., roads. They give rise to usurpation of public space, blockage of the traffic and squeezing tightly into space. This study seeks to uncover such a behavior that is aggravated by the trip makers, and associated activities such as street vending. Findings have shown that habitus of actors and their virtual networks of illegal, informal activities sustain their existence.

### Keywords

*Dual-society, habitus, contestation of public space, meta-space*

## 1. INTRODUCTION

The practice of transport planning in Indonesia has been characterized by a Euro-centric empirical model. Such an approach overlooks what really is in reality. It denies the actual modes of the public transport in Indonesia that indicates the reality of the socio-economic practices and conditions of the society as a whole in urban formation and development. While the urban population continues to increase at an unprecedented rate and the gap between the rich and poor is widening, the resolution of transport problems has never been conclusive. The critical state of urban transport in Jakarta as a whole has become alarming. Some scholars have envisaged that in the coming year up to 2014, Jakarta will risk a total congestion.

However, parallel to the issues of congestion in a macro level, there are critical micro issues regarding the movement problems that are worth requiring a serious attention and study. It is a corresponding problem related to transport movement. It is a socio-cultural issue rather than technical. Within the road design and the carrying capacity of it, in practice, there has been a 'pressing problem' of public transport behavior and associated informal economic activities along the way. Such urban informality practices have never been seriously investigated. This research focuses on this particular issue – traffic behavior and its associated issues.

The research seeks to unravel the deep structure of so called 'illegal activities' associated with urban transport with a particular reference to the Urban Transport Terminal at Kampung Melayu, Jakarta. Such a structure is conceived in terms of its spatial formation, production and reproduction. The research objectives are to uncover *habitus* and tactics of different actors engaged in the usurpation process of public space – *meta space* (space as perceived and conceived by them like two chess players facing a chess board); and, to establish a contextual transport analysis in Indonesia which is not empirical but explanatory.

## 2. RESEARCH INQUIRIES

Understanding urban transportation issues and systems simply from its mechanism or parametric approach of design in the built environment may overlook the deep structure on how a city works – especially the lived space. This is crucially the case in the country like Indonesia where it is constituted by the dual society, i.e., modern-capitalist/traditional-bazaar, embodied in the duality of formal/informal sectors. Their respective structuration processes evolve and compete over scarce urban space. This includes urban transport problems. Urban transport in Indonesia has long been operated by two modes of services – modern/capitalistic which is very limited in service, and traditional/'bazaar'.<sup>1</sup> They are mutually exclusive in their existence.

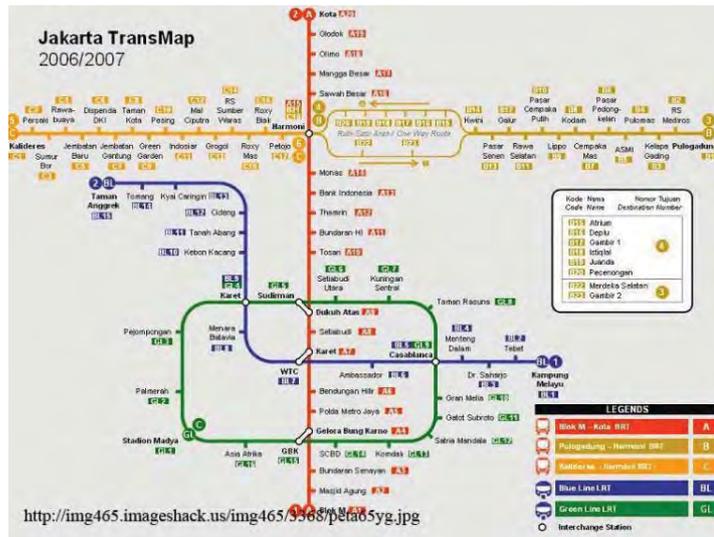

Figure 1  
 Ideal Scheme for the Mass Transit in DKI Jakarta 2006/2007.  
 Public transport system as conceived by transport planners.  
 (<http://img465.imageshack.us/img465/3368/peta65yg.jpg>)

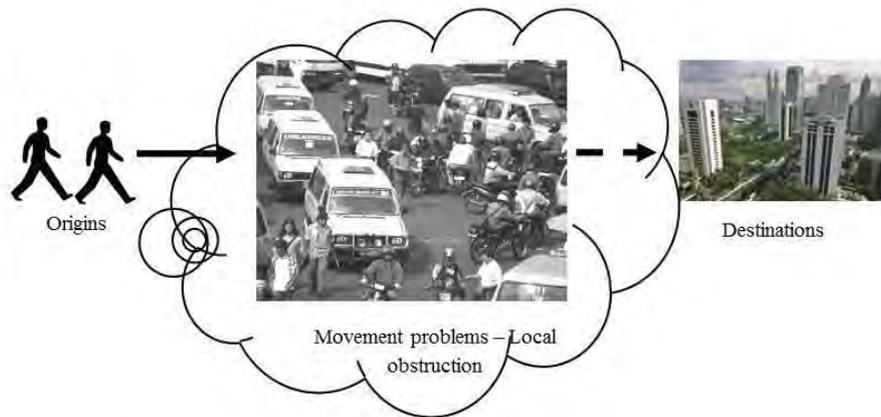

Figure 2. The Problem  
 The 'real world' of people movement in Jakarta – Space contestation amongst public transport operators and other associated activities in public space

Based on such an understanding, the research inquiries why there are enduring problems of black-spots and constrictions generated in the traffic movement in Jakarta, which are not simply caused by the technicalities? What and who are they that generate them?

To answer the research questions and objectives, three main concepts and theories are posited to understand the nature of urban society, its constitution; and its impacts on urban living space, especially to understand the hidden dimension of human behavior, interactions and particularly contestation over the scarcity of urban space.

*Dual-Society*

The theory of dual-society helps us to understand the constitution of the urban society – as a continuum between modern/capitalist and traditional/bazaar economy – its production as well as its reproduction. In terms of the constitution of society, such as two extremities of society produce and reproduce respectively. This production-reproduction has adverse effects on urban space, while the capitalist society manages to negotiate and appropriate space/land, the other in its powerlessness manages to contest and usurp urban space as much as possible.

Herman Boeke<sup>2</sup> in his PhD dissertation in 1910 proposed an influential thesis concerning the apparent dualism of urban culture

in Indonesia. His argument was based on the fact that in Indonesia there were two social and economic systems. The Westernized element in the economy is seen to be materialist, rational, and individualist, and was presented as the epitome of exploitative and unyielding capitalism. The Eastern element, by contrast, was seen to be pre-capitalist, characterized by a prevalence of and preference for self-employment, was unresponsive to variations in prices, and was not profit-orientated. This dualism persists until recently.

Anthony Giddens<sup>3</sup> in his social theory of *structuration*, argues that a society is produced and reproduced through the creation and reproduction of social systems. Systems, according to him, refer to reproduced relations between actors or collectivities, organised as regular social practices. The social systems in which structure is recursively implicated comprise the situated activities of human agents, reproduced across time and space. In social systems the role of human agents or agencies are then crucial. Hence, various forms of human knowledge, worldviews, expertise including planning and design, emerge and are maintained. In this sense, localities of action can be investigated upon how these are politically allocated and dominated by particular groups in the society. They can be observed as both spatially confined and extended.

#### *Social Closure*

Parkin<sup>4</sup> introduces the idea of social closure. In terms of their spatiality, situated activities may signify closures. In this sense, similarly situated practices will also be investigated as a process of social closure. There can be identified three modes of social closures: exclusivity, usurpation, and dual closure (not discussed here). The distinguishing feature of exclusionary closure is the attempt by one group to secure for itself a privileged position at the expense of some other group through a process of subordination. Usurpation is that type of social closure mounted by a group in response to its outsider status, and the collective experiences of exclusion.<sup>5</sup> Dual closure refers to a usurping action against a higher opponent group, for example against the state, combined with exclusionary activities against presumably a lower or a less-organised group, for example, against ethnic minorities or gender related groups. These closures are not static and will depend on the structuration process over time and space.

#### *Habitus*

This theory helps to answer questions concerning behaviour of individual or a group of individuals as a system of disposition. In a society like Indonesia, where cultural extremities are so wide and multifaceted, different conditions for the possibility of social practices may be manifest. Bourdieu terms this condition *habitus*. He argues that *habitus* refers to a “durably installed generative principle of regulated improvisations”, or to a complex net of structured predispositions into which we are socialized at an early age.<sup>6</sup> *Habitus* is constituted in practice and “always oriented to practical functions.”<sup>7</sup> In this concept, social relations among actors is being structured by, and in turn, is contributing to the structuring of, the social relations of power among different positions (of class, gender, etc.). The practices happen in a space called *afield* in which actors play out their engagements with each other.

### **3. Methodology**

The research concerns urban space contestation and seeks to understand the deep structure of extensive existence of ‘informal’ activities in the public space within the domain of transport in the vicinity of bus terminal of Kampung Melayu, in Jakarta. The main objective of the research is to disclose a ‘virtual map’ or *meta-space* of activities generated by various actors associated with public transport services. The conspicuous and chaotic existence of such activities has caused serious congestion. It will focus on the usurpation process of public space by the intensifying numbers of the production and reproduction of ‘informal’ or illegal undertakings almost round the clock. In this mode, spatial structure may manifest by and in multi-layered processes.

It is a grounded research from which theses or theories are based or grounded on data. Respondents such as pedestrians are selected at random. An in-depth interview method is purposively chosen, namely those of transport operators as well as vending traders to ‘capture’ their respective *meta-space*. They are actors that may conceive of different images of a space and supposedly have critical opinions on the consumption or usage of the critical space around the bus terminal.

### **3. RESULTS**

#### **3.1. Understanding *Transport rakyat* People’s Transportation**

The term people’s transportation (*transport rakyat*) is more apt than a generic public transport considering that the population of Jakarta is classified under the low-middle income as still being the majority. They serve this majority of the urban population. This phenomenon results from the very fact of socio-economic duality. *Transport rakyat* emerges as part of the constitution of urban society – modern/capitalist and traditional/bazaar. *Transport rakyat* meet especially the demands for mobility of the urban poor in urban area. It entrenches within the society.

Despite its legal, formal existence, this type of service is, however, comparable to everything under the category of

the 'informal sector'. These services include *Metromini*, a medium size bus; *Mikrolet*, a van type public transport, *Angkot*, mini bus; *Bajaj*, tricycle transporters, and mobile and the omni-presence of *ojeks* or motor-cycle transporters. These modes of transport sustain the life of the urban poor. The dominant *habitus* of these modes of transport are peculiar, distinctive to each community or society. They operate on an 'individual' basis, resulting in competition between one and another. This gives an image of *semrawut* or chaotic activity.

### 3.2. *Transport rakyat* and the Phenomenon of *Supir Tembak* (Substitute driver)

Ideally, the public transport system will primarily serve the public during a rush hour or at the peak periods, particularly in the morning and afternoon; and, outside these periods they normally go back to their depot or garage. However, this is not the case for *transport rakyat*. Once they are all 'out' on the road and serve the public, they will stay on the road until late at night. Such transport vehicles may either be owned by the driver himself (most are male) or driven on behalf of the owner. In fact, both drivers are driven by the target of *setoran* or the amount of money or earnings per day. It varies from 100,000 to 150,000 rupiahs per day.<sup>8</sup> While the pricing policy stipulated by the government states the maximum distance and subsequent charge of about 3,500 rupiahs per person, the reality may be different. It is a very low price if we consider the sustainability of the services, but it is *transport rakyat*. As a consequence, the road everywhere is crowded by *transport rakyat* of different sizes – *Metrominis*, *Mikrolets*, *Angkots*, *Bajajs* and *Ojeks*. Their numbers have already exceeded the demand and as a result they compete with one and another.

To operate the *transport rakyat* that is almost round the clock, the drivers of Metromini, Mikrolet and Angkot must ensure some place to park to take a rest. This is made possible by the help of *preman* (thugs or 'freemen' agents) who have control over certain territory in the public space. This *preman* usually is accompanied by local unemployed persons. The latter are those who are present and visible in the area – organizing the activities in the crowded public space. While the drivers take a rest, there are *supir tembak* or substitute drivers of their kin or friends who replace them, they also desperately need jobs of whatever type they can access. In the low peak periods when the *transport rakyat* 'take a break' and rests or *ngetemon* the road space 'available' that is secured by the *preman*.

### 3.3. Ojek the free rider

*Ojek* operators are *free riders* – those who enjoy the benefits of an activity without paying. They are present in the urban market place due to a simple principle – supply/demand. They are very agile move between traffic jams. There are two kinds of 'free riders' who take advantage of such economic opportunities ie, ojek and street vendors. Ojeks and street vendors usurp the public space side-by-side. In many cases, ojeks park their motorcycles at right angles to concrete curbs, which add to the narrowing of the road space. They are usually much more organized and share cohesion among themselves. This type of independent service is very problematic to be attached and connected into the 'formal' system of public transport. The operators are omni-present like mushrooms everywhere in Jakarta in locations ranging from localized residential areas to the hectic urban environment.

### 3.4. *Habitus* of Trip makers

Trip makers are the triggers and generators of this entirely muddled transport problem. The erratic behaviour of trip makers such as stopping the public transport vehicles both to get in and to get off in any place they like. Pedestrians take the short-cut to move from place to another, including taking the risk to cross the busy roads. The situation is aggravated by the occupation of the side-walk by any kind of vendors. The only space left for pedestrians is the road tarmac.

*Habitus* of trip makers includes crossing the streets, getting on or off the public transport vehicles in whatever places, as well as eating and drinking in the street. In so doing, they predispose responses, thus their actions suit particular purposes that are mutually exclusive amongst each other and in competition to one another. Crowding formed through 'consensual' acts among actors of different interests become inevitable over a limited available space.

### 3.5. Practice of Usurpation

The practice of usurpation of various actors and activities in the public space public spaces is possible by the support of the *preman*. The process uncovers such clandestine operations and organization between *preman* and the oknum or individual authorities such as a police and those form the Traffic and Highway bodies. In return of their warranty and surety or protection, the *preman* bribe them. In the actual operation, the *preman* then employs those local thugs who desperately need the jobs. The practice of usurpation and of closures within the public space is exercised to protect against an invasion of strangers to join these usurping practices.

#### 4. CONCLUDING REMARKS

Dual society, its production and reproduction, has a spatial implication. While the modern/capitalist is capable of negotiating the scarcity urban space, the traditional/bazaar is not. This is no exception in the sphere of public transport services. In Indonesia public transport can be distinguished into such a binary undertaking. I will use the term 'traditional society/bazaar economy' *orbazaarism* – to refer to social attitudes where social institution and way of life are one. This usually manifests in huge numbers, individual and unrelated economic form of petty commerce. Consequently, understanding public transport in Indonesia requires deep comprehension of the society as a whole – an archipelagic nation and its dualism. Traditional society and its bazaar economy straightforwardly will address those of the poor community – rural or urban. In other words, *bazaarism* in the public transport sector means also the engagement of traditional society in transportation. The services of *transport rakyat* are provided by and used by the majority of the urban poor as the trip makers. The latter further complicates the bazaarism in the urban transport services.

The presence of an enormous number of trip makers in the vicinity of the Bus Terminal in Kampung Melayu further invites the *bazaar* economy in the areas where people are gathering with various locals. Usurpation of limited public space is then intensified by various modes of *transport rakyat*, vendors and itinerant traders. This contestation over limited public space is mediated by the *preman*; and the *preman* organize the area through clandestine deals with corrupt individual policeman and those from the authorities of the Local Traffic and Highway Bodies. The *habitus* of those engaged in the 'businesses' and their *metaspace* are inter-connected. This creates as a virtual web of bazaar economic undertakings.

Space around the Bus Terminal convoluted and turned into some kind of 'barricade' in the public space, i.e., in the roads. The severe problems of congestion in Jakarta are then complicated further by such practices

The political issue of the public transport in Indonesia results from the socio-economic conditions of a country, especially related to those of the low income or urban poor. The choice for improvement between the current public transport system adopted either i) to continue and let individual operators involved in the public transport system; and to strictly enforce the traffic laws and regulations. However, problems remain that the government lacks of capacity to detect clandestine operations of bazaar economy in the grassroot level, that, in fact, also involves corrupt government officials; or ii) a more unpopular, authoritative measure, to *take over* current 'informality' of public transport system (i.e. individual operators of the public transport) into the formal system under the local government as well as private management.

## Urban Invasion and Contestation of Space: Houses to Shop-houses to Street Vendors along Madura Island's Primary Collective Road

Dita Trisnawan<sup>a</sup>, Nevine R. Kusuma<sup>b</sup>

 Email: dita.trisnawan@ui.ac.id, ditadesign@gmail.com, nevine\_rk@yahoo.co.id

### ABSTRACT

The invasion of street vendors in many countries has become such a problematic issue. In fact, within the urban spatial management cases, street vendors are mostly agreed as the objects of which disrupting the order of the urban environment, for its invasive existence. The arguments in this paper analyze the position of traditional commercial vendors along the primary collective roads of Madura Island, formed and growth organically from only as strip of houses into shop-houses and later extended as 'formal' street vendors. As the product of 'ribbon developments' in nature, into a complete commercial street then, this phenomenon offers a fascinating approach and discourses to the practice of urban design and planning in dealing with certain traditional and local elements, against the capacity requirements of a planned road infrastructure.

### Keywords

*Urban invasion, contestation of space, street vendors, Madura Island, urban design.*

### PRIMARY COLLECTIVE ROADS OF MADURA ISLAND (SOUTHERN MID SECTIONS)

Ribbon developments have shaped the street frontages (the building forms) along the Madura Islands' collective primary roads. Public Markets (*Pusat Jasa Prioritas/Pasar*) along the Southern Mid Section of the road, have been analyzed and studied based on recent transportation analysis of BPWS Project 2012<sup>1</sup>. The analysis concludes that two public markets will be redesign as they impact the road's designated functions, its accessibility, the road's width, etc. These two are: Pasar Tanjung Dharma–Pasar Bandaran of Sampang–Pamekasan municipality and Pasar Keppo of Pamekasan municipality.

Several causes of the traffic congestions along the roads of the Centers (Public Markets), especially the traditional markets, can be clearly identified, primarily the traffic disturbances in the form of emerging commercial and service activities, which intervene the existence of the southern mid section roads.

External Factors directly impact the market's intensity, they are: 1). The closer the markets to the city/municipality centers, the crowd-ness potentiality and traffic congestion numbers will be higher, related to its higher raises on accessibility and transportation's potential, 2). The closer the markets to the immediate main arterial road (regional level road), the higher traffic congestion numbers will be. Internal factors are coming from inside the Public Markets themselves, impacting the activities. Within the cases of the Public Markets along the regional roads of Madura, these factors consist of these several indicators: frequency of actions/movements, volume: size/scale, and its commodity types. Based on these two factors, the differentiations are then derived into problems, which are spatially analyzed as they exist in reality on location. Road traffic interferences exist in the forms of non-transportation activities along the study areas, following the urban spatial contestations which arose, and the local policies which can be taken toward the growing problems.

## RATIONAL ANALYSIS AND REASONING APPROACH

This research uses rational analysis to understand the complexity of problems within the study area. By breaking the parts of activities within the area, practical methods applied to define strategic physical discovery. The characteristic of rationality any action, belief, or desire, that makes choices optimal under a set of constraints<sup>2</sup>.

Normative concept of reasoning in the sense of rationality derives conclusions in a consistent way. It relates to the conformity between beliefs of one(s) and the other(s), and the beliefs to take action(s) based on those beliefs. A rational is not just reasoned, but also has best possible answer (optimal) in achieving goal(s) or solving problem(s). Determining optimality for rational behavior involves formulation of problems and the definition of key assumptions.

Rationality factors engage how much information is available to complete the knowledge of the related topic. These formulation and background assumptions then became models within which rationality applied. The problems must be framed and formulated by specifying the background model assumptions to achieve a meaningful rationality.

Reasoning is connected with ways of thinking, cognition, and intellect. It is related to what thinking comes from one idea to other related idea. Thus, rational beings understand themselves to think about the reason(s). Reasoning juggles between cause and effect, truth and falsehood, and what is good or bad. Reason is the capacity for consciously making sense of things, for establishing and verifying facts, and changing or justifying practices, institutions, and beliefs based on new or existing information<sup>3</sup>. The concept of reason is sometimes referred to as rationality and sometimes as discursive reason, in contrary of intuitive reason.

The arguments in this paper analyze the position of local fishery goods street traders/vendors along the primary collective roads of Madura Island. Rationally formed and growth organically from only as strip of houses into shop-houses. As reasons (why-ness) took place, these functions later appear extended as 'formal' street vendors along the main road's Right of Way(s). The discourse offers a fascinating approach and discourses to the practice of urban design and planning in dealing with certain traditional and local elements. The research then further discussed the contestation of space between those elements against the spatial capacity of a planned road infrastructure.

## STUDY AREA'S REDESIGNING VARIABLES (REVITALIZATION)

Revitalization becomes significant, whenever most of the key elements of vitality of places have diminished. It is when considerable disturbances and intrusions to the ideal motions condition have become substantial for changes. In the case of Jalan Raya Bandaran, as the Primary Collective Road, the purpose of the site planning process is to revitalize its very existence. During the process, there are several assumptive variables to be considered to use, they are:

- a) **Triggering Activity Factor;** relative distance to city (municipality) center and arterial road, affecting the intensity of the markets' activity, because it relates to accessibility, which then generates denser triggering commercial, service, and logistic activities along the road.
- b) **Site Support and Future Development;** Traffic jamming potentials will get higher as the result of the denser triggering activities within the district. Thus, supporting capacity variables to anticipate the growth become quite important. This also directs the possibilities for area development and other aspects to optimize the study area potential.
- c) **Scale and Size of The Right of Way;** can be used as variable defining the success to manage the problems, especially related to the ability to flow vehicle movements, which are just passing-through the study area, as designated lane of "free or very minimum disturbance lane".
- d) **Market's Activity Frequency;** can be used as variable defining the planning results applied in the forms of policies of Operational Management, can be flexible, depending on and matching with the schedule of 'Hari Pasar' (The Markets' Day), events, momentums and time intervals of activities in every season or the markets' day periods.
- e) **Trading Commodity;** the types of commodities for trading, can be used as variable, which affect the mode of transportation use, since its spatial intervention relates to scale and size, ultimately influence the intrusion (disturbance) of traffic along the study area.

#### SPATIAL ANALYSIS OF PASAR TANJUNG DHARMA-PASAR BANDARAN (KAB. SAMPANG-KAB. PAMEKASAN)

Tanjung Dharma Market and Bandaran Market are categorized as Fisherman's Market, located in between Camplong Market and Tlanakan Market. These markets are positioned on the side of the National Road (Southern Mid Sections) with Primary Collective Road status.

Since the distance between Tanjung Dharma market and Bandaran market around 6.75 kms, and the distance to the main road is less than 50 meters, these markets have strong level of service and accessibility. Spatial condition is within high density level, especially along the southern mid section of this Primary Collective Road, close to Tanjung Dharma market and Bandaran market. (image 1, marked 1 and 2).

Figure 2: Corridors of Street Vendors along PasarTanjung Dharma-Bandaran district

Around Tanjung Dharma market and Bandaran market, there are housing settlement areas and coastal areas, since they are located along the southern coastal of Madura Island. This area has a small traditional fisherman's port, adjacent to Tanjung Dharma market and the coastal zone of the Southern Mid Section of this Primary Collective Road of Jalan Raya Bandaran.

Considering the area condition along this Southern Mid Section, the settlement growth is organically triggered by two factors: 1. The existence of Collector Road, and 2. Estuary and Coastal Access. This model can be seen based on the present growth tendency, which happening along the coastal southwest side, around a couple of hundred meters from Tanjung Dharma market.

Reclamation activities slowly carried out by the fishermen. Since logically their boat can be moored directly, at the backside (water-side) of the fishermen's house. Tanjung Dharma-PasarBandaran markets have uniqueness as fishermen markets, which are bordering and relatively attached to the coastal, along the Primary Collective Road. Its outsides are facing directly to the coastal edges. Based on the field survey, some recent reclaimed lots, on the south side are within the one kilometer radius from the study area location.

Figure 3: .Road/street conditions along the Primary Collective Road (Southern Mid Sections). Houses becoming storages and shophouses, then Street Vendors occupying public (Road) space (Source: Field Survey, September 2012)

Within the next growing phases, this coastal area widens, creating road boundaries, which appear to be narrowed, since they frame the settlement's on the left and the right side of the street/road corridors. The coastal strip area had become land area, with some permanently built housing settlements on top.

Private space established through the pattern of uses. Thus, it is possible for the formation of shifted designation of public into quasi to private. The importance of the pattern of uses, slowly but surely create a sense of belonging. This action provokes territorial behavior of the urban settlers. While private space has fixed boundaries, it is also stationery.

Tanjung Dharma – PasarBandaran markets daily activities happen all day mornings and afternoons, within the interval 6AM – 10AM and 3PM-6PM. Commodities are dominated by fishing products, freshly captured fishes, directly sold in retail, or in wholesale. These can be analyzed based on the field facts, where woods/bamboos' made 'displays' for retail (street vendors), icebox and containers for storage, and ex-liquid jugs, which have been modified for storage purposes. These 'portable' cold storages are used to maintain the freshness of the fisheries products. Beside the street vendors, local groceries (*tokokelontong*) which sell daily needs, primary foods and extras are also open. Within the operational hours, the local traffic is congested from two directions along this Primary Collective Road.

The existences of their (street vendors) equipments which dominate the public area, was causing traffic during the day.

Figure 4: Street Vendors along the main road between PasarTanjung Dharma and PasarBandaran. PasarTanjung Dharma kompleks, under construction (September 2012).

Factors that caused the traffic congestion are:

1. **Spatial/Space Expansion.** The expansion phenomena enforced by the needs to show, the needs to have a 'display space' for the selling products. This behavior had caused the (street vendor) traders, filling the space up to the edge of the main road. The main road's shoulder (bahujalan) is filled with their presences, the movements of traders (buyers and sellers). The most important element of this behavior is the 'requirement' of 'being seen', the need to build the interactions, to define interests and preliminary communication between the upcoming buyers and the sellers. It is all began from the visual contacts among them.  
 The spatial expansion occurred by encouragement of spatial needs in displaying the goods. Thus, this activity engendered claiming over pedestrian space by the seller. In other words, in relation to the nature of performance, the pedestrian area becomes a stage for 'their performance', and their display as 'the setting' has an active part in the performance<sup>4</sup> (Madanipour A, 2003). Moreover, Cohen-Cruz (1998) stated in his book, *Radical street performance*, the more obviously seen, the more people will be attracted to what we show, thus 'we need to be seen'<sup>5</sup>.
2. **The Goods 'Displays' Positions,** the invasion to the pedestrian designated spaces along the main road. The position of their goods display (fish storage and boxes) invaded the pedestrian space. In terms of private and public space in the city, the physical objects, such as boxes and fish storage, seen to be used in establishing their personal space in public area. Likewise, it demarcates a territorial claim over space<sup>6</sup> (Madanipour A, 2003).
3. **Spatial Intervention.** The use of partial body of the main road for (undesignated) pedestrian movement. This spatial intervention shifted several functions enforced by the contemporary/overlapping usages of public space into quasi-public/quasi-private spaces. Hence, it caused a portion of the main road that belongs to vehicles also used by pedestrians in this case the buyers along the road. Public spaces are places outside the boundaries of individual or small group control, mediating between private spaces and used for a variety of often overlapping functional and symbolic purposes. In fact, the nature of public spaces has to be open or available to people and being used or shared by all members of community<sup>7</sup> (Madanipour A, 2003). Otherwise, in this case there was an inequality shared of space.
4. **The Market core Location** (Image 4. righthand-side) is still under construction allocated for the designated Tanjung Dharma Market.

As Primary Collective Class Road, Jalan Raya Bandaran (the Southern Mid Sections) serves as a corridor of public space, one main economic infrastructure for its surroundings. There were reason(s) for it to change overtime. Its shifted usages perpetuate the abnormal condition of its designated service. This condition bares the rationality and reason(s) of a complex substance.

Why this matter could happen? Due to the nature of public space, that is a place of simultaneously, which means a site for display and performance, a test of reality, an exploration of differences and identity and arena of recognition. As a site of display and performance, the urban actors were among individuals who need the very existences, the spatial occupants for different objectives. The reality exist is driven by the power of shifting functions, related to communal (groups) power within the environment, beyond the capacity of the enforcements of laws. The differences and identity are explored to be recognized, where each and every place usually has their own character. Within the case of Pasar Tanjung Dharma – Bandaran, the existences of the fishery traders' equipments that dominated the public (corridor) area, including activities beyond their existences, were causing these predictable traffic congestions during the day.

## VARIABLE AND PLANNING STRATEGIES

Based on the site rational analysis and reasoning approach, the site planning strategy of Tanjung Dharma-Pasar Bandaran Markets needs to consider some of these keypoints:

1. **Road Spaces are free** from or have less intervention form commercial and traffic activities from both directions.
2. Trading **Goods display positions shall not disturb the Right of Way** space of pedestrian corridor along the road.
3. There shall be **designated drop-zone areas**, which are free from any flowing traffic. **Traffic lanes are planned well** separating the normal lane, passing lane, transitional lanes, where curb cuts for property/building entrances, drop-off zones, temporary parkings are technically calculated.

4. Market main area shall have parking and drop zones, which are **NOT within the Right of Way of the Primary Collective Road**.
5. **Road Width** shall be bigger in size, widened from 5 meters to 7 meters, allowing enough space for passing-trough for 4 wheeled vehicles.
6. When it is possible for widening the road, **re-touring traffic flows** are still recommended to minimize the crossings, passing the traffic portion **to some alternative roads**, away from the public market area.
7. **Alternative Roads are proposed with pre-requirements:** a). using the government property land or low priced acquisitioned land. b). able to spread the urban/spatial density, by developing other parts of the vicinity.

# The Triadic Column and Pivot Hinge: To Realize the 'Beautiful House' to 'Wong Cilik' As the Architecture Innovation to Low Cost Housing

Yuke Ardhiati<sup>a</sup>

<sup>a</sup>Faculty of Fine Art and Design, Trisakti University of Jakarta  
E-mail : yuke\_ardhiati@yahoo.com

## ABSTRACT

The national problem in settlements in Indonesia is found reduction costs to provide housing for “the lower class” people. On the other hand, the professional architect role their social responsibilities to find the national problems. Through social media, they can socialize their ideas to the lower class in suitable architectural design of their condition. After investigation the problem settlement, formulated a concept house for “Wong Cilik” as “the lower class” people to improve their dignity as the based philosophy. Refers to Grounded Theory, formulated a beautiful house for “Wong Cilik” among others: a) the minimal dimensions, b) the design innovations aimed at reducing costs, c) the efficiency of design, and d) enhance the facade as well as the art expression, and vertical garden. The cost reduction changes to the original design of practical column rectangle into a triangle, and reduce the door frame element, and replace it with a swivel-pivot hinge. Create the ‘open space’ design with the service zone at the side of the house to maximize the function. To raise the ‘Wong Cilik’ dignity, create in vertical of façade as the surface of the aesthetical work and vertical garden.

## Keywords

*Low cost housing; the triadic column practice; the pivot hinge; vertical façade*

## 1. INTRODUCTION

The term of “Wong Cilik’ is Javanese language is a concept used in my paper to discuss the need of lower class people for architectural design that meets their condition. ‘Wong Cilik’ is the low-income peoples is a part of the national problem in Indonesia. The low cost housing is the important discourse related to provide their settlement to the low-income people. Between in the 1970s and 1990s, noted the participation of the people in housing and human settlement became the central issue by the government and the non-government organizations. They found the solution by develop of housing and human settlements from “top-down” to the “bottom-up” approach. The stake holders, among other: the universities, academia, the professional, and developer were involved to finding the various solution related to the preparing low-income urban housing and settlements.

Unfortunately, the low-cost house design majority preparing by not seriously as the housing developer because they only find the minimal margin versus to prepare the exclusive housing. The low-cost house always under grades of housing standard, always show the bad performance in all aspect. The visual ugly and the under grade material accelerate the nation generation degradation. The child is not has a challenge to learn the aesthetical aspect as the basic of all of the etic code. They ever seen the order of thing as the basic philosophy to preparing the order of the mentally of their mind set.

On the other hand, in the IAI – *Ikatan Arsitek Indonesia* chapter, the professional architect is also role their social responsibilities to find the national problems. Through social media, they can socialize their ideas to the lower class in suitable architectural design of their condition. Architects can socialize their ideas easily to find the partner to collaboration to provide the low-cost settlements. In the information era, especially the social media impacts, the media used to covering their ideas of low-cost housing design.

## 2. RESEARCH METHOD

### 2.1 Grounded Theory to Finding the Characteristic of ‘Wong Cilik’

The research study is a part of architecture investigation to express the low-cost house architectural design refers the Qualitative Research as a part of the seven ideas of Groat’s architecture research method (Groat, 2002: 173). The study in the qualitative refers to Grounded Theory Research, to reveal the characterized of low-income people - ‘Wong Cilik’ activities. After data collected, the categories named in to the coding data analysis. And finally the research concluded into the memoing

– to build a new theory (Glaser, 1967). To ensure the data accuracy of research based on phenomenological investigation at several *kampoeng* in Central Java. The one of is *Kampung Mlaten* in Semarang is the first *kampoeng* of rental housing in Indonesia during the Colonial. The *kampoeng* is still exist until today . They divided into several types start from 15 m<sup>2</sup> of housing dimension (Ardhiati, 2013). Post investigation on the Thomas Karsten work in *Kampung Mlaten* in Semarang, inspired the basic design of criteria of housing dimension within open plan multiuse housing.

## 2.2 The Research Finding

The research objectives to find the housing design include to increase the 'Wong Cilik' dignity. The research finding the formulate of the concept house for "Wong Cilik" as "the lower class" people to improve their dignity based on their activities job. The philosophy of their house role is, the content to stay and activities job, so they need the optimizing their own houses.

The formulated of a beautiful house for "Wong Cilik" among others: a) the minimal dimensions, b) the design innovations aimed at reducing costs, c) the efficiency of design, and d) enhance the facade as well as the art expression, and vertical garden. The cost reduction changes to the original design of practical column rectangle into a triangle, and reduce the door frame element, and replace it with a swivel-pivot hinge. The 'open space' design with the service zone at the side of the house is the best solution to maximize the function.

A house like a poetic space refers to Bachelard, is also the dreams of the low-cost income people. By intensive research of the several low-cost settlements, found the criteria of the house contextual of their conditions by the innovation design in: a) the minimal dimension refers to Housing and Developers Association of Indonesia (APERSI) based on post the Constitutional Court determined the number 1 of the Law 2011 on Housing and Resettlement Zone. Yet, the minimal housing dimension in 36m<sup>2</sup> is contrary to the 1945 Constitution.

Post research investigation in several low-cost house settlements formulated their hidden need. They need to explore their dignity as human by own their house. The result investigation is reveal the main criteria of beautiful house for "Wong Cilik" among others: a) the minimal dimensions, b) the design innovations aimed at reducing costs, c) the efficiency of design, and d) enhance the facade as well as the art expression, and vertical garden. And, the best solution of 'Wong Cilik' dignity, create by the vertical of façade as the surface of the aesthetical work and vertical garden.

## 3. RESULT

### 3.1 The 'Beautiful House' to 'Wong Cilik'

The low-cost house is shift the new paradigm. The house is not role as the residence only, but also to expression their dignity, because its content of their dreams, the preferences, responses, and perceptions towards their house and environment.

The design by research to low-cost income offer among other ; a) the minimal dimensions is around 22m<sup>2</sup>, b) the design innovations aimed at reducing costs, with the reduction cost through change the practice column. Yet, the rectangular shape changes into the triadic. The usually need the door frame is reducing by used the pivot hinge. To efficiency of space is created the open plan concept without the wall partition especially the bath room. And, finally to express their dignity is enhance the facade vertically as well as the surface to art expression, and create the vertical garden.

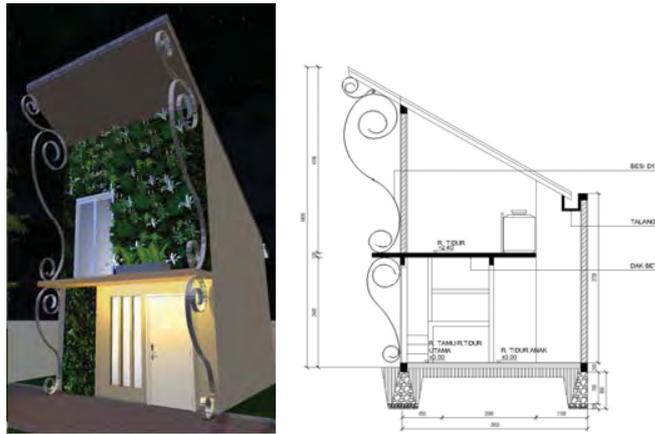

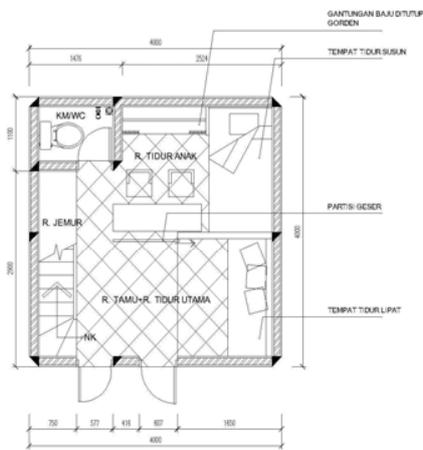

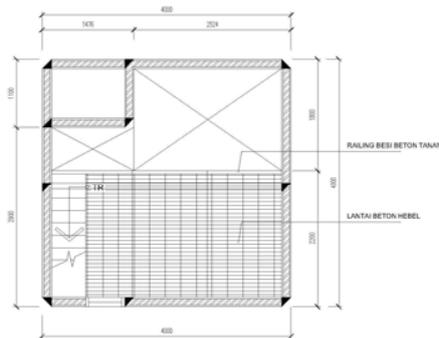

Figure 1: Greening And Beautifying The Housing Façade

DENAH LT. 1  
 SKALA 1:100

DENAH LT. 2  
 SKALA 1:100

Figure 2: The Low-Cost House Plan

### 3.2 Triadic Column Practice to Reduce the Building Material

The housing cost reduction's conventionally by reduce architectural building structures. The normally form of the column as usually in square form change into the triadic form by reduce the amount of the building structure material.

Figure 3: The Triadic Colomn to Reduce the Building Structure Material

### 3.3 Pivot Hinge of Door to Reduce the Architectural's Element

The one of building house will low-cost by reduction cost for the structure material items. The expensive architectural part is the frame door and hinges. The reduction of hinge solution is reduce the frame's door and put the pivot hinges.

Figure 4: The Pivot Hinge to Reducing the Door Frame

## 4. DISCUSSION

### 4.1 The House as the Dignity Expression

The low-cost house is the way to express the people dignity. Its the chalengge to vis a vis the low-cost house as usual. The facade vertically is of the best thing to increase the house performing. The vertically surface is have the opportunity of the house to expressing their hidden need as well as to expresss the art and aesthetic sense. The normally low-cost building façade as horizontally change into the vertically façade to be a pride suggestion like the body upright and gallant. The vertically façade is approach by two stories design to get the visual effect of elegance of the design house. By design the facade vertically, we have the opportunities to create the house greeny by vertical garden and the house beautifying the surface to create something creative like; greening by plants, decorated by mural, mosaic, painting by color, or filled the surface by natural ornamentation as the low-cost people doing their creative process in them life.

## 5. CONCLUSION

The architectural design of low-cost house with innovation design is need to share to 'Wong Cilik' to find the right developer in order to inspire them to provide the house settlements. The social media is the right medium to socialize the design solution. In other side of the architectural idea is include the intellectual of property right. The architect or researcher have obligation to improve the 'Wong Cilik' dignity by create the innovative design, and the government protect them by the intellectual of property right as PATEN or HKI. By using the social media, the architectural research finding will be published as the academia contribution.

The issue published of 'the Beautiful House' to 'Wong Cilik' is the first step to declare the architecture design finding, is a part of the engineering field protect by intellectual of property right of the Architect as Industry Intellectual Property Right – HKI and the innovative design as PATEN. The social media publication is the medium to declare the state of the art of the architect researcher.

## ACKNOWLEDGMENT

I would like to acknowledgment to the low-cost communities in Kampung Mlaten Semarang, and my best friends; Mas Ardi, Bayu Widhitama, Mohammad Fauzi, A'a Agoes, and Mr. Eddy Ganefo the President of Apersi for offering my architecture design the 'Beautiful House' to 'Wong Cilik' become the reality model.

## Lesehan Culture at Yogyakarta Tourist's Night Space

Klara Puspa Indrawati, S. Ars and Evawani Ellisa, Ph.D.

Department of Architecture Faculty of Engineering, University of Indonesia, Depok 16424  
 E-mail: klarapuspa.indrawati@gmail.com  
 E-mail: ellisa@eng.ui.ac.id

### ABSTRACT

The "informal" establishments of public spaces into tourist spaces by local communities in Yogyakarta indicate the growing tendency of local economic development in tourism industry. Financial problems for obtaining "formal and legal space" have drawn local people, called *angkringan* sellers community, to utilize ineffective public spaces. Located in Wongsodirjan Street, the northern boundary of the Tugu Station, they utilize the area of two opposite sidewalks of the street as the culinary space at night. *Angkringan* creates a unique place as visitors could enjoy and practice *lesehan* culture. This paper discusses how local people modified the empty public space through socio-cultural strategy to create tourist space in Yogyakarta. *Angkringan* adds the repertoire of tourist destinations and counteracts the emergence of malls and shopping centres, which in fact merely afforded by particular consumers and ironically lack of local character. This research supported by in-depth observation conducted between February-May 2012 at *Angkringan Tugu* Yogyakarta. We concluded that the tactic for arranging *lesehan* has been employed as socio-cultural strategy in helping *angkringan* sellers modifying the space to offer low prices foods and drink for long duration visits.

### Keywords

*Angkringan Tugu*, *lesehan*, culture, tourist space, socio-cultural

### 1. INTRODUCTION

Yogyakarta is well known tourist city in Indonesia and has been grown as major tourist destination after Bali in term of visitor numbers. One of the tourist's main access is the line between Tugu Station and Mangkubumi Street connected to Malioboro Street. Here the informal tourist spaces spread out the city offering culinary, relaxation, and gathering pleasure, especially during the night. In Wongsodirjan Street, a street located in the northern boundary of the station, a group of *angkringan* community utilized the under-use pedestrian and transformed it into another tourist line. The street provides the opportunity for the people to informally participate the socio-economic and cultural activities.

The activity begun when the sellers found the pedestrian was less functional as only few people walk on. Later on, this space has successfully functioned as a social space which is affordable for all groups of dwellers of Yogyakarta. Through modification of public space, *angkringans* have been colonized almost the whole area of the two opposite sides on the street. It created the place of culinary with a unique character. Along the side walk, the visitors practice the Javanese social interaction called *lesehan* where people sit on mats. In Wongsodirjan Street, local people initiated the formation process of new tourist destination in Yogyakarta through modification of public space that emphasizing the strength of local culture. This "new kind" of public space meet the people's longing for simple interaction place, a situation that can not be found in formal public tourist space such as malls and shopping centers. In these formal places, there is no people's participation in design process. As a result, they are afar from the spatial practice and daily necessity of local people.

### 2. A BRIEF HISTORY OF ANGKRINGAN TUGU

*Angkringan* is a kind of hawker from Yogyakarta. They are offering cheap foods either hold by *pikulan* (bamboo stick bearer) or carried by moving cart. *Angkringan* term came from Javanese word *angkring* means sit freely and relaxed [1]. The consumers can raise or fold up one leg while sitting on the wooden bench near the stopped cart. The other form of hawker similar to *angkringan* also can be found in Solo and Klaten. Local people in both city call them *hik*, an abbreviation of phrase in Indonesian for *hidangan istimewa kampung*, which means special villager's dishes. Nowadays, *hik* is still well known in Solo, while people in Yogyakarta are more familiar with *angkringan*. The first *angkringan* seller in Yogyakarta did not use moving cart but simply hung the two sets of equipment, including a stool for the seller, tools and ingredients for making beverages, cooked foods and snacks, and an *anglo* or coal stove. The first generations of *angkringan's* equipment are very simple since the sellers have to move frequently.

The initiator of *angkringan* at the area of Tugu Station was Mbah Pairo who came from Klaten and promoted *angkringan* since 1950. In 1969, he transferred his business to his son, Lik Man. Lik Man had been moved several times from Tugu Station to

Mangkubumi Street in 1970 and then finally he moved to Wongsodirjan Street in 1975. Since then, numbers of *angkringan* sellers at Wongsodirjan Street were growing. Hereafter, the *angkringan* sellers gradually changed from mobile into immobile. They set their business at the same place and time everyday. One of Lik Man's worker explained that the reason for moving was because visitors continuously increased and required a larger space. As Mangkubumi Street could not accommodate the business expansion anymore, they move to Wongsodirjan Street. This was the best choice as the street has direct connection to Mangkubumi Street, which is adjacent to Malioboro Street.

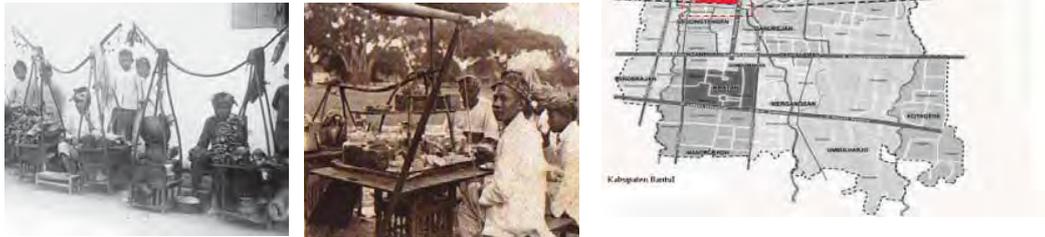

Figure 1: The Old Time Angkringan (left) and Angkringan Tugu Location Map (right)  
 (Source: kaskus.com, ikiangkringan.blogspot.com, cerita-kota-loenpia.blogspot.com, jogjareskrim.wordpress.com)

Wongsodirjan is the street with 6 m width. One side of the street has the sidewalk adjacent to the wall of Tugu Station that creates an empty edge. The opposite side of the street consists of the line of houses. Since its streetscape consists mainly of single-use building (houses) and empty wall with virtually none of the street-level commercial bustle, walking in this street is not appealing and unproductive. William H. Whyte's concept of social life of small urban spaces has stated that blank wall along one street will prevent public activities [2]. Corresponded to that statement, our observations during the day and the night showed that pedestrians prefer not to walk on pedestrian sidewalk but on the edge of the street, seemed to avoid blank station wall.

When Lik Man, Lik No, and Pak Seh located their *angkringan* at this street, they decided to occupy the sidewalk area adjacent to the north wall of Tugu Station. Following Lik Man, Pak Seh and Lik No who also came from Klaten became a new comer of *angkringan* sellers. As consumers steadily increased, other new *angkringan* sellers emerged. Since then, Wongsodirjan sidewalk was totally transformed into *angkringan* district. It is well known as night eating and gathering place that opens from 18.00 until dawn. As sellers did not have enough money to set a permanent kiosk, utilization of public space through negotiations is the best choice. The transformation of empty public space into business space indicated the process of take over from public space into commercial space for the benefit of the collective communities [3]. *Angkringan* communities had transformed the empty street into livable street and increase the mobility of pedestrians.

### 3. LOCAL PEOPLE'S STRATEGY IN DESIGNING TOURIST SPACE: *LESEHAN* CULTURE

#### 3.1 *Lesehan* as the Daily Life

Daerah Istimewa Yogyakarta (DIY) maintained to be administratively and socio-culturally led by Sultan or the King of Java. Formally, Yogyakarta is registered as a city since 1757. The city was laid on the basis of cosmic axis lines between Merapi Mountain at north and Indonesia Ocean at south. The cosmic center of Yogyakarta is placed along Malioboro Street as the main access from city to king's palace [4]. Yogyakarta's long history describes the strong establishment of local culture. This is a well-known city of culture, art, and education. It is also one of the main local and international tourist destinations.

The way of living is one of the keys to discover one place's character. Character is defined as dominant atmosphere in experiencing one place. Space gets its own reality in the context of location, because space is not only signified by physical boundaries, but also by its character to give space its certain meaning [5]. Experience of space can only be felt through the experience of one place's character, such as *lesehan* or the way of sitting in Yogyakarta society. *Lesehan* is the traditional element of spatial formation of architecture in Yogyakarta. The origins of word *lesehan* in Indonesian shows meaning for a way of sitting on the floor [6].

Traditionally inside the house, local people widely practiced *lesehan*. People just started using chair in the 19<sup>th</sup> century and in the beginning, it was limited only for the aristocrat. People usually *lesehan* on mat or *ambén* or a low platform made of bamboo for informal social interaction in the family. It is casual in character and comfort becomes priority. Chair was used when the head of one family needs to formally express their authority to the guest. In *lesehan* culture, we can find two different settings based on its spatial orientation. One called sociopetal or center oriented and the other called sociofugal or periphery oriented. Sociopetal *lesehan* occurs in a long-term activity, such as eating or visiting. Sociofugal *lesehan* occurs in short term

for spontaneous activity. Proxemics theory argues that sociopetal setting will develop interaction, while sociofugal will prevent it [7].

*Lesehan* is popular among local people in their daily life because it is comfortable enough to accommodate the long term of daily activities. *Lesehan* also give chance for variations in sitting position. In fact, before the 19<sup>th</sup> century, the aristocrat practiced *lesehan*. It gave impact to the way of traditional dance that must be performed on the level of the *lesehan* audience [8]. *Lesehan* culture signified the characteristic of local space in Yogyakarta. Furthermore, *lesehan* culture creates a fluid and flexible space arrangement. Unlike chair, there is no specific placement for individuals in *lesehan* formation. *Lesehan* has its own social norms, such as disallow to pass in front of the parents without say permission. This way of sitting not only related to functional aspect, but also to Javanese philosophical aspect about the closeness relation between human and earth. Javanese culture understand floor as representation of earth, the source of life who give existence to human. Human is the earth's offspring, while sky is deity sphere. Javanese terminology of *bumiputra* is the manifestation of this philosophy and generally used to refer Indonesia's indigenous people [9].

Figure 2: *Lesehan* Culture in Kota Gede, Yogyakarta  
 (Source: Bambang Tri Atmojo, 2007)

### 3.2 The Chances

Before discovered by *angkringan* sellers, Wongsodirjan Street is more like barrier rather than street. The sidewalk was one side at the edge of Tugu Station's northern wall with height of 1.35 m. The street gave rise to the feelings of monotony, which repel pedestrian to pass. In the other side of the street, home fences lined along the street. Here pedestrians would feel to be on the expansion of homeowners' private area. The heights of home fences, that are located along the sidewalks, are 100-110 cm. Some houses even erected right in the periphery of street. From the sidewalk, people could see inside of the house through the fence when windows or doors left open.

Figure 3: Wongsodirjan Street Utilization Map Before Occupation of *Angkringan* Sellers (top left), Location of *Angkringan* Storage Area (bottom left) and Panoramic View of Sidewalk in front of Line of Houses (right)

(Source: Klara Puspa Indrawati, 2012)

Lik Man, Lik No, and Pak Seh saw the initial opportunity at Wongsodirjan sidewalk. They demonstrated an understanding of spatial practice that encourages reproduction of sidewalk area. The sidewalk is not just a pedestrian crossing space, but also a social space between street users and the residents [10]. The three initiators of *Angkringan* Tugu District modified the sidewalk in order to optimize its presence, although by contesting new functions to sidewalk function. The spatial occupancy had been seen as the business opportunity for the trio of *angkringan* sellers. Now, *angkringans* do not only visit by people of Yogyakarta, but also tourists from other parts of Indonesia as well as foreign tourists.

*Angkringan* sellers formed their spaces by setting up tents modules with size of 6 m long and 3 m wide. In 2012, there were 11 *angkringan* vendors on the sidewalk adjacent to station wall. Mass media helped promoting *angkringan* sellers at Wongsodirjan Street as one of Yogyakarta culinary area and recommended it as destination for tourists. *Angkringan* offers simplicity and strong atmosphere attracted visitors for gathering at night. *Angkringan* also offers dining and culinary at a low cost.

The local government supports *angkringan*. Each seller gets the opportunity to use area of the sidewalk for free. They only need to report their presence for official registration. The size of the tents constructed according to the economic capacity of the seller. During our observations in 2012, there are 3 sellers who use 3 tent modules, 5 sellers who use 2 tent modules, and 3 sellers who use one module. *Angkringan* operates from 18.00 to 04.00 but sellers start to set up the tent from 12.00. For illumination, lightings are channeled from an old store at the junction between Wongsodirjan Street and Mangkubumi Street. For any lighting used by sellers, they are charged 1.000 Rupiah/day. Every vendor is required to properly manage his/her *angkringan* equipment, including undo the tent and dispose all the trash at the end of street.

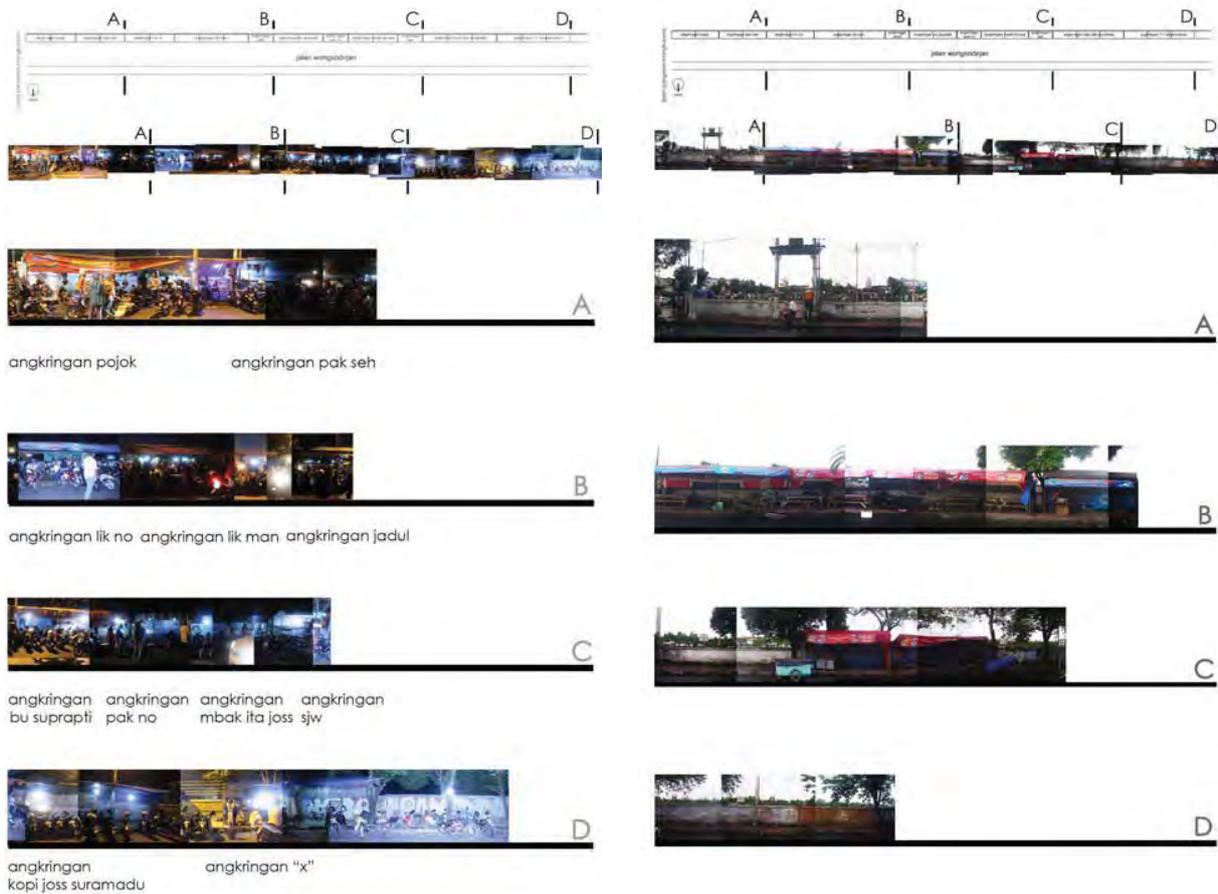

Figure 4: Panoramic View of Angkringan District at Night (left) and Day (Right)  
 (Source: Klara Puspa Indrawati, 2012)

Before leave, sellers store all *angkringan* equipment in shared storage located at the east of Mangkubumi Street. In the morning *angkringans* are totally disappear and the sidewalk can be used again for pedestrian. At noon, *angkringan* cycle starts to move again. Seller erected tent on the 25 cm raised sidewalk. Here sellers and buyers defined the area by the semi fixed

features consist of seller's equipment and simple elements for customers such as benches, tables, and mats. No any seller gains ownership from the plots at the sidewalk except their own temporary tents and mats. Each *angkringan* seller owns an agreement to divide his/her area of occupation.

There are three types of *angkringan* space's formations. First is the formation of a seller area and a buyer area with bench. Second is the formation of *lesehan* where the seller area and the buyer using the mat. Third is the combination of the first and second type. We found that first type used by four merchants, the second type used by six merchants and the third type used by one merchant. If sellers use *pikulan* as the place for serving food and processing beverage as well, they will provide 20-30 cm wide and 70 cm raised serving table rounded to *pikulan*.

Figure 5: Wongsodirjan Street Utilization Map After Occupation of *Angkringan* Sellers (left) and The Second Type of *Angkringan* Formation (right)  
 (Source: Klara Puspa Indrawati, 2012)

This formation enabled customers to enjoy meal at the same level with the sellers and create the same interaction level between seller and buyer. This also represented the original formation of *angkringan* of which the seller and buyer formed intimate interaction. However, at Wongsodirjan Street, merchants more prefer to choose the second type or *lesehan* using the mat. By *lesehan*, customers enable to freely sit cross-legged, a situation impossible to be done using a bench. Mat is more flexible for serving different group of customers, so that more customers can be accommodated. Without tables and benches, *lesehan* also reduced the cost. During peak hours when *angkringan* crowded, customers will create groups of circular formations.

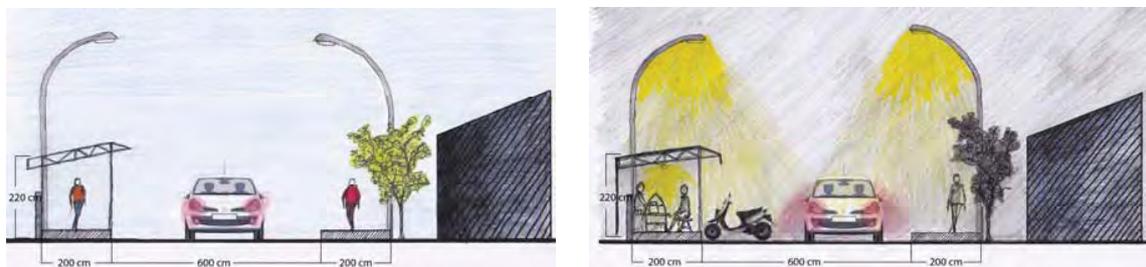

Figure 6: Section of *Angkringan* District at Day (left) and Night (right)  
 (Source: Klara Puspa Indrawati, 2012)

### 3.3 *Lesehan* as The Strategy for Spatial Conflicts

Visitors recognized *angkringan* at Wongsodirjan Street as *Angkringan Tugu*. The special menu which attract local and foreign tourists are *sego kucing* (literally means rice for cat) or cheap small portion of rice and *kopi joss* or coffee dyed by hot charcoal. This area gains popularity by the growing number of visitors, especially during weekends and holidays. In 1990s, when visitors increased and they often come as groups of four people or more, *angkringan* needed expansion. As merchants relied on tables and benches, it became difficult to cope with the increasing numbers of customers anymore. This situation triggered sellers to consider for using the area located on the opposite side of the street. However the problem is that the area proximately located just in front of line of houses. Utilizing these spaces would raise conflicts as it would annoy the residents whose properties need to be directly accessible to the street.

To solve the problem, the seller's applied four tactics. First is that as long as in the morning until noon there is no anything left over, they could utilize the space for extending the *angkringan* space. Second is that sellers need to quickly form and remove the space, while at the same time they also need to accommodate large numbers of customers. For that reason, sellers use roll mat, which is easily stretching along the sidewalk in front of the houses. Third is that mats are only used when large groups of visitors are coming. Forth is that to respect the rights of homeowners, sellers avoid laying mats at the certain position, of which it is directly adjacent to the door. Using these four tactics, sellers could save the cost since there is no need for purchasing

tables and benches. Roll mats also enable the sellers to flexibly arrange and leave enough spaces for the homeowners enable to directly access to the street. In William H. Whyte's analysis, we found people's effort to create a proper sitting position by moving their chair from one place to another place [11]. However by practicing *lesehan* on mat, the visitors can be more flexible in manipulating their position. *Angkringan*s only operates during the hours when the homeowners already at homes, so that eventually the conflict can be avoided. Among the seller, there is informal agreement that they may extend the space expansion for customers, right across their tents at the opposite side of the street within the same area as their tent's border.

Figure 7: The Expansion for Customer's Spaces (left) and Section of *Angkringan* District at Night After Expansion (right)  
 (Source: Klara Puspa Indrawati, 2012)

Expansion of the customer's spaces are no longer defined by the border of the tent, but by the space formed by mats and bodies of *lesehan* customers on the sidewalk. Soon after the visitors come, the seller immediately spread the mat along the sidewalk and gave instructions to the visitors to take their positions for *lesehan*. As visitors need to adjust their own space in accordance to the numbers of visitors, *lesehan* create the fluid and flexible space. Interestingly, *lesehan* also create strong character of *Angkringan* Tugu and make it more popular. *Lesehan* offers visitors to immerse themselves in groups. While for Javanese sitting on an armchair in the house described the owner status, enjoy *angkringan* through sitting on a bench or *lesehan* create the ambience of relax and informal. The identity of each visitor submerged in the form of *lesehan*.

Figure 8: Scenery of *Lesehan* Culture at *Angkringan* Tugu District During Night Time  
 (Source: Klara Puspa Indrawati, 2012)

As in other typical street foods served by any street hawker or *kaki lima*, people doubt about the hygiene level at *angkringan*. There is no enough lighting provided at *angkringan*, so that at night the atmosphere is not bright enough to clearly recognize the figures and faces of customers. As a result, customers do not pay much attention to the cleanliness of *angkringan* area. To attract and get attention of customers from the main streets, *lesehan* are now expanding until Ratih Guesthouse at Pangeran Mangkubumi Street. Although the street scale is smaller, *lesehan* at Wongsodirjan Street is more spacious and comfortable. Overwhelmed by shade and vehicles in the parking area, the tent formed space with good ambience. The space extension in the opposite side of the street is entirely open and flexible. Practices of *lesehan* sitting at this space of expansion created two kinds of setting. First is converge (sociopetal) and the second is lined (sociofugal). One night we observed that in the *Angkringan* Tugu, we found 39 groups of customers, 14 groups of them applied the sociofugal setting and 25 groups applied sociopetal setting.

Proxemics study that sociopetal setting encourages interaction while sociofugal reduce the interaction was not effectively fully applied in the expansion space of the *Angkringan* Tugu. Among customers, who apply both sociofugal and sociopetal practice setting do intensive interaction with the group. Both settings were chosen based on considerations, such as comfort and ambience. Customers of *lesehan* prefer more sociopetal setting than sociofugal. Customers who sat in sociopetal setting are customers of 2 to 8 persons. They usually choose sociopetal setting in order to establish more enclosed group. Crowded and the surrounding environment is not their concern. Each group focuses on the interaction within the group while enjoying his/her dishes. The group eventually bonded togetherness. Within more enclosed space, individuals within group are not severely affected by the crowded and the noisy speech of others. At the most crowded, distance between groups could almost close to 10 cm or intimate distance. At this intimate distance, the sound of other group will be heard very clearly. But this is

not a problem. Each individual in the group merely focuses on the speech in the circle group and she/he just ignored the conversation outside the group.

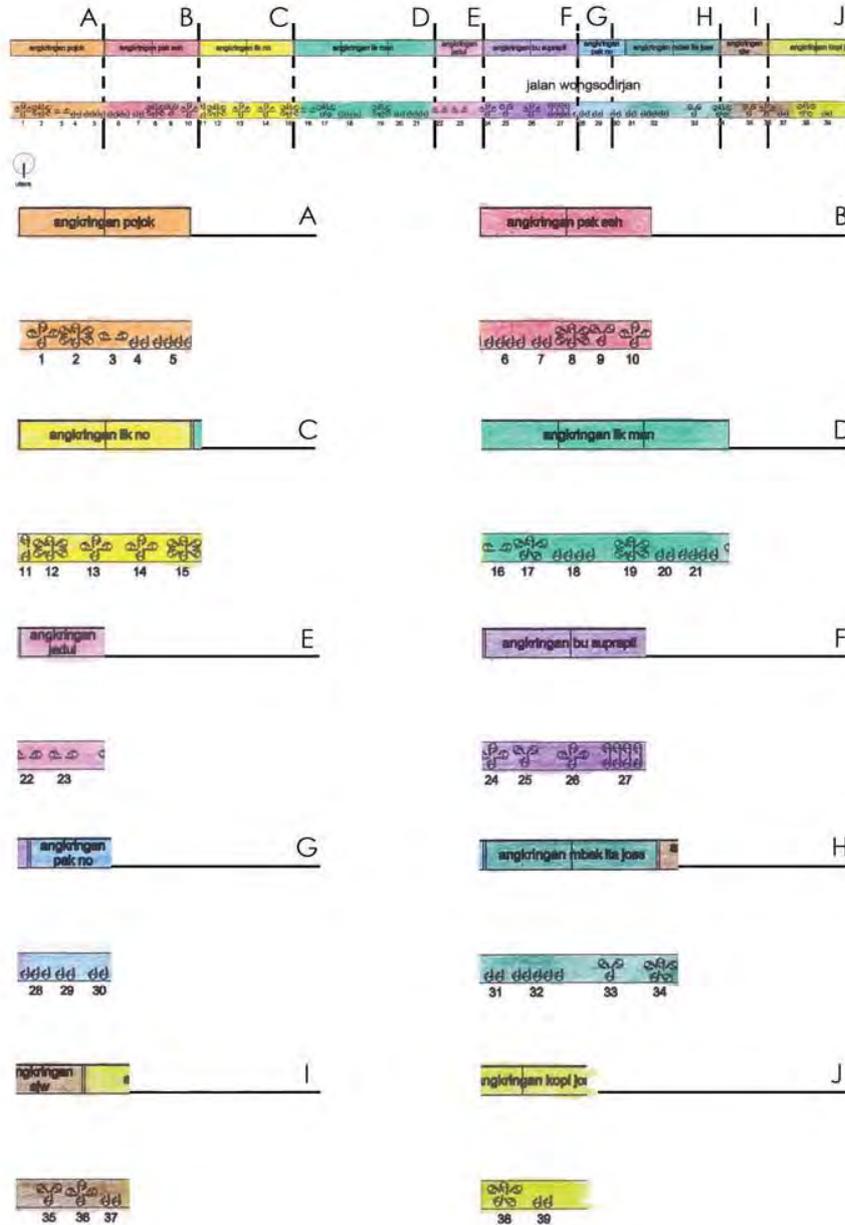

Figure 9: Diagram of *Lesehan* Plot for Each *Angkringan*  
 (Source: Klara Puspa Indrawati, 2012)

*Lesehan* customers are sitting on the floor in groups of 2 to 5 persons with sociofugal setting. We found 8 customer's groups consisted of two people who usually are a couple. They chose the sociofugal *lesehan* because they can sit more comfortably by leaning on the boundary wall of Tugu Station in one side or fence in opposite side of the street. The *angkringan* crowded did not reduce their comfort, as the communication between couples remained intense. From 39 customers we had observed, we found that the average distance between customers are 73 cm or in the range of social distance. This is a convenient distance for gathering activities. When a group determined the space and its distance to other groups on other side, they do not take into account the space for other groups who would visit. The upcoming groups will adjust the remaining available space. In fact, during holiday season, the group is not only sitting adjacent to other groups sit in left or right side, but also in front of or behind. Cheap food and drink and comfortable *lesehan* sitting attracted visitors to enjoy the ambience of the place. *Angkringan*

is a simple gathering place for an unlimited duration. Customers are allowed to stay until *angkringan* closed with no requirement to buy more food or drink. By purchasing any food or drink, visitors can use the space as long as they like. The efforts of *angkringan* sellers to expand their *lesehan* space is not solely driven by economic motivations, but rather response of the demand for inexpensive dining, drinking, and hanging out.

*Angkringan* generated tourist place which more emphasis on the social significance. This is because customers do not only spend time to eat and drink. It was the social interaction at night that became the major attraction of the place. *Angkringan* sellers serve almost similar food. The main menu is varieties of drinks offered by sellers. It is the drinks that accompany visitors during the long duration of interaction among customers. *Angkringan* Tugu creates economic opportunities for many people, such as a parking attendant and street artists. Various street arts by street artists also take parts to shape the evening festivities at the street. The definition of architectural space formed by the body of the customers physically weak, but it can be understood and operated by users [12]. Visitors who practiced *lesehan* along the street both in front of the Ratih Guesthouse at Mangkubumi Street and Wongsodirjan Street depict a strong relationship. Wongsodirjan Street is an interlude space for both sidewalk of *angkringan*. Passing passengers of motorbikes and other vehicles as well as people who walk will discover the landscape of tourist's night space along the sidewalk. The wall and the fence form the space enclosure. They also functioned as a backrest for customers who sit *lesehan*. The appearing lights of passing vehicles help to create the missing illumination. Both sides of the sidewalk transformed into a stage. Here people enjoy performance of various activities of social interactions, economic, and cultural.

#### 4. CONCLUDING REMARKS

Local traders of Yogyakarta initiated the process of place making of *Angkringan* Tugu and created tourist's night space that is accessible to all. *Angkringan* sellers emphasize the local culture of *lesehan* as the strategy to transform the "lost space" of Wongsodirjan Street into "finding place". Local inhabitants and tourist enjoy the atmosphere of Yogyakarta at night in an ephemeral space formed by simple open strip bordered by walls and fences. *Lesehan* also represent the culture of Yogyakarta. Therefore, *Angkringan* Tugu became one of the main destinations for tourists. *Lesehan* is a common seating practice among local residences which emphasizes the significant meaning of flexibility, informality, cosiness, familiarity, and confirmation of human existence on earth. *Lesehan* also attached to *angkringan* character as a kind of temporary business. We argue that the seller's initiative to develop the tourism space was not only enhance the 'pro-poor' local economy but also enrich the space for social and cultural aspects. Such bottom up small scale business space has triggered an emergence of attractive culinary street. We also assume the temporary *angkringan* district and existing residential place will create a fascinating mutual socio-economic place in Yogyakarta's main axes since the home owners also play role as consumers and *angkringan* sellers keep the pedestrian area clean after their night occupancy. In broader scale, it offer unique night sidewalk and open space scenery which is defined by the bodies of *lesehan* visitors.

### ABSTRACT

This paper is focuses on an inclusive, vibrant and convivial street environment in the city centre. City centre is an important area because many people come to work in the city centre. There are some problems in the city center such as full crowded, full of skyscrapers, air and noise pollutions, daily traffic jams, and unhealthy place to live-in especially for children and elderly people. Every morning and evening rush hours cities become packed with vehicles. This study investigates this problem by combining qualitative and quantitative methods with three steps: Selection of appropriate sites to be included in the operational assessment; Collection of observational data of pedestrian and driver behavior; and Statistical analysis of the data. The new design created using 3D. The objective of this research is to examine the possibility of BRO works, and the main purpose is to stimulate economic activity through increased pedestrian activity when it is really implemented. This study shows that the design of BRO can be apply in the city centre of Malang to reduce vehicles speed and it makes comfortable for pedestrians, calm and clean, easy to move by public transport, kind to children and elderly people, easy to cooperate with citizens and visitors.

## 1. INTRODUCTION

Streets are complicated place because they must serve a variety of functions, particularly those related to the movement and traffic circulation, interactions, exchanges, and other social and community activities. Streets are not only complicated. They are also immensely important. In Europe, and even more in the USA, streets represent perhaps 80% of the public realm of the urban environment (Hamilton, 2010). Streets have five principle functions: place, movement, access, parking, and drainage, utilities and street lighting (MfS, 2007). These functions are derived from *Paving the Way* (CABE, 2002). Street design should be inclusive. Inclusive design means providing for all people regardless of age or ability. There is a general duty for public authorities to promote equality under the Disability Discrimination Act 2005 (DDA, 2005). Designers should refer to *Inclusive Mobility*, *The Principles of Inclusive Design*, and *Guidance on the Use of Tactile Paving Surfaces* in order to ensure that their designs are inclusive (DfT, 2002; CABE, 2006; DETR, 1999). The specific conditions in a street will determine what form of crossing is most relevant. All crossings should be provided with tactile paving. Further advice on the assessment and design of pedestrian crossings is contained in Local Transport Notes 1/95 and 2/95 and the *Puffin Good Practice Guide* (DfT, 1995; CSS, 2006). Related to the LOS of the road, there is a relationship between land use changes and the LOS of the road (Budi et al., 2012).

City centre is an important area in the City because many people come to work in the city centre. It consists of stores, government building, banks, and cultural attractions. There are some problems in the city centre such as full crowded, full of skyscrapers, air and river pollutions, daily traffic jams, and unhealthy place to live-in especially for children and elderly people. Every morning and evening rush hours cities become packed with vehicles. If city centre can not grow anymore and it also so many problems, citizenry will be move to the rural-urban fringe because this area is not so far from city centre and it has many positive advantages compare with city centre (Agustin and Kubota, 2012). Related to this condition, here are two solutions: firstly, we create an appropriate strategy for rural-urban fringe area (Agustin and Kubota, 2012). Secondly, we create BRO design to improve the design of existing in city centre. The design of BRO in this research adopted TDO concept by Kubota (Kubota et al., 2006). It is a little different because this research combines shared-space concept and TDO concept. This research investigates city centre's problem using combination qualitative and quantitative methods with three steps: Selection of appropriate sites to be included in the operational assessment; Collection of observational data of pedestrian and driver behavior; and Statistical analysis of the data.

The objective of this research is to examine the possibility of BRO works, and the main purpose is to stimulate economic activity through increased pedestrian activity when it is really implemented. Firstly we discuss about the definition of BRO (Berbagi Ruang Omotenashi). Secondly, we identify an appropriate location for the application of BRO. Thirdly, we create a new design to manage traffic speeds and improve the pedestrian experience by narrowing the carriageway, using tighter geometry, de-cluttering the street, providing street seating etc. Then, the outcome of this research can be used by city government to creating a new design of street for the sustainability and livability of the city centre in the future.

## 2. METHODOLOGY/ EXPERIMENTAL

In this research, we used combination between qualitative and quantitative methods with three steps: Selection of appropriate sites to be included in the operational assessment; Collection of observational data of pedestrian and driver behavior; and Statistical analysis of the data. The new design created using 3D.

The location of the study is the city centre of Malang City, East Java, Indonesia. The present study selected Klojen Sub-district and one site, which have a total area of about 8.83 Km<sup>2</sup>. In 2012, there were 106,017 inhabitants and population density is 12,006 inhabitants/km<sup>2</sup> (Statistic of Malang City, 2012). The study area located between 112.06° - 112.07° (East longitude) and 7.06° to 8.02° (South latitude). The study area has a topography that is most flat (96.3 per cent) with slope 0 per cent to 15 per cent and a height of 380 meters to 667 meters above sea level. Detail of the location of three sites can be seen in Figure 1.

Figure 1: The location of BRO design

One site and 6 links were selected based on site visits and site maps (which detailed the street layout and key characteristics). Firstly we make photo analysis to identify characteristic of the sites and the links in two categories: no activity and full activity. Secondly, we make a cross-section of each links in accordance with the existing condition in two categories: no activity and full activity. Thirdly, we mapped public transportation routes in accordance with the existing condition that passes through the study area. Then, we try to improve the existing design with the new design of street, more livable for pedestrian in the city centre. The research design can be seen in Figure 2.

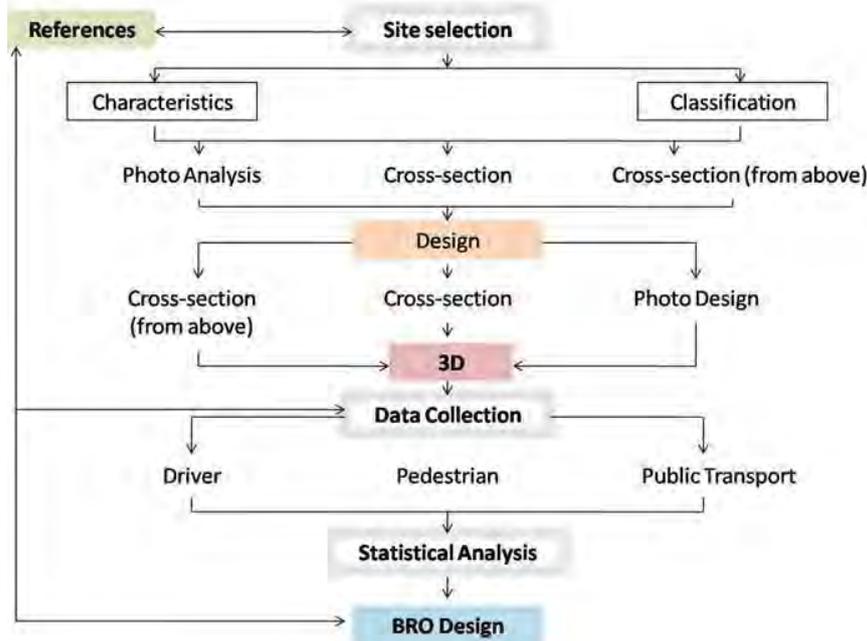

Figure 2: Research design

### 3. RESULTS AND DISCUSSION

Analysis of the characteristics of the street evaluate patterns and conditions of the street network, in which street network is an infrastructure that has an important role in the region, and the street as well as the access link from one place to another. Various analysis were conducted to determine how important the function of the street to support the accessibility and the mobility of a human activity. Here is the analysis of the condition of the street network in the city centre plaza area of Malang City, East Java, Indonesia (Table 1).

Table 1 Characteristic of streets in the study area

Sites	Links	Characteristics	Analysis
City centre plaza area 	Jl. SW. Pranoto	<ul style="list-style-type: none"> <li>- hierarchy of the street is secondary local</li> <li>- total of street reserve is 6.5m</li> <li>- the users are pedestrian, vehicle, motorcycle, and on street parking</li> <li>- there is no complementary street</li> </ul>	Based on the hierarchy of the street and street users, there is needed a plan to 'street design' for users in the area of City centre plaza, so that it can be create a comfortable community. Street design conducted by
	Jl. Merdeka Utara	<ul style="list-style-type: none"> <li>- hierarchy of the street is secondary local</li> <li>- total of street reserve is 12m</li> <li>- the users are pedestrians, vehicle, motorcycle, and on street parking</li> <li>- there are complementary street ie traffic signs</li> </ul>	
	Jl. Merdeka Selatan	<ul style="list-style-type: none"> <li>- hierarchy of the street is secondary local</li> <li>- total of street reserve is 5.5m</li> <li>- the users are pedestrian, vehicle, motorcycle, on street</li> </ul>	

Sites	Links	Characteristics	Analysis
		parking and some illegal activities - there are only a few complementary street ie street signs	observing street users and the types of activities that are in the area of City centre plaza.
	Jl. Merdeka Barat	- hierarchy of the street is secondary local - total of street reserve is 10m - the users are pedestrian, vehicle, motorcycle, and on street parking - there are complementary street ie traffic signs	
	Jl. Merdeka Timur	- hierarchy of the street is secondary local - total of street reserve is 12m - there are complementary street ie street signs	
	Jl. Basuki Rahmat	- hierarchy of the street is secondary collector - total of street reserve is 10m - there are complementary street ie street signs	

The majority of LOS in existing conditions for some links increased to get better when tested using BRO design (Table 2). The capacity of on-street parking also has improved when tested using BRO design (Table 3).

2	Jl. Basuki Rahmat	0	29	113	2	14	60	0	29	113	14	20

BRO is designed specifically for the vehicle with low speed. Pedestrians have the same privileges to the vehicles. Several characteristics of BRO design are: (1) Elimination or removal of separation between motorcycle/vehicles, pedestrians and other street users; (2) Elimination of the traditional distinction between footpath and street, thus providing more space for pedestrians and other street activities (street restaurant, music, etc); (3) The device street such as curbs, lines, signs, signal is removed. It is replaced with integrated utilization, which is oriented to the public space so, walking, biking and driving the car into a controlled activity and instead holding a 'BRO' point of entry and exit to the city centre. BRO design is contradicting to the principle of segregation, the idea of separating functions and different users in the city. We put some design elements such as street furniture, artwork and other plants or flowers around the space. It encourages the speed of vehicles being slow.

Table 4 Design concept of BRO in the city centre plaza of Malang City

Sites	Concept
City centre plaza	<p>Travel way</p> <ul style="list-style-type: none"> <li>▪ Limiting the width of travel way only for 6 meters.</li> <li>▪ The use of paving materials as its pavement. There is no asphalt.</li> <li>▪ There is a difference in color between pedestrian and travel way.</li> <li>▪ There is no difference in 'high levels' between pedestrian and travel way.</li> </ul> <p>Pedestrian</p> <ul style="list-style-type: none"> <li>▪ There is no difference in 'high levels' between pedestrian and travel way.</li> <li>▪ Widening the pedestrian way, the widest possible use of the remaining existing travel way narrowed.</li> <li>▪ There is a difference in color between pedestrian and travel way.</li> </ul> <p>Ornament</p> <ul style="list-style-type: none"> <li>▪ There is added planter on the right side of the street.</li> <li>▪ On-street parking is eliminated. Car/vehicle can stop within a specified period.</li> <li>▪ There is added street lights on both sides of public space</li> <li>▪ There is added pots of flowers on pedestrian</li> <li>▪ There is added public seating in the area of public</li> </ul>

Figure 4 Photo design and 3D of Jl. SW. Pranoto

New design of Jl. SW. Pranoto can be seen in Figure 4. There is no difference in 'high levels' between pedestrian and travel way. Public transport and motorcycles have their own lanes. Their lane is different with private car lanes. This is intended to avoid congestion. The design of the cross-section and longitudinal section of the concept of BRO in City centre plaza sites can be seen in Figure 5.

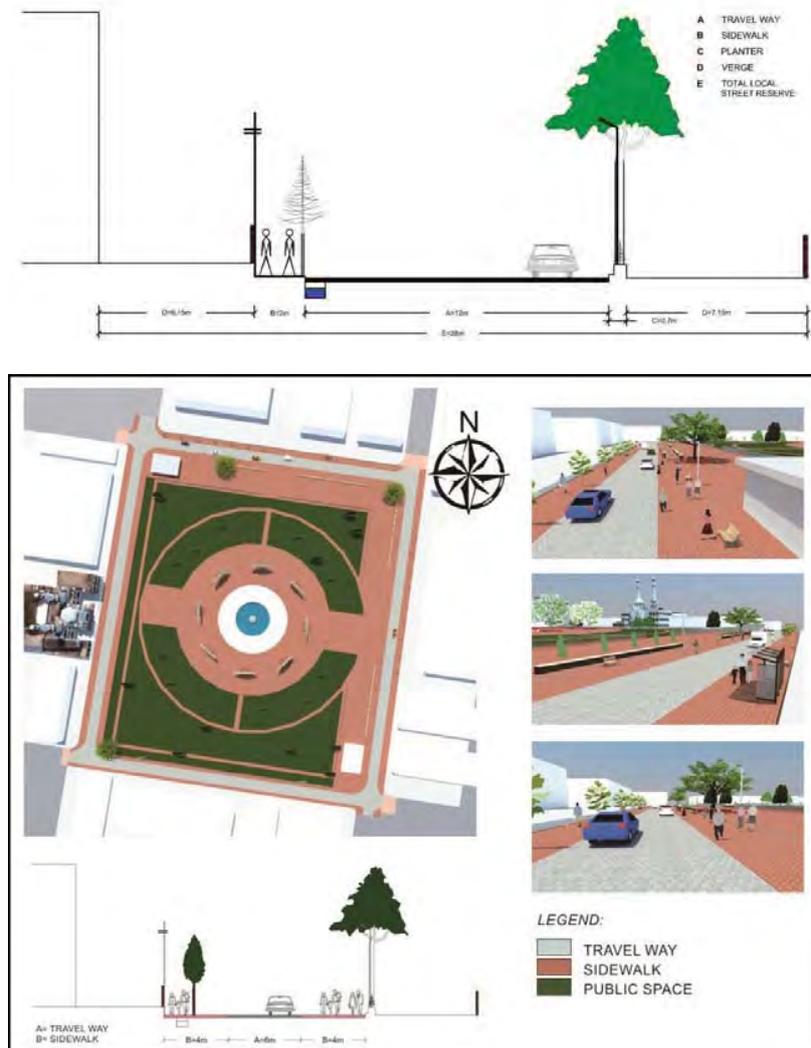

Figure 5 The design concept of BRO and cross-section of BRO design in the City centre plaza

### 3. CONCLUSION

The design of BRO can be apply in the city centre plaza of Malang City to reduce vehicles speed and it makes comfortable for pedestrians, calm and clean, easy to move by public transport, kind to children and elderly people, easy to cooperate with citizens and visitors. This design is safe. This is due to both motorists and pedestrians are encouraged to be more careful with the surrounding environment and to each other. Example: the driver will instinctively slow down and make eye contact with pedestrians in the vicinity.

The authors hope that this study will give a new idea that can be used by other researchers and city government to creating a new design of street for the sustainability and livability of the city centre in the future

### 4. AKNOWLEDGMENT

The authors wish to express their gratitude to all members of the urban regional planning studio in University of Brawijaya and also UTG laboratory in Saitama University for their cooperation and support.

 E-mail : antonimation@gmail.com

## ABSTRACT

Among the recent research and theories in urban planning, it is argued that street is a public space that should have equal access for the city inhabitants to use it. However, this character of street 'publicness' is always being contested. The various users, occupation and control of street use have become a daily practice of urban life, especially in developing countries, which consider street as a place of a person's livelihood beside its main function as a path or transportation access space. This creates a street space contestation which demands for space justice. It is argued throughout this paper that municipality with a top-down governance approach has difficulty to create and manage public space equality. At the same time, indigenous community is capable to control street space activities and users by adopting the traditional value to create 'justice' in community practice. This argument is accessed through an examination of empirical qualitative data of Denpasar Street life, Bali.

## Keywords

Public space, justice, governance

## 1. INTRODUCTION

*"Public space is, in this sense, the space of justice. It is not only the space where the right to the city is struggled over; it is where it is implemented and represented. It is where Utopia is both given spatial form and given lie to. Utopia is impossible, but the ongoing struggle toward it is not."*[1]

A street, a Public Space, is an important urban element of physical, economic, social, culture and identity[2-5]. Especially in Denpasar, a street has been used daily as a transportation path but also as economic and social life. It is inevitable that the use of street space being contested everyday. Madanipour [6] argues that street as an urban public space should be accessible and consumed [7] for everyone than the challenge has developed into a more complicated matter such as degree and control of accessibility, which is disputed. Newman [8] states that local municipalities have this responsibility to maintain the users and function of streets for transportation circulation[9]. When local officials want to segregate activities and localized activities as its urban planning direction, it will face another problem of maintaining street space as social space [10]. This section will focus more into the power and authority to govern public space in a democratic practice that people should have the right to participate and express their voice in public space [11; 12]. Therefore, questions of this section are which actor who has the main role to participate in street use justice, and followed by a question of how they can manage it?

The municipality power to define and redefine public space will be contested in this section. The lack of common municipality engagement in the community in a matter of budget limitations and other provincial procedure for off-office work makes another negative perspective of present Denpasar official. In Denpasar, the community creates a specific agent of space control that can determine access and activity in their territory area (*Pecalang*) this phenomena has occurred as a response of low space control into the increasing awareness and participation of indigenous people to repossess and classify the existence of public space into community space. It creates civic space which is still accessible for everyone, but it is controlled and maintained by indigenous/ local residents group. One obvious advantage of community participation is the high level of attachment of place, in this case a street space. Balinese attachment of space as an element of territoriality behaviour[13] determined by inherited value and identity relation of individual and related family experience of space. Geertz[14] stated that the history of the development of Denpasar city that resulted from several compounds of family-interrelated kinship make a specific urban space is being valued as family-personal space. Then the question of how to create a democratic space of historically 'private' communal space should be accompanied with the interdependent question of who will guarantee the regulator fairness, authority, and balance of management and maintenance of street space in a sustainable manner.

This sub-section is organized into three sections that will examine and discuss thesis argumentation of the role of indigenous community groups and organization in the production of equal public space and how they can manage this 'justice' in a sustainable urban practice. The first section focuses on the native norm and community classification called '*krama*' of society to maintain community justice. It is a traditional classification to create a society order. The fairness of this native power to control street space is discussed in the second section which explores '*gayah*' as the traditional social concept that can bind

the justice in community responsibility. The last section describes the effort of indigenous community to preserve the traditional value and norm as a guideline for its sustainability.

## 2. SOCIETY CLASSIFICATION (OR SEGREGATION) FOR JUSTICE

In Traditional Balinese society and also Denpasar community, it is well-known and applied the social community classification called 'krama' [15; 16]. It is based on religion, ingenuity, local-based identity, caste, economy and ethnicity differences. It consists of three types of *Krama*. *Krama* is for indigenous local residents with Hindu's religion; *Krama Tamiu* is for Hindu's residents but not originally (inherit) from local community/place and time for other residents who is not included in class of *Krama* and *Krama Tamiu*. To simplify things, in the common daily practice, Balinese often called this categorization of residents as *Warga Adat (Krama)*, *Warga Dinas* (officially registered as resident but not inherit an indigenous identity) and '*Bukan Warga*' for others. This traditional classification is written in indigenous social norm and regulation called 'awig-awig' [17]. Beside the classification of residents it defines the other society regulation and norms that related to everyday life in public space, in the human relation and the creation of balance relationship between society, the environment and God which known of '*Tri Hita Karana*', a Balinese concept of life. The differentiation of rights and duties in every member of society is detailed written in this indigenous document while it is also stated that the existense of society norm that unwritten in 'awig-awig' also have their *de-facto* power to regulate communities.

*One must therefore construct the objective class, the set of agents who are placed in homogenous conditions of existence imposing uniform conditionings and producing homogenous systems of dispositions capable of generating similar practices; and who possess a set of common properties, objectified properties, sometimes legally guaranteed (as possession of goods and power) or properties embodied as class habitus (and, in particular, systems of classificatory schemes) [18:101].*

The social creation of classification should be valued as a positive community action towards social justice. It should be comprehended that justice not solemnly relates to equality that everyone should have the same amount of resources. Social justice relates to equity, equality and welfare [20]. The competition of street use that leading to horizontal conflicts are often resulted from the misinterpretation of public space for freedom of use by the public. Highly accessed space that defines publicness of space is no permanent relation to the ability to control. There are many debates through the act of public space occupation, possession and privatization [10; 21] that eventually potentially produce horizontal conflict. Creating justice in public place requires an agency that can maintain the justice of use and act of territorialisation. This must be a persistent action not just a scheduled or a random process of control. As stated by one of the street vendors,

*'We usually sell our groceries right here (on the street) start from 5 to 6.30 am. These are our daily activities working hours that we are organised in conjunction with other vendors and parking man, as well as we share a sum of money to pay parking man as they lose some space for motorcycle parking. We are here working and cooperate in cooperation with our living, to earn money to buy some food and pay our child's school fee for our family at home not more... We know that government prohibits us to sell our stuff on the road, but they rarely come here to control us, .. And if there will any plan of inspection for several municipality reasons (... i.e special inspection from higher municipality, president or other important national events), we know a day before from Pecalang that always came here three times a day, it has happened so we can organise and help them by following the regulation (temporary). Anyway, we know the officials quite well; we are friends...'*

In this statement, it stated that municipality conducts street inspection irregularly. As it is becoming common understanding in the Denpasar community that the governance of a neighbourhood (including the street space) is their basic right as hereditary the space and resources is their belonging therefore the benefit and cost of territorial resource management better become their authority. Municipality aware of this understanding and minimize their presence to avoid states-community, a Top-Down conflict. Controlling street activity is a huge challenge in economic and mainly socially interconnected problems, and irregular control of the street space is an inappropriate one.

Based on reviewing municipality and community empirical dispute about right to manage street, It can be summarized that municipality seems to have a (save) neutral position, which also can be categorized as the lack of direct actual action as it tight relation to law enforcement, regulation, justice and bias of political security. On the other hand, community (indigenous) groups have their grounded and in depth comprehension through every second of street or social events and identification of street users in their environments.

Community classification such as differentiation of local and non-local residents is not merely social segregation but a way of managing right and responsibilities. As local residents more responsible to their territory through everyday activities such as cleaning, offering, praying over all community public space than they have more right, the feeling of belonging than another, as empirical data also shown that non-local (especially) vendors have a low level of public space environment quality even more they make destructive action by littering or polluting neighbourhood.

Classification based on religion also has its own importance to maintain social justice harmony. Denpasar community consists of 63% Hindus, 29% Islam, and other religion such as Catholic, Protestant, Buddha below 4% each [22]. It is indicated in census data that the proportion of Hindus community (indigenous one) still dominates the population followed by Islam's community in the second. These two groups of religion take a strong position in the governance of the city. The Hindu represents indigenous and Islam represents the municipality (or nationality) as an Indonesian biggest majority religion, a religion that has full financial and political support from central government. On the level of street neighbourhood, Denpasar community landscape, these groups of community based on religion create their individual community cohesion and exclusion indicated by their particular symbol, attitude, language and activity system. As stated before in *Awig-awig* (indigenous regulation), that non Hindu's community classified as *tamiu* (community guest) that have different right and responsibility with Hindus (the indigenous) which is practically conducted successfully in the present societies. Balinese Class domination is based on Tri Hita Karana concept, to share and maintain a relationship with others. This is the key of creating social class justice. Classification in a Balinese democratic society means the right of the majority to serve and support the minority class right and activity which resulted in a respect of minority to majority that lead to social order.

Community classification as a part of Place-based justice is a requirement of social order. Indigenous community (Hindus) with their social value of creating balance between human, environment and god have positioned themselves in the process of sharing community resources and right and duties, benefit and cost. For example, Hindus community will be more responsible in maintenance and cost of their public space, especially sacred public space as it is related with their daily worship. It is also found in the empirical data that several street vendors are classified by their interrelationship with home, shop, temple owner of the street. For a Place that considered high local-sacred valued it is inhabited by Hindus community that has certain knowledge for place worship and offering. Classification of actors who reflected in character of street use, creating a definition of locality, an initial indication of private (certain group) place in public space. Classification of community is made to maintain the conflict, which not certainly means segregation but more into the appropriation of the community members right, action and activities around a specific territory. Justice can be achieved without fear with understanding people through respect for certain inherited value.

### 3. COMMUNITY PARTICIPATION PROGRAM FOR EQUALITY

In Denpasar, there is a social participation concept called '*Ngayah*'. It is a term for an individual, family representative, or group of people to work and spend their time for any community event based on scheduled affair or unscheduled one such as family birth, marriage, funeral ceremony, temple birthday and other event ordered by community leaders. It is usually unpaid job and consume a specific amount of time with a definite consequence for opposing this social activity, that is being secluded and confronted with physical and social punishment. For example, a Balinese person that in purpose avoids a series of '*Ngayah*' then when there is a ceremony related to that 'naughty-lazy' resident than the community can embargo that specific event, street access and even social access to the religion leader who related with. As Made, a Balinese resident said.

*'.. Everyone must attend and involve in every 'ngayah' session, if they are not joining this social work for several times, it is against our community norm and social fairness, which also implies disrespect to God and Prajuru Banjar (community leader) and societies, especially if they not come when there is a 'Ngayah' for funeral ceremony. We can punish them with boycott their funeral ceremony when the days it comes. Not allowing their dead body to enter and pass through our neighbourhood street... we should help each other, that's the key... if they want to replace 'Ngayah' with money, I also have money. And if everyone wants to play .. So who will help this ceremony to be happening .. No other reason, but they have to join 'Ngayah' whenever and wherever... as we do it for parahyangan, pawongan, and palemahan... (God, community and place)..'*

From the interview statement, it can be concluded here that some factor influencing the degree of participation in a community is good leadership, which reflected in degree of obedient and respect to the leader (Balinese leader: *prajuru banjar* and God), community (social) punishment and equality besides materialism (money). The interesting finding of Balinese community equality is the effort to avoid the materialism factor in community governance. Money as the top rank of the social practice generators is not generally applied to this empirical study result. When community aware that the materialism can distract the successfulness of governance then immaterialism (value, religion, god, social norm) can be used as a generator to create a community order. One way to minimize social class status is by treating them socially equal. Rich, poor, high caste, low caste, active or not busy residents have the same obligation to conduct '*Ngayah*' community (unpaid) work.

Social consequences become an important factor of community participation. It ensures the equality of responsibility corresponded to the various differences of community equity and welfare. It is claimed that punishments have a greater impact if it is a social / community –based, immaterial one. When the community has the equal consequences of participation then awareness of active responsibility can be built as well as reduce social class distinction.

#### 4. SUSTAINABILITY OF ACTIVE COMMUNITY PARTICIPATION

Judd and Fainstein [23] argues social, environmental, institutional and economic defines sustainability, which is influenced by level of care, democracy and justice. Based on the empirical finding, It is found that sustainability also shaped by three other elements such as transformability, commonality, and dedication to immaterial value. Bourdieu (social) class and capital argue this communal power called social capital is an important factor for small based enterprises, and consequently. It is reflected on the degree of cohesiveness that constitutes people's perception, right, and exclusivity.

Transformability is the ability of the community to adapt, adopt and adjust their social behaviour with the change of individual and resource development. Transformability will relate to the fluidity of regulation and regulator to manage society. Awig-awig as indigenous community regulation is not a solid regulation and is kept, transformed and adjusted following the variety of stakeholders, therefore, there is no identical awig-awig around Bali. One media that had been found in the research is a de facto (legal) communal meeting called 'paruman' which can produce additional norm and regulation instead of inherited one to adapt the change of resources. With direct voice, idea and expression from all community's inhabitant, the regulation product of 'paruman' is a result of democratic approach. Although there are differences and debate of ideas and power as it heard and witnessed by all, it is one way to create sustainability of participation that guarantee the equality to express voice. Another common understanding of community is that awig-awig has created from a generation that has huge difference to the recent community condition. Therefore, it should be modified democratically for community good will.

The second factor of sustainability is the proud, respect and attachment of indigenous value. In this case concept 'Tri Hita Karana' balance relation with God, human and environment which is a fundamental concept but easily applicable to everyday practice. Other indigenous practices such as traditional event, ceremony and activities that being preserved nowadays is the other evidence of relativity with a traditional concept can bind cohesiveness of society, which develops a greater degree of people attached to the physical and social environment. In a simplify way that expressed by the respondent that express confidence of Balinese people to preserve this tradition as it is not only a physical tangible product but more into social valuable entities. Leaving tradition and indigenous value does mean leaving the physical attribute of a locality which is not difficult to conduct, but leaving the social relation, value, meaning memory with friends and relatives still a greater factor to be preferred.

Classification, Caste and leadership are other keys of sustainability factors. Community classification is socially constructed based on individual possessed resources and hereditary. It exists, therefore, should be consumed carefully in the perspective of social justice. Dominancy of power and class is used to maintain equity and community welfare. As awig awig states the difference right and responsibility of every class of the community, it should be applied to balance of right and responsibility in analogy of the balance of social benefit and cost. To achieve this, social solidarity is a key factor together with the ability to actively control and manage this solidarity among the community.

#### 5. CONCLUSION

Diversity of and class in the community are an on-going social construction process through variety, similarity, the cohesion of identity. Generalizing community diversity into an equal identity of the community will face some difficulties in the process and product of justice. The indigenous Balinese classification called 'Krama' is not merely a segregation tool for community difference but as an indicator to achieve social justice in distributing community rights and resources. Balinese aware with this unavoidable class difference, therefore, several regular community events were conducted called 'paruman', community meeting and 'Ngayah', a community social work, with equality of class and social punishment for noncompliant one. It is a social activity that reflects an active community participation towards their environment, neighbourhood space and God. These indigenous values and activities have the important factor that should be kept for its sustainability such as transformability, respect and attached values.

### ABSTRACT

More than half of the world's population now lives in cities, making the creation of a healthy urban environment a major policy priority. The city or urban area is a set of infrastructure, other structures, and buildings that create an environment to serve a population living within a relatively small and confined geographic area. The lives and livelihoods of the population are supported by interrelated systems around which the urban area and society function. Most public space in urban areas is provided by streets. Well designed streets can offer opportunities for recreation, social interaction and physical activity. Poorly designed streets can be indifferent or unwelcoming, contributing to community severance, reducing social cohesion as well as suppressing levels of walking and cycling. They can also have a negative impact on local economic performance. In the City of Cairo and According to the World Bank Report Cairo Consider One of the most crowded cities that assumed there is a lake of public spaces which has a great impact on the social activities and the local economic performance. That what led me to propose the need for integrated concept to enlarge the public spaces within the city. The shared space is an existing streets or places designed to improve pedestrian movement and comfort by reducing the dominance of motor vehicles and enabling all users to share the space rather than follow the clearly defined rules implied by more conventional designs. The main objective of this paper is to increase the public spaces within the cities inner districts without affecting the traffic and the infrastructure and to improve the road safety by encouraging negotiation of shared areas between different road users. An analytical study was done on the city of Cairo, in order to understand the society needs using SWOT analysis to evaluate the efficiency of the different solutions. The study found that Shared Spaces does not offer a ready recipe for the organization, design and equipment of public space. Individual problem situations demand tailored solutions. Nevertheless, there are a number of general basic principles for the design of people space. To promote socially conscious behavior, the design should be based on local characteristics and one should use as few as possible traffic engineering and regulation elements. Priority signals should be replaced by human interaction.

### Keywords

*Urban, resilience, shared roads, public spaces, Cairo.*

### 1. INTRODUCTION

More than half of the world's population now lives in cities, making the creation of a healthy urban environment a major policy priority. The city or urban area is a set of infrastructure, other structures, and buildings that create an environment to serve a population living within a relatively small and confined geographic area. The lives and livelihoods of the population are supported by interrelated systems around which the urban area and society function.

Recently cities are getting larger and denser, but they are balancing processes of out-migration, suburbanization, and the creation of extended urban landscape that combine cities, towns, and interspersed rural landscapes into a functioning whole. Other cities are decreasing or only maintaining their population, but even they are engaged in efforts at transforming their structure and function in order to maintain their vitality. Whether they are growing or not, cities and their associated regions are competing to be regional, national, and international hubs.

Most public space in urban areas is provided by streets. Well designed streets can offer opportunities for recreation, social interaction and physical activity. Poorly designed streets can be indifferent or unwelcoming, contributing to community severance, reducing social cohesion as well as suppressing levels of walking and cycling[5]. They can also have a negative impact on local economic performance.

**The main objective of this study is** to determine enhance ways to increase the public spaces within the cities inner districts without affecting the traffic and the infrastructure and to improve the road safety by encouraging negotiation of shared areas between different road users.

**Greater Cairo city center was chosen as the main case study** because Cairo According to the World Bank Report Consider One of the most crowded cities that suffering from lacking of public spaces which put pressure on land, services and increase settlement inside the city, that has a great impact on the social activities and the local economic performance.

### Questions the Research Answers:

This study aims to demonstrate to what extent urban strategies can be helpful for solving the urban problems that related to the continuously growth inside the cities. And how those strategies can be useful in developing better plans for managing urban public spaces . To that end, it proposes a hypothetical solution depending on urban resilience management strategies. The main research questions are formulated as follows:

- What is the resilience urbanization strategy?and what is its importance?
- What is the importance of the open public spaces? And is it possible to enlarging / expanding them within its existing boundaries?
- What are the shared roads and its importance?
- How shared roads can be useful in providing the concept of sustainability inside cities?
- Why the Greater Cairo City needs urban resilience strategy?

## 2. WHAT IS THE RESILIENCE URBANIZATION STRATEGY? AND WHAT IS ITS IMPORTANCE?

Change is a constant in our world especially with the rapid calls for Urbanization and not all communities are dealing successfully with the issues of growth. Some communities must manage the issues that derive from decline.

Urbanization is both an opportunity and a challenge and according to that, many urban management strategies appeared to dial with the city dynamic growth impacts and its consequences':

1. **Urban growth management strategies** that consist of the various tools used to manage the amount, type, extent, rate, and quality of urban development. In other words, these tools can be used to manage how much growth occurs, what kind it is, where it occurs, how fast it happens, and with what impacts.
2. **Urban disaster recovery management** that takes steps to anticipate and mitigate the impact of disasters, incorporating monitoring and early warning technologies to protect infrastructure, community assets and individuals, including their homes and possessions, cultural heritage, environmental and economic capital, and is able to minimize physical and social losses arising from extreme weather events, earthquakes or other natural or human-induced hazards.
3. **Urban resilience strategy** can be define as guidelines & action plan that help the cities to be able for respond, implement immediate recovery and quickly restore basic services to resume social, institutional and economic activity after any threatens or crises. And we can Consider the city where people are empowered to participate, decide and plan their city together with local authorities and value local and indigenous knowledge, capacities and resources. a resilient city.

According to above we can define Resilience as a prevailing theme of the discourse on disaster preparedness, response, recovery and mitigation; it is a measure of the system's capacity and the ability of these systems to absorb changes that caused from the different variables.

Without doubt, resilience is an evolving concept. Understanding resilience perspectives from multiple fields requires further research. In my study, I share the perspective that resilience has multiple levels of meaning: as a metaphor related to sustainability, as a property of dynamic models, and as a measurable quantity that can be assessed in field studies of urbanization. The concept of resilience is useful for urban designers who strive to create cities that are adaptable to changing conditions and needs.

## 3. WHAT IS THE IMPORTANCE OF THE OPEN PUBLIC SPACES? AND IS IT POSSIBLE TO ENLARGING / EXPANDING THEM WITHIN ITS EXISTING BOUNDARIES?

Great cities all over the world became featured with some common urban features, which is clearly could be noticed in the main urban components of the centers of great cities, those components may be not exist in the rest of the city, such as the historical heart that represent the oldest part of the city, CBD, the main stations for public transportation networks, and many other urban components, the public spaces are considered as one of the common urban components in the great cities centers at the same time they don't exist as the same as in the rest of the city, such as central parks, specialized gardens, pedestrian grand plazas and squares which may include national symbols concerned by the citizens of these countries, those unique public spaces represent the social life of a great city and considered as a measure of its vitality. [7]

The public spaces of the great cities centers became logistic nodes acting new urban roles and functions. Nodes where pedestrians are being collected and distributed to different destinations within the city center or its borders by using Entrances and exits of main public underground transports networks, The main train station or to be linked to its Main bus stations, which are good connected to the public spaces[2], these nodes providing the common urban roles of the public spaces besides its new role, the common roles were appropriated to the new fast rhythm, the public spaces became more complicated and contains some specified spaces inside the main public spaces, those new specified spaces usually private but their exists help the main public space to act its new role as a logistic node besides its original urban roles.

In the current City center the public spaces in which the pedestrian participate to the different social and leisure activities limited only to the pavement which its width can be (3-4) meter long in the best case. These public spaces can be temporarily expanded horizontally (including the street/ road – which will increasing the public space about 8-12 meter) to absorb the huge

agglomerations of people in the national events, festivals, which will affect the future design of those spaces and the surrounding pavements, streets to be flexible to meet the multi-functions uses the best concept for that is the Share roads and shared spaces that intend to increase the public spaces within the cities inner districts without affecting the traffic and the infrastructure and to improve the road safety by encouraging negotiation of shared areas between different road users.

#### 4. WHAT ARE THE SHARED ROADS AND ITS IMPORTANCE?

The concept of designing public roads, junctions and spaces as so called Shared Spaces/ Roads is increasingly popular in recent years and is seen as a chance to reduce the car-dominance in cities throughout Europe. It creates extra urban flow paths.

**Shared Road** is a term used to describe an emerging approach to urban design, traffic engineering and road safety in Europe and, increasingly, in North America. It was identified a common thread in the approach of a number of countries on how to reduce the adverse impacts of traffic in towns.

However, shared road could also be seen as the default mode before the separation of vehicles and pedestrians became the accepted approach to designing public spaces. It was the status quo ante for most streets and public Spaces before the introduction of segregation during the last century. Streets that encourage sharing of the space are not new. Many historic streets operate as shared spaces, particularly narrow streets in historic core zones and residential districts. Visit any Italian hill town, such as Siena, or smaller Mediterranean settlements, and shared space will be evident in any traditional streetscapes where modern traffic engineering has yet to have an impact. Even today in the UK, almost all car parks, courtyards, mews developments, market places, village squares, campsites and country lanes involve the informal sharing of space for different uses and by different modes of movement. [3]

In shared Road designs, the segregation between motorized and non-motorized traffic is removed, creating an integrated space without traffic signs or signals, curbs and road markings. Instead, traffic flows are controlled by social interactions and supported by infrastructure measures like colored road surfaces and the thoughtful placement of road furniture.

Shared roads are not, ultimately, defined by the design or configuration of the built environment. Design and detailing are important, but only as a catalyst to changing the way in which people interact within the public realm.

##### **The Shared Road design team:**

Shared space schemes tend to have wide-ranging objectives beyond more traditional single-issue such as traffic management schemes – objectives such as inclusiveness, street vibrancy and regeneration.

It is therefore beneficial to assemble a multi-disciplinary project team which, in addition to the project sponsors, could include the following, for example: (Highway/traffic engineers - urban designers - town planners / conservation officers - landscape architects - accessibility/mobility specialists - maintenance team managers - lighting engineers – contractors).

##### **General Design Consideration for shared roads:**

Shared road does not represent a particular type of street. It is more a broad set of design approaches aimed at encouraging sharing as a way of improving the street's place function. It can achieve this, in part, through minimal use of traffic signs and other traffic management related street furniture. Traffic signals are often removed, with indications of priority at minor junctions omitted. These changes modify the way the street operates by creating an environment that encourages drivers, pedestrians and cyclists to behave in a more co-operative manner.

The surface level is often intended to remove a physical and psychological barrier to pedestrian movement. It can also indicate to drivers that pedestrians are not confined to the footway and that they can expect to encounter them in the whole of the street.

**Data must be collected before and after the reconstruction to a Shared Road[4]** because as we have explained previously, Shared Roads are rather a design guideline with multiple different ways of interpretation instead of a ready-to-use design which is implemented the same way in all projects. Thus we must admit that the findings for a specific project are not necessarily transferable to any other Shared Space. It can, however, be used as the basis for verifying and refining existing guidelines.

1. **A classical traffic survey** must be conducted counting the vehicular flow and the number of pedestrian crossings at different times of the survey period.
2. **The Road users** must be classified into pedestrians, bicycles and cars and tracked during their time inside the origin/destination measurement lines.
3. **Space usage** must be identified rather it is a commercial, Administrative, Government zone or Residential District.
4. **Speed distribution** is important indicator that investigates the speeds and flows of both the pedestrian and motor vehicle.
5. **Safety aspects** that focus on the interaction between and within motorized and non-motorized traffic, using indicators of time as objective and quantitative measure to reduce the severity of conflicts.

#### 5. HOW SHARED ROADS CAN BE USEFUL IN PROVIDING THE CONCEPT OF SUSTAINABILITY INSIDE CITIES?

Good quality living environments reduce stress and make life more pleasant through providing sufficient indoor and outdoor space with few personal hazards, minimum noise, a location close to family and friends and easy access to desired services,

recreation and facilities for safe participation for the different social activities. All those facts must have parameters and indicators to be measured, that what led to the concept of sustainability which in its main Concept is how to provide the needs of the present without compromising the ability of future generations to meet their own needs.

**Figures 1, 2:** All today habits and busy lives can make us forget that urban spaces and pavement can be more than a path along which to deliver between two points. We can enhance our perception to help in revitalize our town centers, boost economic performance, support regeneration and build community pride and social integration and interaction. The Sharing Roads allows having multi uses activities in the same space (vehicles road, cafe, play yard) but not at the same time except in some places not used by children.

**5.1 The Benefits and potentials of the shared roads that providing the sustainability:**

Sustainable development which is the a process which enables all people to realize their potential and improve their quality of life in ways which protect and balances the Environmental, Social and Economical parameters / issues.

**5.1.1 Environmental Benefits:**

1. **Improving the Air quality with** Reducing traffic congestion for vehicles; which is the main cause of the air pollution with high rates of greenhouse gases emissions caused from the incomplete combustion of vehicle exhaust gases, which in turn affect air quality and public health and ecological footprint in the end. Not only that but also that led to increase the temperature inside the center of the cities which known as the urban heat island effect phenomenon.
2. **Reducing the Noise pollution** which the temporary or permanent hearing loss is the best know health impact, although high noise levels are also known to be one of the critical stress factors that cause blood pressure, heart and respiratory rates, central nervous system and influence mental disorders and social pathologies.
3. **Reducing the Visual pollution** that caused from cars smug that attached to buildings' facade. And reduce the distribution of the suspended particulate matters that causes the foggy vision and increase the effect of the dust dome.
4. **Increasing the Greening spaces & Trees** providing vital effects :
  - Reducing the Air pollution and the Co& Co2 gases ratio in the air.
  - Air Quality can be improved through the use of trees, shrubs and turf. Leaves filter the air we breathe by removing dust and other particulates.
  - Trees and other vegetation can mitigate the urban heat island effect because they shade buildings, intercept solar radiation and cool the air by evapotranspiration. trees reduce evaporative emissions from vehicles and other fuel storage.
  - Finally trees and vegetation can help in reduce noise, which is highly valued in urban areas. They also provide shade from harmful ultraviolet radiation, particularly in open spaces.

**5.1.2 Social Benefits:**

1. Every street represents a balance between **movement** (the capacity to accommodate through traffic) and a sense of **place** (the quality which makes a street somewhere to visit and spend time in, rather than to pass through). Shared space is a way of enhancing a street's sense of place while maintaining its ability to accommodate vehicular movement.
2. **Increasing the social communication and connectivity** as a result of providing more spaces and locations close to family and friends. And easy access to desired services, recreation and facilities. For safe participation to the different social and leisure activities.
3. **Support town centre** regeneration by providing a high quality civic space in the town centre suitable for flexible uses. Particularly where there is a level surface that can allow the street to be used in different ways. For example, street cafes and the like may be present during the day, while at night the area occupied by daytime activities could be given over to

people visiting night-time entertainment venues. A Street could also host regular street markets or occasional events such as street theatre.

4. **Enhancing** livability and quality of life.
5. Death and injuries from motor vehicle accidents have become an increasingly significant component of all premature death and injuries in urban centers. The **shared roads increasing the ratio of Safety** with improving pedestrian movement by reducing the dominance of motor vehicles and determine a certain times for motor vehicle to use the shared roads and reduce the speed limit as well and encouraging drivers to behave more accommodatingly towards pedestrians. [1]
6. **Providing safe environment** for children to play and communicate.
7. Redevelop the link to have the feel of an urban square in which people will want to **spend time** but maintain bus movement in the town centre.

#### 5.1.3 Economic Benefits:

1. Reducing the risks caused by motor vehicles accidents and high speed. And increasing the participation of the new public space (provided by the shared road) users and the district inhabitants inside the city center commercial zone. That will increase the opportunity for enhancing the Economic Sector performance.
2. Increasing property values.

### 6. WHY THE GREATER CAIRO CITY NEEDS URBAN RESILIENCE STRATEGY?

Cairo According to the World Bank Report Consider One of the most crowded cities that suffering from lacking of public spaces which put pressure on land, services and increase settlement inside the city, that has a great impact on the social activities and the local economic performance.

Cairo downtown (city center) includes the central business district which set between the main squares of Cairo city - Ramses, Ataba, AbdulmonemRyad, Abdeen and El Tahrir on area of 88 hectares. And this area considers the most crowded district in Cairo. **Cairo city center suffers from many problems that affect livability and quality of life:**

1. High residential density in main existing agglomeration.
2. Rising traffic congestion in Cairo city center cause increasing of heat / GHG emissions and air pollution that have bad effects not only on the pedestrians or social activities contributors but also on the residents who lives inside city center.
3. The high land value of the city center prevents the urban designers and the governmental authorities from expanding or making use of already vacant sites for Public Spaces.
4. The public spaces of Cairo city center attracted many informal commercial activities such as street vendors; that affect the commercial performance and reducing the pedestrian walk side and plazas that prevent them from participation to the different social and leisure activities and even walk.(see figure 4)
5. Many of the motor vehicle streets/ roads not used efficiently which is the main reason for the High traffic congestion-the street/ road can be five lanes but only just three or two lanes are used. According to the occupation of two lanes for parking and may be another one or two for the Invasion of the street vendors. That indicates the essential need for management strategy that not only reducing the traffic congestion but also to make space defragmentation to provide safe and fare share for every use without making any conflicts that cause fatal consequences.(see figure 5)

#### 6.1 The Main Objectives for applying a resilience strategy to Cairo city center:

1. Achieving all the (Environmental, Social and economical) benefits that the shared roads provides.
2. Increase safely public open spaces area within the city.
3. Reduce the traffic congestion and its consequences'.
4. Reduce the pollution ratio in city center with increasing friendly environmental activities.
5. Increasing the social connectivity and communications and the opportunity for enhancing the economic sector performance.

#### 6.2 Using the SWOT analysis to evaluate the Public spaces in Cairo city center:

There are many opportunities can be achieved with applying a resilience strategy depending on the concept of shared road. ThisSWOT analysis depends on the observations were noticed last summer by several times life visits to the greater Cairo city center public spaces, the Main issues of evaluation were:

1. Public transportation and the infrastructure.
2. The Proposed expand public spaces.
3. The urban structure and the current public spaces.

#### The conclusion of the SWOT analysis showed the follows:

1. As a result of the low area of public spaces the green areas were too low also.
2. The squares and plazas were mainly designed for Motor vehicles.
3. The pedestrian pathways are new to the Cairo city center, some few local streets were converted to share roads, but that wasn't efficient enough to respond the need for the public spaces.
4. Unusual spaces were converted to be used as public spaces, like the wide pavements of the bridges along the river Nile from city centre to west areas of the city, the pedestrian use these pavements as a terrace providing a panoramic views of Cairo city centers, with street food, drinks vendors who offers chairs for money.

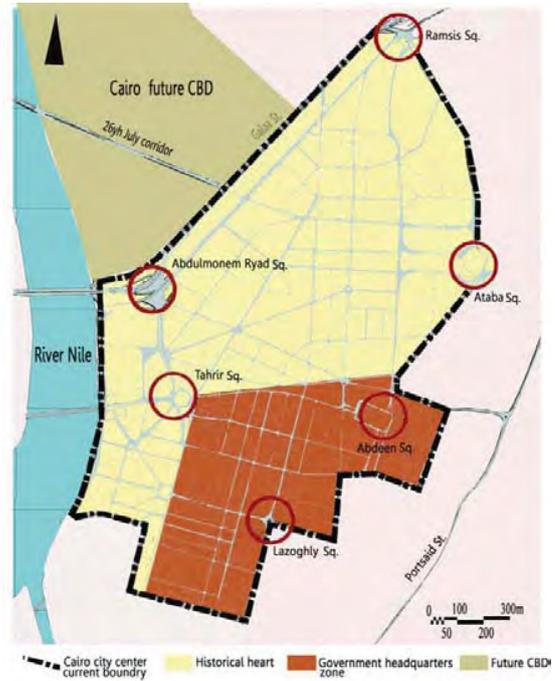

- Most of the public spaces became more complicated as main public spaces with other minor spaces mostly semi-private or private spaces.

**Figures 4:** Traffic Congestion and informal commercial Invasion forcing the pedestrian to walk in the street-Typical scene in city center roads.

**Figures 5:** Traffic Congestion according to reducing the street width with car parking in its both sides.

**Figure 3:** Cairo downtown (city center) includes the central business district which set between the main squares of Cairo city - Ramses, Ataba, Abdulmonem Ryad, Abdeen and El Tahrir on area of 88 hectares.

Table 1: The SWOT analysis to evaluate the current situation of the Public spaces in Cairo city center

	Strength	Weakness	Opportunities	Threats
<b>Public transportation and the infrastructure</b>	<p>Providing good public transport means connecting the city center public spaces to the rest of the city. Especially the underground train (Metro).</p> <p>Providing the city with an integrated infrastructure serving the public spaces is supporting the current urban roles of those public spaces.</p>	<p>Most of the public spaces in the city center were designed according to the concept of segregation between motor vehicle and pedestrian to meet the needs of motor vehicle. Streets and squares were mainly designed for motor vehicles.</p> <p>The inadequate of cars parking in the city centers is preventing wide sectors of society to use the public spaces.</p>	<p>The future governmental plans of the city center supported the services of the public spaces, such as offering new public transport lines to connect the main public spaces to the rest of the city. And using electric cars for reaching the new shared roads inside the city center.</p>	<p>High traffic congestion in Cairo city center and concentration of the central governmental/ and business facilities gives indication that it is very hard proposing to reduce the motor vehicle flow in city center.</p>

<p><b>The Proposed expand public spaces</b></p>	<p>There are various alternatives in case of converting number of streets to enlarge / expand the Public Spaces Whether to be shared roads or completely pedestrian streets.</p>	<p>The annual increasing rates of the land prices besides the inadequate of providing enough areas for the existing needs for public facilities like cars multi-story parking.</p>	<p>The existing plans of converting more tracks paths into pedestrian public spaces.</p> <p>The progress in the drilling and underground constructions support the possibility of offering more spaces for some land-uses like cars parking to be underground which will offer more spaces for public spaces.</p>	<p>The difficulty of providing safe and fare share for every use without making any conflicts.</p>
<p><b>The urban structure and the current public spaces.</b></p>	<p>Most of the city center public spaces enjoyed remarkable livable unique sites which considered as hubs for variant activities and services like the underground entrances, bus stations... etc.</p>	<p>The current landscape design, street furniture of the public spaces is not suitable for the current urban roles of those spaces.</p> <p>Can't Act several variant activities at the same public space smoothly and efficiently.</p>	<p>The possibility of using new architectural urban concepts to offer new extra spaces like using public institutes roofs and many other ideas.</p> <p>The new growing urban roles will help to evaluate the future plans to offer innovative public spaces.</p>	<p>The growth of the future need of the common land-uses of the city center may affect the current public spaces to be reduced.</p>

### 6.3 Assessing existing Shared Roads experiments inside Cairo Downtown:

Cairo Downtown already has a few pedestrian streets such as Al-Alfi, Al-Borsa and Al – Mu’izz streets, and there are already proposals to apply shared roads and places vision to more downtown streets. The following tables will present three experiments for the shared road inside Cairo downtown; showing the advantages and disadvantages to each of them, to stand on the main obstructs that those experiments are facing and draw the main guidelines for applying the shared roads in correct and efficient way:

Table 2: Al-Alfi, Al-Borsa and Al – Mu’izz street analysis and Assessment, Downtown, Cairo city center.

#### Al – ALFI Street:

Overview Description	Assessment
<p>Al-Alfi Street located in the northern boundary of Cairo city center, within the Historical Khedivial Cairo Zone. It was originally designed as a vehicles and automotive street, it is (12-15 m) in width and (approx. 200 m) long, and it extends from Orabi square on the west to Al- Azbakya garden on the east. 12 years ago a part of this street (approx. 100 m) converted into a pedestrian street, it includes various entertainment activities of fast food, Cafes and Cabarets.</p> <p>The Flooring and Pavement material is manly of concrete. Seats are provided and distributed along sides with rows of shrubs, and the Cafes furniture extend to outdoor without specific order.</p>	<ul style="list-style-type: none"> <li>▪ The Street is ineffective because it locates far distance from the commercial area (on the northern boundary of the city center) and the lack of adequate commercial services, and palaces on a small number of fast food restaurants, which mainly serve its surrounding area at day time.</li> <li>▪ The lack of proper social atmosphere due to the presence of casinos and cabarets which attracts limited categories of adults, that Prevents families with children from participating in social activities at night. Moreover the number of seats is insufficient, poor lighting in the night and less security.</li> </ul>

Figures 6: Converting some downtown streets into pedestrian promenades was promising idea. The Cairo governorate support it time ago to reduce pollution and traffic congestion in the city centre. This resulted to have wide and safe pedestrian social space on sections of Al-Alfi and Saray Al-Azbakiya streets. However nowadays the removal of many unused fixed element can provide extra spaces. Moreover changing some shops uses and activities can provide more social interaction. Al-Alfi Street.

#### Al – BORSA Street:

Overview Description	Assessment
<p>Al-Borsa Street located in the heart of Cairo downtown, within the Historical Khedivial Cairo Zone. The area known as Al-Borsa, named after the Egypt’s stock exchange building located at its heart, consists of a network of pedestrian streets. It has plethora of outdoor cafes that consider a popular respite from the noise and traffic of the city. It was originally designed as a vehicles and automotive street, it is (8-10 m) in width and (100-200 m) long.</p> <p>The Flooring and Pavement material is dark raw basalt interlocked tiling and concrete tiling in some areas, Seats are not provided but specific places for car parking are determined, and the Cafes furniture</p>	<p>Although there are many cafes and which represent a suitable atmosphere for old men and youth to participate in many social, cultural and political activities, but it is not suitable for children or women to engage in any social activities in such a place according to our traditions and habits.</p>

extend to outdoor without specific order. And There are direct and indirect lighting units are well distributed but still not sufficient for night social activities.

Figures7: The area around the stock exchange is congested with cafes making lively scene especially at night time. Moreover private car parking and restricted roles in managing the time between vehicle and pedestrian make it safe to socialize in this area. Different shots to Al-Borsa street, Downtown, Cairo.

### Al – MU’IZZ Street:

Overview Description	Assessment
<p>Al-Mu’izz Street located in the western Side of Cairo city center, within the Historical Medieval Cairo Zone (UNESCO World Heritage Site).the street was designed as the spine of the gated city (one kilometer long is adomed with monuments of different historic periods), al-Mu’izz street is a typical medieval street that had been developed along a thousand years, narrow in section, with spontaneous varied widths and heights, creating interesting vistas and views along its path. It was originally designed for pedestrians, light vehicles and carriages (horses and cattle), the narrow and sinuous street has been transformed into an over-populated typical residential/commercial district due to the change in demographic characteristics of its users.</p> <p>Main activities – besides residential – are Specialized crafts and small trades of jewelry, copper, leather, clothes, herbs; each activity located in a specific section of the street.</p> <p>The newly flooring material is dark raw basalt interlocked tiling, and light stone cladding for pavements. There are a few seats in front of the monuments in the wider shop-free sectors of the street. There are direct and indirect lighting units are well distributed. [6]</p>	<p>Although Al-Mu’izz Street is a very good example for a pedestrian street with its entire commercial, Social and touristic attraction, and its accessibility (near location) to many of public transportation (Underground Metro, Buses, Taxis...etc). And although it had been prepared to be shared road/space and provided with many facilities (Fixed and movable) such as Cars barriers, Signs and even gates on the main entrances and exits. It is unfortunately suffer from neglection, not only to the regulations and roles that organize the street using (pedestrian – vehicle)-(as Loading and emptying goods became problematic; many customers suffer have to make an effort in reaching some destinations; moreover ambulances and fire brigades cannot reach some off-streets easily and number of passing bikes are considered to be dangerous) but also from the insufficient paving material (rough basalt) which causing walking difficulties. Also the lack of regular street cleaning and litter clearance make unweelcome message to the passerby and users and even to make any social activities.</p>

Figures 8: the Egyptian government carried out extensive renovations to the historical buildings, modern buildings, paving, and sewerage to turn the street into an "open air museum". On April 24, 2008, Al-Mu'izz Street was rededicated as a pedestrian only zone between 8:00 am and 11:00 pm; and cargo traffic is allowed outside of these hours. Different shots to Al-Mu'izz street, Historical medieval Cairo, Cairo.

### The main Lessons that we can conclude from these experiments, to promote efficiency to the Shared roads/ spaces:

1. Small design changes can make a big difference to the attractiveness of a space and the way it is approached and used, and can help reinforce the local vision for the kind of place that want to be created.
2. The main Target of designing Shared/ Public spaces/roads is to create a space where people of all ages and abilities can work, rest, relax and play. Not for limited categories or ages otherwise it is not achieve its goal of Social interaction.
3. The quality of the walking environment is a main factor in people's shopping choices, and encourages them to spend more time with wider range of shops, than visitors arriving by cars, buses or bikes.
4. One of things that can limit creative and exciting use of public spaces is the challenge of managing and maintaining them. Hence active management of public spaces is vital to their usability and people's enjoyment of them, and can deter anti-social behavior. Regular maintenance will be required, including regular street cleaning and litter clearance, emptying litter bins, removing graffiti, fly-posting and clearing trade waste and any fly-tipping. All public space users

have a role in maintaining it. For example community and business engagement and creative design, choice of materials and pre-emptive surface treatment of these, can minimize such problems and ease remedial action, and it can also help to get everyone involved in reporting and problems and get agreement on whose job it will be to take remedial action when needed.

5. The space must be measured in relation to flows, so it can contain all the users and passerby social activities.

## 7. CONCLUSION

1. The study found that Shared Spaces does not offer a ready recipe for the organization, design and equipment of public space. Individual problem situations demand tailored solutions. Nevertheless, there are a number of general basic principles for the design of Public space and shared roads. To promote socially conscious behavior, the design should be based on local characteristics and one should use as few as possible traffic engineering and regulation elements. Priority signals should be replaced by human interaction.
2. Possible causal explanations could offer simple solution for the conflicts that may happen when we make a preliminary resilience strategy. Design participation is essential for this kind of project that required many public auditing be made before preceding the specialists meeting to finalize the conceptual strategy and the detailed action plan.
3. Applying the resilience strategy to the Cairo city center depending on the concept of shared roads helped in:
  - Conserving city center's land value with expanding and Increasing of the public spaces with providing a high quality civic space that is suitable for flexible uses.
  - Improving the Air quality according to the traffic congestion Reducing. That provided also safe social and commercial environment.
  - Cairo has the highest concentration of historical sites in the entire world with supporting the shared road concept and many and certain zones Cairo can be open walk able museum. That will encourage the Tourism and will affect positively on the Economic Sector.
  - With encouraging the public transportation and enhancing/ upgrading its facilities inside city center that will reduce the using of the private cars and that lead to reduce the traffic congestion.

# ‘Urban Legend’ of *Wakaf* Cemeteries at Jalan Pangeran Antasari and Kemang

## ABSTRACT

This writing is a result of my analysis on seven *wakaf* cemeteries at Jalan Pangeran Antasari and Kemang. These cemeteries are facing some new developments: flyover and grandeur commercial place. Knowing there must be conflicts between people who retain them and developer who is tempted by the land, I try to look beyond functional matter of the *wakaf* cemeteries by questioning their existence for the people around them. I try to look what the cemeteries stood up for by searching the ‘urban legend’ that spreads around them and observing the spatial relation between them and the people. Eventually, this paper tries to explain that the *wakaf* cemeteries have special meaning to be looked for before massive developments annihilating them.

## Keywords

*Urban legend, wakaf cemetery, development, local culture*

## INTRODUCTION

Naming the street with one figure’s name is very common in a city, including Jakarta. However, some name is not known as important as figures in short of heroes or stakeholders. Some name, such as Haji Muhi or Haji Thalib, is a name without any big historical background. At the same time, near those streets, there are also *wakaf* cemeteries—a benefaction land for burial—which were mostly given by the important people: *Haji(s)*. “*Haji*” and “*wakaf*” are actually Islamic terms. In Islam tradition, there is a certain rule for wealthy people to give charity for poor people. One of the ways is to “*wakaf*”—to endow something “...which is dedicated in perpetuity to some pious or charitable cause” [1]. Usually the *wakaf* land’s status cannot be changed. It shall be maintained as what and how the giver wanted. Despite the fact about the land is potentially contested, some cemetery has even its own legend and sacred place no matter how modern Jakarta develops itself. This phenomenon also happens near Jalan Pangeran Antasari, South Jakarta. Facing the big development of Blok M- Jalan Pangeran Antasari flyover and the rise of commercial places, some *wakaf* cemeteries exist with their own entity. Some developer might see the cemeteries as potential property while the people keep maintaining it. Their status are in between—whether they can be functionally useful for the development if it was demolished or they can be something that makes the development restrained.

This writing is not trying to answer which one of the cemeteries’ status is the best. The fact that the *wakaf* cemeteries striving by the people living near it leads me to some questions: “what is actually the *wakaf* cemetery stood up for? Why is it so defended by the people?” By answering the question, it will lead us, especially urban experts, to know beyond functional matter of the cemetery.

Basically what I did to answer the question is observing seven *wakaf* cemeteries near Jalan Pangeran Antasari to Kemang. These seven cemeteries are currently facing the development of one of the biggest superblocs in south Jakarta: Kemang Village. At the same time there are also flyover project hovering Jalan Pangeran Antasari and the fact that Kemang itself was already gentrified by expats since long ago.

For this paper, I came to the cemeteries and tried to know how the people treat them (physically and non-physically) and if there was any ‘urban legend’ that had spread around them. What I mean ‘urban legend’ in here is a story, which is always told and preserved by the people about the cemetery without knowing whether it is authentically right or not, including the story of *haji* that gave them the land. Knowing the ‘urban legend’ of the cemetery would inform me what the cemetery represents for the people.

However, I would not report how the society reacts to the cemeteries in details. Instead of telling what they do when one of them passed away or how and why they pilgrimage, I aligned this writing by focusing on the spatial relations between the cemeteries and the people, the exclusivity of the cemeteries, and the story of *hajis*.

## ‘URBAN LEGEND’?

Before narrating the trip, I would like to explain about ‘urban legend’ first and why I use this term for the case. This term was probably first used (or at least famously used) by an American folklorist named Jan Harold Brunvand. In the introduction of *Big Book of Urban Legends*, Brunvand wrote, “Urban legends...are true stories that are too good to be true, and they are always said to have happened to a Friend of a Friend (or FOAF) [2].” In other words, ‘urban legend’, in Brunvand’s conception, is a kind of story whose main point is not the truth of it but how it is used by people to thrill another people.

Of course, Brunvand’s ‘urban legend’ represents urban life, especially in America, since many of his stories use modern phenomenon, such as automobiles, pets, sex scandals, etc., as the background or the topic. However, some ‘urban legend’ is actually ‘old’ legend which is told from one generation to another generation [3]. In other words, what changes in ‘urban legend’ from the old one to the new one is the context of time. Although the message of the story is still the same but the sense of ‘present’ is needed so it can be felt as something that happens presently near the people.

At the other hand, Koven in *Film, Folklore, and Urban Legends* also emphasized that ‘urban legend’ showed in films and other popular culture had some “motif spotting”—motifs or types of traditional narration which appears in popular films and television [4]. This also means that popular culture is important to look at to know what (urban) people believe or how they maintain their tradition in urban lifestyle. This also happens in Indonesia where many cinemas keep on showing horror movies. One of the most famous horror Indonesian movies is *Hantu Jeruk Purut*—“The Ghost of Jeruk Purut” (2006). Using Jeruk Purut Cemetery located at South of Jakarta as the background, *Hantu Jeruk Purut* is famously known with the character of headless priest. At the beginning of the movie some teenagers challenged themselves to explore the cemetery. Feeling disturbed, the headless priest sadistically killed them. At the end, the movie tried to show its message: do not disturb the ghost in the cemetery. I guess this is not the only movie which shows that kind of message, naming *Sundel Bolong* (1981), *Perjanjian di Malam Keramat* (1991), *Tusuk Jelangkung* (2003), *Kereta Hantu Manggarai* (2008), and many more which approximately show the same message no matter how old the story is—that the dead may not be disturbed and people should respect them or the dead may not rest in peace before they take revenge.

From the explanation above I can conclude that ‘urban legend’ is an unverifiable story that probably came from the past whose message is maintained by using contemporary media, including popular culture. Although popular culture maybe interesting to be seen deeper but in this writing I have to explore ‘urban legend’ in realm of urban space. Thus, the ‘media’ to maintain the story is represented in space where people usually refer to when they talk about it. Cemetery is, of course, the most popular place as the setting of the story. Since ‘urban legend’ is also presented in contemporary stuff, to observe it, then, is to see what presently has happened in the cemeteries and how they maintain what has become history. So, ‘urban legend’ in this paper is not about seeing what exactly the truth of the story is. Here, ‘urban legend’ is used to know beyond the place where the story emerged. This is a tool to gather information about what and how people believe in their urban life. It is important to be observed in urban design and planning realm because it also impacts on the urban space, including cemetery.

To know ‘urban legend’ of a place is also to know how the people make relation to the place itself from time to time. By walking through the seven cemeteries, I could get ‘urban legend’ which was told by people nearby. In other words I asked people what they think about the cemeteries and how the images of the cemeteries affect their everyday life. Some of them used and hid the cemeteries at the same time; some of them considered the cemeteries as what they belong; some of them thought the cemeteries was important because their ancestors buried there. I assume that ‘urban legend’ in this case is not only about the maintenance of some stories about cemetery but also the continuity of traditions and history of ancestors. Past, in here, is consequential.

## THE ‘UNSEEN’ CEMETERY

After knowing what ‘urban legend’ was, I was interested to observe some cemetery in Jakarta. It was because the frightening image appearing on the cemetery made me want to know the story about it –whether if it had impacted the cemetery as the space of the dead or not. I also wanted to know what the role of the cemetery in the middle of the rush of Jakarta modern living was. The seven cemeteries at Jalan Pangeran Antasari and Kemang became my choice because they were facing the hustle of new development.

Figure 1: The Seven *Wakaf* Cemeteries at Jalan Pangeran Antasari and Kemang

So I started my trip from Blok M terminal to Jalan Pangeran Antasari. It was a very bright day to take my steps on. Sadly, the sun could not shine fully on that long road because of hovering flyover. It was not yet ready but its shadow already darkened the space below it. I took a left-turn after seeing the district office. After walking for a couple of meters I found a junction. I was counting on my maps on the phone since I had not been at the destination. “Makam Bank” was written on the map and according to it I had to turn right to get to the cemetery.

Makam Bank was located next to an elementary school and surrounded by houses. Like other six cemeteries, Makam Bank had physical boundary: brick wall about 150 meters surrounding the area. From the outside we may not realize there is a cemetery behind that wall. All we could see were just top of trees. But this isolation did not mean that the people living there did not take care of it. There was a *gubuk*—a very simple small shelter from wood—for cemetery guardians to take a sit or a break so they could get comfort while doing their job. At the other part there was also a box with words written on it: “SUMBANGAN UNTUK MAKAM WAKAF” – “CHARITY FOR THE CEMETERY”. So I warded my hypothesis that the cemetery was not considered as something important by the people. The wall was not a mere solitary cover to separate the living with the dead.

I continued my journey to another cemetery nearest Makam Bank: Makam Kemang Raya. It would take a long walk that I decided to stop a bus. About five minutes had been spent to reach the cemetery with bus but punctiliousness was needed because there was no specific sign that marked it, except a black small gate. There were two men with their vendors in front of the gate. According to them the gate could not be opened and the only way to reach the cemetery was to get in from another gate. So I brought myself to another way to find the gate.

The other gate was behind one of the most famous restaurants at Kemang. The smell of food from the kitchen was lingering when I brought my step into the cemetery. It was still look alike Makam Kemang which had only trees and burials. But at one part of it there was a small building which was clean and with proper rooftop. Apparently it was the sacred burial. I asked a man nearby whose burial was that. He did not know that but was pretty sure it was considered very important by people around there and suggested me to not ‘disturb’ it.

After wandering for a while at Makam Kemang Raya, I ran on my trip chronologically to Makam Kemang Selatan, Makam Haji Thalib, Makam Bunga Cempaka 3, Makam Bunga Cempaka 1, and Makam Bunga Cempaka 2. Although Makam kemang Selatan and Makam Bunga Cempaka 1 were located near busy street, both of them were not differently treated like the other cemeteries: they were surrounded by wall.

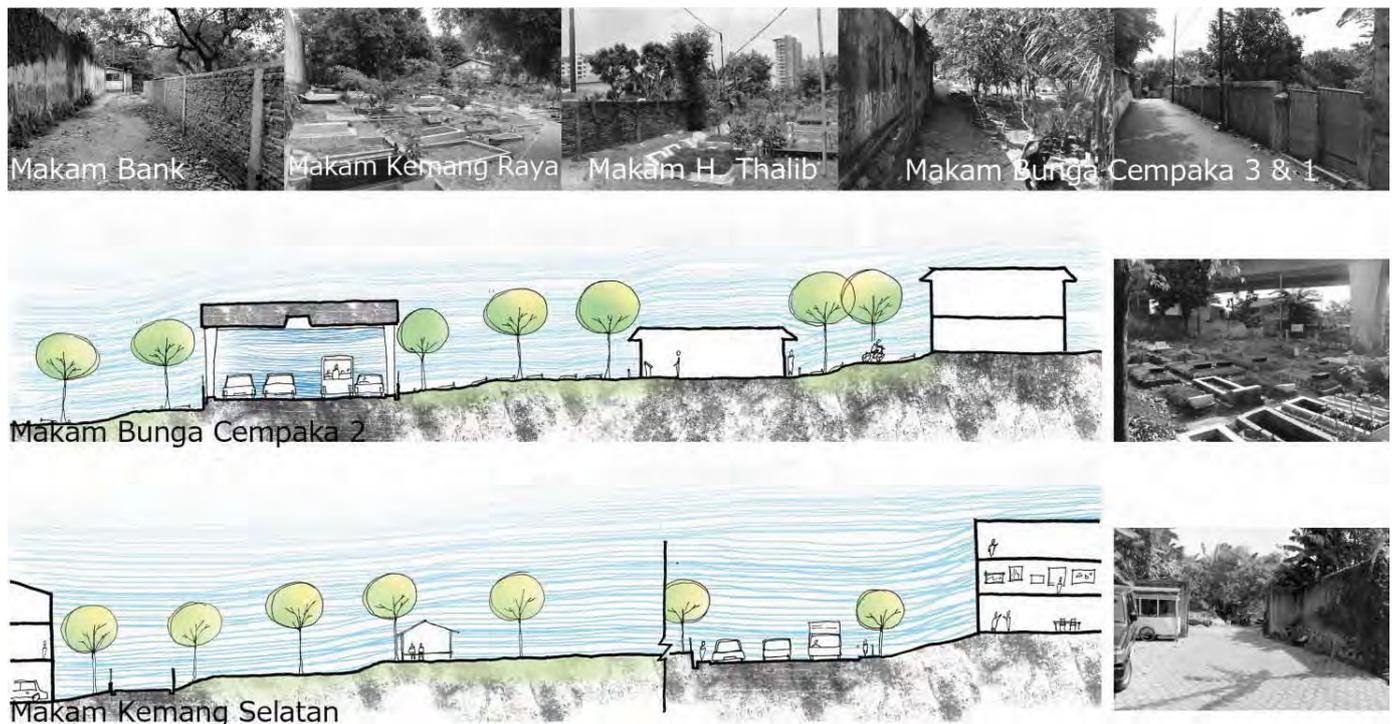

Figure 2: Surrounding by the Wall

The tendency to make a clear separation between space of the dead and space of the alive was always be there. However, people could not actually be apart with death itself. They still had an obligation to come to the cemeteries to pilgrimage or pray at the sacred burial. Thus, people surrounding the cemeteries tended to consider them as meaningful places.

At the same time, looking at how the burials set up, the cemeteries were not designed as something significant or monumental. They mainly emplaced spontaneously so that the orientation was not the same. There was no landmark or sculpture marking the place either. Makam Kemang Raya was the only *wakaf* cemetery I observed that had a specially threaten building for the ancestors. Still, a small simple building that looked like a house did not make any significant physical statement for its surrounding.

The seven cemeteries were also surrounded by settlements and commercials. It pointed out a sense of closeness between the dead and the alive. Paradoxically, the people seemed did not interest to make the cemeteries grandeur or physically standing out, yet they knew the cemeteries were important on behalf of their past time and cannot be separated with their everyday life.

## THE EXCLUSION

The absence of landmark could not obviate the distinction between space of the dead and space of the alive. Regarding to what I have explained before, Michelle Foucault once wrote about his conception of 'other space' that he called 'heterotopia', "Everyone can enter into these heterotopic sites, but in fact that is only an illusion—we think we enter where we are, by the very fact that we enter, excluded [5]". Any cemetery always pushes us to do certain gesture which makes us feeling excluded—instead of feeling like entering public space, coming into a cemetery is more like going into a private space. However, at the seven cemeteries, the sense of exclusion did not only make the visitor, especially an outsider, do certain gestures. It was not only about coming into space that had different nuance from its surrounding. It was more like entering a place that guarded by its surrounding. Unless we really familiar with its surrounding or people that lived around it, we would feel the exclusion.

The sense of exclusion assumedly came up because of the activity around the cemeteries. Some of the cemeteries were used for informal gathering and social interactions, such as Makam Bunga Cempaka 2 and 3. The others were not used like that but not far from it there were people gathering around. The cemeteries were indirectly guarded by them. Even though we knew the cemeteries could be entered easily but an urge to ask permission would usually come up.

The seven *wakaf* cemeteries, not like formal cemetery, were more private. They were only used for certain (dead) people. Makam Bunga Cempaka 1, Makam Bunga Cempaka 2 and Makam Bunga Cempaka 3 were managed by one foundation named "Yayasan Bunga Cempaka". So were Makam Haji Thalib (managed by Yayasan Fatahillah) and Makam Kemang Selatan (managed by Yayasan Al-Ihsan). Those five cemeteries could only be used by the foundation members. Makam Bunga Cempaka 1 even had more specific rule: only inheritors allow to be buried in there. That was the same rule with Makam Kemang Raya's. Meanwhile, Makam Bank was also used only for certain people although it was not managed in one foundation. Basically the people nearby who managed it. They also paid some charity for it. In other words the connection between the cemetery and the people could be long lasting because of the sense of belonging. Hence the seven cemeteries did not only exclude other 'community' or outsiders but were also maintained to keep what belonged to the community.

In an interview, the headmaster of Madrasah Ibtidaiyah Al-Ihsan gave his opinion about the excluding rule of the *wakaf* cemeteries, "if I give you something, will you share it freely to other people?" After explaining that *wakaf* land was usually given by *haji* as the important figure for people around him, he mentioned that the cemetery could only be used by people nearby as what the *haji* had wanted. Of course, there was an exception for indigents who had no relatives.

The exclusivity that people originally from near the cemeteries had would restrict their 'movement'. Because of the land that was given for their future sake, the people tend to live long time nearby or go back to where they come from after wandering outside their homeland. Moreover, most foundations facilitated their 'native' members with education and house for orphans. The price for the burials was also cheaper than public cemetery's so that the people felt helped by the foundations. This also affects the hierarchy of the society, which was mostly lead by the inheritors of land giver—the *hajis*.

## HAJI(S): LEGENDS ON THEIR OWN WAYS

So who are these *hajis*? “*Haji*” is the Indonesian word of “*Hajj*” which means “one who has made the pilgrimage to the holy city (Mecca)” as accomplishment of the fifth pillars of Islam [6]. In this case, *haji* is not a mere title but also a person that had taken important roles at the past and had specially been known for his abroad knowledge. Mostly they had been rich so that they easily gave their land for public facility, including cemetery. There were several *haji*'s names which were mentioned in my interview with some ‘caretaker’ of Makam Haji Thalib. One of them said that in 1970s Haji Abdul Majid gave his land, including the land for the cemetery and the street near it. At the other part, the head of Yayasan Al-Ihsan said that Makam Haji Thalib was given by Haji Kholid who was very knowledgeable. So many names of *hajis*, people nearby did not really know who they were and which one gave the land. But the head of the foundation was actually keeping the picture of Haji Kholid itself since the *haji* himself was his father. He also said that the students who had been taught by Haji Kholid often did pilgrimage to the cemetery and he also encouraged his followers to do the same. Which cemetery to be came in exactly –makam Haji Thalib or Makam Kemang Selatan that was near it too? I don't know for sure due my lack of time for this observation.

Meanwhile, at Makam Kemang Raya head of the neighborhood nearby said the sacred burial belonged to a Syekh—an Arabic term meaning “leader”[7]. The Syekh was his ancestor. He believed the Syekh's spirit would protect the neighborhood. Thus, people kept on coming and praying at the sacred burial before celebrating some events, such as wedding. But Syekh himself was not really famous. Even head of the neighborhood's son did not know his exact name. Though, he warned me to be respect to his burial.

Figure 4: The Sacred Burial at Makam Kemang Raya (left) and Activities around the Cemeteries (middle and right)

Presently, new generation did not know for sure who Haji Kholid or Syekh were. They knew there was someone who once owned the land and generously gave it for people's good. But some of them still do the tradition of pilgrimage, not in memorizing what the *hajis* had done, but more like to respect the spirit whom they believed could protect them. Indirectly they saw the burials as entities that connect them to God yet it became their precious to be kept on. They also became the reason to restrain the land from developers. By showing the legal letter, which told that the land was given by the hajis, people knew the developers could not do anything to grab it.

It seemed *hajis* (and syekhs) were indeed infamous legends that had their own ways to be known. One of them was giving some space that can be used and maintained by people to pray for them. As there were plenty of foundations establishing public and education facility, endowing some land became a way that should be emulated. And this way, I believe, would be done from one generation to generation.

## NO CESSATION FOR WAKAF CEMETERY

Seeing through the ‘urban legend’ of the seven cemeteries made us now that even a simple search like that can collect much information about the existence of *wakaf* cemetery:

1. The ‘unseen’ part of the cemeteries telling us how people tried to make a clear distinction yet they cannot live apart of it. The cemetery is still connected with their everyday life. They know it, walk through it, maintain it, and even use it for gathering. The wall then is just an announcement to separate which space is for the dead. But it only happens to people who live around it. For outsider, the wall is clearly a statement to make exclusion.

2. Generally, *wakaf* cemetery is usually maintained because of the rule in Islam restrict them to do so. Looking back on the observation, this rule eventually made the people consider it as something that belong to them. The *wakaf* cemeteries are stood up by the people in a sense to maintain their identity. Its entity became a statement to exclude whomever that did not belong there. At the same time, some burial is believed as the elongation from God so that it can be the center of blessings. That is also why the people defend it. Community needs it to maintain what they think that belongs to them. But this conclusion also has weakness because ironically not all of the people surrounding the *wakaf* cemetery intentionally pray or pilgrimage. I might say it is an indication of minority struggling which only some community still tries to retain what they have. Kemang itself is used to be (or still be) lived by many Betawis [7] who mostly believe in Islam. This fact probably impacts the way of the people to treat death since Betawi culture is more concerned in taking care of the dead than of a new born baby [8].
3. The foundations take important role in maintaining and keeping the *wakaf* cemeteries. This is not only by taking care of the cemeteries but also by giving the people education about their religion which can give them knowledge about *wakaf*. At the same time, the people may not know every personal of the *hajis* but they know that being a *haji* is good. The foundations can give a kind of opportunity for the people to know more about *haji*. Hence, the 'urban legend' of *haji* can be well spread.

The *wakaf* cemetery cannot be said as a civic space—in term of public space where people can come together to discuss their idea, like Agora in Ancient Greek. Nevertheless, it actually accommodates public activities. It is the extension of the community to preserve their past and to develop its tradition. If it works well then it can be the characteristic of the community. Therefore the big development, such as Jalan Pangeran Antasari Flyover and Kemang Village, cannot abruptly cease them to exist.

What I have done is just first step to take notice about one of urban phenomenon in Jakarta. There are still many more things on *wakaf* cemetery to be observed to enrich the study of urban planning and design; such as how *wakaf* cemetery can be valued as a property of the people or how *wakaf* cemetery impact the city. In other words, further study is highly recommended to do.

## ACKNOWLEDGMENT

Work on this paper was supported by Department of Architecture, University of Indonesia. The author thank Evawani Ellisa and Herlily for comments on earlier draft of this writing; and Amri Mahbub Al Fathon for discussions that encouraged the idea of it.

## Women's Space of Activities in Slum Areas: Territories and Negotiation

Nur Fatina Risinda<sup>a</sup>

Department Architecture, Faculty of Engineering, University of Indonesia, Depok 16424  
E-mail : indarisinda@gmail.com

### ABSTRACT

As part of society, women who lives in city's slum areas, usually didn't get much attention about their existence. When we talk about their roles in slum areas, actually these women have three roles. The triple roles is reproductive role (domestic role), as they should do the housekeeping and take care of family; productive role, as primary or secondary income-earners to help her husband; and social role in community management (Moser, 1988; 1993, cited in Miraftab, 1995). Women in slum areas are special because she must live under limited resources and bad condition of settlement. They must face the family structure too, as in system patriarchy in family, man is the dominant one. This affected their own space to do all their activity. But this women still can use their space effectively and efficiently. They even can merge the boundary of their space very naturally. So with qualitative approach, ethnographic and mental map method, this research want to figure out their process of making this space, and how this women make interaction.

### Keywords

*Women, slums, space of activities, territory, negotiation*

### 1. BACKGROUND

Slum areas is one type of settlement that usually exist in big cities or even in suburban areas that had been caused by city's unpreparedness to accommodate the need of settlements since the population is getting bigger because of urbanization [1]. Slum areas has definition as overcrowding, poor or informal housing, inadequate access to safe water and sanitation, and insecurity of tenure [2]. But from this definition, there is a tendency to see the slum areas based only on its physical condition, whereas actually there is a lot of events and actors that involve, such as residents, merchants, children, local authorities, men, and of course women. Women become an important topic as one point of view to see and understand the slum areas, especially from gender view. This is not only because women are part of the society, but also because there is many artifacts of women's activities, starts from inside their houses to the outside, the public areas.

One evidence that can prove us that women has important roles in slum areas is an article that tell us the story about women that trying to protect their house from eviction and she's got beaten because of that [3]. But Miraftab (1995) said that sometimes women's condition in slum areas and the importance of their house as their survival place usually being forgotten [4]. That is why sometimes there is misconception of the government, usually in developing countries, to make rules or development that actually did not match with what women really need [5].

This happen too with the space that women use. Spain (1992) said that there is gender dimension in space that society made, especially in patriarchy culture which said that women already had their own roles and it is a domestic roles, childbearing and do the house keeping [6]. This make women be gendered as someone that usually at home, whereas outside the house or public space is men's space (masculine), because men is the one who work and find the resources [7]. This will be different with women who lives in slum areas and lives under bad economy condition.

Suparlan (1996) said that slum areas reflect the people who live there [8]. In this case that is the poor people. Poverty made women that live in slum areas should face the truth that their roles not only inside their house. Moser (1987) said that actually women in slum areas have three roles, not only do the activities relate to domestic or household tasks associated with children and family (reproductive), but because their husband's wages can afford their daily needs, these women should work to help her husband (productive), at the same time, this women have responsibility to take care the society too (community management) [9].

Here comes the conflict between the roles that women have, that makes women only can stay inside the slum areas, whereas they should face the limited resources and space there [10][11]. These women have their roles and activities, and this needs spaces. Where slum areas have only a limited space, it shows us that there must be another person who needs the space too, in this case that is the men or their husbands. So when there is some kind of room division by gender, it considered as a constraint

for women to easily do their roles. But Ostergaard (1992) said that women will make adaptation so the limited space in slum areas can still become their space of activities. This space is an adjustment of their activities and their family, so they still can focus on their family too, and they can do it under pressure or bad condition [12].

If it said from gender view that space inside the house is feminine space and outside the house is masculine space, then when there is a liminal zone like the front door, or there is fusion of boundary of space, it must something happen between people who lives inside the house. This fusion can show the position in the family and members' own space requirement. This space requirement leads to a territory, or as Storey (2001) said as the area that claimed by one person, or group, or even big institution like country [13]. Territory is bounded space, so when there is a boundary fusion, it means one person meet the other and then have their on way to make that fusion, and so about these women's space of activity.

## 2. STATEMENT

The boundaries of women's space of activity related to the concept of gender between man and woman in the family, and about their position especially in patriarchy system [14]. But before that, there is difference about concept of sex, gender, and feminism. Sex is how to differentiate man and woman based on their vital organ, by their biological form. Gender is a stereotype that made by social and culture norms about personality, behavior, characteristic between man and women that usually determine society opinion about man and woman, and it then become a social control [15]. Feminism is a concept more like a politic view, because feminism involved 'taking sides', especially from women side, that there should be equality between women and men [16]. Gender view is more about rights and responsibilities of women than judging what women should be.

As women should live with men, in this context as wife and husband, there must be space requirement as what they need. When this condition met the limited resources and bad condition in slum areas, it then results a negotiation and agreement than finally forming their space territories. For women who live in slum areas, this negotiation can make them didn't look like as an exploitation here, that they are not passive [17] because negotiation process concerned of agreement decision or the position of the decision making in the process of forming the boundary and territory of space [18].

So, if these women in slum areas have needs of space for their activities and they can make it as what they need, either inside their house or even it can be expand from their house (feminine spaces) to their alley, street, or another public spaces (masculine spaces), then it means this women can blend their need of space with their husband's need of space. In this case is with negotiation. So from that, we can say that the slum areas maybe reflects these women's roles and activities so clearly.

To prove this statement, the main question is about the process of how these spaces are made. Then research start from questions like how is the relation of these women and their husband in their daily life, what is the need of space for these women and their husband, then relate it with space that already exist in slum areas. Then what kind of negotiation that happened there, how can it give influence to their need of space and existing. Of course researcher will observe who is the actor and the hierarchy of them (family structure), and when and where this negotiation usually takes place. What kind of territories were made as a result of this negotiation, how about the boundaries, is there any transformation or not, what kind of transformation that happened.

## 3. METHODE

For this research, researcher will use ethnographic methode, especially about space ethnography. Ethnography is one of methode to do qualitative research. The goal is to capture poeple's point of view about how they interact each other, and the point of view with their world and surrounding (like vision, hearing) [19]. Ethnography also capture people's social interaction, behaviour, and perception that happen within a group, organitation, or communities [20]. Ethnography is about learn from people, not to studying people [21]. There are nine points that should be learned from people : space, actor, activity, object, action events, time, goal, and feeling [22]. From this nine points, researcher try to look how informant, in this case is women, use and form their own space of activities.

The research start with finding the location, and then finding the informants, and then do the participant-observation with the informant to capture how they make and use their space, by follow the informant a whole day to watch their daily life. Informants are women who live in slum areas that will become the case studies. Approaching include the pre-observation with the informant, participant observation, and writing ethnographic field notes. In pre-observation.the reasercher will make a permission to the leader of neighborhood and then find the informant. With the informant, which is women who already married and their age around 25-60 years old, the researcher will introduced herself and this aim of research. The main point of

this pre-observation is asking permission to the informant that she will become researcher’s informant for at least 1 month and then the researcher will enter their activities to learn what really happen with their space while they do their activities.

After that, the researcher will do the participant observation. It means the researcher will take participation in informant’s daily life, build good relationship with the people in the setting, and observe everything that happen while do the observation [23]. With this methode, researcher hope to find how every palce in slum areas is really important for women, as slum areas is the place that this women already made for their activities.

#### 4. CASE STUDIES

Case studies location is in RT 11 and 15, RW 10, Kelurahan Bukit Duri, Kecamatan Tebet, Jakarta Selatan. From geographical context, this location have been chosen because it is the poorest area in the area RW 10, and it is located exactly in the Ciliwung riverbank, so when rain season come, this location get easily drown by flood (up to 2 meter or more). Because of it, the condition of this area is so bad, especially about sanitation and drainage. Most of the building here is not really have formal land tenure, because it is located in riverbank which is owned by government, so they just pay tax for the building, not for the land. RT 15 has 450 people, whereas RT 11 populated by 500 people, with the ratio of women and men is 50:50.

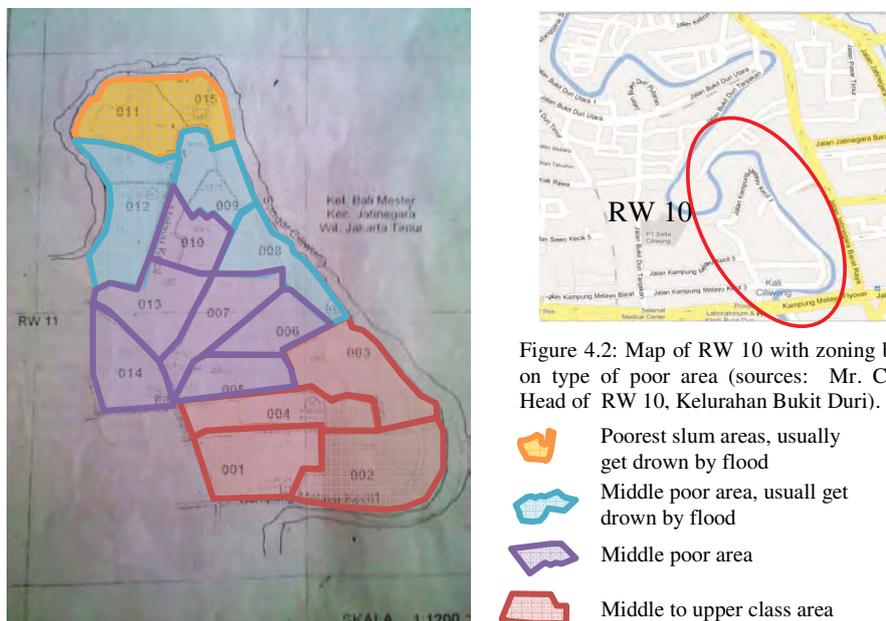

Figure 4.1: Map of RW 10 from ‘google maps’

Figure 4.2: Map of RW 10 with zoning based on type of poor area (sources: Mr. Cecep, Head of RW 10, Kelurahan Bukit Duri).

- Poorest slum areas, usually get down by flood
- Middle poor area, usuall get down by flood
- Middle poor area
- Middle to upper class area

For the specific site, RT 11 and 15 are shown by the orange color in picture 4.2. This area is the poorest area based on Bappeda DKI Jakarta Government standard (1997). This areas located in the lowest land of RW 10, while in upper land is middle to upper class settlement (red color in picture 3.2). This is related to women who live is RT 11 and 15, that as an adjustment of distance of their three roles, they work not far from their house, as in both RTs, there’s some women who work as a part time housemaid in another RT which is middle and upper class settlements in RW 10 (red area in picture 3.2). The other women work in home-based work, like small *warung* or small home industry that they own themselves. Only small number of women works as employer or work in office or department store, but some of these women work as seller in Jatinegara market. This is show us how these women, at the same time should help her husband to find the secondary resources or maybe the first one, but they still meet conflict with their roles and their space of activities. This is the main reason why the researcher chooses the location as case studies.

Figure 4.3: condition in RT 11 and

For this research, researcher will choose informant that is work and married. They must be still live until now in the location of case studies and already familiar with the culture in that location. One more important point is because my approach is participant observation, so researcher should make sure that informant agree to become this research informant and have time to be involved in this research.

## 5. FINDING

Actually as a pre-observation, researcher had already made some observation for under graduated thesis in location of study case with 10 women from RT 11 and 10 women from RT 15. As a pre-observation, researcher tried to learn about the daily life of informant and their house especially their typological functional spaces. Researcher try to learn how is the condition of space that already existed in slum areas especially in these women house. But for the explanation in this paper, researcher as the writer will explain two informants that has job and is married.

Theses example of women life in RT 11 and 15 relates with Moser's theory [26] about women's triple role: reproductive, productive, and social management as Miraftab said [27] that women in low-income family who lives in slum areas not only have a big responsibility to take care their children and family, but also as someone who find money for family daily needs. But what makes the pre-observation unique is women that usually work, do not really like to go outside their house after they come back from working. They prefer stay inside their house to rest than go out and meet the other women. But it doesn't mean that they are introvert, because they still connected with the other women by open their house door.

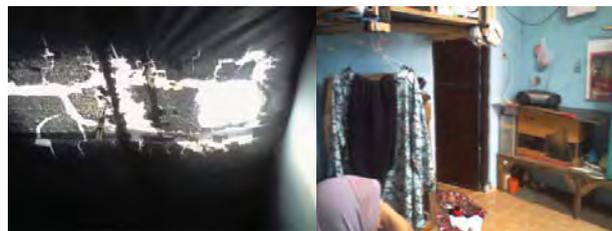

Because building condition in slum areas is usually crowded, just open the door still can make the women inside the house see their surrounding easily, and still keep her eye to watch their children while their children are playing outside the house. And because the door is open too, women who love to go around the neighborhood can come and share the story there. Like what happen to one of informant, named Mrs. Jml. She always open her front door to make people come and watch television together, while she still can rest inside her house.

The fact about inside and outside the house can be connected just by open the door and so the women inside can chose to stay inside but they still can socialize themselves is connected with what Arendt [28] said that balanced laboring body and laboring head will determine the quality of human's life. That is why women who work do not really like to go outside their house, because they use their house really well to re-product their labor so they can do the work. It makes women's roles so important because they must do the reproductive activity and do the productive activity, but at the same time, while they do the reproductive activity is for preparing themselves for doing the productive activity.

From observation in Mrs. Jml's house, it is known that the most of the room in her house is under her control. Like the living room, where a television is there, this is a place where she prepare her snacks and cakes too. After moving around her neighborhood (RW 10) to sell her cakes, she will stay in this room to watch television while resting. Because she opens her front door that directly connect to living room, her neighborhood or another women can come and watch television together. Her position in house reflects in her 2<sup>nd</sup> floor too, as she is the one who design the 2<sup>nd</sup> floor's roof to be changed by some kind of transparent materials so her 2nd floor can still bright without electricity (to reduce electricity cost)

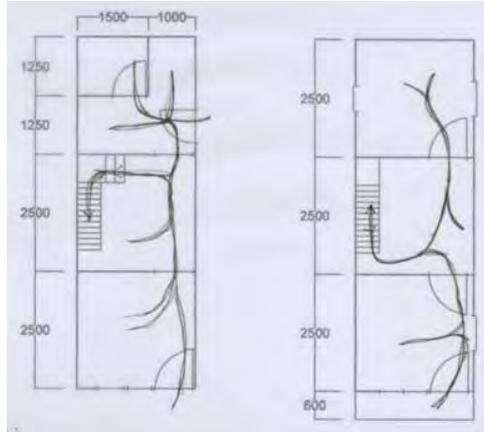

Picture 5.1 Mrs. Jml's living room

Picture 5.2 Mrs. Jml's 2<sup>nd</sup> floor's roof (left) and the effect of material in the room

As women who works in her own home-based work, it shows clearly how the house shows her position in the house and family. If we relate it to her husband, it relates how her husband is very seldom come home, because husband works as truck driver in expedition to another island that usually travel a lot. When her husband come home, he will spend most of his time resting in bed room, and the next day, he will go to work again. So that is why her control of her house is big because her husband did not really pay attention of what happen inside the house, and because Mrs. Jml is work too and use her house as the place where she can do half of her work, she has most authority to make her own territory.

Her son is one of her family member who already can earn money, so inside the house, he has his own territory too, that is his bedroom. But when he goes to work, his room is part of his mother space too, to do the house cleaning. That is why, Mrs. Jml movements is not so intense as in 1<sup>st</sup> floor (picture 5.3).

Picture 5.3 Mrs. Jml's movement inside her house in 1<sup>st</sup> floor (left) and in 2<sup>nd</sup> floor

Another interesting story is about the slope stair and the small space under it. Women in the site usually use a small space under or near the stair to become their space of activity. It shows us that even though they only have limited space available in their house, every small space inside the house can be used as space of activity.

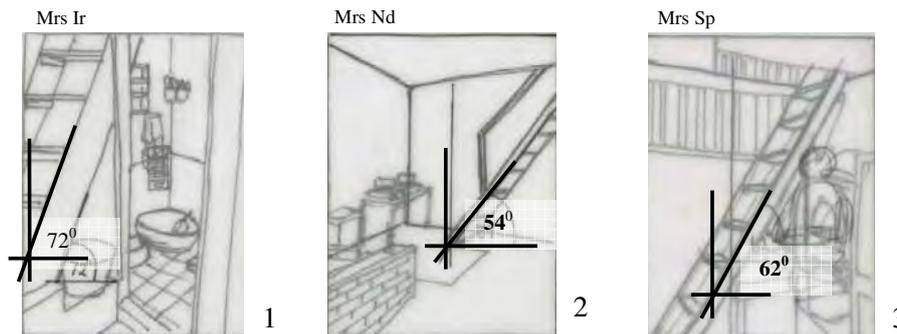

Figure 5.3: Some sloppy stairs inside informants' house: bathroom under the stair (left), bath room near the stair (middle), kitchen under the stair (right)

Most of informant uses the space under the stair as they kitchen or bath room, so even though the space for them to cooking only small space, but still they can do their roles as someone who prepared the food for family and even though there is only small space left inside the house but they still can use it as useful space.

Same as kitchen, some informant prefer bath room inside the house for bathing than they should do it in public toilet. One of informant, Mrs. Nd said that when she married with her husband, she got part of her parents-in-law's house that had been divided for her husband and her. Because it's only part of a whole house, there is no bathroom inside it. But because Mrs. Nd works as one of employer in handicraft industry that usually make the craft in their house (not in some kind of factory), she usually stay inside the house, she asking her husband to make a small bath room inside the house, so her husband make her small bath room inside the house. This is showing us how negotiation can take a role in decision making about space inside the house.

In this case, patriarchy that means man domination happen as Mrs. Nd's husband then make her bathroom, it is his responsibilities as man has a power more than women to do hard work. But when Mrs. Nd asking about the bath room, is a moment where women too can show her existence to openly show her opinion, that she needs private room to do the laundry, clean the dishes, and of course clean herself, and so she ask her husband about it, and her husband agree to make it inside the house.

## 6. CONCLUSION

From these two stories of the informants, we can see that women in slum areas, especially who is work and married, has a high position in spaces in slum areas, especially in their house. For example Mrs. Jml, can get this authority to merge the boundary because her husband rarely in their house, so Mrs. Jml exist with good position in house, so she can expand space inside the house to outside the house. Different story from that is about Mrs. Nd that needs bathroom inside the house, so she made a negotiation with her husband as the one who really own their house to make a small renovation, so they can have bathroom inside the house, and so Mrs. Nd can do reproductive role (washing and cleaning) and do her productive role (work) easier than she should go to the public toilet. This negotiation leads an agreement that her husband agree to build small bath room inside the house. This process show us that as head of family, husband in patriarchy system, have a big authority of what should have been in family, including space divided inside the house, but this case show that woman also has big position as the one who has activity inside the house and neighborhood more that the man, so when Mrs. Nd as a wife told something to her husband her need of space, she can negotiate it to get what she needs.

Beside these two main cases, actually there is a lot of story from other informants, but these two cases can be the first example before the next research that can show us how space inside the slum areas made by a big participation from women activities, as they are the one who spend most of time in this settlement. As sometime we realize in crowded settlements, there is a place such as security's post or head of neighborhood's house as the place where men usually meet each other and make interaction, there must be a big space and place inside the settlements that show how women also have big position in this community. And for the conclusion, it makes women is an important part of slum areas that of course should not be forgotten.

## ACKNOWLEDGMENT

This paper presented for all women that already become very good informants, very good teacher for this research. Thank you for my professors, especially Ms. Ir. Herlily, M.Urb.Des and Mr. Dr. Ing. Dalhar Susanto for helping me and always assist me from the start. Thank you for Mr. Cecep, head of RW 10; Mr. Husein, head of RT 15; and Mrs. Rahmawati, head of RT 11, for all the permission to do this research. Thank you for my parents, my sisters, and my brother that always support me. Last but not least, thank you for all of my friends that always stand beside me and always give me support.

## Developing Squatter Kampung, a Political Resolution Case Study Kampung Lio, Depok, Indonesia

Antony Sihombing<sup>a</sup>

<sup>a</sup>Department of Architecture, Faculty of Engineering, Universitas Indonesia  
 a.sihombing@eng.ui.ac.id

### ABSTRACT

Urbanization is the main trigger to the emergence of squatter kampongs on spatially and environmentally fragile area. Characterized by filthy, dense, and unhealthy, the illegal kampongs can pose as anaesthetic problem and a treat for environmental damage for the entire urban area. Without adequate financial ability and knowledge, the low-income communities that live there really need some helps from other such as the government in improving their environment. In other hand, the government shows a big concern in helping environment improvement in squatter. One example is the government of Depok City, Indonesia, that forms a partnership with the community of Kampung Lio to improve the infrastructure and environmental condition of the illegal kampung. It based this paper to question of 'why the government has the willingness to help the arrangement and improvement of squatter kampongs?' To answer the question, this research is done by interpreting the results of literature review and precedents study on investigating the conditions of Kampung Lio. People of Kampung Lio have citizen identity card and have the right to vote on governmental elections, which make them feel important politically and give the chance to ask for helps from the government. The helps come in the form of partnership, where the community can be actively participated. The Depok City government gives fund assistance, while the community of physically involved in the environment improvement activities. In helping the community of illegal kampung, apart from the social motive to help the poor, political motives are the main reasons that the government has a willingness to help the people of squatter kampongs. The government has the responsibility to provide the proper kampung environment for all its citizens. Also because a good quality of kampung environment, especially for the poor on squatter is a political subject that can be used to measure the success of a government.

### Keywords

*Squatter kampung, partnership, low income community and government*

### 1. INTRODUCTION

High rate of urbanization that cannot be accommodated by urban capacity is the main trigger to the emergence of squatter kampongs in Indonesian urban area (Robie, 1986) [1]. Based of legality aspect, Sihombing (2007) explains that *kampung* consists of two settlement, which are legal and illegal (squatter) settlement. Legal *kampung* is spontaneous settlement that built on the legal land has certificate of formal land published by government. Meanwhile, according to Sihombing (2010) [2] squatter *kampongs* (illegal *kampongs*) are usually built up on spatially and environmentally fragile area, without legal ownership on the land. Squatter settlement is settlement occupying the prohibited land, e.a.: the coastal zone, water catchment area, lakeside, riverbank, marshland, and undeveloped green belt area. This research is done in squatter *kampung*.

A squatter is characterized by filthy, dense, and unhealthy *kampung* and these conditions can pose as an aesthetic problem and a treat to health of urban environment, and also becomes vulnerable area for many crimes to take place (Gouri & Abdullah, 2005) [3]. The communities that live in squatters are usually low-income communities with unorganized and undisciplined lifestyle, with low awareness on environmental hygiene and health (Gouri & Abdullah, 2005) [4]. These lifestyles make the squatter to be disaster prone, such as flooding, fire and environmental damage. With the limited knowledge and low income, the squatter communities really need some helps from other parties such as industries and government in improving the quality of their kampongs.

In other hand, the government with consciousness of its limitation in providing legal and proper dwelling for all citizens, especially for the communities of squatter kampongs, shows a big concern in helping to improve the quality of environment in squatter *kampung* (Brueckner & Harris, 2009) [5]. One example is what the government of Depok City does in Kampung Lio, by forming a partnership with the community there to improve the infrastructure and environmental condition of the *kampung*.

Kampung Lio is a squatter that locates on the edge area of 'Situ Rawa Besar' lake, Depok City. Although it is an illegal *kampung*, but the Kampung Lio community still get the help from the government of Depok City to improve the condition of their settlement environment, in the form of partnership between the government and the community. The government gives fund and planning concept, while the community actively involved in supervising, and physically involved in environmental improvement activities. Based on the government and community partnership that happened in Kampung Lio, this paper aims

to answer a question of 'why the government has the willingness to help the arrangement and improvement of squatter *kampungs*?'

## 2. RESEARCH FRAMEWORK

### 2.1 Research Methods

This study begins with a literature and precedent reviews related to partnership between the government and squatter community, including the roles of each party in environment improvement of squatter *kampung*. Then, the study focused on the government's role in the partnership, to figure out the reasons why the government, as a legal institution can have the willingness to help improving the environment quality of an illegal *kampung*.

Based on the research background and objective, this research was carried out by investigating the physical, environmental and social conditions in KampungLio, related to the partnership between the government and the community in environment improvement. Information collected with a qualitative approach, which was selected based on an understanding of the qualitative approach that can be applied to examine the meaning and process of human activities. In this case, to study the meaning and the process related to the efforts of the government in improving the quality of squatter *kampung*, with active involvement of the community. A qualitative approach, according to Wang (1954) [6] can be distinguished on three ways of research, consists of grounded approach, ethnography and interpretation (*interpretivism*), and this research specifically was done with interpretivism approach.

Geertz in Wang (1954: 186) [7] reveals that the interpretation approach is done by reading and interpreting the processes of human activities, assuming that social facts are real objects. The result of literature and precedent studies about partnership between the government and the community of squatter *kampungs*, as well as the motives behind the helps that government give to an illegal settlement, will be interpreted on the condition in KampungLio. This will be the basis in answering the research question 'why the government has the willingness to help the arrangement and improvement of squatter *kampungs*?'

### 2.2 Learning From Literatures

In practice, a partnership involves the relationships among authorized parties (stakeholders), with their own distinct interests, which led to the need for an arrangement or 'managerialism' in partnership activities (Turner, 1976) [8]. 'Managerialism tripartite' theory proposed by Turner who see a simple way to divide the parties involved based on their role in three groups of activities in the implementation of the partnership, those are planning, construction and management. While based on the actors, Turner categorized participating in the partnership, into three sectors (tripartite), those are popular sector (community) as user, the commercial sector (private) as a supplier, and the public sector or the government as a regulator. Community is the most important sector, because it is the party that will directly feel the results of the partnership. The active participation of the community will determine the quality of the partnership in order to fit their own needs, which in this study focused on partnership in improving the quality of a squatter settlement.

According to Arnstein (1969) [9], 'community or citizen participation' refers to 'citizen power', it means that in an order of a social life and governmental institution, every citizen has an important role politically. The 'citizen power' is formed, because every citizen has a role as supervisor and controller, beside as the consumer of governmental policies. The citizen will make sure that the government makes the right decision in creating public policies and fund expenditure in the sake of social justice for the community. In democracy countries, where the leaders are directly elected by the community, every citizen means a lot to give one vote. Because the political role, the government cannot ignore its responsibility to the community, including the responsibility to provide proper settlement environment for every member of the community that occupies both legal and illegal settlements.

Habraken proposed the concept of 'support' and 'infill' to describe the partnership relationship between the government and the community in providing proper settlement (Habraken, 1976) [10]. 'Support' is provided by the government, such as roads and utility networks infrastructures, from regional to neighborhood level. While the community "infill" the public infrastructure, by building their own dwelling with or without the help of others. The community also has the role to maintain the infrastructure provided for their own sake. An active involvement of community in this 'support' and 'infill' concept is to make the result of the development, especially in settlement improvement process, will be suitable with the final user, which is the community itself.

### 2.3 Learning from Other Countries

The debate about the relationship between the formal and the informal sectors in developing countries like Brazil, still focused on how creating an appropriate legal framework, considering the problems encountered is the growing of illegal settlements in urban areas, such as Pavao-Pavaozinho, Rio de Janeiro, Brazil (Elisabeth, 2012) [11]. Government with its limitations cannot legalize the status of the settlement, caused residents of the settlement automatically becomes the second grade community in acquiring public services and facilities. With its rundown condition, the illegal settlement also becomes a hotbed for distributing narcotics and other criminal activities such as fighting and killing. This shows that without adequate and legitimate

dwelling, residents of informal settlements are limited to obtain justice in access to facilities, services, public safety and comfort, as they should be.

Meanwhile, in the African countries, the government plays an active role for the provision of formal housing for low-income community through monetary policy and administration of licensing in the housing market (Boudreaux, 2008) [12]. But, in fact, employers in the housing sector think government complicates them with the complexity and high cost of bureaucracy. This difficulty is also felt by the community in obtaining adequate and legal housing. By so, there are informal housing and settlements in Africa that can be classified in two categories, namely settlements built by the community independently, and mass housing built by developers without any role or permission from the government. It appears that in providing decent housing in African countries, the two informal parties play the role illegally.

Many efforts have been made by governments throughout the developing world to improve living standard and secure land tenure in squatter settlements. While legalization of land ownership still becomes difficult to realize, social and political motives are the main reasons why governments of the countries help the squatter communities to improve their settlement environment (Gouri & Abdullah 2005). Participatory approach is considered the most effective way in facing the squatter, compared to direct apply of authoritative decisions. Information on community's views, ideas and choices will show the government how to make regulation and give the helps that most suitable with the community (Herbert, 1999).<sup>1</sup>

#### 2.4 Learning From KIP (*Kampung Improvement Program*) in Indonesia

Cities condition in Indonesia that grows and serves as the center of activities, inviting residents of other towns and smaller cities or villages to come to find a job and a better living. They come from various backgrounds of social, economic and living conditions, and mostly without a clear plan about their life in the big cities. Instead, these cities are still not ready yet with a plan to develop urban systems in order to accommodate the increasing number of activities and people, with various aspects and implications, including the receiving, managing, and utilizing the 'newcomers' as part of the urban planning and development. It then causes the forming of activities pockets, including squatter *kampungs* that grow and expand beyond the expected plan.

Most of these activity pockets are in the form of housing and *kampung* neighborhood that develops either on an existing residential neighborhood or unmanaged lands that does not exist in the plan designation, while the built infrastructure and basic facilities has not been prepared adequately, it results the declination of the environment condition. Most of people in these illegal *kampungs* are on low and middle income societies, with limited ability to improve their environment. This condition emerge the idea to carry out environment improvements in urban housing and *kampungs*, especially in urban village (*kampung*) that still need to be assisted by the government.

'Indonesia Department of Public Works' has initiated and developed the '*Kampung* (village) improvement projects' that have been recognized by *Mohammad Husni Thamrin (MHT)* Project in Jakarta, *WR Supratman* Project in Surabaya, and *Sartika Goddess Project* in Bandung. Through these *kampungs* and environment improvement programs, combined with the development of the potential and activeness of the communities, supported by various funding sources from both government funds and foreign loans, these projects spread to other cities across Indonesia, which was then known as *Kampung Improvement Program (KIP)* or City Housing Environmental Improvement (*Perbaikan Lingkungan Perumahan Kota (PLPK)*).

The purpose of these program are to complement and enhance the neighborhood infrastructure and basic services for the villagers as well as encourage and promote public or community participation in order to improve the income and productivity of the community itself. In its implementation, it is also addressed to the effort to plan *kampung* environment, by curb ownership boundaries of each parcel and legal status of ownership on land. Basic infrastructure improvement activities implemented according to the priority needs such as increasing the quality of road, water supply, building and neighborhood safety, electricity and provision of information.

The communities of squatter *kampungs*, with fund and knowledge limitations need the help from other parties such as private sector and the government in improving the quality of their environment. The limitation also makes them difficult to acquire legal dwelling, while the government cannot make a regulation and decision that can legalize the squatter *kampungs*. In other hand, the government realizes that every citizen has an important meaning politically, and an improvement quality of urban area, especially the fragile area like a squatter *kampung*, can give a good rapport for the government.

### 3. CASE STUDY

*Kampung Lio* is a fairly dense settlement, located on land that was formerly a marshy swamp area on the edge of 'Situ Rawa Besar' lake (Figure 3.1). The lake is in less good condition, with murky colored and bad smells water, as well as a lot of rubbishes pooled on it. Besides its bad condition, the existence of the lake was easily ignored from the highway because the access to this area is not clear enough.

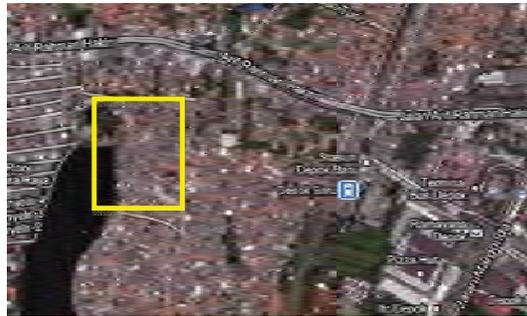

Figure 1: KampungLio and its surrounding

Access condition between KampungLio with other areas, such as public and social facilities like railway stations, bus terminals, places of worship, and traditional markets are close enough but without a clear and adequate road or access infrastructures. The entrance from the ArifRahman street is a main road, which can be passed by four-wheeled vehicles, but from the main road leading to the *kampung* and each dwelling in KampungLio area right on the edge of Situ, only in form of narrow footpath, which tend to be a dirt road, and have not hardened with asphalt or other materials and mostly can only be passed by foot.

Figure 2: People activities around Situ Rawa Besar

*KampungLio* also known as an area where the low-income community lives, as a settlement of beggars, scavengers, and other informal workers who have frequently gotten interventions from the NGOs, students, and other society at large. The economic conditions of the people can be seen from the settlement, environment, and housing condition. The environment circumstances tend to be dirty and wet (with dirt roads and open sewers). The majority of its citizens are as laborers, beggars and used plastics washers, with revenues under 2 million rupiahs per month.

Figure 3: Condition of the building (dwelling) on the edge of the lake (Situ)

Most inhabitants are migrants who have lived in this village more than 10 years. They live in a house that was built without a legal building permission by the government, and some of them lived in the dwelling by renting. The *kampung* condition reflects the poor and less fortunate condition of the people. Building structure is very irregular and generally not permanent, with an area per dwelling under 36 m<sup>2</sup>. Roofs are made of leaves or similar material, while the walls are made of woven bamboo that has not been processed yet. Drainage facility is also very inadequate make it very easily flooded in raining season.

Figure 4: Drainage and street/lane conditions in slum areas of *KampungLio*

Most people stay living here, because their economic limitation in acquiring legal and more proper dwelling. Apart of that, the proximity with their workplace is another reason, where most of them work on the near railway stations, bus terminals, traditional market, and around the lake. Most people always have willingness to improve the quality of their dwellings and environment, but limited by the lack of financial and knowledge ability.

From the 'Department of Spatial and Settlement Planning of Depok City also held a house improvement program that randomly selected some indecent houses from the entire houses in Depok city. With the limited quota only two houses per year from the entire city of Depok, the opportunity for *KampungLio* to get the help becomes very little. However, from the Depok City Government, the *kampung* gets financial assistance as part of the 'revenue and expenditure budget' annually for environment improvements, such as road, drainage facilities and water supply improvements, also in providing public and social facilities. In spite of the illegal status of the settlement of *KampungLio*, the community lives just like other citizens. They have citizen identity card (KTP) and have the right to vote in governmental election. They have access to public and social services just like other citizens.

#### 4. RESEARCH FINDINGS

Based on the government and community partnership in *KampungLio*, it shows that the government is conscious of its responsibility to give proper settlement environment for all citizens; both lived on legal and illegal land. While the illegal community, are still very concerned in improving the environmental condition of the settlement. Their knowledge and financial limitations make them need the assistance from other parties like the government.

The partnership is in the form of 'supports' by the government, and 'infill' by the community. The government provides funding and planning assistance at the regional level, for environment improvements. While the people of *KampungLio*, with mutual cooperation and their togetherness physically involved in activities for improving their neighborhoods and the dwelling units.

The illegal community economically, cannot afford more proper dwelling in a legal *kampung*. While the government cannot provide affordable settlement for the poor people in other location, and also cannot legalize the land ownership of the land, because *KampungLio* locates on a environmentally fragile area, on the swampy edge of a lake. These are the main motives that form the 'political partnership' between the Depok City government and the illegal community of *KampungLio*.

From the community point of view, there is no reason to refuse the help and partnership offered by the government. But, it is questionable why the legal institution like Depok City government has the willingness to help the community of an illegal *kampung* like *KampungLio*. Besides the help to improve the *kampung* environment, the people also gets recognition by the government by getting citizen identity card (KTP), and vote for election, as well as mutual access on public services and facilities just like people that live in legal *kampung*.

Every citizen that has the right to vote is important for governmental leaders, including votes from an illegal *kampung* community. *KampungLio* is popular as a settlement of the poor that need many helps and interventions from other parties to be improved. Both reasons make *KampungLio* important for the Depok City government politically.

#### 5. CONCLUSION

In helping the community of illegal *kampung*, apart from the social motive to help the poor, political motives seem to be the main reason why the government has a willingness to help the arrangement and improvement of squatter *kampung*s. Because 'citizen power' can be 'political power', where every citizen has a right to vote in election, which means the governmental leaders need to make the people believe on them.

Because a good quality *kampung* is the basic need of people in urban areas, the government has a big responsibility to provide it, especially for the low-income community. Politically, *kampung* environment for the poor, specifically illegal *kampung* is a main subject that can be used to measure the success of a government on its citizens. The illegal community itself realizes that they are a political object, and make it as a chance to ask for helps by the government. The helps come in the form of partnership, where the community can be actively participated in the environment improvement activities.

## ABSTRACT

*This paper discusses the changes from city open space in the city of Semarang in terms economic, social, cultural and physical. Population growth in the capital city Central Java is Semarang has increased every year. This increase will impact on the need for a place to stay, so the government will think of expanding residential areas and begin to ignore the open space area of the city. Open space set by the city government's policy is 20% from the city area, but in Semarang not complies. However, the changes public views about the town for some time is become the main focus, change the behavior of Semarang city started looking for open space this is due to the space they are confined within the house. Seeing this phenomenon, Government of Semarang City is keen to build open spaces of the city. But people tend to congregate in open space area which is in the center of town. So the difference in public open space and passive open space that serves is not visible. And this will bring a new impact to the city is the bottleneck. The results of this study can be used as input for urban planning and design of open space in the city of Semarang. The development policy of Semarang city government should be synchronized with sustainability issues in an effort to build a sustainable city. So the construction and arrangement of the town to be more controlled.*

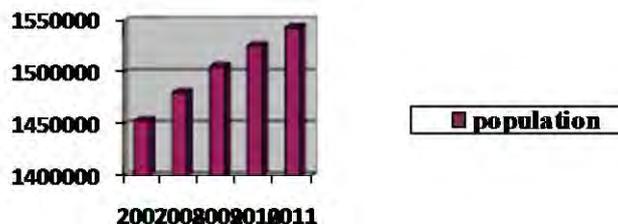

## Keywords

*Open Space, population growth, sustainability city*

## 1. THE DEVELOPMENT OF URBAN OPEN SPACE IN SEMARANG CITY

Semarang is the capital of Central Java, which has a population of 1,543,557 people or about 13.54% of the total population of Indonesia. Population growth in the city of Semarang has increased each year by the percentage of births increased 57.80% from the previous year. An increasing number of people can be seen in chart 1.1,

Chart 1.1 Semarang city population growth  
 Source: Center Statistic Center of Semarang City

This population growth resulted in a growing need for land; a land area of 373.70 km<sup>2</sup> Semarang must be able to accommodate the number increasing of people getting high. The problems that arise from the increase in population is the need for housing increases, changes in land use, traffic, and the structure of the chaotic city. The main problem of the city is a matter of the need for space.

According to Zahnd (1999) City is not something that is static because it has close connection with the life of the performer who carried out the fourth dimension: time. So the growth of the population formed the basis for the development of a city. In the development of the city through many changes, according trancik (1986) three basic problems of urban development are: (1) more urban buildings are treated as a separate object rather than as part of a larger pattern, (2) decision-making on the development of the region taken by urban plans that are two-dimensional without much attention to the relationship between buildings and spaces that form them, which actually is three-dimensional, (3) lack of understanding of human behavior. Development scale in town only aims to meet the needs of society regardless of city open space is actually very important to the life of the urban community.

Actual land use zoning is set so as to develop an area should be held on the written rules. Zoning regulations is basically a tool for control governing land use requirements and space utilization control provisions prepared for each block / zone designation (Law number 26 Year 2007 on Spatial Planning), which blocks / zone designation which is used to set through a detailed plan layout. Zoning regulations is more popular known as zoning regulation, which says zoning is meant to refer to the division city neighborhoods into utilization of space zones where in each of these zones defined control land use or apply the provisions in different laws (Barnet, 1982).

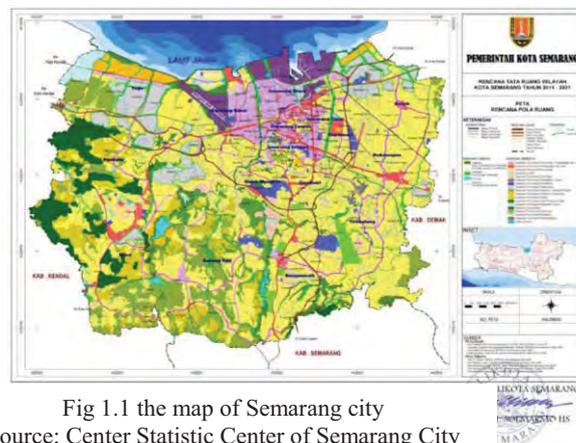

Fig 1.1 the map of Semarang city  
 Source: Center Statistic Center of Semarang City

Local Regulation Number 1 Year 1999 on Spatial Plan of Semarang, the basic concepts of urban development oriented to meet urban infrastructure services. Implementation of the above concept has many challenges, this is due to the wake of urban infrastructure has deteriorated sharply and functions.

## 2. THE RESEARCH METHODOLOGY

This study uses Post positivistic approach to research method that uses rationalism rationalistic in developing a theoretical framework and give interpretation of research results, and to use in examining empirical positivisms specific object (Muhadjir, 2000)

With this rationalistic and positivist approach to research methodology qualitative, generalization is constructed from the average individual or mean frequency diversity by monitoring errors are possible. This method requires a research design that specifies the object explicitly eliminated from other objects that are not investigated. Logical thought such as correlation, causality, and interactive while the objects were arranged in order and think the categorization and continuation with interval.

Exploratory study, as explained in the previous description, among others, addressed to:

1. satisfactory curiosity researchers to gain a better understanding,
2. examine the possibility of more in-depth studies, and
3. develop methods that will be applied in a more in-depth study

As an exploratory study, knowledge of the theory is still very small or vague, because it is through the observation then the problem can be formulated in more detail and be prepared hypothesis. The research was conducted by field exploration methods.

### 3. THE DEVELOPMENT OF PARK IN SEMARANG CITY

Semarang city there are many different open spaces of the city, one of the city parks. Garden City is a park located in the city that serves as the scale of the lungs of the city, and as aesthetic greening the city. State park consists of two kinds:

#### 3.1 Active State

Active Garden is a garden located in an area of town that is used as a community gathering area as community adhesive, and there are activities in it. Not only as a green area of the city.

#### 3.2 Passive Park

Passive Park is a park that was established as a town green area of the city region in which people are not allowed to indulge. Since the purpose of this park is just as green areas, infiltration areas.

The number of city parks in the city of Semarang in the next 5 years is only slightly increased, as can be seen in tabell.1:

Table 1.1 Added parks in the city of Semarang  
 Source: Center Statistic Center of Semarang City

No.	Tahun	Active Park	Passive Park	Total
1	2007	36	144	180
2	2008	37	149	186
3	2009	37	149	186
4	2010	27	149	186
5	2011	37	149	186

In the Semarang city, there are many different kinds of open space since the first was planned by the government to accommodate social interaction Semarang people. For example, KB Park, Simpang Lima square, Sri Gunting Garden, etc. However, some time ago in Semarang open space is not utilized well by the people of the city. Many city parks are not used unpunished. However, the situation turned around in 2 years, the city of Semarang looks hungry for open space. Active parks that was empty of visitors such as the park KB, Sri Gunting Park, and Gajah Mungkur Park invaded by Semarang people, even a passive park like Tugu Muda park, Diponegoro Park, Simpang Lima Square become a target of Semarang residents. Another thing is some road corridors being targeted as central Semarang residents gathered corridor of Pahlawan corridors, corridor of Pemuda.

Fig 1.2 the activity Semarang people in Tugu Muda Park, Simpang Lima squares and Pahlawan street corridor  
 Source: Survey data, 2012

This phenomenon is increasingly highlighted by the Semarang city government, a number of reasons such as changes in people's behavior began to run out of space for themselves in their environment, the lack of open space in their homes, the lack of open space environment in the city is the reason they look for places are considered able to meet the need for open space for them, this is a problem that occurs as a result of the increasing number of people in the city of Semarang.

Semarang city government who see the phenomenon and then give answer to the concerns of those people that looks hungry for public space of the city, the government began building city parks that had been active useless, ranging restructure plazas used a gathering place for the community, as well as rearrange the layout plan space and one urban area to improve the city park as shown in table 1.1.

#### 4. PASSIVE PARK CITY TUGU MUDA SEMARANG

Park serves as a symbol / identity or a landmark, will find a few sculpture in garden. According Spreiregen (1965) Landmark are forms a striking visual of a city. Tugu Muda Park is a park that became landmarks in Semarang because the park is designed as an integral part of the Tugu Muda monument which incidentally is the landmark of Semarang.

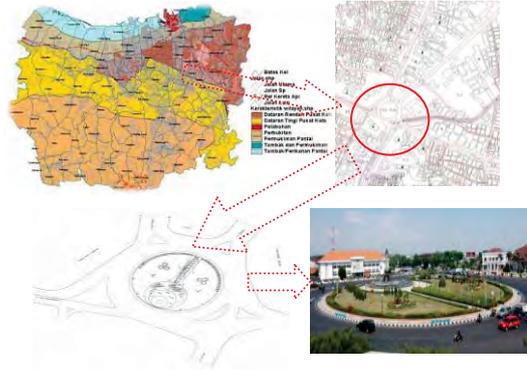

Fig 1.3 the location of Tugu Muda Park in Semarang city  
 Source: Survey data 2012

The park is located in the government buildings, and can't be separated from its essence as a memorial to fighters in Semarang who participated to gain independence from the colonizers. But what happens when this Tugu Muda Park is a magnet for the city of Semarang, every day the park is never empty of visitors. Passive Park is transformed instantly into an active park that is sure to impact the environment. The park is considered a puller as there is Tugu Muda monument as an icon city of Semarang.

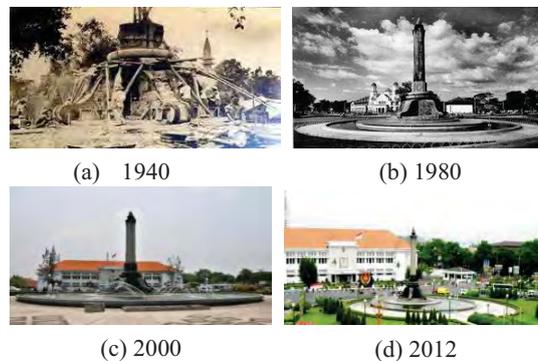

Fig 1.4 The transformation of Tugu Muda Park design from 1940 to 2012  
 Source: Survey data 2012

Tugu Muda Park design changes from 1940 to 2012 continued to improve, as a passive city park this park is considered to be quite good in terms of the elements of garden design and garden accessories. Changes are most apparent are the increasing number of green plants and the use of hard materials ranging reduced. This is used as a puller for the citizens of the city of Semarang so many who visit this park although not as Active Park. The existence of people to the park also bring adverse effects such as congestion caused by the lack of parking for visitors, the park being dirty, and many traders come into the park area.

## 5. SIMPANG LIMA SQUARE IN SEMARANG CITY

Semarang Simpang Lima Squares is the field that is in the middle of downtown or can be referred to the town square. Semarang city government planned Simpang Lima intersection that contains a big green area as city lungs.

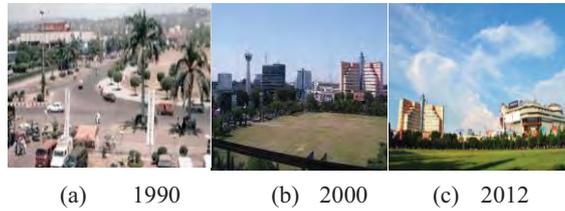

Fig 1.5 Transformation Simpang Lima Squares from 1990 to 2012  
 Source: Survey data, 2012

Currently, the Simpang Lima square turned into the center of the intersection of community in Semarang. All the residents gathered there to perform various activities, such as sports (rollerblading, basketball, and volleyball), playing, and just chatting. These changes result from the government changing form of plaza Simpang Lima to a new form, more modern. Basketball, volleyball until the jogging track is on actual field designed as the lungs of the city. Besides that, the green material is also reproduced in this Simpang Lima square. This phenomenon is considered as the cause of the Simpang Lima square use as public space of the city. Consequences arising within the Simpang Lima square are become jammed; traffic flow becomes blocked due to unavailability of parking space. The government's intention to improve the system of open space the city became one of the targets.

## 6. KB PARK IN SEMARANG CITY

KB Park has been built by the local government from 1973 until 1975. Park development objective is to utilize an empty area created by the meeting of traffic around the park. Parks became active in the middle of the town park as the lungs of the city as well as a recreational park. But in its development park KB is not very appealing to the city of Semarang, active park should be a place to play, a place of social interaction became a deserted park and unkempt. With the rise of open space needs for the city, the Semarang city government redesign active park, the park is surrounded by typical food Semarang is designed so that it becomes attractive gardens to visit.

Enthusiasm Semarang city residents come to the park increased than before, but the increase was not proportional to the number of people crammed into an open space other cities. Parks KB still not as busy intersection of five, young and memorial park road corridors hero. The park is expected have a high appeal to the citizens of the city of Semarang government just does not match expectations.

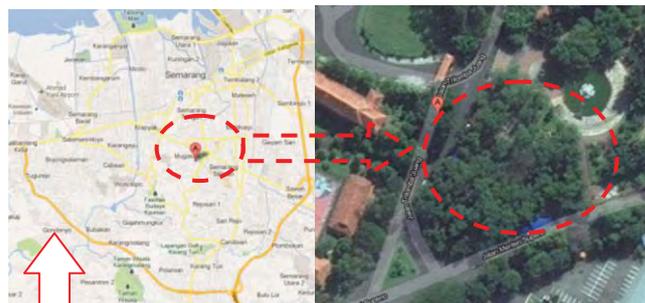

Fig 1.6 map of KB Park semarang  
 Source: Google map, 2012

Fig 1.7 KB Park semarang  
 Source: Survey data, 2012

## 7. ANALYSIS

Passive Park is a park that was established as a town green area of the city region in which people are not allowed to indulge. Since the purpose of this park is just as green areas, infiltration areas. But the gardens are located in the city of Semarang as Tugumuda Park, "Simpanglima" Field that it is intended as a passive park crowded. This is because its location is in the center of town, so visitors from various regions in Semarang can reach them. Unlike the Garden KB planned as an active park it was not too crowded visitors. As the results of interviews with visitors at the "Simpanglima" Field:

*"I went to "Simpanglima" Field when night of the week because here there are a lot of activities, from children to adults, I could bring my kid to skate and I can enjoy a night of Semarang city."*

According to Trancik (1986) the basic problems of urban development behavior not understand humans. Development scale in town only aims to meet the needs of society at the expense of open space the city is actually very important to the life of the urban community. This theory applies in this research problem, the people are wrong to apply the Government's goal to develop open space. The government intends to develop open space either park or plaza in the city of Semarang are taken too high by the city of Semarang, because the gardens are crowded even Passive Park. This is because the city of Semarang lacks space for their home environment, such as an interview with one of the visitors at the park Tugu Muda:

*"I am delighted to the Young Memorial Gardens because they can enjoy being with other visitors, and enjoy the city of Semarang. As well as boredom can be cured at home"*

With the development of open space in Semarang was not always bring positive effects but also negative effects, but what happens when it is an open space in the city of Semarang has undergone rapid change, becoming more modern, better, although considered Semarang people do not fully understand the concept of from the open spaces of the city. As the results of interviews with "TuguMuda" park visitors:

*"This park is made better than ever, and I think that people can come"*

This statement is precisely contrary to the purpose of government to change the appearance of the "Tugu Muda" park be more visually appealing with the aim of making the city a more beautiful Semarang. Not as a place to visit.

From the analysis above, it can be finding that the government's role to increase the open space the city is necessary to study on the wishes of the city of Semarang. As well as modern designs not always be in all the parks, there should be a significant difference between active and passive park design.

## 8. CONCLUSION

The increase of population in the city of Semarang making increasing need for land to grow, the need for housing increases, so that the narrowing of the land settlement. This resulted in reduced public space area private residences, housing up to an impact on the lack of land for public space of the city. So the government began to neglect the importance of public space to the city continue to improve land settlements. Unconsciously it will actually result in the saturated area of the narrow house; they then go out to find a place for social interaction, so their goal is the public space of the city.

Public space sought by the city actually been around a long time, but it was not touched by anyone. So when people experience boredom in the environment, they use existing open public space. The error that occurs is that people are not able to choose which city public space is really planned as a public space of the city; they just look factor "pleasure" only. What happens is wrong with the selection of the target public spaces of the city.

Governments who have an awareness of the importance of public space city began fix the city public space infrastructure which is available, ranging from golf, parks, and pedestrian ways. It is precisely this that makes people not being able to choose which public space that can be used and can't be used as a center of interaction. Precisely city public space which is the core region of Semarang city was invaded by the community. They do not know that what they use is passive city public space area.

Government regulations are made regarding the zoning application areas to be more enhanced, so that the spaces can urban areas as required, especially the open spaces of the city. City open spaces are enhanced not only the scale of the city, but also the scale of residential and community environment that is expected to satisfy the need for open space and not make people

converging at certain points they consider open space of the city. City open space should be designed according to function; in order to avoid the wrong target as of now this happens.

## 9. SUGGESTION

Government regulations are made regarding the zoning application areas to be more enhanced, so that the spaces can urban areas as required, especially the open spaces of the city. City open spaces are enhanced not only the scale of the city, but also the scale of residential and community environment that is expected to satisfy the need for open space and not make people converging at certain points they consider open space of the city. City open space should be designed according to function; in order to avoid the wrong target as of now this happens.

Another input is active and garden design standard passive park needs to be distinguished, so in accordance with the objectives and functions. Passive parks do not need to be complemented with attributes such as garden bins, seating, etc., so that people are not wrong perception park function. Modern design is not always on target so that the necessary studies before redesigning a garden.

### ABSTRACT

This paper presents a work in progress on the exploration of the idea of void as a delaying space in architecture. The problem of presence and absence as a form of representation should be understood for the transformation of void mechanism concept. Spatial context approach is used to translate the mechanism of void space as development of design method. The element of absence-presence and tangible-intangible becomes an important way to read the trace of void. Based on the exploration of the void mechanism, this paper concludes that there is a system of spatial discontinuity which works in the delaying process. The process helps to define the traces of void that was formed which then offer opportunities to be developed for further design work.

### Keywords

*Void, delayingspace, spatialdiscontinuity, absence-presence, tangible-intangible*

## 1. BACKGROUND

Void : containing nothing; empty; vacant; not occupied; not filled ; Noun : the state of nonexistence; an empty area; a vacuum ; Verb : declare invalid; clear for occupants; to be emitted or evacuated, emptiness, nothing, zero, heaven, Ma, rem, chipper, sky.

The problem of representation of space is constantly emerged in the discussion of architectural space, either in the form of the presence or the absence of space. To understand this matter, it is important to see things that were shaped like an "absence" prior to determining the form from the presence of the space itself.

The artist Roslyn Piggott introduced the element of emptiness through her work by collecting various kinds of air sample in the tube [1]. This work demonstrated a mechanism in which the container forms the material it contains. The space is moved by the transformation of container, in various forms, such as long tubular, hollow, transparent, or solid tube. Indirectly, it represents a form of space inside the tube by the material and the surface of the container exterior. Therefore, the meaning of emptiness captured by our senses is the same as the external element that enclosed the space.

StraBmann suggested that space was present by means of occupying the emptiness of space itself and captured by our sense as observer through visible things [2]. In this way, we can feel the textures of space visuality. The presence of dark space is basically not caused by the absence of the light in the space but by being negative against the element of presence. The light actually is not the opposite of the darkness. In the darkness, we have no means of seeing, therefore we acted as the subject with the absence in our perception. In this way, our thinking, captures the presence of void, which is actually only a trace about the image structure that is present simultaneously with the traces of absence in the space.

The above ideas suggest that the presence of void, the state of absence is emerged as a temporary moment which has occurred. The essence of the visible things is located at the residue of the invisible things as in memory. This paper addresses the presence of space which is deformed as another story of void ideas. This idea becomes important to discuss the contexts of unoccupied, unexploited, dan unprogrammed space [3].

The discussion in this paper begins with the understanding of void as presence and absence, in order to explore various related elements. Then, these elements are used as the approach in studying the spatial order. The results suggest some parameters that become the basis for developing design method, which will be developed further.

## 2. LAYERING

Void : unidentified, invisible, unconscious connections, uncanny, effacing, empty set, the dash, experience, impossible, discontinue, transition, connector, unseen, closed off, veiled, invisible, hidden, secret, memory, sign, movement, scenario, stage layout.

One example of the empty space exploration through memory is Jewish Museum in Germany. The Architect, Daniel Libeskind [4], defined the quality of space in the museum building by displaying communication among mental, personality, and emotional level of the museum visitor and the dimension of the historical Berlin City.

Figure 1: Jewish Museum Libeskind

For example in Jewish Museum the quality of space was shown along the corridor or bridge which are connected to each other as a performance of the “absence”. One of the interesting things in the journey through building space is the void which appears not only as the physical void, but also as the presence of space in memory throughout the museum. The experience and the quality of space become the elements that contribute in producing the memory of void. As a result, the museum visitors were encouraged to imagine what they feel about the void inside the museum. The attachment of the furniture objects as the space filler does not lock the meaning of void in the space. Therefore, the idea of “the absence” of the space still appear simultaneously with the conveyed text of memory. The idea of absence in this case does not mean exposure of the absence at all, but rather the problem of “delaying” so that it is still present as a sign [5].

Sign in the structure of spatial representation contains lines and diagrams which create opening and closure around each other [6]. However, such mechanism of opening and closure depends on the dominant area, because the line area is not exactly the opposite of diagram and vice versa. This area could also be an affirmation or negation between them. This operation has the same mechanism with the void translation in the matter of presence and absence of space.

The idea of void as “presence” refers to the moment of absence, in which the absence becomes the displayed condition. There are two parameters as the main element in the “moment of absence”, the empty set [7] and the dash [8]. The empty set or regularly symbolized with { } refers to a set that has no members at all as a result of intersection of two unrelated elements. Furthermore, the results of intersection was present as an impossibility because it was blocked by the boundary connection of another universe. Meanwhile, the dash refers to a sign of separation or connection between the two unrelated sentence. This sign is the element of grammatical structure which gives a new meaning to the whole sentence. It functions almost like a colon, marking the limit boundary in a series of words so that it presents a meaning that gives orientation to the series. A whole sentence basically consists of a series of pattern languages separated by meaning. This separation becomes a cryptic space, in which the dash breaks into that structure. This break finally gets into the delay condition, which connects the assumption from the original statement to intention. In the end, the existence of void in this presence has resulted in the space as a medium between two substances or it can be termed as the in-between space. However, this “in-between space” might be identified or unidentified depending on the spatial context.

The idea of void as “absence”, relates to the problem of absence that can be inverted to presence in architecture. Eisenmann named it as a rhetorical figure [9], that is the situation of new form that disappears from the final form and loses the meaning. That process of losing is translated into the absence situation. This process involves an order as a representational figure which represent, something external. The difference between rhetorical figure and representational figure is the meaning of

absence within and not related to the outside. Arepresentational figure presents something in that absence, while a rhetorical figure contains that absence and therefore, opens possibilities.

The layer of absence consists of two parts, the unknown space and the image of absence. And both parts might affect the idea of void. First, the term of “the unknown space” refers to the unconscious connection [10], that was a cross connection about the different what is seen and what is imagines, whether it is materialized or not. However, what I want to reveal here is about how the unconscious connection is related to reality and the term of uncanny. Hegel [11]proposed the concept of uncanny through the visionary notions in which the absence was expressed through fragility in the emptiness. This suggests that the condition that was seen normal, homely or safe, basically kept something secret or unhomely thing inside. In other words, there is a crypt meaning which hides among the invisible.

Second, “the image of absence” [12]refers to the condition which consists of invisible form but still can be felt. In other words, it can be said that space is present in different materials. The way of reading “the image of absence” can be done with two methods, by remembering the tracks or by experiencing the space. The method of remembering the track is called “effacing”. It can be known by looking at the remains of memory or trace of sign. In this way, it is possible to separate the visible matters and the stated matters as the translation of void in architectural space. Goulthorpe [13] revealed that exploring of the absence trace also can be done by writing as image and then, the image will create spatial of repetition and temporary transformation. This method allows us to record the meaning of absence in image by tracing object in the most recent condition of reality. Related to this idea, Brook [14]defines the absence is not only as a literally empty space, but also by the movement of activity inside the space. For example the meeting point between spectators and actors in a boundary, creates interaction between object and subject in that space. Therefore, the absence involves the movement, scenario, and layout of stage which are present through the movementsduring the performance.

Based on the above discussion on void as absence an presence, we can conclude some elements that are involved in the idea of void in two kinds of translation.

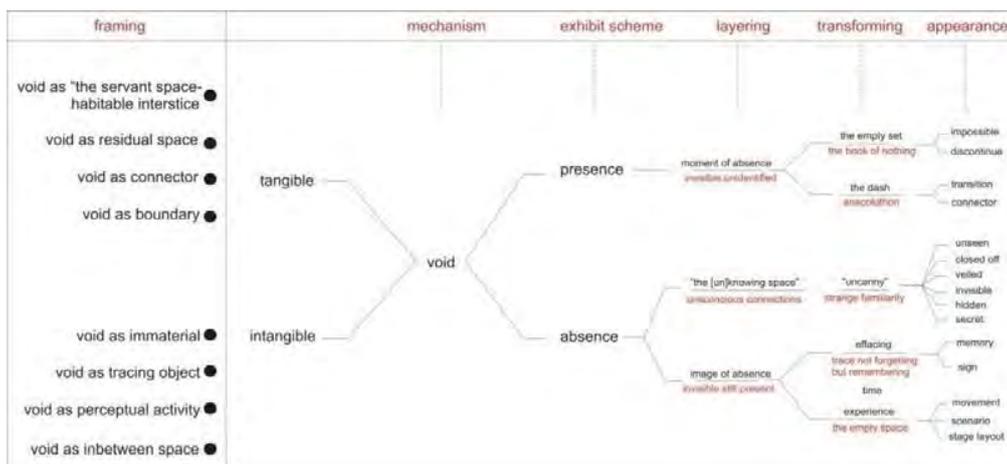

Figure 2: Framing of Void Mechanism

There are eight parameters that form the discontinuity mechanism based on void exploration which are void as boundary, void as residual space, void as connector, void as the servant space, void as immaterial object, void as tracing object, void as perceptual activity, and void as in-between space. These parameters become the basis in “reading the void”.

Both the absence and presence have a different mechanism of void. The idea of “moment of absence”, refers to passive observation. We just need one time slicing in object observation because the object is tend to be static condition. On the other hand, the idea of “image of absence”, needs the object observation that could capture thedynamic condition of space experience and activity. In addition, there are some characters present in “the moment of absence” such as the invisible and undefined transformation of absence in the space. Meanwhile “the image of absence”, we can still feel the object through its trace although both of them arephysically invisible. Therefore, the state of absence can be found through experiences in the space.

### 3. FRAMING

Void : tangible, intangible, the servant space, residual space, connector, boundary, immaterial, tracing object, perceptual activity, inbetween space.

To discover the absence and the presence in the ideas of void, we try to explore that the idea within spatial context through qualitative analysis. This exploration is to see how each element of void can work with the context-related elements. It also questions whether the ideas of void work with the keyword in the same way or changed into other mechanisms. One of the parameters that we use in studying the spatial context is explaining “singularity” [15] contained in the site context. The location of site context that we chose is Kampung Pulo, Jatinegara in East Jakarta. There are five spots that were analyzed in the study of the void, corridor area, gathering area, house yard area, space in between houses and the edge of main street. This qualitative reading of the void in the context will reveal different ways of understanding the void.

Figure 3: The Reading of Void as “boundary”

Figure 3 illustrates the reading of void as boundary in the corridor area. The shaded parts show void area, which is the building wall. In this case, the void refers to an “impossibility” as shown in “the empty set”. It is formed by the boundary which separated the universe in that area between the outside and the inner parts. The outside consists of the street and the courtyard, and the inner parts consist of elements in the house such as living room, kitchen, and bedroom. Therefore, the void space revealed in this area is an invisible and unidentified space.

Figure 4: The Reading of Void as “Intermediary”

Figure 4 illustrates the reading of void as intermediary in the corridor area. There are two functions of voids which work in this area, as connector and as separator [16]. These functions refer to the opening space like door, window, and ventilation. These openings become the connector and separator between architectural order and social order [17]. Concept of space as intermediary is also related to the concept of transparency. Rowe and Slutzky [18] described this transparency as simultaneous perception in different spatial locations. The simultaneous perception is present as overlapping images with slicing between them. Finally, the slicing represents intermediary space in the idea of void.

Following the similar methods, all the five spots in Kampung Pulo were analyzed to explore the idea of void. The analysis is presented in Figure 5.

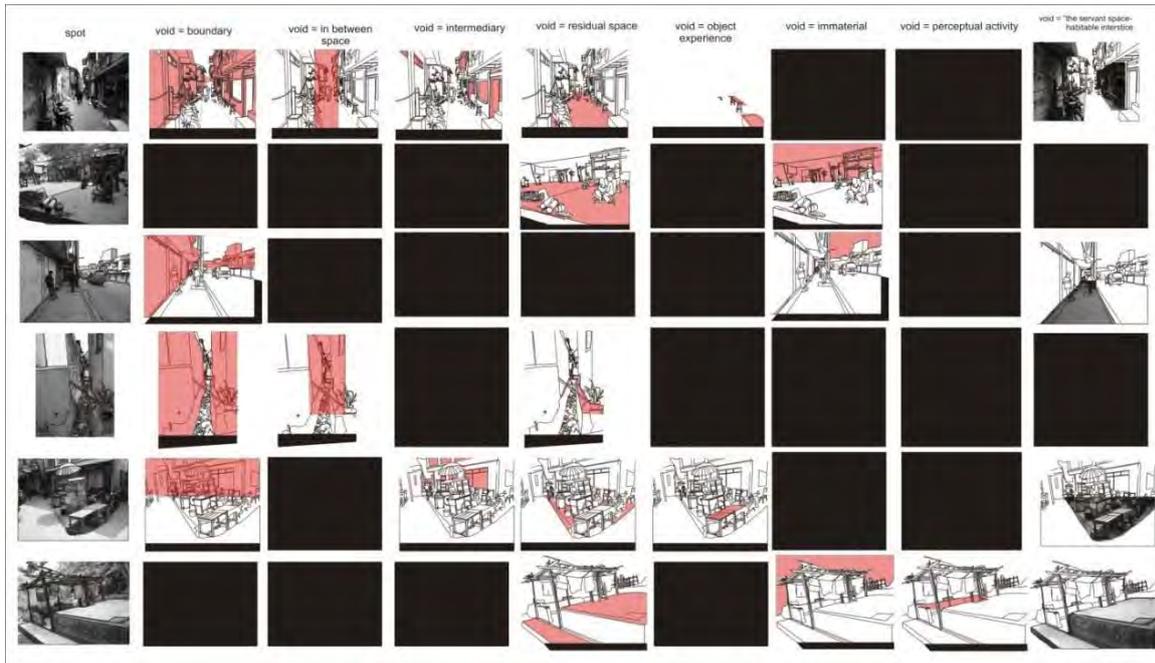

Figure 5: Exploration of Void Mechanism in Spatial Context

Based on the analysis, the ideas of void can be explored at spatial context in a comprehensive way. The ideas of void can be classified into two categories, the tangible area and the intangible area. In the tangible area, void is presented as a form that can be seen and felt directly. Meanwhile the intangible area, void merge with the abstract space that must be defined following the “presence” and “absence” mechanism in that space.

#### 4. CONCLUSION

From the exploration of void and the spatial context above, we conclude the idea of void as a delay or void as a delaying event. In this context, the event captures a moment as a discontinuity of time within an image. The discontinuity establishes the absence of space as a void. Tschumi [19] also explained that the idea of discontinuity is derived from dislocation phenomenon. The understanding of absence in discontinuity is important so that the delaying elements can be defined and transformed in architectural space. Libeskind defined an absence by referring to the silent space [20] which is a space that is intended for predator or terminator, and space that cannot be passed. This space is also not for architects because architects tend to do something like an actor in theatre. They always want to appear and act, so that the way for following the silent space for architect is divergence. Divergence is separation between symbol and experience from previous path. Therefore, the way of understanding the spatial absence from previous path is cutting the time that is running at that moment. So the spatial does not produce the history translation in one kind, but diverse to many stories. The steps of stories decide new meaning of the delaying, that is interspace.

This paper has illustrated a work in progress on development of design method based on the ideas of void. Although the analysis was limited to certain spatial context, the findings suggest opportunities for this approach to be applied in other various context. This paper concludes a possibility to explore further the delays space through discontinuity mechanism at the spatial context. There are eight parameters that making the discontinuity mechanism based on void exploration at spatial context, that are void as boundary, void as residual space, void as connector, void as the servant space, void as immaterial object, void as tracing object, void as perceptual activity, and void as inbetween space. The purpose of these parameters is for the reading of the spatial issue and the translating spatial program within the architectural design process. These findings open some possibilities to be applied in further design work.

## ABSTRACT

*This paper tries to present several activities that are of use to help people in accelerating village development through institutional arrangement. Institution is one of the important elements for development process. In Bali as part of the Indonesian archipelago where culture ties people strongly and influences Balinese way of life, the informal institutions have stronger influence than that of formal institution. Through the so-called IbW that stands for Ipteks bagi Wilayah (Technology for Region), community engagement is hoped to be attainable. The community empowerment programs were carried out in two sites namely Angkah village and Bengkel Sari village. In Angkah village and Bengkel Sari village of Bali Province where some groups of community had already existed, many empowerment activities were conducted. For example, a half of cattle raiser group members took their cows in the communal barns and sixty percent (60 %) of micro enterprise products were sold to the other villages. In summary, what people in Angkah village and Bengkel Sari village do is, indeed, very useful for technology dissemination. It is this community empowerment programs that show the process of knowledge transfer among community members which can be utilized as a means of institutional arrangement.*

## Keywords

*institutional arrangement, village development, community engagement*

## 1. INTRODUCTION

It is irrefutable that development involves tangible and intangible aspects of human life. As they refer to infrastructure used as built capital, the tangible aspects are easily seen from the physical parts of development outcomes. To support the development, built capital includes various human-made objects and systems like sewers, water systems, electronic communication, equipment for processing plants, and even soccer fields (Flora, 2008). The intangible aspects seem equal to what it is defined as social capital. Social capital reflects the connections among people and organizations or the social glue to make things, positive or negative, happen (Coleman, 1988; Portes and Sessenbrenner, 1993 in Flora, 2008). Development that primarily aims at managing environment and gaining human welfare involves social capital for it plays a significant role to create a healthy ecosystem and a vital economy (Triglia, 2001; C. Flora, 1995, 1998a, 2000; J. Flora, 1998 in Flora, 2008).

This paper focuses on the utilization of institutional arrangement and community engagement as parts of social capital to accelerate village development. As the operators to gear the development in rural areas, universities should participate in rural areas development. Flora (2008) proposes the involvement of academics with their institutions in accelerating development through biosecurity. To interpret this involvement, university investments in both bridging and bonding social capital are often key entry points for participatory rural development. As a good start, it is suggested that universities should begin working for biosecurity to increase inclusion. In a wider sense, working for biosecurity means to involve people in preserving their environment in the support of invasive species eradication. Saving rural area environment should include community participation. Community members should show their engagement so that the planned development programs can touch the grass root in their implementation.

Furthermore, Flora (2008) emphasizes that universities can optimistically hope that investment in social capital, communities and regions results in improved initiative, responsibility, and adaptability. "The indicators showing a balanced increase in social capital are a shared vision (which takes time and trust to develop), building first on internal resources (which means the community has together determined their existing assets that can be turned into capitals for participatory rural development, looking for alternative ways to respond to constant changes (rather than the silver bullet solution that a certain investment will solve everything), the loss of the victim mentality (feeling overwhelmed by globalism or climate change), and loss of a cargo cult mentality (where the community waits for an outside investment to rescue them)." (Flora, 2008).

Inspired by the fact that universities can be involved to encourage village development through various community service programs, the IbW programs funded by the Indonesian Directorate General of Higher Education in collaboration with the government of Tabanan regency in Bali Province were conducted in two villages namely Angkah and Bengkel Sari. In the Indonesian language, *IbW* that stands for *Ipteks bagi Wilayah* which literally means technology for region. Therefore, the funding is used to conduct several community service activities to drive the community development through the transfer of technology. The programs began in the early of 2010 that lasted two years. All planned activities finished in 2012 covering the

activities to establish some farmer groups and manage their farming through collective works, to encourage the farmers' capacity building in technology transfer among the existing groups as well as to promote strong production power for the community welfare.

The IbW programs are primarily dedicated to community service. To empower community in rural areas, universities should utilize the existing capitals where the programs are implemented. The general aims of the IbW are to strengthen the social capital and to provide ongoing mentoring. How can universities strengthen the social capital and provide ongoing mentoring for the community living in rural areas and ensure that their investments support sustainable development? The answer for this question is reflected in the benefits that people gain through several designed and implemented IbW programs. Take for example, the groups of farmers in rural areas are able to access the wider prospective market to sell their crops by adopting the bigger enterprises' success. In this way, the IbW programs facilitate the groups of farmers to gain more profit as they are able to either map or reach all of the possible markets to sell the rural community's products. In addition, the farmers are also able manage the waste of their plantation and pet to produce organic fertilizer. For the women small enterprises, the IbW programs are proposed to explore women' skills and creativity. Generally, the proposed program aims at managing their home industry. Management knowledge that women adopt is expected to benefit them in transferring their ability for the sake of family's welfare.

Tabanan regency is one of the rich regencies in Bali Province. The government plans to drive new village development more actively. The important strategy for a new village development is implemented through local institution building. In the regency where seventy percent of the community members are farmers, capacity building must be performed through the institutional arrangement. However, Tabanan government has limited staffs to implement all programs in many villages and to develop all potentials as the assets of the villages. The university involvement and investment in accelerating village development is part of the efforts to improve the quality of education, research and services. Hence, the implementation of the IbW programs is the alternative to cope with rural community's problems which, at the final end, is expected not only to arrange the existing formal and informal institutions but also to make farmer wealthier through their land production.

In the third world or developing countries including Indonesia, institutional arrangement is one of the elements that is significantly needed. The role of institution is very important. In Bali as part of the Indonesian archipelago where culture ties people strongly and influences Balinese way of life, the existing institutions need to be seriously arranged. The informal institutions in Bali have stronger influence than that of formal institution. Hence, through the *IbW* that stands for *Ipteks bagi Wilayah* (Technology for Region), community engagement is hoped to be attainable. In addition, community is also facilitated to build several groups of team work in order to increase community capacity building. Among their existing groups, the farmers, women and cattle raisers in the villages where the IbW programs were implemented participate actively. Through the interaction and communication in many occasions, they can explore the opportunities to build their contribution to each other. Both knowledge transfer and capacity building may be expected to take place at the time the groups of farmers conduct their collective works, meetings to solve their problems in farming, raising their cattle and expanding their small enterprises. In this way, community engagement and institutional arrangement are the capitals to be utilized in accelerating village development.

## 2. LITERATURE REVIEW

Development is a process to gain the aims of a group of people, community or nation for better economy. This definition is often used to measure how development shares its benefit for people. It is a process that is believed to be an alternative to solve community problems including all aspects of people life such as poverty, socio-economic gap, crime, justice, art and culture, agriculture, etc. Arif (2000) states that nothing but development is the best way to solve the problems that exist in people life such as socio-economic problem and unemployment. As the outcomes are dedicated for human welfare, development takes place in all countries in the world. Developed countries had undergone lots of processes that make them be on the state of being 'developed'. The USA, UK, Japan and many other countries in Europe are the examples that come easily in people's mind to be called as developed countries. For sure, development does not only take place in the developed countries. In the third world countries like Indonesia, development is the key factor to cope with a group of people's, community's as well as nation's problems. However, development for the third world countries may sometimes become a nightmare because the development outcomes only take people to worse condition. For example, poverty alleviation cannot be perfectly done in development due to mismanagement. This often happens continuously since the policy makers in government fail to fulfill people's needs. In addition, some developed countries tend to expand their power for the sake of more economic profit. This motive will affect the poor countries that are still on their track to fix several national problems.

As known as the agricultural country, one of the specific meanings for development in the Indonesian context is the development for the agricultural production. In marketing their farming crops, the community members are often disappointed due to the low price when they sell their product. This makes them not produce the commodity anymore. On the other side, the gap of the poor and the rich in Indonesia is obviously seen. People who have money will buy the imported products. It becomes their lifestyle since it feels more prestigious to buy foreign products. As a result, the Indonesian products have no competitive power and lower selling price. The impact of this situation is that all community basic needs are hard to afford due to people's low income.

Crewe and Elizabeth (1998) state that the success of development is subjective. It depends on the values used to measure the success and the failure of development. They illustrate two projects used as the examples to strengthen their assumption. The first project is how technology innovation in Rome was used for the benefits of poor people. This small

fishery project was conducted to improve people's nutrition. As the project began, many people were involved in the technology adoption process. Even women showed their active participation in this project. At the end, without a good support from the government, this project was only a story for the history. The second example is the use of stoves with an easy technology. The project aimed at reducing the use of woods for cooking in the households so that the wood cutting is under control. However, on the due date, the funder is not satisfied because it is considered that the project gives nothing for national economy, wood preservation and the measured global pollution. On the other side, women were, in fact, helped by the project program. They could feel that the project make their burden lighter. This demonstrates that the development failure is partly caused by how the project is implemented. Many projects have the features of 'top down' that easily make people the ones who cause the failure.

Facing such phenomena, Ife (2002) states that the bottom up management is more useful than the top down management. The top down management disharmonizes community objectives with the government policy while through bottom up development, community can manage their resources in smart manner. People also know what they really need. The best way to implement the development programs is based on community engagement. When community is engaged to realize several planned programs for development, environment and social justice should always be on the top of priority list. The policy makers should be smart in designing the programs that are not only beneficial for a short period but also be of use for long period of time. Instead, it should be sustainable and convenient. Once the programs fail to fulfill the principles of social justice and equality, people may become skeptical. Or, to make it worse, there will always be victims in the long queue waiting for some cash that lasts only for several days.

Falk (2011) tries to see development from sociological perspective. He starts with a question, "what is 'development'?" He considers that this apparently a simple question is not really so simple. Development programs are regularly based on the assumption that people's behaviour can and should be changed. "There are two dimensions to change processes. If it is assumed people *can* change their behaviour, there is a clear strategic dimension of the research, whereby aspects of change at individual, community and policy levels are desired by someone or some group for some purpose. If, on the other hand it is assumed people *should* change, this implicates an ethical and methodological dimension." It is because the justification for assuming the right to intervene (Fox, 2009 in Falk, 2011) in people's lives involves both an ethical question, situated in time and culture (Simons & Usher, 2000 in Falk, 2011), as well as a methodological one. For the methodological question, Falk refers to Christie (2006) as the example.

Furthermore Falk (2011) discusses why ethics is at the basis of development. It is stated that the word 'participation' is just another word for 'intervention' is clear. After all, any process of knowledge sharing, participation, intervention, collaboration, change and many other terms, involve intervening in people's lives. "Essentially, *what* people do is always and irretrievably embedded in a process –*how* people do it. There is no *what* without *how*, and it is the *how* that determines the success or otherwise of development as well as the success of its outcomes. A process must involve interaction as the basis, and interaction may result in people changing. Change is what intervention relies on and is the basis of development." In support to the importance of community engagement in development, Falk (2011) adds that development then is concerned in some way with interventions. Interventions are a partnership between people with a common interest. Such partnerships are not necessarily easy to develop or support. These partnerships may have several characteristics like complexity, resource poor, lack staff stability and reflect the divisions or inequalities in any society. Development relies on building trust between the participants. Trust that the intervention is indeed in the best interests of the participants.

With regard to how development should be designed and the involvement of universities in accelerating development, Flora (2008) shares her perspectives on maintaining social capital which usually divides into bonding and bridging. It is found that investment in both bonding and bridging social capital including accepting the time it takes to build trust and reciprocity, is often an important entry point. A particularly effective way to build social capital is to work with diverse groups in the community to strengthen, for example the youth groups as human capital. The university as participatory rural development practitioner must have the patience to build trust and reciprocity through doing what they say they will do. The question of how universities with its academics can do in taking part to rural development is best answered through a constant and well-connected rural presence. The investment can also be done by giving local people a way to reciprocate in a way that maintains their dignity and meaning.

With regard to how institutional arrangement should be understood, according to UNDP's website, "institutional arrangements are the policies, systems, and processes that organizations use to legislate, plan and manage their activities efficiently and to effectively coordinate with others in order to fulfill their mandate." It is also explicitly stated that institutional arrangements should be managed by involving universities, public administration and the private sector. This reflects that the universities involved in community services should consider the typical institutions exist in community. As Moers (1999) states that institution plays a significant role to improve and accelerate community development especially in remote area. In Indonesia, institution arrangement includes formal and informal institution. Even though some experts state that the role of institution is still neglected, the importance of institution, in fact, strongly affects the economic system. In Bali, the concept of institutional arrangement in rural areas is closely related to the existence of local informal institution which ties people and their custom strongly. The informal institution is useful to drive remote community activities since this institution has stronger effect than that of formal institution. Thus, strong local informal institution often becomes the key factor to accelerate rural development.

### 3. METHODOLOGY

This research utilizes qualitative methodology which was performed by doing observation, interview with community members, and government staff in Regency and District level. The interview was conducted with groups of male and female farmers. Through in-depth interview, the representative data describing the quality of community life in Angkah village and Bengkel Sari village were gathered. In addition to the interview with the farmers, the observation was of use to clearly see the benefits that people gain from the IbW programs. The improvement of people's quality of life can be felt through some trainings provided for students of vocational school and village community.

The objectives of utilizing qualitative methodology in conducting this study were divided into two categories. Generally, the objective of this method was to investigate the improvement of community awareness on the importance of building local institution in community level to drive the capacity building. This will result in the establishment of community engagement and institutional arrangement. Specifically, the qualitative method applied in this study was to clarify to outcomes of several community service activities that have been performed. To make it clear, the aims of designing some programs invested in Angkah village and Bengkel Sari village were:

- (1) to encourage the fruit farmer groups to join the training about how to manage plantation and to avoid the pest and diseases attack
- (2) to assist farmer to eradicate and clean their plantation with organic fertilizer to improve the plant growth
- (3) to assist farmers in taking care of their cows
- (4) to provide an applicative technology to produce organic fertilizer from cow manure and organic waste
- (5) to share tips on how to produce the hygiene product to gain good market and price
- (6) to conduct a training to manage small enterprises.

### 4. DISCUSSION

#### 4.1 Accelerating Village Development

One of the sustainable development criteria is that the actions taken by the authority have to assist people to gain benefit from the development programs released for the good of community. Sustainable development should not only be profitable in economic aspect but also be beneficial for the community to manage the environment for the next generation. This is in line with Sastrapratedja (1986) who states that sustainable development orientations include action oriented, quality oriented, goals oriented and future oriented. The four orientations can assist the policy makers to determine the priority in performing the activities for the sake of gaining the expected development outcomes. In Bali, development is also conducted to give more benefits for Balinese people. The strong power of culture and religion in community assists people to live in harmony among the households. Each community member bases their action on the philosophy of *Tri Hita Karana* (THK) that is fully respected since the concept of creating the harmony between the creator and the people, the harmony between person to person and the harmony between community and environment.

Table 1: The Natural Resources, Human Resources and Infrastructure in Angkah and Bengkel Sari Villages

POTENCY	ASPECT	PRELIMINARY SURVEY RESULTS
NATURAL RESOURCES	Agriculture	<ul style="list-style-type: none"> <li>• The farmers are not yet satisfied with the harvest from about 780, 3 Ha rice field, even more, it is now raid by rats</li> <li>• The enthusiasm to carry out organic farming on rice fields is still low</li> </ul>
	Dry Field Farming	<ul style="list-style-type: none"> <li>• The farmers are not yet satisfied with the harvest from about 802,2 Ha plantation</li> <li>• The harvest of mangosteen and sawo is satisfying</li> <li>• Market networking has not been optimal</li> <li>• The farmers are still being hampered by product continuity which is not optimal yet</li> <li>• Land sanitation and fertilizing have not been carried out by the farmers effectively</li> <li>• Mangosteen and sawo waste has not been managed well</li> </ul>
	Livestock	<ul style="list-style-type: none"> <li>• The farmers are still letting their cows wandering outdoor (no cowshed yet)</li> <li>• Modern technology used in livestock feces and urine waste processing is still limited</li> </ul>
	Water Resources	<ul style="list-style-type: none"> <li>• River utilization has not been conducted</li> <li>• Waterfall potency has not been utilized</li> </ul>
	HUMAN RESOURCES	Education
	Law	<ul style="list-style-type: none"> <li>• Lack of knowledge on community law which includes:               <ul style="list-style-type: none"> <li>• Village boundary</li> <li>• Traditional law</li> <li>• Traditional law of inheritance</li> <li>• Land certification</li> </ul> </li> <li>• The life skill capability of the housewives &amp; PKK members of making plaited mats and traditional cakes for ceremonies is not yet satisfying</li> <li>• Low creativity in terms of home industry diversification</li> </ul>

	Creative Economy	<ul style="list-style-type: none"> <li>• Low capability of home industry product packaging</li> <li>• Low capability of marketing the products of home industry</li> </ul>
	Economic Institution	<ul style="list-style-type: none"> <li>• Farmers, breeders/cattlemen, and creative economic enterprises as well as women have not yet been institutionalized</li> <li>• Products marketing has not yet been done collectively so it still depends much on collectors</li> <li>• The access to financial aids is still limitedly opened because institutional effort is still weak</li> </ul>
	INFRASTRUCTURE	<ul style="list-style-type: none"> <li>• There is one improper type machine in the village office</li> <li>• There is one bad-condition computer in the village office</li> <li>• No internet access yet</li> </ul>
	Government	<ul style="list-style-type: none"> <li>• Incomplete kindergarten playing equipment</li> <li>• Insufficient facilities for primary and secondary school libraries</li> </ul>
	Health and Sanitation	<ul style="list-style-type: none"> <li>• Chikungunya attack is still a serious problem in the two villages.</li> </ul>

In the first year, the IbW programs in Angkah village and Bengkel Sari village had resulted in positive impacts for communities in the two villages i.e Angkah and Bengkel Sari. Prior to knowledge transfer process between the groups in these villages, building several groups and encourage the capacity building among the existing groups of community members are necessary. The close relationship and strong partnership give positive influences to accelerate community engagement in the two sites. The community in Angkah village and Bengkel Sari village also support each other. For example when community in Angkah village conducted training for the improvement of their farming activity, some of Bengkel Sari's farmer groups willingly joined the training. Similarly, the Angkah village groups of farmers would also join the activities performed by the groups of farmers in Bengkel Sari village. This demonstrates that communication between two communities may help the establishment of knowledge transfer processes.

Several activities had been undertaken in Angkah village and Bengkel Sari village to manage the villages' potentials and to utilize them as the capitals in accelerating the village development. The programs cover the improvement in building the small existing enterprises such as women home industry, farmer groups, and fruit farmer group to sell and promote their production. Through the IbW programs, the groups of farmers are expected to sell their product in a wider market by implementing by the bigger enterprises' tricks to access the prospective market. The IbW programs also include the efforts to facilitate groups of farmers to access all of the possible market for rural community's products so that the members of farmer groups and small enterprise groups gain more profit. Other activities had also conducted by the community in Angkah village and Bengkel Sari village through the IbW facilitation like building the village animal barns and giving some training for the farmers to manage the waste of their plantation and pet to produce organic fertilizer. For the women small enterprises, the IbW programs were designed to train women to explore their ability both for managing their small home enterprises and for transferring knowledge from one groups of women to the others. The result of this women group encouragement is that the groups of women had gained more profit. For the cattle raiser groups, the impact of waste management can be seen on the organic farming activities in the two villages. In addition, the cattle raisers took their cows in the village barns collectively and the farmer groups called *wana sabo* had used organic fertilizer. Table 2 demonstrates the activities that had been performed in the village of Angkah and Bengkel Sari.

Table 2: The activities and the outcomes of the IbW programs in Angkah and Bengkel Sari villages

No	Activities/Products	Produsen	The Sites
1	Making various cakes for offerings in performing Balinese Hindu	The Groups of Homemade Industry called Mekar Sari	Bengkel Sari Village
2	Nonrice cakes made for household needs and for the offering	The Groups of Independent Household Industry in Angkah Village	Angkah Village
3	Export quality mangosteens which are not produced in its harvest period and the use of organic fertilizer	The Groups of Samsaman Kaja Mangosteen Farmers	Angkah Village
4	Export quality sawo which are harvested after the use of organic fertilizer	The Groups Kelompok Sawo Wana Sabo	Bengkel Sari Village
5	Wine and crackers made from sawo	The Groups of Homemade Industry called Mekar Sari	Bengkel Sari Village
6	Juice made of mangosteen	The Groups of Independent Household Industry in Angkah Village	Angkah Village
7	Compos and Bio Urine Made of Cow Manure and Urine	The Groups of Cattle Raiser Called Dina Tirta	Bengkel Sari Village
8	The Offerings Waste	The Women Groups	Angkah Village and Bengkel Sari Village
9	The activities were conducted by giving some training to groups of rice paddy farmers, farmers who plant corn, groups of farmer during the harvest time, the mapping of water	The IbW team of Mahasaraswati University and the community involved in the programs	Angkah Village dan Bengkel Sari Village

#### 4.2 Institutional Arrangement and Community Engagement

The synergy between institutional arrangement and community engagement is necessarily needed to establish capacity building in order to gain the expected objectives. How important is institution for a country and its development? Institution is one of the important elements for development process. Institutional authorities are the decision makers who are expected to encourage people to involve themselves in development. Despite the statement of some experts who state that the role of institution is still neglected because institution is considered not important, the importance of institution, for instance, strongly affects the economic system. Nowadays in the economic area, institution plays a significant role (Moers, 1999). When the economic theory is widely expanded, institution is necessarily needed to be a guarantee for minimizing transaction cost and constructing conducive atmosphere at community level. For its role to be significantly needed to motor the development, particularly in rural areas, community engagement is no different. How can development outcomes be attainable if community does not want to participate either individually or collectively? As important as the existing institutions that should be arranged, community engagement in development is also a key point since the government programs need people participation to make them successful. Besides being the object of development programs in the sense that programs are designed to improve the people quality of life, people are the actors to perform the policies of authorities. Therefore, they have to be engaged in development through the activities conducted by their groups in community.

Capacity building of farmer groups in community village will drive community to raise the awareness to identify their problems and then to be able to cope with them. It can also be useful to encourage people to cope with their problems independently without government support. It is important to raise community confidence and try to make people have a critical thinking especially the young generation. Improving the capacity building of community will encourage the young generation as the innovators who are able to encourage their community to live a better life. If people have their innovators, there is a hope that the transfer of knowledge and technology among groups in the community village will succeed. Nowadays, as the matter of fact, the support from an agriculture field assistance staff that is sent by the government through the agriculture department is very rare. Sometimes the authorized staff sent to community depends strongly on the government policy. This condition may challenge the community to actively and independently find the answers for their own problems.

In regency level, there are policies designed for development programs that are included in the middle term strategy and long term strategy. To gain the expected outcomes for the sake of human welfare, these two strategies have to engage community since interaction among people is the capital that can be utilized as the glue in collective works. People believe that the important step to accelerate regional development is through community engagement. The main objective of community development has to be related to environment sustainability and social justice (Ife 2002). In developing countries the government policy sometimes tends to be not applicable. As a result, it is difficult for the community members in rural areas to raise their awareness and to manage their life. Say, for example, the program of direct cash services and rice for the poor. The phenomenon taking place when the programs were conducted demonstrates how poor people are really in hunger of services. They live in poverty continuously that those two programs are not the sustainable alternatives to improve the quality of their life. Hence, community management in remote area should be a government focus. It must become the priority of the regional development in the aims of alleviating the poverty. It is widely believed that until today the majority of people living in poverty is found in the village. For this reason, the central government has to drive the regional government to make a priority of village community management. The regional government may involve more people to participate in performing development programs. Through community based management, the government can measure to what extent the designed plans benefit people.

In the efforts of improving and accelerating development especially in remote area, two significant elements that can be continuously utilized in accelerating village development are institutional arrangement and community engagement. Institutional arrangement may take place if there are institutions established by the community on which they rely some activities. Then the existing institution in rural areas encourages community engagement. This will happen through the groups of community that people participate in. In their groups, people show their participation, create their partnership, interact to each other to maintain communication. Communication among their peers can help community to talk more about the issues they need to discuss like technology in farming and raising their cattle, the use of fertilizer and the eradication of pest and disease. As can be seen in figure 1, these two elements are the pillars in the 'house' of village development. The synergy between institutional arrangement and community engagement in accelerating village development plays a significant role to lead people in living a better life.

This paper tries to put forward the issue of accelerating village development through the implementation of IbW programs which involves universities as the scholars in collaboration with the local government to accelerate development by strengthening the existing social capital where the programs are implemented. This demonstrates a synergy between universities and government that needs the academics' support to provide ongoing mentoring to address the community problems. The specific focus of this study is to show the utilization of institutional arrangement and community engagement as

the two pillars to ensure the implementation of all development programs. For the institutional arrangement, the informal institutions that have strong power to involve community's participation in the planned development programs should be wisely utilized. In the sites where the IbW programs were implemented, the community was strongly tied by their religious activities ranging from performing ceremonies in their family shrines to reflect the level of households' activities to conducting collective works for the village temple ceremonies to demonstrate the need of communal participation.

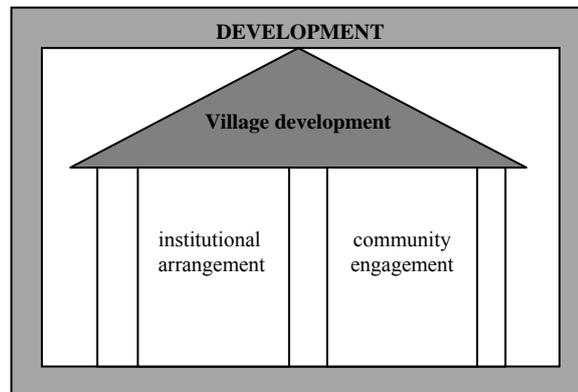

Figure 1: The synergy between institutional arrangement and community engagement

## 5. CONCLUSION

The community in two villages i.e. Angkah and Bengkel Sari villages where this community service was conducted agree that the IbW programs are beneficial for them to create many encouraging activities. One of the main sustainable development points gained through this program is that the university investment in the village has assisted people to increase their quality of life. The expected sharing benefits of the programs are not only profitable in the economic aspect but also sustainable to strengthen the social capital. The IbW programs are also intended to train the community to manage environment for the next generation. The strong impact of IbW programs in Angkah and Bengkel Sari villages is how the institution especially local institution can drive community to increase the awareness on the environment management and to independently face the challenges by themselves without government support. In the first year of the IbW programs that was in 2010, several works had been successfully conducted such as building farmer groups, managing small enterprises, and encouraging entrepreneurship habit in community to improve the family's and village's welfare. Here, the farmer groups were assisted to manage their plantation, to eradicate pest and disease attack as well as to give fertilizer in the farmers' plantation based on organic farming. The groups of farmers, women and cattle raisers in the two villages are the informal institutions that should be managed to help the establishment of community engagement to be used as the capitals in accelerating village development.

## 6. ACKNOWLEDGMENT

We would like to thank Directorate General of Higher Education in giving the funding for the programs we are willing to implement in two villages of Tabanan Regency, Bali Province, Rector of Mahasarawati University Denpasar, the Director of The Centre of Community Services, and the Government of Tabanan Regency that have already facilitated this program through the moral and financial support. We would also like to express our gratitude to Angkah and Bengkel Sari communities that have already focused on all of the IbW programs conducted in their village.

# Coping in Widows Who Have Children with Moderate Mental Retardation

Bania Maulina<sup>a</sup>

<sup>a</sup>Faculty of Medicine, Islamic University of North Sumatra

E-mail : maulinania@yahoo.co.id

## ABSTRACT

*Stress appraisals could include harm/loss, such as loss of a loved or valued person. The other one was to care for a handicapped child. This study is also a follow up that initially analyzed quantitatively. The researcher was interested in one of participant that was raising a disabled child, i.e moderate mental retardation and at the same time, she became a widow. But, she showed different reactions from the others generally. It was a unique case. A qualitative method was chosen to gain a detailed description about how the participant reacted to, how to deal with and how she could survive related to her current condition. Moreover, there are many problems arised. Data was obtained from depth interview and observation. Analyzing of data was also associated to the coping theories. The result found that belief in God as her coping and took on a major role. But, it was not only involved cognition and emotions, but also spiritual aspects. Maybe, there is other approaches that could explain the aspect, deeper than the coping theory.*

## Keywords

*Widow, coping, stress, belief in God, mental retardation*

## 1. INTRODUCTION

Certain environmental demands and life events produced stress in substantial numbers of people. Stress appraisals could include harm/loss, such as loss of a loved or valued person. The others one was caring for a handicapped child. Many researches related to stressful experiences impact to lost a spouse or raising a disabled child.

The stressful effects of the death of a spouse in a large sample of women and men. It found that women and men were more likely to exhibit serious depression during the first year after the death of their spouse than were a married women and men who had not lost their partners. The other studies also found that middle aged widows were involved in various forms of compensation, such as the consumption of drugs, alcohol and sometimes were diagnosed mental disorders. They tended to use drugs to cope with the loneliness problem. Many middle aged women could not adjust well related to their status as a widow. This feeling is reinforced by the frustration of sexual urges that could not be met and the family income will not meet again for fulfilling family life<sup>1,2</sup>.

Being a mother and father at the same time required additional responsibility that could ultimately led to the overload role<sup>1</sup>. Some conditions were related to widowhood, such as a sense of grief, economic problems, sense of deep loneliness, less leissure, e.g chance of being interested in activities outside the home or do activities with their neighbor together contributed to the level of stress experienced. Widows were also facing social problems, i.e reluctant to leave the house alone and seem strange when there was no partner. The length of their widowhood were also associated with the level of stress experienced. A woman who had been widowed less than 5 years tend to experience greater stress, included dissatisfaction of revenue and had more negative emotions than women who had been widowed for more than 5 years<sup>1,2</sup>.

But, it did not appear on a woman that now became a widow. This widow was 42 years old when her husband died and has been a widow approximately 1.5 years. The researcher did preliminary obeservation before and found that she did not exhibit negative behaviors like the previous researches. This widow was still doing her rountine activities, such as going to market, going drive her child to school and opened a business selling clothes.

Beside as a widow, she also has a handicapped child. Research on the widows' coping who was raising a handicapped child, had done. The presence of a disabled child in the family is the most disappointing. Negative feelings, such as angry, rejected, sadness, shame, guilt, self-pity, depression and even conceal or refuse to admit the child as hers. The stressors experienced by widows also included grief from the loss of a normal child, child's handicap severity, the chlid's lack of social skills,

dependence upon someone, fear regarding the safety and health of the child, prospect of children lifelong, social isolation, huge expenses, such as fee for therapy<sup>1,3</sup>.

One kind of handicapped children is mental retardation. The American Psychiatric Association (APA) describes mental retardation in the Diagnostic and Statistical Manual, 4<sup>th</sup> Edition, Text Revised (DSM). In the DSM, a diagnosis of mental retardation requires an IQ of approximately 70 or below as well as deficits in areas of adaptive functioning. The DSM definition further codes mental retardation by severity. Mild mental retardation has an IQ range of 50-55 to approximately 70, moderate mental retardation has an IQ range of 35-40 to 50-55 and severe mental retardation has an IQ range of 20-25 to 35-40. Persons with an IQ below 20 or 25 are diagnosed as profoundly mentally retarded<sup>4</sup>.

Further, research on widows who are raising handicapped children is also scarce. The previous studies found the widows experienced stress related to behavior problems of their children and stress would increased along with the bad behavior or difficult emotions<sup>1,5</sup>. The previous studies also found that stress in mothers of children with moderate mental retardation had higher than children with mild category<sup>6,7</sup>.

Coping in mothers of children with disabilities also tend to be less adaptive than mothers who did not have children with disabilities<sup>8</sup>. The previous research findings indicated that some mothers thought eventually would get better with the medication<sup>1</sup>. The other study found that middle-aged widows who caring for handicapped children may be at risk for stress, depression and less adaptive coping. Further, in-effective (in-adaptive) coping, included withdrawal, aggression, self medication and defense mechanisms<sup>9</sup>.

But, it also did not appear on a woman who was raising a moderate mental retardation child. Although at this time, she was in middle-aged widow and had been widowed for less than 5 years, but she did not show like behaviors in the previous findings. Based on preliminary observation found that this woman showed different reactions from the others generally. Actually, she always care for her disabled child, take her handicapped child wherever she goes and goes drive her child to school.

This study is also a follow up that initially analyzed quantitatively. The researcher was interested in one of participant that was carinf for a moderate mental retardation child and at the same time, she became a widow. The researcher often interacted with this women before and saw her routine activities. The researcher thought that it was a unique case because she showed different reactions from the others generally. In the most cases, the widows usually showed negative reactions, such as aggression, self medication and defense mechanisms, but this women did not. The researcher interested to get a detailed description of how this women could survive related to her current condition. Moreover, there are many problems arised. So, to provide a detailed description of how the widow deal with her problems and how she could survive with many problems until now, which could be approximated by coping theories. One of them is the coping theory of Lazarus and Folkman.

The coping theory of Lazarus and Folkman related to cognitive approach. Concept of cognitive appraisal refers to evaluate cognitive process, that is the person evaluates the significance of what is happening for his or her well being. Coping is an effort to change cognitive or behavior to manage internal or external demands, that are assessed as a burden or something that is beyond the limit of individual ability. There are two general types of coping. The first, termed problem focused coping, is aimed at problem solving or doing something to alter the source of the stress, such as seeking of instrumental social support, taking direct action. The second, emotion focused coping, is aimed at reducing or managing the emotional distress that is associated with the situation, such as avoidance, seeking of emotional social support, acceptance and turning to religion<sup>10,13</sup>.

Cognitive has a significant role in the stress response and can be drafted into the interaction of two processes, termed: appraisal and coping<sup>11</sup>. Appraisal is a fundamental component of the process of coping that determine whether a situation is considered stressful. Changing cognitive appraisal of individual can reduces stress. Coping begins with the individual's cognitive appraisal of the meaning or significance of the problem to his or her life. It means that if a person feels that something is a stressful situation, coping is needed and otherwise, if a person does not feel something as a stressful situation, coping is not necessary. Perceived stressful situations can be minimized through effective coping skills<sup>10,12</sup>.

A qualitative method was chosen for this study to help the researcher gain a detailed description about how the widow reacted to her condition, how she cope with some problems and how this widow could survive related to her current condition. Moreover, there are many problems arised.

## 2. METHOD

A qualitative method was chosen for this study to help the researcher gain a detailed description about how the participant reacted to her condition and how to deal with some problems. This study is a follow up that initially analyzed quantitatively. The researcher was interested in one of participant that was caring for a moderate mental retardation child and at the same time, she became a widow. The researcher often interacted with participant before and saw her routine activities. The

researcher thought that it was a unique case. Based on preliminary observation found that the participant showed different reactions from the others generally. In the most cases, the widows usually showed negative reactions, such as aggression, self medication and defense mechanisms, but this participant did not like that. The researcher interested to get a detailed description of how this participant could survive related to her current condition. Moreover, there are many problems arised.

Because of sample size limitations, that was so difficult to find participant according to the research criteria, so this study only involved one participant. After the rapport built up, the researcher asked her permission to participate in this study. Data was obtained from depth interview, observation and document. It was done to get credibility. It meant that data obtained from the participant actually a picture of the participant herself. The researcher prepared an interview guide. It started from the problems related to widowhood and her experience who caring for mentally retarded child. The participant was interviewed in her quite room. The interviews lasted between 60 till 90 minutes. The researcher required some meeting to discuss the problems related to her experience as a widow who was raising a moderate mental retardation child. The Observations conducted in two sessions, the time of the interview and and outside the interview schedule, include expression, body language and her current daily activity. But, the researcher did not find some document.

So, because of the research purpose is to provide a detailed description of how the participant deal with her problems and how the participant could survive with many problems until now, which could be approximated by coping theories. One of them is the coping theory of Lazarus and Folkman.

At last, the researcher also confirmed the time for data retrieval. The interviews were audiotaped and transcribed verbatim. The researcher got a narrative data. So did the observation data. The researcher analysed the transcribed verbatim that have been collected. The researcher changed it into transcript. The transcripts were re-read to identify the ideas and meaning being expressed. After that, analysis and interpretation of the participant as a single case was done. Finally, the researcher will obtain a complete picture of participant that has a unique characteristics. Analyzing of data was also associated to the coping theories.

### 3. RESULT

The death of her spouse was a social condition that could led to a change of her life and required her to adapt. The participant must adapt to go somewhere alone without her spouse. It was something unusual for her. Many of the feelings experienced after the death of her spouse, such as reluctant to leave her house alone, felt unsecure and finally this feeling made her to be withdrawn, that reffered to in-effective (in-adaptive) coping. It meant that actually, the participant also felt a grief, showed reactions impact to her death of her spouse or in other words, it could conclude that the participant used coping in-effectively (un-adaptively), like Gass Sternas's findings. But it was not happened for a long time like Gass Sternas's research. The participant did not require a long period to cope with her condition. She only took a shorter time to adapt than widows in the previous research. The adaptation process from having a husband to became a widow occured in a short time than the others.

The adaptation process, namely having a husband then did not have a spouse encouraged her to adapt and this process influenced to stressful experiences, but it was happened in a short time. The participant absolutely need more time to adapt this condition. It was happened for several period but she got social support, especially emotional social support from her family and encouraged her to adapt to her current condition.

The observation data showed that the family member, like her elder or youngest sisters looked to visit her in the house to tell stories and joke with her. They also asked her to leave the house (go outside) to go on holiday or stay at the other family member's house out of the town. Family members took on a role as assistance, providing advice and someone in whom to confide private feelings. At last, she began to open to social activities again.

‘Need a long time to adapt with widowhood..First, after death of my spouse, if there is a invitation, I never go. Because no partner. I feel blame.. If I go somewhere alone, I feel clumsy, awkward.. For forty days, I never go outside. For sweeping the yard, I feel blame..’

‘..Approximately five months later, after my sister persuades me to go somewhere and give me support. After that, I will attend invitation. Sometimes, I will sweep the yard...’

It was similar to Lahey's statement that having someone to talk to, receive advice from and be cheered and reassured by is an important factor determining individual's reactions to stress. Individuals with good social support are less likely to react to

negative life events. Women were much less likely to become depressed after the death of a family member perhaps because women tend to have greater social support from friends. There was a common belief in the culture that the simple act, such as telling someone else about the problems is good for them. In this study, Social support from participant's family member took on a role that influenced her to be adaptive (adjust well).

How an individual deal with the problems may differ from the others because it was influenced of person factors (resource). Person factors included all characteristics of an individual, such as cognitive, e.g beliefs. Faith in God enable people to create meaning out of their life, even out of stressful experiences and maintain hope. In this study, the participant reported that lost a spouse as something was under the control of the God. It was a God's way to see how strong the participant could survive. It also meant that the situation was appraised by participant as something uncontrollable. There was a belief that an event is not contingent upon one's actions but upon fate from the God.

Beside that, the participant also assumed that source of stress, namely the death of her spouse could not removed. Then, to adapt to her condition, she tried to deal with the problems by changing her interpretation. Great faith in God changed her interpretation of stressor (the death of her spouse). She assumed that it was the God's trial to make her more stronger than before. She found an interpretation that is realistic and could minimized the source of stress.

"Now, I think that it's the God's Fate.. Allah might tested me..I could be strong or not to accept the God's trial.."

But, beside making an interpretation, when the source of stress (the death of her spouse) could not realistically removed or changed, the participant also used another ways to deal with the problems. She tried to manage her psychological reactions to stress (manage unsecure feelings). She reported that when she felt stress, she would do something that make her happy and relax. She assumed that it was a successful way for her to deal with the problems.

'If I feel stress, I will go outside, e.g playing volley...''Therefore, doing religious activities, chatting with friends, taking my youngest child to school.."

Many problems appeared after a woman became a widow. So was the participant. She had some problems related to her current conditions, namely education of children and economic problems, disabilities and prospect of children lifelong. It education of children problems was not significant because she got instrumental social support. To pay the tuition of her two normally children had financed by her family members and for the tuition of her disabled child had financed by government. It meant that she reported no problems with it.

"My family members help me for the tuition of my children, especially my oldest girl and the middle one. For my youngest child..His school doesn't receive school fees. It's free..So, I never had a problem.."

Related to economic problems, she reported that this condition was difficult for her because she has no permanent occupation.

She only had a boarding room rental business. Sometimes, her monthly income would not meet again for her fulfilling family life. So, to cope with the problems, she would choose to removed the source of stress because the source of stress could be handled by her. When she did not have enough money to pay something, she used one way to deal with. She tried to remove source of stress by doing direct something, such as negotiation. That is led to problem focused coping.

"After the death my spouse, economic conditions became a serious problems. It's so difficult... I don't work. I am only a housewife. My income just come from boarding room rental and vendibles. Certainly, it's not enough.."

"It will occur when ahead of Ied...I don't have enough money to pay in installment. I buy television on installment.

"So, I go to the his house and make negotiation..I requested time to pay in...'

Similar to adaptation process, for economic problems, she also used the same way to cope with something that could not handled by her. She would choose the other ways to cope for a uncontrallable problems. She decided to do something for minimizing this condition. Generally, she always turn to religious (Faith in God) to deal with. It meant that at first, the participant analyze situations for indentifying the problems. She analyzed that the problems. If it already could be handled by her or not. If the problems could be dealt with and considered as something controlllable, she would take a direct action, but if the problems could not be handled and considered as something uncontrollable, she would create meaning and maintain hope in difficult circumstances. A great belief in God affected to produced positive interpretation. She interpreted something positively. In the end, she returned everything to the will of the God.

Generally, theme of belief in fate always appeared as a way to deal with her problems. If the participant could not cope with her problems and she appraised as uncontrollable situation, she always turn to religious. Belief in fate meant that an individual accepted a stressful experienced and to do nothing about managing situational demands. Belief in fate could led to an appraisal of helplessness that in turn discourages relevant problem focused coping effort. It meant that she did nothing to modify stressful condition that it led to emotion focused coping effort. It was directed at regulating emotional response to the problem.

“But, I don’t concern it... I accept this conditions... Because of the God...”

The adequacy of the individual’s resources that often is conceptualization in terms vulnerability which also influenced to human adaptation to deal with the stressful problems. The vulnerability, such as psychological. The participant had good psychological aspects. First, she had a great belief and always used interpretation something positively. Second, she generally had positive feeling to response to her problems. If the positive feelings will occur, so negative feelings will be managed and led her to be adaptive. Beside that, she also had a strong motivation. The will to live for her children generated to survive or “fight feeling”. Overall, it was directed at her coping behaviors are adaptive

Source of stress was not only arised from her life events, but also because of conflict. Conflict occurs when two or more motives cannot satisfied because they interfere with one another. When one of family members gave a negative response about her disabilities of child, actually the participant would be angry but she could not express her emotion because of a reason, namely family relationship. It meant that actually the participant had the need to be with other people and to have personal relationships. In this case, the participant impressed to have aggressive motive (angry as a response) and affiliation motive. Both of this motive could not meet together. If the participant distributed her aggressive motive, it would produced a negative impact on affiliation motive. If the participant expressed her anger, it would be a negative impact on social relationship, whereres essentially, she had a strong affiliation motive.

Finally, it caused conflict and encouraged unsecure feelings. She was undoing as a reactions because of that. According to psychoanalysis approach that when conflict arises because the superego blocks an id desire. It meant that superego is more dominan than id. It caused an individual felt unsecure. So, ego tried to find safe and realistic ways to meeting the needs of the id and to depend individual from a bulid up of uncomfot feeling, that is the functions of ego and the process called defense mechanism. In this case, undoing as one of defense mechanism. She did it only to regulate emotional response. It was aimed at reducing or managing the emotional distress that is associated with the situation.

For some occasions, resources are in fact adequate, but the individual does not use them to their fullest because to do so might create distress. According to coping theory, the terms of superego is similar to cultural values. Internalizing cultural values proscribe certain type of action or feeling. Culturally derived values serve as norm that determine when certain behaviors and feelings are appropriate or they are not. The cultural values restricted the ways the participant to distribute her anger or used aggressive behavior to cope with.

“My youngest child was singing. At the same time, my niece was hearing him and made a crack. She said “it’not good..You can’t sing well..’After hearing it, I cry. I can’t scold my niece...’ I’m not comfort if I scold her.. Because, she is my niece. We are family...”

Beside that, actually the participant ever showed negative reactions associated to her unnormal child, like the previous findings. She felt sadness, self-pity, and sometimes became annoyed. She also complained about her child condition that has not been independently. But she did not show some behaviors like conceal or refuse to admit the child as hers. Even, based observation data, she always bring her handicapped child to go everywhere. She also entered her child on extraordinary educational program. Significant development of the child make her happy. These positive behaviors appear motivated by her love and concern.

“My youngest son has a weakness (she’s pointing at him)..Stupid..I feel sad and pity. Sometimes, I feel annoyed..”

“He isn’t nomally child..He hasn’t been independently. But after taking my child to attend studies, there was a significant development. That’s it, I’m grateful, I’m happy..He has followed the lessons in school for a long time..He’s a special school student..”

Similar to prospect of children lifelong problems, actually, she felt anxiety. It was same with the previous study. But she make an interpretation about what she can do with the child’s condition like that. She appraised that with the child’s disabilities, just can be acceptance. The previous research found that an individual who accepts the reality of a stressful situation would seem to be an individual who is engaged in the attempt to deal with the situation. First, individual appraised that the stressor was as real

evident, but after that she did nothing to cope with. It was done only for minimizing negative emotions. In this case, disabilities problems was viewed as reality that could not be removed and acceptance was a way to survive. This reactions was predicted because of her great belief in God. Belief in fate encouraged her to accept it, but actually it was impressed her helplessness reaction that could not be removed the problems.

“About my youngest child’s future..How else would, with his disabilities, I just accept..”

#### 4. DISCUSSION

There was a contrast between the result of this study and the previous research findings. This study found that the participant did not require a long period to cope with her condition. She absolutely took a time but she did not need much time to adapt. She only took a shorter time to adapt than widows in the previous research. The adaptation process from having a husband to became a widow occurred in a short time than the others. It was influenced by social support, either emotional or instrumental support, resources and a great belief in God. There was a common belief in the culture that the simple act, such as telling someone else about the problems make them felt good. Social support took on a role as assistance, providing advice and someone in whom to confide private feelings encouraged her to rise up or to be adaptive (adjust well). It is supported by Lahey’s statement that having someone to talk to, receive advice from and be cheered and reassured by is an important factor determining individual’s reactions to stress. Individuals with good social support are less likely to react to negative life events.

The others factors that also determined the way an individual deals with the problems is motivation. Motivation is a term applied to explanations of why individual behave the way she do, why she start some activity, choose its direction and persist in it. This factor also was had by the participant. She had a strong motivation, e.i the will to live for her children, the will to survive or “fight feeling”. Similar to the great belief, especially Faith in God. This belief always encouraged her to make interpretation positively. Belief in God created meaning out of her life, even out of stressful experiences and maintain hope.

The way an individual copes with the problems is influenced by many factors. Problem solving skills is one of them. Ability to search for information, analyze situations for the purpose of identifying the problem in order to generate of action that are referred to problem solving skills<sup>9</sup>. In this study, a good problem solving skills was existed by the participant. To deal with the problems, at first, she would do analyzing and identifying. If the problems was considered as something controllable, she would take a direct action, but if it could not be handled or considered as something uncontrollable, she would create meaning and maintain hope in difficult circumstances. In other words, she always turned to religious that led her to produce positive interpretation, that is everything to the will of the God.

The participant had many factors that encouraged her to cope with adaptively so she could survive until now. But, on this participant, belief in God took on a major role. That is also a major theme in this case. So, to discuss belief in God, it required other approaches to produced a deeper findings. Because, belief in God as a coping was not only involved cognition and emotions, but also spiritual aspects. Maybe, there is other approaches that could explain the aspect, deeper than the coping theory. Maybe, the transcendental approach could be used for that.

#### 5. CONCLUSION

This study found that the widow was caring for a moderate mental retardation child had many problems. Changing in the status of having a spouse then became a widow with a moderate mental retardation child. All, it required adaptation process. But, all of the problems could be dealt with adaptively. She used problem and emotional focused coping to deal with her problems. Coping adaptively also was influenced by many factors. The participant had many factors that encouraged her to cope with adaptively so she could survive until now. The factors are motivation, belief, problem solving skills and social support, either emotional and instrumental support. But, on this participant, belief in God took on a major role.

This study also found that source of stress was not only arised from her life events, but also because of conflict, but her internalizing cultural values proscribe certain type of in-effective (in-adaptive) coping.

## ACKNOWLEDGMENT

I thank to my participant who was so willing to talk to me. I am also grateful to my supervisions for her/his suggestions on my paper.

### ABSTRACT

Many development institutions perceive corporate social responsibility (CSR) as a potential mechanism to improve development. As a highly influential economic organization in the international development, multinational companies have moral obligation to practice their CSR in order to reduce negative impact of the development and created prosperous society. A multinational company in Malaysia, Johor Corporation (JCorp), proposed a corporate waqf mechanism to develop other business as an approach to sustain CSR. Through the corporate waqf mechanism, JCorp pledges to dedicate some of its annual dividend, payout from the shares transferred into waqf, to support charitable causes. While, some others are reinvested to ensure continuous growth of the waqf assets thus translate it into higher distributable income for the benefit of society at large. The corporate waqf can be considered as a CSR model based on Islamic business ethics, including for community development. This is due to the principle that property is a trust where its earnings and utilization should be accountable to ensure shared prosperity, social justice, community balance and stronger community.

### Keywords

Corporate social responsibility, waqf, community development

### 1. INTRODUCTION

Development is a key focus concerned by all countries in the world, both developed countries and developing countries. This issue is mainly concerned with the development of the domestic economy of developing countries [1]. According to United Nations Development Programs (UNDP), the poorest 40 percent of the world population—the 2.5 billion people who live on less than \$2 a day—account for five percent of global income, while the richest 10 percent account for 54 percent. Never before has the goal of abolishing poverty been within our reach: there are no longer any insurmountable technical, resource or logistical obstacles to achieving it. Yet, more than 800 million people suffer from hunger and malnutrition, 1.1 billion people do not have access to clean drinking water and, every hour, 1,200 children die from preventable diseases. Despite a growing world economy and significant advances in medicine and technology, many people in developing countries are not reaping the potential benefits of globalization [2].

The above situations require a significant contribution of development actors, including multinational companies. The company's activities give impact on development, but profit-maximizing motives are often incompatible with good development practice [3]. Therefore, companies are required not only to maximize profits, but also should pay attention to social and environmental aspects. Company is not just an economic entity, but also a social institution that is in a social environment as well as have a great social responsibility towards all stakeholders. Company has to practice CSR.

Nevertheless, CSR field presents a proliferation of approaches, which are controversial, complex and unclear. CSR theories related approaches in four groups: *first*, instrumental theories, in which the corporation is seen as only an instrument for wealth creation, and its social activities are only a means to achieve economic results; *second*, political theories, which concern themselves with the power of corporations in society and a responsible use of this power in the political arena; *third*, integrative theories, in which the corporation is focused on the satisfaction of social demands; and *fourth*, ethical theories, based on ethical responsibilities of corporations to society. In practice, each CSR theory presents four dimensions related to profits, political performance, social demands and ethical values [4].

in this context, a multinational company in Malaysia, Johor Corporation (JCorp), was being promoting Islamic model CSR through the implementation of the concept of corporate *waqf*. JCorp argue that the concept can ensure sustainable and equitable development. JCorp's corporate *waqf* concept is also a new concept in *waqf* development for enhancing the value of community.

Therefore, this article specifically is to analyse the concept of JCorp's corporate *waqf* as an Islamic model CSR for community development on international development perspective. Model elements of JCorp's corporate *waqf* will be analysed to understand the concept of corporate *waqf* and to show how relevant the concept as an Islamic model CSR to contribute to sustainable community development.

## 2. THE ROLE OF CSR IN DEVELOPMENT

Development has been defined as the process which facilitates for every human person and all peoples the enjoyment of economic, social, cultural and political development [5]. Thus, development is a comprehensive process, aimed at the improvement of the entire population and all individuals [6]. It can be done through activities to eradicate poverty, increase society health and education and so on. It is a fundamental goal of the international community, and is a clearly stated objective of The United Nations. The UN is enjoined in its Charter to promote higher standards of living, full employment, and generally conditions for economic, social and development progress [7]. This open-ended concept of development has now been given a more concrete content by the international community in the form of the United Nations assembly Resolution – The Millennium Declaration or The Millennium Development Goals (MDGs).

The MDGs is commitment of international community to achieve sustainable social and economic development by creating and expanding global cooperation. The MDGs constitute eight goals to be achieved by 2015, that are : halve extreme poverty and hunger; achieve universal primary education; empower woman and promote equality between women and men; reduce under-five mortality by two-thirds; reduce maternal mortality by three-quarters; reverse the spread of diseases, especially HIV/AIDS and malaria; ensure environmental sustainability; create a global partnership for development, with targets for aid, trade and debt relief [8].

To achieve the development goals, the commitment of international community is needed to expand global cooperation, including role which claimed to multinational companies. This is because multinational company has been regarded as part of development actors. Multinational company was very strong development actor compared other development actors. Their strength of capital have made they own great influence in world economy, even in political. They have penetrated political economy conditions strongly both in developing countries and developed countries. Their investments strengthened his capital through much profit and their contribution would be vital for costing political campaign [9].

Their extraordinary capital and their willing to continue resulting long-term profit cause the multinational companies must be involved in international development which can ensure all as well, namely sustainable development. According to The World Commission on Environment and Development (WCED), as in 1987 Brundland Report, sustainable development was defined as development that meets the needs of the present without compromising the ability of future generations to meet their own needs [10]. That development paradigm was explained again in The World Summit on Sustainable Development (WSSD) in Johannesburg, Africa, year 2002, that development must be including sustainable development concept as a new approach based on consideration of intersection and interdependency among economic development, social development and environment development [11].

Involvement forms required from multinational companies in sustainable development is through their CSR practices. CSR is a concept which contains understanding that a company must be responsible on social and environmental impact, sometimes conducted beyond law. On the other hand, the company must be responsible on code of behavior other parties with who the company trade. Also, the company must cooperate and make relationship with society, whether for business purposes or to increase society's value, or both [12]. Due to this, CSR would be a powerful way for the company to participate in improving development and contribute actively to sustainable development.

Theoretically, in the concept of CSR, the relationship between business and society is embedded with ethical values. This leads to a vision of CSR from an ethical perspective and as a consequence, firms ought to accept social responsibilities as an ethical obligation above any other consideration [13]. It is because at least three reason: firstly, company indeed shaped and managed by individual or those people derived from civil society; second, accumulation of the company investment is impossible be achieved without civil society which is their market; third, the company activity cause impact to society [14]. It means that company must do activity its business well in order to do not cause negative impact to social and environment, even could help create society is more prosperous. Through distribution some profit achieved by a company to society will raise positive impact to create social justice. Thus, in the concept of CSR, a company not only has responsible to gain profit but also to carries welfare for society and to ensure existence of nature persistence [15].

One aspect of CSR is community development. It is seen as the key corporate responsibility in some developing countries [16]. Community development is a process conducted by community members. It is a process where local people can not only create more jobs, income and infrastructure, but also help their community become fundamentally better able to manage

change. The “concrete” benefits of community development, such as employment and infrastructure, come through local people changing attitudes, mobilising existing skills, improving networks, thinking differently about problems, and using community assets in new ways. Community development improves the situation of a community, not just economically, but also as a strong functioning community in itself [17].

### 3. ISLAMIC VIEW OF CSR

A being stated that business organization has always played a vital role in the economic and social life of all people throughout the ages. In Islam, business activities are not undertaken to satisfy only material needs and wants but more importantly it should be undertaken to fulfill religious obligation and to achieve other non-material objectives such as to secure social needs. Social responsibility refers to the obligations that an organization has to protect and contribute to the society in which it function. Social responsibility in Islam stems from the concept of brotherhood (*ukhuwwah*) and social justice. The practice of social justice will prevent Muslims from doing harm. Social justice is strengthened through the concept of brotherhood. Brotherhood makes Muslims responsible to each other. The commitment of Islam to justice and brotherhood demands that Muslim society take care of the basic need of the poor [18].

The Islamic view of CSR takes a rather holistic approach. It offers an integralistic spiritual view based on the teachings of the *Qur'an* and the *Sunnah* providing a better alternative philosophical framework for man's interaction with nature as well as his fellowmen. In fact, the moral and ethical principles derived from divine revelations are more enduring, eternal, and absolute [19]. Thus it may serve as better guidelines for corporations when exercising their business and social responsibilities simultaneously.

Comparing with CSR concept of Western, CSR concept of Islam is not novelty. In the past the more secular approach of western capitalism with its focus on materialism, competition, profit maximisation and shareholder primacy [20]. More recently, western capitalism has begun a transition toward a model which recognise the business case for socially responsible behavior. This transition has been widely documented and researched and is well known amongst both academics and practitioners. It opens up the prospect that differences in management styles may become less acute and less of a barrier to successful international business ventures. In turn this might lead to positive returns as the opportunities of closer integration deliver wider benefits all round [21]. Whereas from Islamic perspective, CSR concept being long and becoming guide for who involved in business. Even, development goals in Islam give several points on CSR, such as human resource development, useful production, quality of life and balanced development [22]. Thus. It can be said that CSR concept which campaigned by current Western corporate governance is a part of Islamic corporate governance concept.

CSR for Muslims assumes a broader and more holistic significance. Obviously, the concept is not merely perceived as a strategic or instrumental initiative, which the corporations undertake for the sake of enhancing goodwill or boosting long-term financial performance. It is also not just an act to legitimize the existence of corporations in society and others within the framework of the legitimacy theory or the social contract theory. Instead, the concept of CSR in Islam encompasses a broader meaning embracing the *taqwa* dimension (God-consciousness) by which corporations as groups of individuals, assume the roles and responsibilities as servants and vicegerents in all situations. By so doing, they are ultimately responsible to God, the Owner of their selves as well as the resources they are utilizing and managing. This responsibility to God is, in fact, a function of the intrinsic quality of the Muslims' lives as a trust from God [23].

An example of CSR practice in Islamic perspective is in Turkey. It undertaken through *waqf* mechanism. Among multinational companies in Turkey which conduct activities of Islamic CSR are K09 Group, which is Turkey company first entered in Fortune 500, and Sabanci Group, has 50,000 employees and has USD10.6 total asset billion in year 2005. Those companies actively involved in the programs of through partial distribution their profit directly to hospital, school, and so on [24]. Whereas in Malaysia, there is a multinational company, Johor Corporation (JCorp), which introduce a corporate *waqf* mechanism as a new approach to Islamic model CSR particularly to contribute to sustainable community development.

### 4. JCORP CORPORATE WAQF: TOWARDS REACHING OUT TO THE COMMUNITY DEVELOPMENT

*Waqf* is an Islamic system that stems from the idea of institutionalising voluntary giving in order to guarantee sustainability. It has strengthened and empowered communities since the early days of Islamic history. Inspired by the spirit of *waqf*, on 3rd August 2006, JCorp took the first bold step into totally uncharted territory towards transforming itself into a full fledged Trust Corporate Institution via the Islamic *waqf* approach. This "Corporate *Waqf*" move involved the transfer to *Waqf* RM200 million (on net asset value basis) of JCorp's shareholdings in its public listed subsidiaries [25]. The Corporate *Waqf*, a first ever undertaken by a corporate business institution in the world, can be considered as an Islamic CSR program initiated by JCorp to

integrate business into serving a higher social cause. The aim is to institutionalize the link between the wealth creation and value addition effort of JCorp as a corporate entity with meeting the needs of the marginalized and the alienated in society on a structured and sustainable basis.

This corporate *waqf* concept may be carried out by creating firm and company organization which not possessed by particular individual. Nevertheless, Muslim community actually have not many aware about it even though it has long in Islamic. For example, Taj Mahal building is actually *waqf* building and when India is independent, the government has taken over. Similarly is Turkish government which built many large and aesthetical mosques, those used *waqf* approach. Also, Al-Azhar University in Egypt is even *waqf* practice which later copied by West people which established foundation enable those build Oxford University [26].

JCorp's corporate *waqf* is also testimony to JCorp's commitment towards ensuring 'giving back' to society and reaching out to the community. Through the *waqf* mechanism, JCorp pledges to dedicate 25% of the annual dividend payout for the shares transferred to *waqf* to be spent towards supporting charitable causes and religious institutional activities to meet the needs of the larger community of all ethnic and religious backgrounds, particularly for the benefit of the disenfranchised and the less privileged in society. Then, as much as 70% of the dividend is distributed to reinvestment, while its 5% is distributed to Johor Islamic Council [27].

Underlining its role as an 'Amanah' (Trust) Corporation, JCorp is conscious of its responsibilities to ensure that its business objectives and corporate successes are achieved based on methods and approaches that are aligned with Islamic and universal values that will, in the long run, benefit the society at large. Right from the start, JCorp has always adopted a much broader dimension to its corporate obligations in meeting with the aims and objectives of its CSR.

As a part of the entities in society, JCorp believes that the company, including its employees, morally should take an active participation in community and social development through CSR. The active participation is not only believed will increase JCorp image, but also will help to raise economic and social development. Due to this, JCorp trusts that by conducting corporate management through the concept of corporate *waqf*, practices of JCorp's CSR will be more ascertained continuity.

JCorp makes 'no injury principle' as important principle in implementing CSR. This principle refer to the rule which motivate corporate actions in relation with society. The relationship based on 'no injury principle' can prevent or reduce corporate negative action to others or society, selfish, or actions that may cause injustice to others. It also referred to effect of product or service to consumer and environment.

At JCorp, non-profit associations and bodies are known as Amal Business Organisation (ABO). ABO functions as a medium for JCorp to contribute towards the development of the ummah through various aspects of charity, well-being and recreation as well as entrepreneurship. In 2011, a total of 27 non-profit organisations are operating under JCorp's ABO. These ABOs are divided into four categories namely Social & Public Welfare Development, Entrepreneur Development, Sports and Recreation Development and lastly, Staff Welfare [28].

For its efforts of CSR, JCorp was awarded Best Corporate Social Responsibility Award by Halal Journal, in conjunction with The World Halal Forum 2006 [29]. Then, in 2011, JCorp was awarded Outstanding Development Project Award for CSR by Association Development Financing Institutions in Asia and The Pacific (ADFIAP) [30].

## 5. CONCLUSION

Generally, *waqf* property more developed through traditional ways, for example *waqf* property used immediately for school construction, religious worship and basic needs of society by social and religious institutions. Whereas corporate institutions having tight role and influence for development.

JCorp's corporate *waqf* is a new concept to develop *waqf* property. Through the corporate *waqf* mechanism, JCorp pledges to dedicate some of its annual dividend, payout from the shares transferred into *waqf*, to support charitable causes. Whereas, some others are reinvested to ensure continuous growth of the *waqf* assets thus translate it into higher distributable income for the benefit of society at large. The concept can be considered as an approach to sustain CSR for community development based on Islamic business ethics. This is due to the principle that property is a trust where its earnings and utilization should be accountable to ensure shared prosperity, social justice, community balance and stronger community.

## ABSTRACT

*This study has been done in Putri Hijau Hospital Kesdam I/BB Medan to the regular patients in the in-patient wards. The purpose of this explanatory survey study was to analyze the influence of service quality on the satisfaction of in Putri Hijau Hospital Kesdam I/BB Medan. The data for this study were obtained from 140 regular patients through questionnaire-based interviews and then were analyzed through multiple linear regression tests. The result of this study showed that the quality of service measured based on the aspects of tangible, reliability, responsiveness, assurance and empathy had influence on the satisfaction of regular patients in Putri Hijau Hospital Kesdam I/BB Medan. Empathy dimension was the variable that had the biggest influence on the satisfaction of regular patients ( $\beta = 1.402$ ). The Putri Hijau Hospital Kesdam I/BB Medan is suggested to improve their quality of service for the regular patients to pay attention to the dimension of service quality that can improve the satisfaction of regular patients. The dimension of empathy needs to be especially paid attention because it is the most dominant aspect influencing the satisfaction of regular patients.*

## Keywords

*Service quality, satisfaction, patient*

## 1. INTRODUCTION

Patient satisfaction is a function of the assessment of patients for health services that provided by the hospital in the hope before the patient receiving of health care from the hospital as a provider; the patient will be satisfied if the quality of hospital services is higher or at least equal to the expected patient.

Advances in science and technology is rapidly causing the changes in the external environment and internal hospital, so the hospital managers must change the paradigm or worldview that hospitals today is not merely a social organization, but is oriented towards profit organization . Increased medical technology with other components force hospital managers to think and applying socioeconomically in hospital management in the face of market competition [7].

According Tjiptono [6] along with the progress of science and technology, in which changes take place rapidly, the higher education community, so that the needs, desires and demands of the community as an hospital customers are also increasingly complex. To achieve and sustain patient satisfaction, hospital organization must do the following four things: First, identify who are the customers. Second, understand the level of customer expectations for quality. Third, understand the strategy of quality customer service. And the fourth is to understand the cycle of measurement and feedback of customer satisfaction.

Level of customer satisfaction is highly dependent on the quality or the quality of a product or service offered [5]. According to Parasuraman *et al.* in Shahin [4], the quality of a service is determined by the 5 (five) dimensions, namely direct evidence (tangible), reliability, responsiveness, guarantee (assurance), and empathy. These dimensions were used to evaluate the performance of the company's customer service, so as satisfaction and dissatisfaction will depend on the fifth dimension.

Parasuraman *et al.* in Shahin[4], the anticipation of the quality or quality must be made by the hospital to survive and thrive is to increase the income of the patient, because the patient is the source of income of the hospital either directly (out of pocket). Without the patient, the hospital cannot survive and thrive given the cost of hospital operations is very high. Therefore, in order to increase patient visits to the hospital then the hospital should be able to display and give satisfaction to the patient.

One way to differentiate primary health care services, including inpatient services is to provide quality health care services than the competition consistently. The key is to meet or exceed the expectations of patients about the quality of care delivered. After receiving the health care services the patient will compare the service they experienced with the services expected. If the service is experienced under the expected service, the patient no longer interested to the health care provider. If the services of experienced meet or exceed expectations, patients will use the same healthcare provider in the future [5].

Parasuraman *et al.* in Shahin[4] identifies the gap between consumer perceptions and perceptions of service providers resulting in failure of the delivery of quality services. Services providers do not always understand exactly what the customer wanted. Furthermore Parasuraman *et al.*, in Shahin [4] states that the assessment of the patient's quality is determined by two things: the quality of patient expectations (expected quality) and the patient's perception of quality (perceived quality).

Based on these considerations, the measurement of the success of a company's services in this hospital are determined by assessments and patients' perceptions about the quality of services provided by hospitals with all the elements that exist in the internal and external environment which interact and influence the success of the hospital in achieving patient satisfaction.

According to Kotler [1] sense of satisfaction as feeling happy or upset someone who is experienced after comparing the perception of a product performance or results to expectations. Nevertheless, Supranto [5] states that many referred to the definition of satisfaction is based on the *disconfirmation paradigm* concept. Under this paradigm, satisfaction is formed from a reference comparison is to compare the results received with a certain standard. Comparison of the three possible forms: first is when the perceived service exceeds expectations where services received or perceived exceed expected service, the second when the quality of service to meet the service expectations if perceived as expected and the latter if the services received under expectations when service perceived worse than expected service.

In the goal-oriented patient satisfaction, as well as aspects of the role of the hospital facility resources such as doctors and nurses both medical and non-medical are very important because they will determine the performance of the patient's perception of the services provided. Perceptions of the patient toward the quality delivered will continue in the formation process of the general perception of the hospital.

According Wasisto [8] quality of health services is influenced by many factors in the hospital as a system. These factors are hospital management, health care, finance, healthcare facilities and technologies that used, and interaction-driven activity through certain processes and procedures by utilizing existing resources to produce a service.

According Puti [2], the quality and satisfaction are inseparable like two sides of a coin that are interconnected and influence. Quality gives an impulse to the patient to establish a strong relationship with the hospital. Relationships like this in the long run allow hospitals to understand thoroughly the needs and expectations of patients. Thus, hospitals can improve patient satisfaction in hospitals through a pleasant patient experience and minimize or eliminate unpleasant experience. Patient satisfaction in the end will be affect to the fidelity of patients to hospitals that provide a satisfactory quality.

One effort that patient satisfaction can be met will require information about what is considered important by the patient's perception and how the performance of the hospital today, whether better meet patient expectations or not. According Ranguti [3] level of customer expectations (patients) is one way of measuring patient satisfaction compared with the interests of the hospital, is expected by the necessary information will be known and what factors should be improved in order to give higher satisfaction to the patients.

Putri Hijau Hospital Kesdam I BB Medan is one of the hospitals owned by the Indonesian National Army in the city of Medan who receive public patients. Based on the strategic plan of the Putri Hijau Hospital Kesdam I BB Medan in 2010-2014 within Chapter III of the duties and functions of the hospital stated that in improving health services to the community as a whole, the targets are not limited to members of the army and their families, but also organizing health services for the general public.

The problem faced is the low level of satisfaction of patients using the hospital because of the quality of service provided does not meet the expectations of patients.

Based on a preliminary survey in January 2012, the general patient visits hospitalized at the Putri Hijau Hospital Kesdam I BB Medan in 2010 and in 2011 has decreased, from 2826 people to 1865 people so a decline of 34.01 %.

The results of interviews with 10 people hospitalized patients generally there were 8 people who complain about the patient's general health services such as hospitalization, medication services are not satisfactory, a consultation with the doctor is very limited, less comfortable wards, not firmly visit time of doctors to a hospitalization patient and nurses being less friendly to patients. The results of interviews with the patient to describe the phenomenon of regular patient dissatisfaction associated with the dimensions of quality of health care in hospitals.

Based on the description above and the low satisfaction of general patient that hospitalized at the Putri Hijau Hospital Kesdam I BB Medan the researchers would like to know "The Influence Perceptions of Service Quality on Patient Satisfaction Of Regular in the Inpatient wards in Putri Hijau Level II Hospital Kesdam I / BB Medan "

## 2. METHODOLOGY

This study was an *explanatory* survey, which aims to analyze the influence of perceptions of service quality on patient satisfaction of regular patient in the inpatient ward in Putri Hijau Hospital Kesdam I / BB Medan that conducted on a sample research of 140 people.

Method of data collection for the primary data in this study was obtained through direct interviews and secondary data from other official documents, especially the data in Putri Hijau Hospital Kesdam I / BB Medan. The data analysis processed was using multiple regression tests.

## 3. RESULT AND DISCUSSION

### 3.1. Perceptions of Quality of Care in the Putri Hijau Hospital Kesdam I / BB Medan

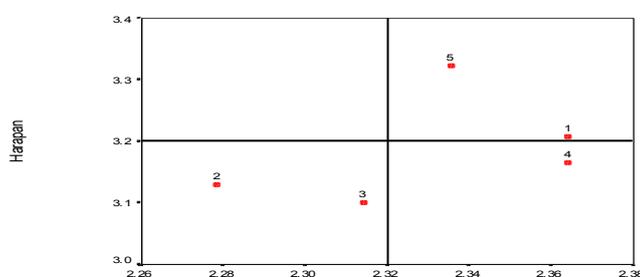

- 3.1.1. Dimensions of physical evidence (tangible) in the quality of care at the Putri Hijau Hospital Kesdam I / BB Medan by the results showed neatness of administrators uniform in accepting hospital patients is not well stated by 89(63.6%) respondents, neatness of physician in examinations and treatment is not well stated by 70 (50.0%) of respondents, the cleanliness and neatness of nurses in the treatment to the patient is not well stated by 59(42.1%) of respondents, the availability of equipment and health facilities in hospital is not well stated by 55(39.3%) respondents and comfort around the hospital environment is not well stated by 44(31.4%) of respondents.
- 3.1.2. Dimensions of reliability in the quality of care at the Putri Hijau Hospital Kesdam I / BB Medan based on the study indicates that the administrative management does very well stated by 92 (65.7%) of respondents, the ability of physicians to provide services examination and treatment are not well stated by 70(50.0%) of respondents, the ability of nurses to provide nursing services is not well stated by 56(40.0%) of respondents, suitability and adequacy of prescription drugs is not well stated by 52(37.1%) respondents and nurses timelines of the work is not good stated by 46 ( 32,9 %) respondents.
- 3.1.3. The dimensions of responsiveness (responsiveness) in the quality of care at the Putri Hijau Hospital Kesdam I / BB Medan based on research shows cost transparency, and the ability of administrators to explain about the fees charged to the patient in detail is not well stated 88(62, 9%) of the respondents, the ability of physicians to be responsive in resolving complaints of patients is not well stated by 68(48.6%) of respondents, dexterity (responsiveness) of nurses in helping patients at the time of need is not well stated by 56(40.0 %) of the respondents, dexterity (responsiveness) laboratory personnel in conducting laboratory tests on patients is not well stated by 60(42.9%) of respondents and dexterity (responsiveness) hospital janitor in a hospital environment does not handle well stated by 56 (40.0 %) of respondents.
- 3.1.4. Dimension of guarantee (assurance) in the quality of care at the Putri Hijau Hospital Kesdam I / BB Medan by the results showed that treatment guarantees given to patients is not well stated by 83(59.3%) of respondents, the ability of clinicians to establish diagnosis and cure the patient's complaint is not well stated by 72(51.4%) of respondents, courtesy and friendliness of clinicians are not well stated by 64(45.7%) of respondents, the ability of nurses to provide care is not well stated by 56(40.0 %) of the respondents and the courtesy & friendliness of nurses to serve patients is not well, stated by 67 (47 %) of respondents.
- 3.1.5. The dimensions of empathy in the quality of care at the Putri Hijau Hospital Kesdam I / BB Medan based on the results of the study showed concern administrative staff in providing information to patients about hospital services is not well stated by 68(48.6%) of respondents, attention physicians in dealing with patients and physician willingness to provide a special time for consultations to patients is not well stated by 57(40.7%) of respondents, the attention of the nurse in providing care services is not well stated by 61 (43.6%) of respondents, treatment of the hospital to the patient is not well stated by 65 (46.4%) of respondents and sympathetic physician in calming anxiety to the patient's illness experience is not well stated by 62(44.3%) respondents

### 3.2. General Patient Satisfaction for Service of Putri Hijau Hospital Kesdam I / BB Medan

- 3.2.1. Respondents expectations of administrative services at the Putri Hijau Hospital Kesdam I / B Medan discovered: as many as 55(39.3%) respondents expect neatness of officers uniform, 66 (45.7%) of respondents stated they were quite expecting compliance with service procedures in serving patients, 51(36.4%) of respondents stated they were quite expecting the response that given by officers in serving patients, as many as 78 (54.9%) of respondents stated that they were quite expecting certainty patients to obtain administrative services, 82 (58.6 %) of respondents stated that they were quite expecting the attention and attitude of administrative officer.

The reality of administrative services at the Putri Hijau Hospital Kesdam I / B Medan discovered: as many as 62 (44.3%) respondents were less satisfied neatness clothes officers, 53 (37.9%) respondents were less satisfied about the suitability of the procedure for the serve patients, as many as 62 (44.3%) of respondents said less than satisfied about the response of a given officer in the service of patients, as many as 47 (33.6%) respondents were less satisfied about the certainty of the patient to obtain administrative services, as many as 44 (31.4%) of respondents expressed concern the lack of satisfaction about attention and attitudes of the administrative officer.

*Cartesian analysis of administrative services*

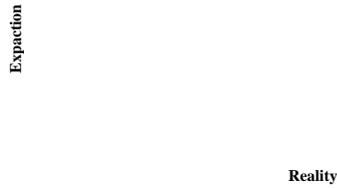

Figure 1 : Cartesian diagram of Administrative Services

3.2.2. Respondents' expectations of physician services at the Putri Hijau Hospital Kesdam I / BB Medan was found: 44.3% of respondents expect the neatness of clothing doctors, 37.9% of respondents stated they were quite expecting conformity with the procedure for physicians to serve patients, 33.6% of respondents stated they were quite expect the response given by the doctor in the service of patients, 40.7% of respondents stated they were quite expecting certainty physician services, 47.9% of respondents stated they were quite expecting attention and physician attitudes.

The reality of physician services at the Putri Hijau Hospital Kesdam I / BB Medan discovered: as many as 75 (53.6%) respondents were less satisfied neatness of attire doctors, as many as 67 (47.9%) respondents were less satisfied about the suitability of the procedure for doctors in serving patients, as many as 66 (47.1%) of respondents stated are not happy about the response given by the doctor in the service of patients, as many as 51 (36.4%) respondents were less satisfied about the certainty of the patient to obtain medical service, as many as 52 (37.1%) of respondents expressed the lack of satisfaction of attention and physician attitudes concern.

*Cartesian analysis of physician services as in the following diagram:*

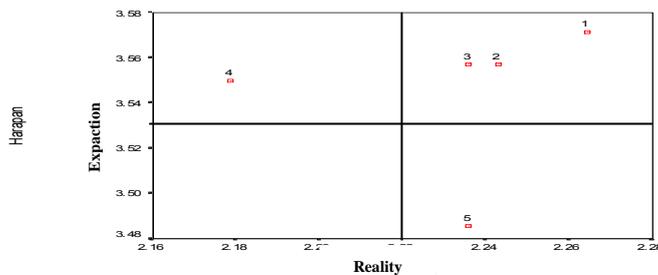

Figure 2: Diagram Cartesian of Physician Services

3.2.3. Respondents expectations of nursing services at the Putri Hijau Hospital Kesdam I / BB Medan discovered: as many as 53 (37.9%) of respondents expect neatness nurse outfit, as many as 44 (31.4%) of respondents stated they were quite expecting conformity with the procedure for nurses in serve patients, as many as 48 (34.3%) of respondents stated they were quite expecting the response given nurses in serving patients, as many as 68 (49.6%) of respondents stated they were quite expecting certainty patients to get care nurses by 76 (54.3 %) of respondents stated they were quite expecting attention and attitude of nurses.

The reality of nursing services at the Putri Hijau Hospital Kesdam I / BB Medan discovered: as many as 55 (39.3%) of respondents were less satisfied with the neatness nurse outfit, as many as 66 (47.1%) of respondents were less satisfied about the suitability of the procedure for nurses in serving patients, as many as 57 (40.7%) of respondents stated are not happy about the response given nurses in serving patients, as many as 46 (32.9%) of respondents were less satisfied about the certainty of the patients to get nurse services, as many as 36 (25.7%) of respondents expressed concern about the lack of satisfaction and nurse attitudes

*Cartesian analysis of nursing care as in the following diagram.*

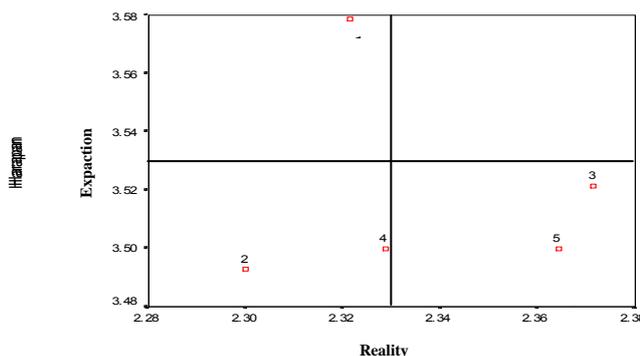

Figure 3: Cartesian Diagram of Nurses care

3.2.4. Respondents expectations of laboratory and pharmacies officer services at the Putri Hijau Hospital Kesdam I / BB Medan discovered: as many as 62 (44.3%) of respondents expect neatness of uniform of laboratory and pharmacies workers, as many as 59 (42.2%) of respondents stated they were quite expecting compliance with procedures of laboratory and medicine services officer in the service of patients, as many as 56 (40.0%) of respondents stated they were quite expecting the response that given by laboratory and pharmacies officials in serving patients, 60 (42.9%) of respondents stated they were quite expecting certainty patients for laboratory and pharmacies workers care as much as 86 (61.4%) of respondents stated they were quite expecting attention of laboratory and pharmacies workers attitudes.

The reality of the service of laboratory and pharmacies officer at the Putri Hijau Hospital Kesdam I / BB Medan discovered: as many as 47 (39.3%) respondents were less satisfied with the neatness of uniform of pharmacies and laboratory workers, as many as 53 (38.1%) of respondents said less satisfied about the suitability of the procedure for laboratory and pharmacies officials in serving patients, as many as 49 (35.0%) respondents are not happy about the response that delivery of laboratory and pharmacies officials in serving patients, as many as 49 (35.0%) of respondents stated not happy about the certainty of the patient to receive care of laboratory and pharmacies workers, as many as 48 (34.4%) of respondents stated they were quite satisfied about the care of laboratory and pharmacies worker attitudes.

Cartesian analysis of laboratory and pharmacies workers services such as the following diagram:

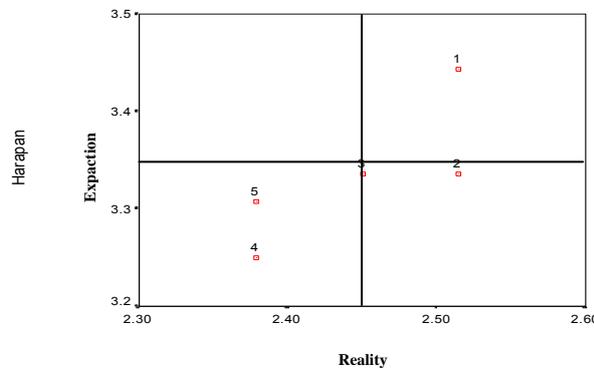

Figure 4 : Cartesian Diagram of Laboratory and Pharmacies Services

### 3.3. Perceptions of Quality of Service to the General Patient Satisfaction

3.3.1. Based on the *Pearson* statistical correlation values obtained  $r = 0.641$ ,  $p = 0.000$ , indicating a significant relationship between the dimensions of physical evidence to the satisfaction of the general patient at the Putri Hijau Hospital Kesdam I / BB because the value of  $p = 0.000 < 0.05$ . *Pearson* statistical correlation between the dimensions of reliability and general patient satisfaction obtained value of  $r = 0.699$ ,  $p = 0.000$ , indicating a significant relationship between the dimensions of reliability and satisfaction of general patients at the Putri Hijau Hospital Kesdam I / BB Medan due to the value of  $p = 0.000 < 0.05$ .

3.3.2. *Pearson* statistical correlation between the dimensions of responsiveness with the general patient satisfaction obtained value of  $r = 0.710$ ,  $p = 0.000$ , indicating a significant relationship between the dimensions of responsiveness with the general patient satisfaction of the Putri Hijau Hospital Kesdam I / BB Medan due to the value of  $p = 0.000 < 0.05$ . *Pearson* statistical correlation between the dimensions of patient satisfaction with general insurance obtained value  $r = 0.699$ ,  $p = 0.000$ , indicating a significant relationship between dimensions of security with the general patient satisfaction of the Putri Hijau Hospital Kesdam I / BB Medan due to the value of  $p = 0.000 < 0.05$ . *Pearson* statistical correlation between the dimensions of empathy with the general patient satisfaction obtained value of  $r = 0.738$ ,  $p = 0.000$ , indicating a significant relationship between the dimensions of empathy with the general patient satisfaction of the Putri Hijau Hospital Kesdam I / BB Medan due to the value of  $p = 0.000 < 0.05$ .

## 4. MULTIPLE REGRESSION ANALYSIS

Based on the multiple regression test results obtained the variables in the regression line equation becomes:  $Y = -73,235 + 0,860X_1 + 1,114X_2 + 1,075X_3 + 1,115X_4 + 1,402X_5$

For maximum value  $X_1 = 20$ ,  $X_2 = 22$ ,  $X_3 = 19$ ,  $X_4$  and  $X_5 = 20 = 19$ , then the equation can be established as follows:  $Y = -73,235 + 0,860(20) + 1,114(22) + 1,075(19) + 1,115(20) + 1,402(19)$

$$Y = -73,235 + 111,931$$

$$Y = 38,696$$

Based on the regression equation settlement calculations showed that the level of General patient satisfaction for Putri Hijau hospital Kesdam I / BB Medan of 38.696. If the calculation of the equation assumed in units of percent, the level of General patient satisfaction is 38.696%.

Regression determination of coefficient ( $R^2$ ) = 0.679 indicates that all independent variables can explain the variation in the dependent variable (general patient satisfaction) of 67.9%.

## 5. CONCLUSION AND SUGGESTION

### 5.1. Conclusion

Perceptions of service quality dimensions measured from the physical evidence (tangible), reliability, responsiveness, guarantee (assurance) and empathy influence on general patient satisfaction in Putri Hijau Hospital Kesdam I / BB Medan. Dimensions of the most dominant influence general patient satisfaction is dimensions of empathy ( $\beta = 1.402$ ).

### 5.2. Suggestion

5.2.1. The Services of the Putri Hijau Hospital Kesdam I / BB Medan (administration, physicians, nurses and medical support) need to consider the dimensions of service quality (tangibles, reliability, responsiveness, assurance and empathy) in conducting health services so as to improve general patient satisfaction.

5.2.2. The dimensions of empathy for the patient should be of particular concern to the health officials at the Putri Hijau Hospital Kesdam I / BB Medan, due to the attention that delivered to the patient is the most dominant aspects that affect the general patient satisfaction. Efforts to increase the dimensions of empathy can be done by carefully monitoring each patient and immediately fulfill the things that are required of patients, for example, administrators can provide information to patients, physicians were able to perform the treatment according to the patient's condition, the nurse able to perform services in accordance with the stages of the nursing care and medical support personnel capable of carrying out laboratory and pharmacy services (drugs) in accordance with the doctor's prescription made.

## ABSTRACT

*This paper presents a case study of the participatory project in the Jombang glass bead craft industry. Economic instability has brought significant business challenges in the community. The involvement of outsiders to collaborate with craftspeople in order to support business innovation as well as strengthen the social capital in the community is essential. However, facilitating a rural community to formulate and implement bottom-up planning needs an integrated approach. In this paper, we explain a participatory project in the rural craftspeople community that resulted in a collective action. The project aimed at uniting and empowering rural craftspeople focusing on the unique skills and knowledge of participants. There are some aspects influencing the success of collective action: the ability to understand the local political situation; the role of facilitators to respect and support the unique potential of craftspeople; and the economic benefit of the program.*

## 1. INTRODUCTION

Traditional craft industries in Indonesian rural areas are decreasing significantly. One of them is the traditional glass bead craft industry in Jombang, East Java. Only 20 industries operate today while 200 existed in early 2000. To prevent the situation from worsening a community development program is needed. Previous programs organized by government and other institutions, such as forming clusters, organizing training about management/design/marketing, providing capital loans and supporting exhibition for craftspeople, have less contribution to community development. In addition, government financial support for craft association has triggered conflict among members in it. Instead of developing rural craftspeople community, some programs have lead to social jealousy.

This paper describes a case study of a collaborative project between designers and rural craftspeople. The project aimed at uniting and empowering rural craftspeople focusing on the unique skills and knowledge of participants. It assumes that participants must know better about themselves. However, these people need to be facilitated to “speak”.

## 2. THE CASE

Jombang glass bead craft industry was initiated by 3 local craftspeople in the middle of the 1970s in Plumbon-Gambang village, Gudo District, East Java, Indonesia. Initially, they produced eye-rings. In order to deliver orders on time, they employed family and relatives as craft workers. As the craft workers knew the glass-bead-making technique and the market, later, they ran their business. However, they had limited knowledge about the glass bead market. When most of the craft owners produced the same products and delivered them to the same market destination, the market immediately became oversupplied. It caused stagnancy of glass bead craft industry for about a decade.

In the middle of the 1990’s a lover of ancient beads came to the village and learned to create replicas of ancient beads with some craftspeople. The bead lover was also a mineral expert. He already had a potential market for the ancient beads. Therefore, he conducted an intensive collaboration with craftspeople to explore ways of producing replicas of ancient beads to sell. The collaboration brought about the insight of mixing material, innovative techniques and a new potential market for

craftspeople. Craftspeople gained significant earnings by selling replicas of ancient beads to antique lovers and Indonesian tribes at a much higher price than its production cost. It was a significant point of improvement in the industry.

However, the market shortly became oversupplied causing a drastic decreasing in bead price. Only craftspeople with extraordinary bead making skill focusing on high quality beads got orders, while craftspeople with average skills found it difficult to gain any market.

Fortunately this situation did not take a long time to improve. As Bali is a main entrance to overseas buyers, one craft person attempted to sell his product to Bali. At this time, around 2000, the beads were exposed as a world fashion trend. Accordingly, there was an enormous demand of glass beads from Bali. Therefore, the industries grew rapidly, and reached the peak number of 200 craft industries, not only in Plumbon-Gambang village, but also in the six surrounding villages.

Those glass bead craft industries are small industries with a small production capacity. While a big demand of bead came from Bali retailers, craft owners were encouraged to fulfil the demand by involving their families and close friends. That situation led to the exchange of knowledge about how to make beads, get material resources, share orders or market among friends and families. The supportive economic situation reinforced social relations between craftspeople and fostered the development of the community significantly.

As the glass-bead-craft-business knowledge was spread within the village and surroundings, there were more and more craftspeople who selected Bali as the only prospective market destination. Consequently, the market once again became saturated. Most of The craftspeople chose a low-pricing strategy to face a saturated market, instead of seeking innovative attempts. In addition, as the matter of fashion trend, the bead was no longer exposed and it gradually became obsolete. Bead price inevitably fell. In this situation, the transactions between craftspeople and Bali retailers gave no contribution to increase craftspeople's wealth except for a quick return of their investment [5].

Meanwhile, selling products in a local market also brought another challenge. Local buyers preferred to buy the imported beads than local glass beads. The economic demographic background of local buyers influences the attitude of price-sensitive-purchasing. Local buyers have little information about the uniqueness of local glass beads provided by craftspeople. In the meantime there were abundant supplies of cheap imported beads by local traders, they tend to buy cheaper imported beads. This situation caused some craftspeople prefer to trade the cheap imported bead rather than continue to produce glass bead while the others mix local and imported beads.

Facing those difficult situations, some craftspeople took fraudulent attitudes to save their business, such as: the tendency to avoid payment to take advantage of the proximity of family relationships (this tendency was also notified by Geertz[18]), copying design and taking over other people's order without permission [14], selling products at a far lower price or hijacking smart craft worker. Those attitudes broke the social relationship among craftspeople, therefore, hampered the development of the community.

Portes notified that there will always be an internal competition in a homogeneous community [18]. In this case, when craftspeople faced a difficult economic situation as the result of saturated markets, changing trends and the abundance of cheap imported products in the market, there was an internal competition weakened the social relationships of craftspeople community. The nature of cohesiveness as a result of a close-relationship in rural society, enabled the bigger possibility of leaking information about markets and design, then resulted in unfair practices.

Some craftspeople took unfair practices other than innovation because of their limited educational and cultural background to save their business. On the other hand, craft expertise is a synthesis of cognitive, social, technical and aesthetic skill. In order to follow the rapid dynamics of the current business situation, craftspeople must have complex skills such as business, design and manufacturing. Considering this difficulty, the cooperation or collaboration among craftspeople and stakeholders, such as entrepreneurs and professionals in the design, tourism or other sectors, is needed [15].

### **3. THEORETICAL FRAMEWORK**

Scholars have warned of some current challenges to the survival of a business in a traditional craft industry. This section explores these notions in addition to ideas for the development of the rural handicraft industry. In order to understand the context of rural Indonesia, or more specifically Java, we examine some theories that elaborate on the nature of social relationships in rural Java and how these will influence community development.

Unlike most of the industries based on natural resources, a craft industry is based on culture. As a craft industry produces material goods using traditional techniques that have been employed for a long time, a craft industry is based on material culture. Friel stated that goods based on material culture are more likely to be sustained. This is because a traditional craft industry is closer to local resources and traditional knowledge, and is less demanding of financial capital and technological innovations. In addition, this industry should be more concerned with intellectual property rights to protect their intellectual value [7].

However, uniqueness and skillful expertise of making things may not guarantee business survival in the current era of tight business competition. Succeeding in business in a craft industry takes complex skill in the fields of technology, business and design. Girón et.al examined there were 23 key factors of success in a handicraft industry [9]. They used a quantitative method to analyze success factors of a Mexican handicraft industry. They found that the most influential factors are a pricing strategy oriented to profit, personal recommendations to promote products, product diversification and the information given to customers [9]. Similarly, Fillis observed that internal managerial skills and a supportive personality affect the performance of a craft business enterprise [6]. Furthermore, Friel argued that for the traditional handicraft industry to be able to compete in the era of globalization, changes were needed. A traditional handicraft industry usually produces low quality and low quantity products and this should be transformed into soft industrial design with the ability to produce “design-based goods” of high quality and in high quantity [7].

Despite the potential uniqueness of craft industry as material culture, in order to succeed, traditional craftspeople face complicated challenges. Competition with cheaper products that offer new patterns, new trends or customized design for a niche market, and the weakness to master the rapid development of information technology [5] are some of the challenges to be overcome. Furthermore, as observed by Kamara, rural craftspeople often lack confidence, professionalism, information and specialization and have a weak survival mentality, business and managerial skills and short-term strategies [11]. These factors mean that craftspeople are prone to be exploited by others who aim to gain a larger return, beyond trade purposes [5].

In consideration of the difficult situations that traditional craft industries face for their survival, many advisory programs have been provided by external agencies [16,20,23]. However, the lack of attention to local issues in most of the top-down advisory programs, such as short-term training [10], frequently does not necessarily reflect craftspeople’s needs. Therefore, providing bottom-up programs in which participants could be involved in deciding the program is considered important. A bottom-up program using a participatory approach respects the participant’s uniqueness and considers that participants know their own contexts better than an outsider. Therefore, as specified by Chambers [4], in participatory projects, outsiders have roles as convenors, catalysts and facilitators rather than planners.

Nonetheless, a bottom-up program does not guarantee the increasing possibilities of participation [3]. Scholars have noticed that only in rare circumstances would groups of individuals act in a co-ordinated and co-operative manner, unless there is coercion to force them to do so. This is because they fail to see direct individual benefit for the time and cost they must share, and because of a “free-rider” mentality. However, Olson as cited by Beard [1], concedes that with smaller groups, the free-rider problem is reduced.

Moreover, cultural tensions in the internal community, as well as different interests, could hamper the effectiveness of the program. Since most rural societies are relatively ‘integrated’ [3,12], in order to undertake an effective advisory program for rural craftspeople, we should consider more comprehensive aspects, such as economic and political situations, rather than focus on single aspects, such as design alone. Hence, some scholars implied that encouraging innovations for rural craftspeople is complicated [8,14].

A conscientious understanding of the social network in the community is the first important step in undertaking a bottom-up program [3,13]. In particular, the type of social network affects the success of community development. Scholars investigated social capital as one type of social network that could affect a significant outcome for the development of community [17, 18]. Social capital is characterized by trust, reciprocity and cooperation within the social network [1].

Coleman as cited by Beard [2], stated that the existence of social capital in the community is influenced by closure, stability and the presence of communitarian ideology. Closure is the situation in which there is pressure on a social system, such as a sanction, to maintain the mutual interest of each person. It is more likely to occur in a rural area, when people know each other’s extended families and personal histories very well. Stability is related to the wealthiness of the people in terms of socioeconomic conditions, while communitarian ideology is something or someone that encourages the individual to act, beyond his own interest.

In summary, to succeed in the craft business, complex skills in areas such as management, design and technology are needed. Rural craftspeople with a limited educational background have difficulties in environment of tight business competition. Their social capital that reflected mutual cooperation in the past was broken by the economic difficulties. Top down programs that focus only on one aspect such as management or design, contribute less to the re-development of the community. A comprehensive understanding of the local situation, followed by a bottom-up participatory project has a greater prospect of supporting a community's development.

#### 4. METHOD

The researchers have conducted the participatory project in two fieldworks. The first fieldwork was in 2011. We used an ethnographic technique by visiting the village a few times prior to living there for a month, attending community events and conducting door-to-door interviews. This step was followed by a collaborative design learning project between the designers and a group of craftspeople to explore innovative design participation. This activity resulted in revealing new glass bead designs [22].

In the next fieldwork in 2012, to have a better impact in the community, we broadened the scope of participants by involving craftspeople from different groups in the community as inclusively as possible. Over 2 months there were community meetings on a weekly basis to design the bottom-up participatory project. Two on-going and two newly-graduated design students from a local university facilitated the project.

During the fieldwork, the researcher spoke in the local language (Javanese), and preserved a feeling of equality and closeness with rural craftspeople. The researcher also had a chance to speak in a community forum along with the village head. This moment provided a significant impact as researchers implicitly receive legitimacy from the village leaders. As noted by Puri [19], in some cultures it is very important to involve senior figures to give the project legitimacy and to persuade people to engage.

The craftspeople agreed to meet on a weekly basis to plan programs enhancing the glass bead craft industry. One of the craftspeople suggested, "*Cangkrukan Manik*" as the name of the meeting and this was agreed on by the others. *Cangkrukan* is a Javanese term which has a similar meaning with "hang out", but it means to sit together for no specific purpose. *Cangkrukan* is usually filled with chatting. People usually do *cangkrukan* after work for relaxing. *Manik* (Javanese) means bead. So, *Cangkrukan Manik* means sit together informally, to discuss any issues related to beads.

The *Cangkrukan Manik* meeting brought up the issue of local buyers preferring to buy cheaper imported beads than the local glass beads. Craftspeople and facilitators shared ideas on how to attract the local market. Some craftspeople expressed the opinion that people viewing the glass bead making process would be more likely to buy the products than if they did not directly observe how the beads were made. From this, a question emerged about the possibility of going to the target market instead of waiting for visitors to come to the site. This would be a good opportunity for disclosing the techniques on making beads to the potential local buyers. That idea would be a marketing strategy to increase local awareness of the glass bead craft industry. The participants crystallized this idea in the third *Cangkrukan Manik* meeting as a glass-bead-making workshop. Next, the facilitators assisted the craftspeople to refine their detailed planning of the implementation of the project. After considering the three important aspects, safety issues, purchasing and the power of word-of-mouth to spread the information, the participants decided to select senior high schools surrounding the industry as targets of pilot projects. Facilitators assisted craftspeople to draw up a proposal and approach targets.

Figure 1: Craftspeople showed their expertise of making glass bead in the workshop (doc: author).

After 3 weeks of planning and preparation, participants and facilitators held the pilot project. All the craftspeople contributed to the program in accordance with their ability or the resources they had. Only 5 to 6 craftspeople had available time to be the workshop instructors. The craftspeople who were unable to go to the workshop, contributed their products to be sold and lent equipment.

The craftspeople collaborated with the facilitators, performing the glass-bead-making workshop to four high schools in three cities surrounding the industries. Each workshop took approximately 3 hours, and was attended by 30-60 students. The workshop began with a 30 minute presentation by the craftspeople about beads as ancient jewelry and Indonesian cultural heritage in a talk-show format. The facilitator acted as a moderator. After that, there was an explanation about Jombang glass bead craft industries and a brief story of the entrepreneurial journey of each craftsperson.

Subsequently, the main session was a glass bead making demo by the craftspeople, followed by bead making practice by the students. This session continued with the practice of weaving beads into ready-to-use products such as bracelets, brooches and necklaces. Meanwhile, students and teachers bought many products during the workshop. Moreover, there was immediate feedback from the students and teachers about product preferences, the affordable price and the design idea.

Figure 2: Craftspeople supervised students who learned to make glass beads (doc: author).

## 5. RESULTS

All four glass-bead-making workshops were completed in a week, in the beginning of Ramadhan month. All of the craftspeople are Muslims, and as such, were not allowed to eat or drink during the day in the Ramadhan month. Nevertheless, the craftspeople delivered the workshops successfully. This situation was a sign that they have a strong willingness to succeed in the program. Without such a will, it would be unlikely to happen.

### 5.1 The participants

A total of 18 craftspeople attended 8 meetings of *Cangkrukan Manik*. However, only 7 of them actively participated in the meetings and conducted the glass-bead-making workshops. They attended at least 5 times, while the rest attended just once or twice. The two community leaders, who are the most respected successful business persons in the community, and the leader of the glass bead association, were among those who came 3 times or fewer. Nevertheless, they supported the workshops by contributing materials and some products to be sold at the workshops. They could not come consistently because they were busy.

Although it seems that there were few craftspeople actively involved in the program, this program must not be seen as trivial. Considering that the number of craft owners in the last decade has decreased to numbers in the 20s, the active involvement of 8 craft owners and 1 craft worker in the program was not necessarily a small achievement. Moreover, the backgrounds of the active participants were quite varied. The ages of the participants were between the 20s to 60s. As we stated initially, the local political situation showed an implicit grouping among craftspeople. However, quite diverse groups of craftspeople came and collaborated in this project.

We found that there were only a few craft workers involved in the project. From the total of 3 craft workers who came to the meetings, only one craft worker was actively involved in the program. This active craft worker had a strong personality, made apparent by his courage to share ideas and propose initiatives. The other craft workers who did not continue to attend the Cangkrukan Manik were quite passive. However, the involvement of a craft worker depends on his employer. If the employer supports the program, the craft owner will be more likely to join and be involved.

Interestingly, the craftspeople in relatively stable business conditions were more enthusiastic to join the program than craftspeople who currently struggled for their business to survive. There were two reasons for the lack of participation of craftspeople whose businesses were currently unsuccessful. First, the less successful craftspeople had already changed their jobs; second, they were pessimistic about the future of the glass bead business; third, there were other issues such as their reluctance to join the program because there was no close friend joining or there was another activity that should have been done on that day. This fact shows that the way to involve the less successful in the bottom-up program remains unsolved.

## **5.2 The benefit of the program**

The glass bead making workshop, along with the Cangkrukan Manik meetings prior to the workshop showed some positive signs of support for community development, as it brought social and economic benefit. At least the 9 craftspeople, who actively involved in the program, gained social benefit through knowledge sharing to pursue innovation with the designers as facilitators. In order to pursue the success of the glass-bead-making workshop to build awareness of the local buyers, there was a process of knowledge-sharing between the designers and craftspeople during the Cangkrukan Manik meeting, by collaboratively designing a new brand as part of a marketing strategy as well as a new product design development. The workshop also strengthened the internal social relationship among craftspeople. Craftspeople from different implicit groups worked together, in which this kind of situation is rare, after they experiencing the tight competition. The involvement of outsiders as a trusted third party to enable the collaboration is essential.

Later, craftspeople also made a new network with 4 high schools. The new network can increase the awareness of the industry, as the total of 160 students who participated in the workshop are prospective local buyers. Besides, since there was immediate feedback from students after each workshop, the designers and craftspeople could learn and discuss the feedback directly. This mechanism allows for effective knowledge sharing.

Meanwhile, the program also delivered economic benefit directly and indirectly. The craftspeople took direct economic benefit from the products sold during the workshop as well as the payment for their services as tutors in the workshops. The products sold were about 40%, which is enough to pay the resources (such as the LPG cost and patterned stick glass material). In addition, raising the local buyer's awareness brought an indirect economic benefit.

## **6. DISCUSSION**

The craftspeople community had strong social capital when the glass bead business reached its peak. During that time, craftspeople exchanged material, shared orders and new designs. However, as the bead trend passed, causing significantly decreasing orders, it caused economic difficulty to craftspeople. This situation has triggered tension among craftspeople and altered the mutual sharing into an uncooperative situation with cheating and stealing.

With reference to Coleman's notion that the existence of social capital in the community is influenced by closure, stability and the presence of communitarian ideology [2], we learned that economic instability destroys social capital. As the glass-bead-craft industries' association does not have enough power to apply sanctions, this worsens the situation.

The economic instability of rural craftspeople is due to the occurrence of globalization in many places [5]. Many of the limitations of poor educational and economic backgrounds and limited networks have caused difficulties for rural craftspeople to follow the rapid movements in the globalized era [5,7]. Nevertheless, they must have complex skills to succeed in their businesses. The assistance of outsiders is essential to help craftspeople [15]. However, the assistance must consider the context and preserve the unique potential of these craftsmen [21].

As presented in section 3, many scholars have argued that facilitating a community to formulate a bottom-up program into a collective action will face many challenges [2,3]. That possibility is also likely to occur in rural areas with strong social cohesiveness characteristics. However, in this case, the rural craftspeople of Jombang performed their glass-bead-making workshops collaboratively. This fact indicates positive signs of rebuilding the social capital of the craftspeople's community to support community development.

We studied some aspects which encourage collective action; first, the ability to understand the local political situation; second, the role of facilitators to respect the unique potential of craftspeople as well as back up the required skills to succeed in the program; and third, the economic benefit of the program.

We proved Knop's argument that understanding cultural sensitivity when initiating a participatory project is essential [13]. The approach to community leaders, building a close and friendly relationship with craftspeople, as well as setting up the program to be as inclusive as possible allowed the craftspeople to engage in and easily join the project. The role of the facilitator in encouraging the craftspeople to talk and share ideas in bottom-up planning and then finalize it in a detailed program was also crucial. The glass-bead-making workshops presented the craftspeople's expertise to students and teachers. The expertise of making beads is the craftspeople's passion as they have worked in this field for years. Moreover, the craftspeople gained economic benefit from the sale of products and their service as tutors. This program is more likely to be sustainable as it enabled the self-help potential of craftspeople to get their economic benefit, and not depend on external funding. Furthermore, since the glass-bead-making workshop is a collaborative program, it has the potential to restore the strength of social capital in the community.

## ACKNOWLEDGMENT

The authors appreciate the work of the Jombang craftspeople along with the students and teachers of SMAN 2 Pare, MAN Jombang, SMAN 2 Jombang and SMA Kertosono who were enthusiastically involved in the workshop. We would like to thank the village head and staff of Plumbon Gambang village, the design students (Intan Cheria and Lia Puji), alumni (Arif Dwi Putranto and Ilham Bagus H.), the head and staff of Industrial Design Department – ITS Surabaya, for their cooperation during the project; also Praya Media for the documentation and valuable contribution. This work is supported by a scholarship from the Directorate General for Higher Education (DGHE) on behalf of the Ministry of National Education, Republic of Indonesia.

## ABSTRACT

*Agriculture has still played significant roles in economic development of Indonesia. In Bali province, the existence of subak as customary community for managing traditional irrigation system with a hydrological boundaries basis is very important since the agricultural development programs implementations of government are always conducted through it. However, subaks have faced some problems in the relation to farmers' income gained from their own farming activity on the paddy field. The purposes of this study are to describe social capital performance on subak system in subak system and to explain the ways to strengthen social capital on agricultural development. Subak of Guama was purposively selected for the study since government implemented pilot project of agribusiness development on this subak in 2002. Key informants and samples were drawn during the survey and observation for data collection. These were fully analysed by using descriptive method. Results of study showed that the mutual trust within Subak of Guama (among subak members and cooperative of subak) was very high concerning agribusiness development and other related activities of subak. This mutual trust was based on the subak's philosophy, locally called Tri Hita Karana that mostly based on the harmony life in running farming activities on the rice land. Social norms (called awig-awig) of subak was very strong to govern members and management board of subak in practicing the agricultural, irrigation and agribusiness activities including ritual ceremonies within subak system. Social networking within subak system consisted of social interaction among subak members and management board and the other external sides, such as agricultural extension workers. This social networking is relatively high. The ways to strengthen social capital in subak system for agricultural development, particularly on rice field are: (i) conducting intensively extension and training activities by using participatory approach; (ii) providing economic stimulant for encouraging farmers in sustaining agribusiness program; and (iii) facilitating partnership activity between subak and other agribusiness institutions.*

*Social capital, agribusiness, cooperative, participatory*

## 1 INTRODUCTION

Agriculture has still played significant roles in economic development of Indonesia. It has highly absorbed employment and supported the availability of food for the rural and urban population as well. In Bali province, the existence of *subak* as customary community which manages traditional irrigation system with a hydrological boundaries basis is very important since the agricultural development programs implementations of government are always conducted through it. Nowadays, *subaks* have faced some problems in the relation to farmers' income gained from their own farming activity on the paddy field. Low income of farmers problems are mainly caused by limited purchasing power, availability of market, access to resources [1]. In order to support government's agriculture development program, it has been developed the cooperative based on sub-district administrative, called Village Unit Cooperative since the beginning of 1970s. This was integrated into the Mass Guidance Program for achieving self-sufficient of rice [2]. Such cooperative had functions to provide agro-inputs (seeds, fertilizers, pesticide), credit for members (farmers) aside from rice processing and marketing. Similar to other cooperatives in developing countries, however, the growth of the cooperatives in Indonesia was not good enough wherein these could not sustain their activities with some reasons. Bhuyan [3] assumed that the failure of cooperative is caused by negative attitude of members due to unclear communication between members and management, or lack of educational and operating matter. Sarafshani, et.al [4] found that the agricultural production cooperative in Iran is unsuccessful in achieving the members' goals because of some reasons, such as weak coordination among farmers, little support from government, high prices of inputs, low financial power of farmers, and others. Low participation of members, capital, management skill, controlling, disloyalty of

members because of ignorance, lack of training, conflict among members, are also the problems in achieving the successful cooperative [5] [6].

In Indonesia, the farmers as *subaks*' members, particularly in Bali province were also a part of Village Unit Cooperative together with the other *subaks* located within a sub-district. Awareness of the failure of Village Unit Cooperative, the government was initiated to encourage *subak* to be an agricultural cooperative. Owing to this cooperative was established on the *subak* basis, it is fully expected to raise motivation for gaining mutual benefit and the expectation of collective actions among the members of *subak*. Like in many other developing countries, agricultural cooperatives operate in the context of rural communities, and therefore they are subject to norms and values of social inclusion and solidarity. *Subak* was established with the Balinese cultural basis as a social capital in which this has been still performed in the economic activities.

As a pilot project on agricultural development, the only one *subak* in Bali involved in this program, namely *Subak* of Guama located within three villages scattered in Tabanan district, as a centre of rice farming in Bali province. The cooperative is called KUAT Guama (*Koperasi Usaha Agribisnis Terpadu*=Integrated Agribusiness Cooperative) with the first economic activities for an integrated crops management; crops livestock system; and economic households small credit. These are fully aimed at increasing the productivity and income of farmers as a part of agricultural development goals. The experiences found in several countries wherein the existence of agricultural cooperative established by government seemed to be unsustainable after a couple year operated [7]. In the relation to cooperative on the *subak* basis in established Bali, the purposes of this study are to describe social capital performance on *subak* system in *subak* system and to explain the ways to strengthen social capital on agricultural development for its sustainability.

## 2 REVIEW OF LITERATURE

### 2.1 Existence of *subak* and social capital

*Subak* system is well known in Bali (Indonesia) and other countries as a traditional irrigation system with a particular additional activity, that is, ritual ceremony that has been carried out since the water fetching till harvesting. This performance is a part of Balinese culture in farming activities on irrigated land (rice field) [8]. In general, the main activities of irrigation organization (water users association) are related to distribution of irrigation water, mobilization of resources, operation and maintenance of irrigation facilities, and conflict management [9]. Meaning to say that *subak* is a unique organization with ritual activities. *Subak* could be regarded as a customary institution which is a form of social capital for managing collective resources as they provide structure and develop trust and norms of reciprocity for cooperation and coordinated actions [10].

Social capital is simply defined as "the norms and networks that enable people to act collectively", in which it is regarded as features of social organizations, such as social networks, norms, and trust that facilitate coordination and cooperation for mutual benefits [11]. It can be simply defined as the existence of a certain set of informal values or norms shared among members of a group that permit cooperation among them [12]. Gittel and Vidal [13] tried to have the distinction of bonding and bridging social capital. Trust is defined formally as expectation about the actions of others that have a bearing on one's own choice of actions [14]. Fafchamps and Bart [15] argued that social networks enabled traders to reduce transaction cost under a situation of imperfect information and then have higher margins. Social capital is an important resource for the agricultural cooperative.

### 2.2 Sustainability of farmers cooperative

Based on the Indonesian Law No.25/1992 about Cooperative, the sustainability of cooperative could be achieved by implementing its functions and roles as follows: (i) to develop potential and capacities of members in particular and the community in general in order to improve their welfare; (ii) to actively take a part in enriching the quality of the community's life; and (iii) to strengthen local economic for supporting national economic. Furthermore, it is clearly also mentioned that the principle of cooperative are: (i) open and voluntary membership; (ii) democratic management; (iii) proportional returns to each members; and self-help institution. A cooperative is meant to: 'embody the values of self-help, self-responsibility, democracy, equality, equity and solidarity. In the tradition of their founders, co-operative members believe in the ethical values of honesty, openness, social responsibility and caring for other [16]. These are likely part of social capital within the small institution owned by small farmers. The general activities of agricultural cooperative are marketing cooperatives; farm supply cooperatives; and service cooperatives [5]. and providing other services such as insurance, contract work, accountancy and farm relief [17]. However, it was also found that most of the agricultural cooperatives have relatively small businesses with lower margin.

The agricultural cooperative has important role in rural economic and social organizations with its activities for providing the farmers with production inputs, such as fertilizers, seeds and chemical substances [7]. making lower transaction costs in getting loans, and better access to information; Motiram, and Vakulabharanam [18] Barton [19] clearly mentioned that the primary purpose of cooperative is to gain economic benefit to its members. The sustainability of local institution requires participation of the members [20] [21]. Participation is very important in the successful program of collective actions, such as in the management of irrigation and forestry as natural resources [8] [22]. Participation is regarded as people's involvement in decision-making processes, in implementing programmes, their sharing in the benefits of development programmes and their involvement in efforts to evaluate such programmes [23]. Local people would participate in the program if they assume that their needs could be fulfilled [24]. Thus, they will have sense of belonging and sense of responsibility towards their institution

[25]. In term of cooperative, the its sustainability could be seen from to what extent the participation of members to sustain the cooperative's activities. Sustainability refers to something continues to work over time [26].

### 3 METHODS OF STUDY

In order to achieve the aims of this study that was conducted in *Subak* of Guama, data were gathered by employing semi-structured interviews with 70 farmers out of 544 members of cooperatives and its management officers and using questionnaire. The farmers were drawn by using proportional random sampling, with the basis of sub-*subak* members. It is worth to note that *subak*'s members are members of cooperative, too. The survey had been done from April-August 2012. Collected data was analysed with qualitative method. Measurement of social capital indicators was done by using scale of likert in which the answers of samples towards every question are scored by 1, 2, 3, 4, 5. The score of 1 is given if the answer is not too expected and the score of 5 is given if the answer is very expected. The total score is converted to percentage to make the categorization of social capital indicators that have five categories. The interval of categories is formulated by:

$$i = \frac{\text{Maximum percentage} - \text{minimum percentage}}{\text{categories}} = \frac{100 - 20}{5} = 16$$

Based on the interval cited above, the categories of social capital indicators (trust, social norms and social networking) are shown in Table 1.

Table 1 Categories of trust, social norms and social networking

No	Categories	Score (%)
1	Very high	> 84 – 100
2	High	> 68 – 84
3	Moderate	> 52 – 68
4	Low	> 36 – 52
5	Very low	20 – 36

### 4 RESULTS AND DISCUSSIONS

#### 4.1 General description of site research

*Subak* of Guama with 172 ha rice land is situated in Tabanan regency, Bali Province. Tabanan is a central for paddy growing in Bali. The source of irrigation water of *subak* is from Cangi weir in which this also irrigates the other 7 *subaks*. It is easy to reach the site by public and private vehicles, so it is a good potential to develop agribusiness cooperative in the *subak*. Similar to other *subak* in Bali, *Subak* of Guama is also divides into sub-*subaks*, (locally called *tempek*), that is six sub-*subak* namely: (i) Manik Gunung; (ii) Pekilen; (iii) Kekeran Desa; (iv) Kekeran Carik; (v) Belusung; (vi) Guama. Total members of *subak* is 544 farmers, and the average of rice land holding is relatively small, it is about 0.32 ha/farmer.

#### 4.2 Characteristics of cooperative's members

The average paddy land hold by farmers is relatively small, that is 0.34 ha with its interval between 0,26 to 0.56 ha (see Table 2). This condition is similar to the farmers within Indonesia who are working on paddy land. Some analysed that the small scale of farming system (less than 0.35 ha) for rice crop is economically inefficient. This is one of the dominant problems in Indonesia for the improvement of farmers income. Noteworthy, the farmers are cultivate the land inherited by their own parents. Nobody bought new paddy land for their farming. In the relation to age of farmers, it is approximately 48 years old with an interval between 36 to 56 years. They are still relatively productive persons to work on the larger size of rice field than they own. In term of innovation, they might support the process of extension and training conducted by government field workers, particularly in agricultural innovation such as agribusiness, because they are not too old.

Formal educational background of farmers is relatively low (9.77 years) in which this is equal to graduate from junior high school (in Indonesia, the people go to elementary school for six years and junior high school for three years). Some of them (44.29 %) graduated from senior high school (another three years after graduated from junior high school). The consequence of this, the extension agents should have particular techniques or methods of extension in order that they might be able to easier to understand, thus adopt the innovation disseminated.

Table 2 Characteristics of members

No	Items	Average	Interval
1	Paddy land (ha)	0.34	0.26 – 0.56
2	Age (year)	48	36 – 56
3	Educational background (year)	9.77	6 – 12
4	Family size (person)	5.06	3 – 7
	a. < 15 years	1.36	0 – 3
	b. 15 – 64 years	3.10	2 – 6
	c. > 64 years	0.6	0 – 2

5	Status of farmers (person)		
	a. Land owner	88.64 %	
	b. Sharecropper	11.36 %	

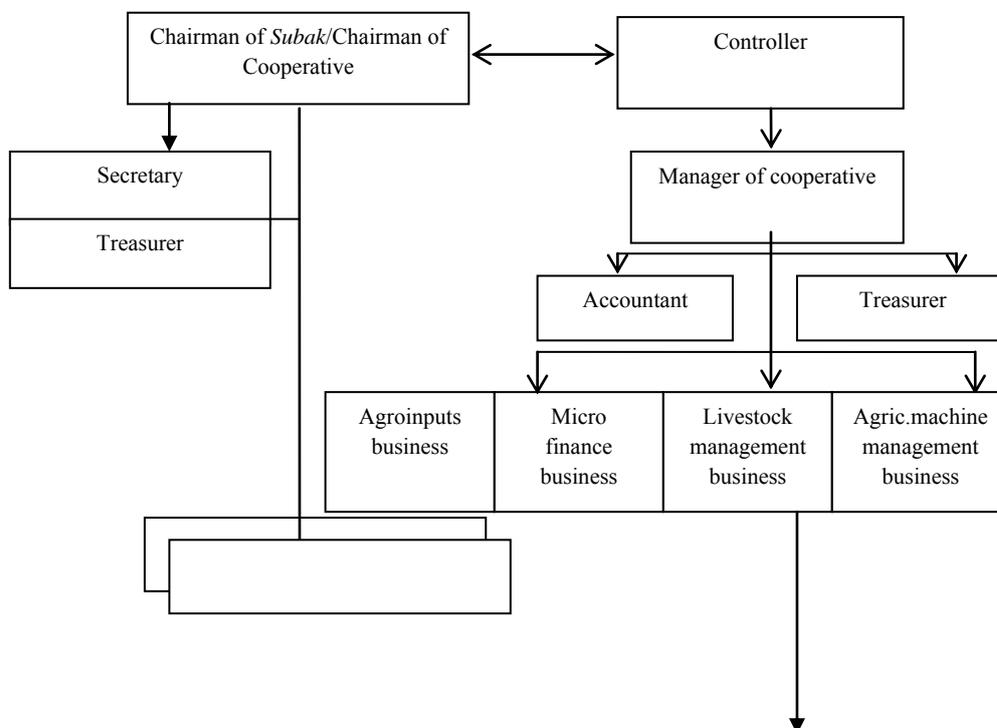

The small size of land of farmers strongly push them to have other jobs for gaining additional revenue of household. All of farmers in the site research have livestock farming as a livelihood source. They make it integrate with the crops they plant, wherein kinds of livestock are mostly cattle and pig. The two are very important for farmers because these are regarded as a saving. The other jobs of some farmers are wager (construction works), local retailer (daily needs of community), and teacher and employee at non-government office. Most of farmers (88.64 %) is the land owner who cultivate their paddy land and the remain is sharecropper. In the research site, there is no legal contract for the land cultivation between the owners of the land and the sharecroppers. They only base on the trust even though this might pruned to a conflict.

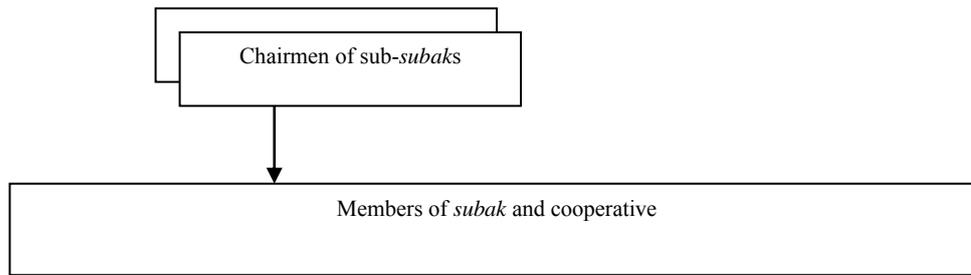

### 4.3 Performance of *Subak* Cooperative

*Subak* of Guama firstly initiated by the government (The Agency of Research and Development for Agriculture-Bali) for having a group for running integrated agribusiness activities. This group had been intensively empowered by providing extension and training on agricultural practices, management, entrepreneurship and agribusiness. This was further developed to be a *subak* cooperative for managing the agribusiness activities within *Subak* of Guama, called *Koperasi Usaha Agribisnis Terpadu (KUAT) Subak Guama* established on April 1, 2002. Based on the national law about cooperative as cited above, this must be strengthen by having legal aspect of cooperative with fulfilling some prerequisites. Finally the government (The Cooperative Service) issued the legal aspect of cooperative with the reference number: 22 / BH / DISKOP/VIII / 2003 dated on Agust 14, 2003. The cooperative management is still under control of *subak* of Guama with some principles, such as openness, togetherness, fair, honesty. The chairman of *subak* has intensively controlled and supervised the cooperative management.

The cooperative manages productive assets and capital granted by external source (the Agency of Research and Development for Agriculture-Bali) and encourages members of *subak* to utilize the services, such as micro credit, agro-inputs provision including livestock inputs, agricultural management and agricultural machine uses, etc. These activities are directly managed by manager appointed by *subak* member as members of cooperative. The organizational structure of cooperative in *Subak* of Guama and relationship between *subak* and cooperative is show in Figure 1. Seeing the structure above, the chairman of *subak* is also being a chairman of cooperative. The management of agribusiness activities within *subak* is professionally handled by a manager with some assistants, such as secretary, treasurer and other officers for some business (agro-inputs, micro finance/loan; livestock management and agricultural machines). They run the cooperative under the internal regulations as a consensus of members in which it is still referred to the national law as guidance.

For the initial agribusiness activities, the Agency of Research and Development for Agriculture-Bali gave grant for the Guama cooperative in 2002 under the Project of Integrated Farming Development for (i) Integrated Crops Management/ICM; (ii) Crops-Livestock System/CLS; and (iii) Home industry credit.. Another activity conducted by cooperative is rice seed production under the supervision of *subak* and government institutions (Rice Seeds Certification Agency, Bali Province and Agency of Research and Development for Agriculture-Bali). *Subak* has responsibility in defining which farmers would be join in the program, while the government institutions strongly takes responsibility in controlling the treatment of rice seeds production. Cooperative, then, makes good package for the seeds before selling to *PT Pertani* (Agricultural Firm owned by government) and other retailers.

Figur 1: Organizational structure of cooperative in *Subak* of Guama

#### 4.4 Social capital within *subak* cooperative

##### 4.4.1 Trust

Trust is a belief of people to others' willingness within a group. In this study, the trust was measured on mutual trust among the members of cooperative/*subak*, members and management boards of *subak* and cooperative. The average score of trust within *subak* cooperative is 84.02 % of maximum score indicating high trust with the interval of 77.39 % to 91.30%. Most of members' trust (72.86 %) are categorized very high (see Table 3). Mutual trust among members of *subak* cooperative is based on the *subak* philosophy, locally called Tri Hita Karana that mostly based on the harmony life in running farming activities on the rice land. As a traditional irrigation system, *subak* organizes their own members to have good togetherness, for instance, in the irrigation management. They always entrust the other farmers regarding the water distribution and allocation flowing to their own rice fields. There is no permanent gate block in the division structure on the canal, even no security for controlling the irrigation water. This means that they have high trust to the others. Trust of members is also strongly influenced by the belief to the God which is reflected on the ritual ceremonies activities for the irrigation and farming activities. The *subak's* members have high trust to the management board for their ways to manage irrigation and farming as well as economic activities. This, furthermore, strongly encouraged members to agree with the plan for the *subak* cooperative establishment. Members ensured that management board could manage well the *subak* cooperative initiated by the government for improving the agricultural productivity and economic benefits of them. In other side, the management board also trusted the members that they could support the new cooperative. They finally agreed to have new management board of *subak* cooperative, in which the chairman of *subak* is being a controller (see the Figure 2 above). In the operation of *subak* cooperative, the members also have high trust to the management board (manager and his staff), especially in distributing and returning of loans, financial management responsibility, and others.

##### 4.4.2 Social norms

Social norms strongly contain the specific actions that are regarded by a set of persons as proper or correct, or improper and incorrect and have potential rewards and punishments for them. In *subak* system, social norm (called *awig-awig*) as an internal regulations is significantly influenced the behaviour of members in irrigation and farming activities as well as economic activities. At least, this contains water distribution and allocation, cropping pattern, cropping schedule, ritual ceremonies, regular and irregular meetings, economic activities, mechanism of credit/loan, membership and management tasks, etc. The social norms of *subak* and cooperatives are written and legalized by the government. Actually, the *awig-awig* of *subak* is very strong without any legalization of government, but the new regulation of government forced *subaks* in Bali to register their own *awig-awig* to be legalized by government. Social sanctions of *subak* have significant influences to farmers for not doing wrong things, such as stopping irrigation water, isolated by the others, etc.

Table 3 Distribution of farmers' frequencies relied on trust, social norms and social networking

No	Category	Trust		Social norm		Social networking	
		Frequency (person)	Percentage (%)	Frequency (person)	Percentage (%)	Frequency (person)	Percentage (%)
1	Very high	51	72.86	54	77.14	26	37.14
2	High	19	27.4	16	22.86	35	50.00
3	Moderate	0	0	0	0.00	9	12.86
4	Low	0	0	0	0.00	0	0
5	Very low	0	0	0	0.00	0	0
	Total	70	100	70	100	70	100

Source: Analysis of primary data

In irrigation matter, members must follow the regulations regarding water distribution and allocation, mutual works for rehabilitation, operation and maintenance of irrigation facilities. Even in farming system, all of members must properly do regulations concerning seeds variety planted, planting schedule, cropping patterns, etc. In addition, the ritual ceremonies must also be followed by the farmers based on the regulations and other consensus decided in the *subak* meeting. In this study, social norms as component of social capital was measured on knowledge, attitude of members toward internal regulation in

*subak* and cooperative, strength of internal regulations to govern members and obeisance of norms. The average score of social norms power within *subak* and cooperative is approximately 85.34 % of the maximum score or categorized as very strong with the interval between 83.00 % to 89.50 %. Most of members have very high score or very strong, that is 77.14 % as shown in Table 3 above.

#### 4.4.3 Social networking

Social networking is regarded as the ties of people in their interaction for achieving the share purposes. In this study, social networking comprises interactions among members, between members and board of *subak*, between members and board of cooperative, and between members and outsiders. Based on survey conducted toward 70 samples of cooperative members, it is pointed out that the average of networking is high category, that is 79.04 % out of the maximum score with the interval between 67.00 % to 86.00 %. Most of them (50.00 %) has high networking. Distribution of farmers' frequencies relied on social networking is shown in Table 3 above.

In general, it is 12.86 % of farmers has moderate interaction among the members and boards of *subak*, cooperative and the outsiders, particularly the agricultural extension agents. For interaction among the farmers, specifically they expect to have benefits for agricultural activities since the network among them could be function as a channel for information and media for informal and formal discussions. In this study, farmers are intensively involved in day to day communication with the others as they stay near each other and have social relationship regarding social activities in the village. The interaction among members might take place in the community hall belong to village and sub-village, and *subak*, coffee shop, and other places such as the individual farmers' house. Interactions between members and boards of *subak* and cooperatives are very useful in the channeling process of information coming from outsider and members, too. This makes two way traffic of communication among members and boards of *subak* and cooperative, such as about the agricultural innovation, the needs of agro-inputs, etc. The interactions cited above are conducted on the local values basis within *subak* and village. Besides, the *subak* and cooperative also have internal regulations as a consensus of themselves. This strengthen the interaction ties among the members and management boards for the *subak* and cooperative activities.

#### 4.5 Ways to strengthen social capital on agricultural development

Sustainability of agricultural development, especially on the program of agricultural cooperative in *subak* system needs some ways to be done by *subak* and other external institutions, such government and private sectors concerning social capital. Based on the research and experiences of Guama *subak*, the ways for sustaining and developing agricultural development consist of (i) conducting intensively extension and training activities by using participatory approach; (ii) providing economic stimulant for encouraging farmers in sustaining agribusiness program; and (iii) facilitating partnership activity between *subak* and other agribusiness institutions.

##### 4.5.1 Intensive extension and training

Even though mutual trust within *subak* of Guama is high, it is still needed to be increased in order to sustain the agricultural program that had been implemented. This could be done through intensive extension and training by the facilitators. This might be fully participatory approaches in which the farmers should be actively involved in the activities relating to agribusiness development. Aside from agricultural practices, the extension and training activities should be on the management and personality development to *subak* and cooperative.

As a component of social capital, mutual trust has a significant role to ensure members and management boards in supporting agricultural development. Mutual trust might strengthen social networking among the farmers and management boards and the external institutions, such as agricultural extension workers under the social norms of *subak* and cooperative. Openness management of *subak* cooperative keep the trust of members to join in the cooperative. Meaning to say that, mutual trusts among the members and management boards of *subak* and cooperative are regarded as a collective energy of *subak* and cooperative for the its sustainability.

##### 4.5.2 Providing economic stimulant

Agribusiness constitutes a new paradigm of agricultural development introduced within *subak* system. This is needed economic capital as resources for its management, such as agro inputs provision, credit and the like. Therefore, economic stimulant is significantly important to start agribusiness activities in *subak* system. Provision of economic stimulant such as seed money might be very beneficial for the *subak* to be motivated in taking the agribusiness program. This, of course, should be followed by the intensive facilitation in order that *subak* could have well understanding of program and seize it into productive activities for improving the productivity of farms and increasing the income of *subak* and its members, through the agricultural cooperative establishment. Experiences in *Subak* of Guama pointed out that the seed money provided by the government could be used properly for the agribusiness activities, such as ICM, CLS and micro credit. Management boards of *subak* and cooperative were intensively encouraged by the government staff for having togetherness in implementing the economic stimulant provided. Meetings and discussions among the members and management boards of *subak* and cooperative were facilitated by government staff to define internal regulation as social norms for its management.

##### 4.5.3 Facilitating partnership

Agribusiness system is an agricultural business that consists of inter-related subsystems, such as farm inputs provision and distribution, on-farm activities, processing and marketing and other supporting one. Owing to complex activities, implementation of agribusiness within *subak* system requires external parties to support the program. Provision of farm inputs (fertilizers and pesticides), for instance, the cooperative of *subak* could not produce by itself, so it has to establish the partnership with a distributor of farm inputs. The agricultural extension workers could facilitate the cooperative to prepare proper partnership with PT Pertani (an agricultural enterprise). By this partnership, cooperative has authority to retail fertilizers for fulfil the needs of famers within Subak of Guama. Another partnership which might be established is with government institution (The Seed Control and Certification Agency) for producing certified seeds. Seed produced by *subak* could be sold to other farmers in Bali after getting certification label from the agency and then cooperative could get profit. Seed production is one of the business activities run by *subak* cooperative under the supervision of government institutions (Rice Seeds Certification Agency, Bali Province and Agency of Research and Development for Agriculture-Bali). In order to produce the seeds, cooperative invited farmers under the *subak* recommendation to join in the program of rice seed production. The willingness of farmers in the program is to have higher price of their product.

## 5 CONCLUSION

One of the agricultural development introduced by government is agribusiness program within *subak* system. In *Subak* of Guama, the main activity for this program was done by establishing agricultural cooperative (KUAT) that managed the ICM, CLS and micro credit, and other activities. The mutual trust within *Subak* of Guama (among *subak* members and cooperative of *subak*) was very high concerning agribusiness development and other related activities of *subak*. Social norms (called *awig-awig*) of *subak* was very strong to govern members and management board of *subak* in practicing the agricultural, irrigation and agribusiness activities including ritual ceremonies within *subak* system. Social networking within *subak* system consisted of social interaction among *subak* members and management board and the other external sides, such as agricultural extension workers. This social networking is relatively high. In order to sustain the agribusiness program, there are some ways that should be conducted, especially to strengthen social capital in *subak* system. These consist of (i) conducting intensively extension and training activities by using participatory approach; (ii) providing economic stimulant for encouraging farmers in sustaining agribusiness program; and (iii) facilitating partnership activity between *subak* and other agribusiness institutions.

## ACKNOWLEDGMENT

In this opportunity, we would like to say thank to Rector of Dwijendra University (Ketut Wirawan) and the Chairman of Dwijendra Foundation (Mr. Ida Bagus Gede Wiyana) for his financial support to conduct the study, and the management boards of Subak of Guama and its cooperative for their cooperation during the data collection and doing participatory approach to their members.

#### ABSTRACT

*Some areas in the urban centers are the informal, unplanned and until recently un-serviced housing areas, which form a large part of most Indonesian cities. Population density in several areas in urban centers exceeds 1,000 persons per hectare, reducing the opportunity for decent living. Most of the physical conditions of housing and habitat do not fulfill the requirements for a healthy environment. Housing affordability for most of urban population is low. The price of urban land is too high and there is limited and private capacity to develop the necessary infrastructure and facilities for housing. The problem cannot be solved by adopting conventional housing approaches. Government and private companies have started providing vertical housing to solve the problems in urban areas in Jakarta. The aim of the vertical housing projects was to provide houses for low-income people and to improve their living conditions. This study aims at an evaluation of the vertical simple housing (Rusunami / Rumah Susun Sederhana Milik) project of Kalibata area, through an analysis of the prevailing conditions and of the opinion of the inhabitants who owned the housing unit. The main finding of the study is that none of the inhabitants are categorized as low-income people. There was a cross subsidy but the sales price of the unit housing was still too high and most low-income people could not afford the unit. The unit housing inhabitants were satisfied with the living conditions and the strength of the building structure, but the degree of acceptance of units' design was low, so that most of them renovated the flat. A rental system may be an alternative for low-income people to have access to healthy housing units in the urban center areas.*

## 1. INTRODUCTION

Shelter is one of the human basic needs, important for human physical well-being. Adequate housing contributes to the achievement of the physical and moral health of a nation and stimulates the social stability, the work efficiency and the development of the individuals. It is also one of the best indicators of a person's living standard and of his place in the society.

The housing problem in Jakarta is mainly caused by urbanization and natural population growth. The increase in population has created severe shortage of houses and has placed burden on the municipal services. According to figures released in "Jakarta dalam angka 2011", Jakarta has a population of 9,607,787 in 2010, with population average density of 13,157 people per square kilometer. The average population growth is 4% per annum.

Jakarta needs around 70,000 housing units every year to cater to its growing population, however the city administration is only able to provide 20 percent of that figure. Since Jakarta has very limited space, housing is very expensive and not always accessible to all the people, especially the low income people. This situation forced the government to develop housing program to solve the housing scarcity. In 2007, President Susilo Bambang Yudhoyono announced the building of 1,000 low cost apartment blocks to accommodate the low income people. So far, more than 200 apartment blocks designated as low income rental units has been built in Jakarta. Each of the apartment blocks can accommodate between 800 to 1,000 units.

## 2. STUDY OBJECTIVE

The objective of the study is to assess the use of vertical simple housing as housing alternative for low income people, especially on how the housing area can improve their living condition and what are their opinions on living in a vertical simple housing area.

## 3. RESEARCH METHODOLOGY

### 3.1 Study Subject

The study subject is people living in rusunami units in Tower A, Kalibata Residence, Kalibata City, South Jakarta. There are fifty people involved, 60% are owner while the rest are tenant.

### 3.2 Study Area

Kalibata City is the biggest super block apartments in South Jakarta, consists of 7 Kalibata Residence (rusunami) towers, 3 Kalibata Regency towers and 8 Green Palace towers. The area is designated for modern city living, equipped with 24 hour security services, shopping area, restaurants, fitness centre, swimming pool, jogging park and adventure park. The apartment area is built in 2008 and started to be inhabited in 2011.

Figure 1: Kalibata City apartment block as the study area, rusunami Tower A is located north-east of the area.

### 3.3 Data Collection

Data is collected by giving a set questionnaire to the study subject. The questionnaire is designed to determine the subject response on the following categories:

- Respondent's identity and household characteristics
- Socio-economic background of the household
- Duration of residence and tenure

- Physical conditions and facilities
- Attitude towards the environmental condition of the apartment
- Preference for type of housing
- Satisfaction and preferences with regards to the house design.

The survey was performed in September 2012.

### **3.4 Data Analysis**

The Microsoft Excel program was used to obtain the sum of values, percentages, counts and frequencies. Based on these, the respondent's household characteristics, attitude towards the flat environment and the general indication of satisfaction, their impressions and opinions can be determined.

## **4. RESULTS AND ANALYSIS**

### **4.1 Socio-Economic Characteristics**

All of the flat units are privately owned, owners purchased their units by paying a down payment and monthly mortgage installments. Some of the owners rented out their units, because they purchased the unit for investment purposes. Eighty percent of owners stated that the security of the units' tenure status is good, while the rest is unsure. The reason for their feeling of security of the tenure status is that the unit ownership is guaranteed by the government's regulation.

The average family size in the unit is 4. The household monthly income varies, but there is no low-income household found living in the flats. Each household has to pay for monthly service charge, solid waste disposal, waste water and ground management. Other extra expenditures consist of cost of potable water, electricity and contribution to community associations. Most of the respondents (91%) stated that living in flats has increased their monthly expenditures.

### **4.2 Physical Conditions and Facilities**

Most of the respondent stated that the apartment living area has better facilities than their previous housing area. There are accessible play-ground, kindergarten, school, a meeting hall, mosque, restaurants, public services and a public hydrant. The quantity and quality of facilities are sufficient, it can be said that the inhabitants' quality of life has improved since living in the apartment area. Respondent stated that the environmental conditions in the apartment area are good, and the available basic infrastructures are also better than their former houses. They believed that the structures of the apartment building are strong enough, and has been built based on Indonesia's building code.

All of the units are served by pipe water, but some of the respondents stated that the piped water is insufficient, and have low quality. Each apartment block is equipped with sewerage treatment plants (STP), and the STP maintenance is performed by the management unit. Solid waste disposal is also managed by the management unit. The inhabitants' opinions on the STP and solid waste services are positive, 74 percent said it was efficient, 7 percent was indifferent and 19 percent claimed it was inefficient.

Every flat has electricity supply, only 6 percent of the flats respondents stated that the electricity supply was inefficient, while 4% was indifferent and the rest of respondents said it was sufficient. Sixty-one percent of the respondents think that the condition of the outdoor lighting in the flat was adequate, however 32% said it was inadequate and 7% was indifferent. Most of the respondents said that the road network is sufficient, but the parking facility is insufficient. Most of respondents think that their floor area has decreased compared to their former housing, and stated that they also lost private yards.

### **4.3 Preference for Type of Housing**

The occupants of the flats were asked if their living conditions had improved or deteriorated compared to their former houses. Fifty-four percent of the respondents said it was closer to their work places, 38% said that the Kalibata apartment has better accessibility than their former houses. Seventy-two percent said that the flats have a better public order and 83% said they have better sanitation; 67% of respondents felt the flats are safer; 63% felt the flats are more convenient, and 47% felt the flats are more pleasant than their former houses, but 24% stated that the flats are the same as their former houses. Sixty-nine percent of them stated that they needed larger housing size than their present house.

#### **4.4 Preference with Regard to Design Features**

Around 66% of the household in the flats were dissatisfied with the size and the lay-out of the rooms in the unit, while 34% of them were satisfied. Eighty-two percent were dissatisfied with the size and lay-out of the kitchen, while the rest was satisfied. Seventy-seven percent of the respondents stated that they were dissatisfied with the size and the lay-out of the bathroom and toilet. Fifty-seven percent said they prefer a larger size and 45% of them said they prefer to separate the toilet and bath. Most of the flat dwellers stated that the available space and number of rooms is not sufficient. There is not enough space for drying clothes, so the back façade is used for drying clothes, and also there is no storage space, because they need space for storing things that are not daily used. Most of the flat owners had modified the lay-out and equipped the unit with air conditioning and kitchen tools.

## **5. CONCLUSION**

Flat inhabitants need time to adjust to their new living conditions, living off the ground is still a new and strange life-style for them. However they felt at ease in their new living conditions, because they had a better environment, in particular access to available infrastructures and good building structure. The degree of acceptance of the units' design was low, so that most of them renovated the flat.

Most of government housing program are designed for owner-occupation. This is, however one of the barriers for inhabitants to have access to adequate housing, because the monthly installments are quite high and low-income people cannot afford them. Rental housing may be a solution for low-income groups to have access to a healthy dwelling unit. It is a more realistic approach, because every citizen has a fair chance of securing a decent and adequate house at affordable costs.

## ABSTRACT

Quality is the important and necessary to get serious attention of the company in running its operations strategy including in the elementary school. Measuring the quality of services is more complicated because of the is intangible that each customer has different perceptions about the quality of services. KANO's model has been widely applied in measuring service quality. The purpose of this study is to measure the level of satisfaction of expectation of parents towards education and perform the classification of the KANO model of educational service attributes. Measurement of education based on 5 dimension of services quality Zeithaml, Parasuraman, dan Berry (1990), that is tangible, reliability, responsiveness, assurance dan empathy. The result showed that there is still a gap between the level satisfaction and expectation that are the completeness of the library books, cleanliness of toilets and computer laboratory. Furthermore, the results of the classification attributes using KANO model of education services found that 25 attributes in the category of One Dimensional, 4 attributes in the category of Attractive and 1 attribute is categorized in Indifferent

## Keywords

service quality, customer satisfaction, elementary school, KANO model

## → 1. INTRODUCTION

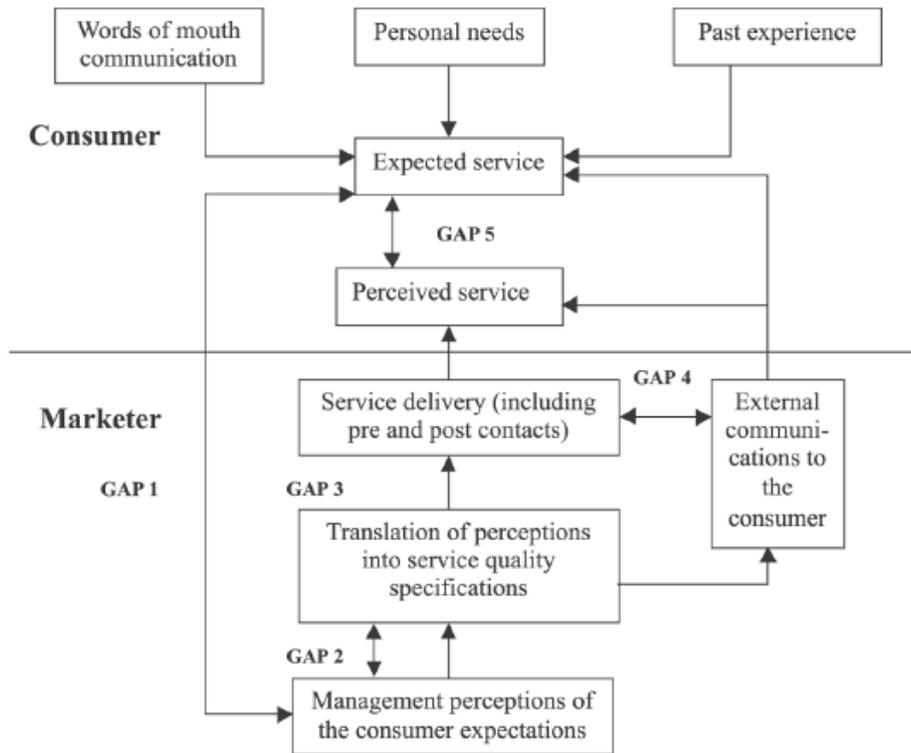

Based on Herzberg's 'Motivator-Hygiene Theory', Kano *et al.* [1] defined the product quality element of different categories that impact customer satisfaction in different ways. Which namely: attractive quality attribute, must-be quality attribute, one-dimensional quality attribute, indifferent quality attribute and reverse quality attribute. Using Kano's model, quality attributes that have the greatest influence on customer satisfaction can therefore be identified, and these can then be used to focus on priorities for product or service development and improvement [2]. With such advantage, Kano model is widely used in quality management [3], logistics services [4] product development [5-7] as well as QFD integration [8-10]. Kano model also used to evaluate quality evaluation of education [11-13]. Quality in education is as important as the quality of business. Elementary school is an important stage of education, where basic values instilled child begins. Basic education in elementary school will influence the child's subsequent development of thinking. Thus every school, including elementary schools, should improve the quality of education services. Considering on this, to understand customer satisfaction of the education institution, we need to understand the customer's need and the expectation. Improving the quality of education would have to focus on customer satisfaction. Kano *et al.* [1] developed a model to categorize the attributes of a product or service based on how well they are able to satisfy customer. Mostly service qualities have both poor and versatile characteristics because service quality is based on the customers' feelings. Therefore, the evaluation of service quality is more difficult than that of the product quality. Parasuraman *et al.* [14] developed the instrument SERVQUAL for measuring customers' perceptions of service quality needs. In this paper, service quality of elementary school was measured and analyzed by service gaps and classified by KANO's method.

## 2. CONCEPTUAL BACKGROUND

### 2.1. Service Quality

A firm in order to compete successfully must have an understanding of consumer perception of the quality and the way service quality is influenced. Managing perceived service quality means that the firm has to match the expected service and perceived service to each other so that consumer satisfaction is achieved [15]. Parasuraman *et al.* [16] proposed that service quality is a function of the differences between expectation and performance along the quality dimensions. They developed a service quality model (Figure 1) based on gap analysis. The various gaps visualized in the model are:

- Gap 1: Differences between consumers' expectation and management's perceptions of those expectations, for example not knowing what consumers expect.
- Gap 2: Differences between management's perceptions of consumer's expectations and service quality specifications, for example improper service-quality standards.
- Gap 3: Differences between service quality specifications and service actually delivered for example the service performance gap.
- Gap 4: Differences between service delivery and the communications to consumers about service delivery, for example whether promises match delivery?
- Gap 5: Differences between consumer's expectation and perceived service. This gap depends on size and direction of the four gaps associated with the delivery of service quality on the marketer's side.

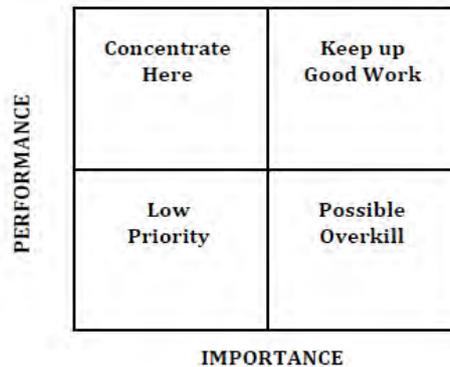

Source : Parasuraman, et.all [16]

Figure 1: Gap Analysis Model

## 2.2. Importance-Performance Analysis and KANO Model

Importance Performance Analysis (IPA) technique is Importance-Performance analysis of the underlying conceptual multi-attribute model to analyze the organization's performance. IPA model is used to measure the importance of customer satisfaction and performance, and develop relationships based on specific product attributes. The main purpose of the IPA is as a diagnostic tool to facilitate the identification of attributes, given their importance, products or services of poor performance or over perform. For this purpose, the interpretation is presented graphically on a grid divided into four quadrants, which according to the average importance and satisfaction (performance)[17]. Four quadrants and the implications of the IPA are shown in Table 1 and Figure 2. The four quadrants are identified are *Concentrate Here*, *Keep the Good Work*, *Low Priority* and *Possible Overkill*.

Source : Haeryip Sihombing, et.all[17]

Figure 2: Importance Performance Analysis Grid

Table 1. Importance Performance Quadrant

<b>Quadrant I</b> <i>Concentrate Here</i>	Attributes are perceived to be very important to respondents, but performance levels are fairly low. This suggests that improvement efforts should be concentrated here.
<b>Quadrant II</b> <i>Keep up the good work</i>	Attributes are perceived to be very important to respondents, and at the same time, the organization seems to have high levels of performance in these activities. The message here is to keep up the good work.
<b>Quadrant III</b> <i>Lower priority</i>	Attributes here are rated as having low importance and low performance. Although performance levels may be low in this cell, managers should not be overly concerned, since the attributes in this cell are not perceived to be very important. Limited resources should be expended on this low priority cell.
<b>Quadrant IV</b> <i>Possible over kill</i>	This cell contains attributes of low importance, but where performance is relatively high. Respondents are satisfied with the performance of the organization, but managers should consider present efforts on the attributes of this cell as being superfluous/ unnecessary.

Source : Haeryip Sihombing, et.all[17]

Parasuraman *et al* [14] defined the 5 attributes dimensions of service quality (SERVQUAL) as the method used to measure the quality of service as follows:

- (i) Reliability: ability to perform the promised service, dependably and accurately.
- (ii) Responsiveness: willingness to help customers and provide prompt service.
- (iii) Assurance: knowledge and courtesy of employees as well as their ability to inspire trust and confidence.
- (iv) Empathy: caring, individualized attention the firm provides its customers.
- (v) Tangibles: appearance of physical facilities, equipment, personnel, and communication materials

Kano *et al.* [1] developed a model to categorize the attributes of a product or service based on how well they are able to satisfy customer needs. The Kano model is a theory of product development and customer satisfaction developed in the 80s by Professor Noriaki Kano which classifies customer preferences into five categories: (i) Attractive, (ii) One-Dimensional, (iii) Must-be, (iv) Indifferent, (v) Reverse. The one-dimension quality model focuses on one quality element. It states that if the quality element is of sufficiency then the customer is satisfied, otherwise the customer is not satisfied. Two-dimension quality model argued that quality elements sufficiency may not enough to satisfy the customers' quality expectation. Sometimes it may result in un satisfaction or no feeling for the customer. This is the core concept of the two-dimension quality model. The concept of the two-dimension quality is proposed by Herzberg in 1987. Kano called the Herzberg's Motivator-Hygiene theory as the quality's (Motivator-Hygiene) M-H theory. Due to this terminology is too complicate to use it. Kano redefines the

quality's M-H theory as attractive quality and must-be quality, and distinguishes the service quality in terms of attractive quality elements, one-dimension quality elements, must-be quality elements, indifferent quality elements and reverse quality elements. The following are the quality elements categories:

These categories have been translated into English using various different names (delighters/exciters, satisfiers, dissatisfiers, etc.), but all refer to the original articles written by Kano (see Figure 3)[18].

1. **Attractive Quality:** These attributes provide satisfaction when achieved fully, but do not cause dissatisfaction when not fulfilled. These are attributes that are not normally expected for example, a thermometer on a package of milk showing the temperature of the milk. Since these types of attributes of quality unexpectedly delight customers, they are often unspoken.
2. **One-dimensional Quality:** These attributes result in satisfaction when fulfilled and dissatisfaction when not fulfilled. These are attributes that are spoken of and ones which companies compete for. An example of this would be a milk package that is said to have ten percent more milk for the same price will result in customer satisfaction, but if it only contains six percent then the customer will feel misled and it will lead to dissatisfaction.
3. **Must-be Quality:** These attributes are taken for granted when fulfilled but result in dissatisfaction when not fulfilled. An example of this would be package of milk that leaks. Customers are dissatisfied when the package leaks, but when it does not leak the result is not increased customer satisfaction. Since customers expect these attributes and view them as basic, then it is unlikely that they are going to tell the company about them when asked about quality attributes.
4. **Indifferent Quality:** These attributes refer to aspects that are neither good nor bad, and they do not result in either customer satisfaction or customer dissatisfaction.
5. **Reverse Quality:** These attributes refer to a high degree of achievement resulting in dissatisfaction and to the fact that not all customers are alike. For example, some customers prefer high-tech products, while others prefer the basic model of a product and will be dissatisfied if a product has too many extra features

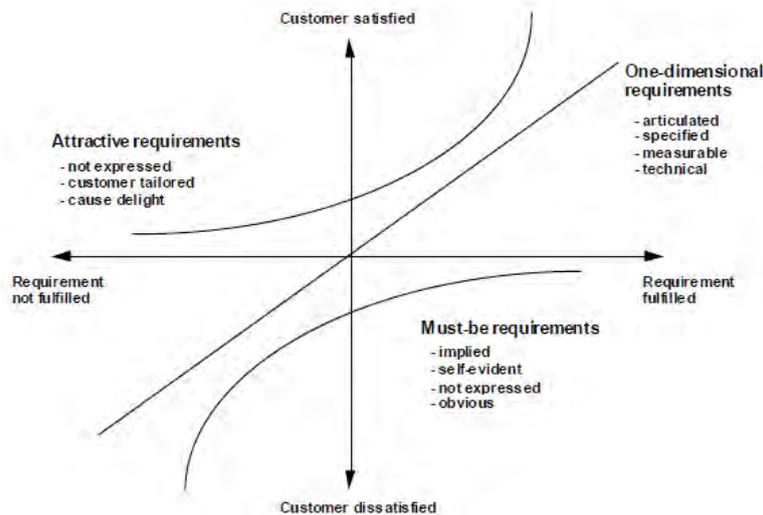

Figure 3: KANO's Model Customer Satisfaction

### 3. METODHOLOGY

The framework of this study can be seen on figure 4.

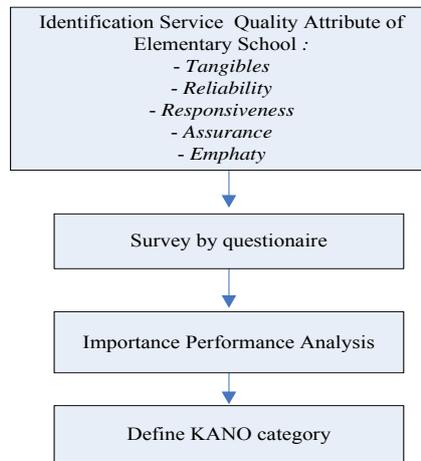

Figure 4. Framework of study

Service quality attribute of elementary school as in table 2 below :

Table 2. Service Quality Attribute of Elementary School

Dimension	Attribute	Code
Tangibles	Academic calendar availability	A1
	Academic calendar implemented as planned	A2
	Teacher have a good capability	A3
	Teachers teach subjects according to educational background	A4
	Teaching are always conducted as scheduled	A5
	Availability of the agenda book	A6
Reliability	Classrooms are clean and comfortable	B1
	Facilities and modern teaching equipment	B2
	A completely of library	B3
	Sports facilities	B4
	Availability of student activity	B5
	Cleanliness of toilets	B6
	Computer laboratory	B7
	Completed and updated school's website	B8
	Cleanliness school environment	B9
	Teachers and staff dressed	B10
	Parking area	B11
School location is easy to access	B12	
Responsiveness	Teachers respond to questions and complaints of parents well	C1
	Teachers are willing to talk to parents about child's problem	C2
Assurance	Number of teacher	D1
	The use of teaching methods	D2
	Availability of textbooks	D3
	The number of students in one class	D4
	Education about manners, responsibility and honesty	D5
Empathy	Communication between teachers and parents	E1
	Regular meetings between teachers and parents	E2
	Parent organization	E3

The survey was carried out through two type of questionnaire to analyze parent satisfaction. The first one is used for analyzing importance and performance. On the first questionnaire, respondents give rank of importance and performance for every

attribute by Likert scale between 1 and 5. The second questionnaire is used to categorize service quality attribute by KANO Model. To apply the Kano classifications to divide the quality elements into attractive, one-dimensional, must-be, indifferent, and reverse quality elements is used by table 3 [19]

Table 3. KANO Evaluation Table  
 Source : Matzler & Hinterhuber (1998)

Product requirement →		Dysfunctional form of the question				
		I like that way	It must be that way	I am neutral	I can live with it that way	I dislike that way
Functional form of the question ↓	I like that way	Q	A	A	A	O
	It must be that way	R	I	I	I	M
	I am neutral	R	I	I	I	M
	I can live with it that way	R	I	I	I	M
	I dislike that way	R	R	R	R	Q

Where : Q= questionable, A = attractive, O = one dimensional, R=reverse, I = indifferent, M =must be

To classify attribute we used Blauth's formulas :

- If (one dimensional + attractive + must be) > (indifferent + reverse + questionable) then the category is maximum [one dimensional; attractive; must be]
- if (one dimensional + attractive + must be) < (indifferent + reverse + questionable) then the category maximum [indifferent; reverse; questionable]

#### 4. RESULTS AND DISCUSSION

This study includes 150 respondents. The respondents are parents of elementary school. Summary of respondent can be seen at table 4.

Table 4. Summary of respondent

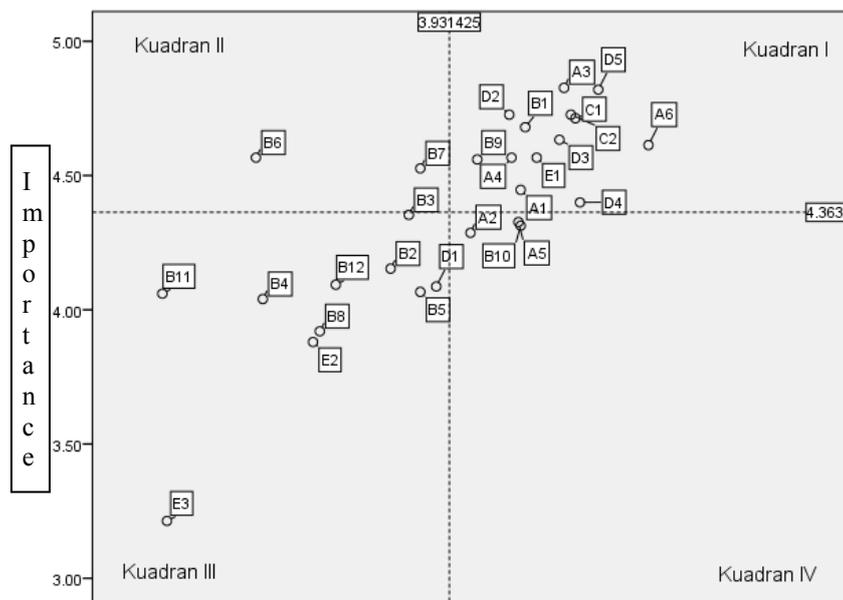

Item	Category	Amount	Percentage
Age	< 25 year	0	0.00
	25 – 30	5	3.33
	30 - 35	34	22.67
	35 - 40	47	31.33
	40 - 45	43	28.67
	>45	21	14.00
Occupation	Gov. Officer	13	8.67
	Private Officer	58	38.67
	Entrepreneur	26	17.33
	Military	13	8.67
	Doctor	1	0.67
	Teacher/Lecturer	10	6.67
	Others	29	19.33
Eductaion	High School	50	33.33
	Diploma	19	12.67
	Undergraduate	67	44.67
	Master	9	6.00
	Doctoral	0	0.00
	Military	2	1.33
	Others	3	2.00

Gap analysis conduct to analyze whether there are differences in the level of importance and performance of each service attribute. Summary of importance and performance of each service attribute can be seen in Table 5. The mean level of assessment and the level of interest then made Cartesian diagram as shown in figure 5.

Table 5. Average of Importance and Performance

Item	Average of Importance	Average of Performance
------	-----------------------	------------------------

A1	4.4467	4.1400
A2	4.2867	3.9933
A3	4.8267	4.2667
A4	4.5667	4.1133
A5	4.3267	4.1333
A6	4.6133	4.5133
B1	4.6800	4.1533
B2	4.1533	3.7600
B3	4.3533	3.8133
B4	4.0400	3.3867
B5	4.0667	3.8467

D4	4.4000	4.3133
D5	4.8200	4.3667
E1	4.5667	4.1867
E2	3.8800	3.5333
E3	3.2133	3.1067

Performance

Figure 5: Cartesian Diagram

From Cartesian diagram, grouping each attribute in each quadrant is shown in Table 6.

Table 6. Grouping attribute to Cartesian Diagram

Quadrant	Code	Attribute
Quadrant I	A1	Academic calendar availability
	A3	Teacher have a good capability
	A4	Teachers teach subjects according to educational
	A6	Availability of the agenda book
	B1	Classrooms are clean and comfortable
	B9	Cleanliness school environment
	C1	Teachers respond to questions and complaints of parents well
	C2	Teachers are willing to talk to parents about child's problem
	D2	The use of teaching methods
	D3	Availability of textbooks
	D4	The number of students in one class
	D5	Education about manners, responsibility and honesty
	E1	Communication between teachers and parents
Quadrant II	B3	A completely of library
	B6	Cleanliness of toilets
	B7	Computer laboratory
Quadrant III	B2	Facilities and modern teaching equipment
	B4	Sports facilities
	B5	Availability of student activity
	B8	Completed and updated school's website
	B11	Parking area
	B12	School location is easy to access
	D1	Number of teacher
	E2	Regular meetings between teachers and parents
	E3	Parent organization
Quadrant IV	A2	Academic calendar implemented as planned
	A5	Teaching are always conducted as scheduled
	B10	Teachers and staff dressed

To categorize service quality attribute by KANO Model is based on answers to questions functional and dysfunctional each attribute. According to KANO evaluation table 3, sum of KANO category for every attribute can be seen on table 7.

Table 7. Sum of KANO Category

Code	Attribute	Sum of KANO Category					
		O	A	M	I	R	Q
A1	Academic calendar availability	81	35	7	15	0	0
A2	Academic calendar implemented as planned	65	36	14	21	1	1
A3	Teacher have a good capability	112	13	9	4	0	0
A4	Teachers teach subjects according to educational background	65	44	9	19	0	1
A5	Teaching are always conducted as scheduled	104	12	17	5	0	0
A6	Availability of the agenda book	99	19	7	13	0	0
B1	Classrooms are clean and comfortable	115	9	8	5	0	1
B2	Facilities and modern teaching equipment	42	55	6	35	0	0
B3	A completely of library	44	68	5	21	0	0
B4	Sports facilities	46	50	6	36	0	0
B5	Availability of student activity	27	74	3	34	0	0
B6	Cleanliness of toilets	123	7	7	1	0	0
B7	Computer laboratory	70	45	8	15	0	0
B8	Completed and updated school's website	53	42	7	36	0	0
B9	Cleanliness school environment	117	11	7	3	0	0
B10	Teachers and staff dressed	76	37	12	13	0	0
B11	Parking area	49	48	11	30	0	0
B12	School location is easy to access	74	36	10	18	0	0
C1	Teachers respond to questions and complaints of parents well	96	26	8	8	0	0
C2	Teachers are willing to talk to parents about child's problem	96	17	16	9	0	0
D1	Number of teacher	70	41	10	17	0	0
D2	The use of teaching methods	104	24	8	2	0	0
D3	Availability of textbooks	96	30	7	5	0	0
D4	The number of students in one class	75	33	5	24	1	0
D5	Education about manners, responsibility and honesty	123	9	4	2	0	0
E1	Communication between teachers and parents	101	15	16	6	0	0
E2	Regular meetings between teachers and parents	39	26	23	49	1	0
E3	Parent organization	15	28	2	89	4	0

Based on the results in Table 7, the determination of KANO categories for each attribute using Blauth's formula can be seen on table 8.

Table 8. KANO Category

Code	Attribute	KANO Category
A1	Academic calendar availability	O
A2	Academic calendar implemented as planned	O
A3	Teacher have a good capability	O
A4	Teachers teach subjects according to educational background	O
A5	Teaching are always conducted as scheduled	O

D5	Education about manners, responsibility and honesty	O
E1	Communication between teachers and parents	O
E2	Regular meetings between teachers and parents	O
E3	Parent organization	I

From the results of respondents' answers to the level of importance and performance of each service attribute as can be seen in Table 5, it can be seen that the average rate of importance of all attributes greater than the performance. However, to give priority to improve attribute can be seen from the Cartesian diagram in Figure 5. Attributes that need serious attention to be improved are the attributes that in quadrant II that is completeness of library, Cleanliness of toilets and computer laboratory, because these attributes are considered bad perform but it is important for parents. This causes the parents disappointed. From the categorization of KANO model in Table 8, most of the attributes as category O (One Dimensional) means the rate of satisfaction is linear-related with performance that mean if performance attributes high will result in higher satisfaction parents. In other words, if we want to increase the satisfaction of the parents is by increasing the performance its attribute.

## 5. CONCLUSION

According to Gap Analysis we can conclude that in general there is gap between expectation and satisfaction of service in elementary school. The attribute that should be improved immediately are completeness of library, cleanliness of toilets and computer laboratory. Based on KANO analysis, 23 attribute are as One-Dimensional, 4 as Attractive and 1 as Indifferent.

# The Relationship between Type 2 Diabetes Mellitus with Diabetic Retinopathy Assessed by HbA1c as A Parameter of Blood Sugar Control

Irmayanti Rangkuti<sup>a</sup>

<sup>a</sup>Faculty of Medicine, Islamic University of North Sumatera, Medan 20143  
 E-mail : irma.uisu.dr.com

## ABSTRACT

*This research was an analysis cross sectional. It has been done in Sumatera Eye Centre Medan and Prodia Laboratory Medan for three months. The purpose of this study was to determine the relationship between blood sugar control with diabetic retinopathy in type 2 diabetes with HbA1c as a parameter of blood sugar control, the long-suffering relationship of DM with diabetic retinopathy, and the relationship of age with diabetic retinopathy. This study involved 30 people with type 2 diabetes by making several measurements such as blood pressure with a sphygmomanometer Hg and steteskop, blood sugar levels with a spectrophotometer, levels of HbA1c by HPLC technique, sharp visiot, intra-ocular pressure (IOP), and fundus eye examination. Between control and diabetes mellitus with diabetic retinopathy obtained,  $p = 0.195$ , controlling blood sugar does not cause the occurrence of diabetic retinopathy ( $p > 0.05$ ). Between long-suffering DM with diabetic retinopathy obtained  $p = 0.05$ , there is relationship between long-suffering DM with diabetic retinopathy, the longer suffer DM the higher risk of developing diabetes mellitus diabetic retinopathy ( $p < 0.05$ ). Between ages with diabetic retinopathy obtained  $p = 0.683$ , there is no relationship between age and diabetic retinopathy ( $p > 0.05$ ).*

## Keywords

*Type 2 diabetes mellitus, diabetic retinopathy, HbA1c*

## 1. INTRODUCTION

Diabetes mellitus (DM) is a metabolic disease characterized by hyperglycemia due to impaired insulin secretion, and or insulin resistance enhancement. Chronic hyperglycemia and other metabolic disorders will damage tissues and organs, such as in the eyes, kidneys, nerves, and vascular system [1]. Metabolic status observation of diabetes mellitus patient is the important thing. Good controlling of disease means maintaining blood glucose level in the normal range. With good controlling disease, the complications can be avoided [11]. Bruce Perkin told that there was a relationship between blood sugar level with complications [5]. Mikihiro Nakayama's research founded that the complication of DM was not only related with blood sugar level. This finding was based on the administration of hipoglikemic oral that maintain blood sugar level could not prevent the complications [3]. Retinopatya diabetic is one of the complications on eye that can cause blindness, the effect of retina defect. This complication was estimated 25 times more be suffered in DM's patients [10]. According to the researches in 26 centers in USA, and 3 centers in Canada for 10 years in patients with insulin dependent DM founded that good controlling of blood glucose could prevent and inhibit the emergence and retinopathy progressivity [11].

## 2. METHODOLOGY

This research used a cross sectional method, an analitical survey research. The technique sampling was consecutive sampling, involved 30 people with type 2 diabetes, by making several measurements and clinical examination and biochemical measurements such as height, weight and waist circumference, blood pressure, blood sugar levels, levels of HbA1c, sharp vision, intra-ocular pressure (IOP), and fundus eye examination. This research was performed in Sumatera Eye Hospital in Medan, North Sumatera, Indonesia. The formula of sampel that was used as two different sampling rates :

$$N = \frac{4 \sigma^2 (Z_{crit} + Z_{pwr})^2}{D^2}$$

$Z_{crit} : 0,05 = 1,96$

$Z_{pwr} : 0,95 = 1,645$

$D = 0,96$

Estimated standard deviation = 8

Minimum expected difference = 10

### 3. EQUIPMENTS AND MATERIAL

Blood pressure was checked by a sphygmomanometer Hg and steteskop. Blood sugar levels with a spectrophotometer, BA-88, a semi auto chemistry analyzer. Levels of HbA1c by HPLC technique, D-10. Sharp vision with a Snellen chart. Intra-ocular pressure (IOP) with computerized tonometer, and fundus eye examination with ophthalmoscopy and fundus photos by visucam NM/FA, a photograph fundus color.

This research used blood patients with type 2 diabetes mellitus to investigate blood sugar level and HbA1c, and midriaticum eye drops is a drug that be given before fundus examination.

### 4. FINDINGS AND DISCUSSION

- 4.1 Patients with more women than men (4:1).
- 4.2 Fifteen people (50%) patients with controlled diabetes mellitus and 15 people (50%) patients with uncontrolled DM.
- 4.3 Youngest diabetic patient aged 42 years, and the oldest 78 years of age. DM is most experienced at the age between 49-56 years with a number of 6 people (40%) in uncontrolled diabetes mellitus, followed by 5 people (33.33%) in the DM controlled group. DM's most lots have been experienced by patients during 7-12 years as many as 9 people (60%) in group controlled DM, and 8 persons (53.33%) in group DM not controlled.

Table 1: The distribution of type 2 diabetes mellitus patients by age.

Age (year)	Controlled diabetes mellitus (person)	Uncontrolled diabetes mellitus (person)
41 – 48	1	5
49 – 56	5	6
57 – 64	4	2
65 – 72	3	1
73 - 80	2	1
Total	15	15

- 4.4 Twenty-three people (76.7%) had no diabetic retinopathy, and 7 persons (23.3%) had diabetic retinopathy. 2 people (6.67%) with controlled diabetes mellitus had diabetic retinopathy, and 5 people (16.66%) with uncontrolled diabetes had diabetic retinopathy.

Table 2: The distribution of type 2 diabetes mellitus with diabetic retinopathy

Diabetic retinopathy	Frequency	Percentage
Negative	23	76,7
Positive	7	23,3
Total	30	100

Table 3: The distribution of controlling diabetes mellitus with diabetic retinopathy

Controlling diabetes mellitus	Diabetic retinopathy		Total
	Negative	Positive	
Control	13	2	15
Uncontrol	10	5	15
Total	23	7	30

Table 4: The analysis of relationship between controlling diabetes mellitus with diabetic retinopathy with Chi-Square Test

	Value	Df	Asymp.Sig. (2-sided)

Pearson Chi-Square	1,677 (b)	1	0,195
--------------------	-----------	---	-------

Based on statistical analysis between controlling blood sugar and diabetes mellitus with diabetic retinopathy obtained  $p = 0.195$ , this means controlling blood glucose does not cause the occurrence of diabetic retinopathy ( $p > 0.05$ ).

Bruce Perkin told that there was a relationship between blood sugar level with complications [5]. Mikihiro Nakayama research founded the complication of diabetes mellitus was not only related with blood glucose level. This finding was based on the administration of hypoglycemic oral that maintain blood sugar level could not prevent the complications [3]. This statement was based on the hypothesis that the complication of diabetes mellitus will happen by arising of polyol pathway activity, stress oxidative increased, and accelerating non-enzymatic glycation [3].

The arising of polyol pathway will form much sorbitol and fructose from glucose that absorb water into the endothel, after that the functional activity of endothel will impair, a leakage and trombosit aggregation.

HbA1c is a parameter of controlling blood sugar in diabetes mellitus patient. HbA1c is product of glycation between glucose (sugar) and blood in 2-3 months corresponding with lifetimes of erythrocyte [2,6]. HbA1c is a product that can be formed after hyperglycemia more over 24 hours, a reversible product, and can change into another product, the irreversible product called by AGEs (advanced glycosylation end products). AGEs is a toxic substance that accumulate in some tissues that can be a source of stress oxidative and relate to the complications of DM [9]. In diabetic retinopathy, AGEs can change the integrity dan the structure of capillary wall by sitocyne induction, growth factor and the arising of oxidative stress. In vitro research found the excess of VEGF (vasoproliferative endothelial growth factor), a product from the stimulation of oxidative stress and eNOS (endothelial nitric oxide synthase) abnormality. There were an increase of AGEs accumulation that were distributed around of retinal vascular of DM patients and the accumulation increased with severity of retinopathy [4].

- 4.5 Twenty-three people do not experience diabetic retinopathy after suffering from diabetes for a mean 11.22 years, and 7 people experience after suffering from diabetes mellitus diabetic retinopathy during the 16.57-year average. Twenty-three people do not have diabetic retinopathy at an average age of 56.43 years, and 7 people have diabetic retinopathy at an average age of 58.29 years.

Table 5: The distribution of type 2 diabetes mellitus patients by long-suffering of diabetes mellitus

Long-suffering of diabetes mellitus (year)	Controlled diabetes mellitus (person)	Uncontrolled diabetes mellitus (person)
1 - 6	2	2
7 - 12	9	8
13 - 18	3	3
19 - 24	1	1
25 - 30	0	1
Total	15	15

Table 6: The analysis of the relationship between long-suffering type 2 diabetes mellitus with diabetic retinopathy with T-test

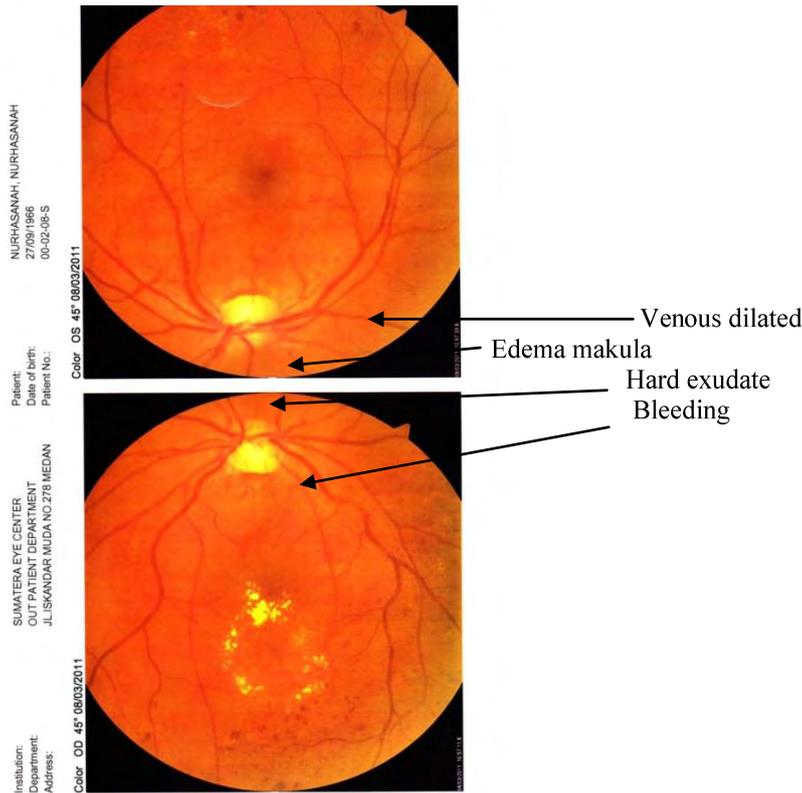

Long-suffering	Df	Sig.(2-tailed)
Equal variances assumed	28	0,05

Between long-suffering DM with diabetic retinopathy obtained  $p = 0.05$ , this means that the longer suffer the higher risk of developing diabetes mellitus diabetic retinopathy ( $p < 0.05$ ). Between ages with diabetic retinopathy obtained  $p = 0.683$ , this means there is no relationship between age and diabetic retinopathy ( $p > 0.05$ ).

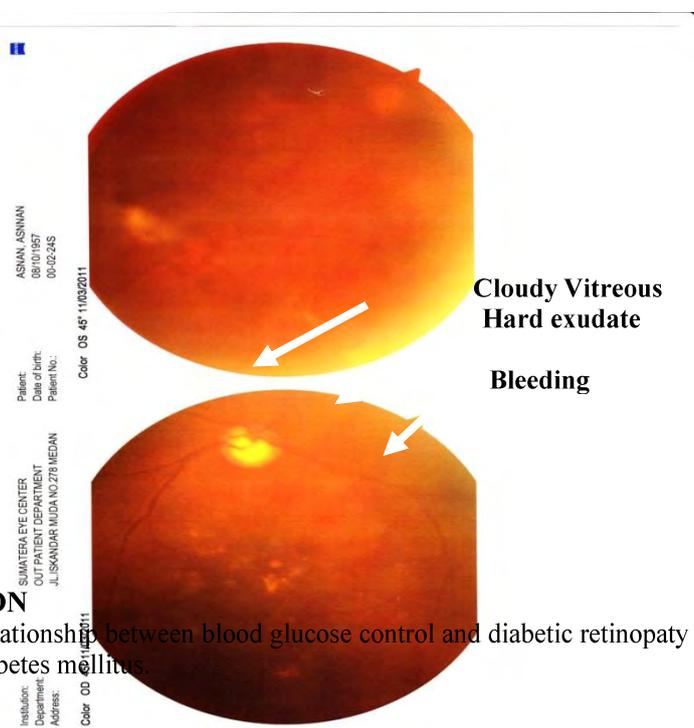

Klein research founded after 10 years suffered type 2 diabetes mellitus, 2.67% patients would be retinopathy, and 10% from all patients had been a PDR (proliferative diabetic retinopathy) patients [7]. The incidence and degree of retinopathy were more related to long-suffering than the severity of this disease, eventhough HbA1c was in a good controlled [8]. The mechanism of complication diabetes mellitus such as the enhancement of non-enzymatic glycation product ADGEs, polyol activity that product sorbitol and fructose, releasing of vasoproliferative factor by retina, endothel disfunction, basal membrane, collagen and smooth muscles, will continue by the time and damage the endothel.

#### 4.6 The fundus photo of type 2 diabetes mellitus patients

4.6.1 Mrs. N, 45 years old, has been suffered of diabetes mellitus about 18 years, non-proliferative diabetic retinopathy

4. years old, has been suffered of diabetes mellitus about 16 years, proliferative diabetic retinopathy

## 5. CONCLUSION

5.1 There was no relationship between blood glucose control and diabetic retinopathy with HbA1c as a parameter blood glucose control in type 2 diabetes mellitus.

- 5.2 There was a relationship between long-suffering DM with diabetic retinopathy.  
5.3 There was no relationship between age and diabetic retinopathy.

# The Effectivity of Single Dose Albendazole to *Trichuris Trichiura* Worm Infection for One, Two and Three Days Therapy

Rusdi Yunus<sup>a</sup>

<sup>a</sup>Faculty of Medicine, Islamic University of North Sumatera, Medan 20143  
 E-mail: dr\_rusdiyunus@yahoo.com.

## ABSTRACT

This research has been done in Sekolah Dasar No. 067230, Kecamatan Medan Tembung, Medan for two months to 165 students which is separated in three groups of medicine giving. This study used Clinical Trial Prospective method with one group pre and post test design. This study was to investigate how long the Albendazole dosage giving one time in a day to get the optimum effect in the curation of *Trichuris trichiura* infection. The research used Albendazole dosage 400 mg a day for 1 day, 2 days and 3 days. There are significant difference in decreasing of eggs quantity before and after medical at 3 groups of medical giving and intensity decreasing of infection at 3 groups. ( $p=0,0001$ ). 400 mg dosage Albendazole one time a day is not effective for trichuriasis with medium and high intensity at 3 groups of medicine, but 400 mg dosage Albendazole one time a day for 3 days is effective for low intensity because it has 96,65 % Cure Rate and Eggs Reduction Rate 99,64 %.

## Keywords

*Trichuris trichiura*, infection intensity, cure rate, eggs reduction rate

## 1. INTRODUCTION

Intestinal worm infection remains a public health problem in Indonesia and some countries in the world especially in developing countries in the tropics. Although worm infections very rarely caused death, but in the circumstances may lead to chronic health problems, such as the result of severe and chronic infection can lead to malnutrition, anemia (anemia), which can indirectly cause physical, cognitive disorders, disorders growth in children, decreased work and quality of life, and the future of patient. Worm infections can affect all age groups, but particularly high prevalence in group of primary school children. Trichuriasis a worm *Trichuris trichiura* infections were estimated at 800 million cases worldwide. In tropical and humid areas in Indonesia, patients with severe and chronic infections, especially in children with typical symptoms frequently, such as dysentery syndrome, anemia, weight loss, accompanied by infectious micro-organisms, can occur even prolapse of rectum. In developing countries, including Indonesia, intestinal worm infections that are transmitted through the soil/Soil-Transmitted Helminths (STH) has a very high prevalence, especially in children aged under five years or class of primary school children.

From the study in 1995 found prevalence of soil transmitted intestinal worm by 60% to 70%. Children of primary school age are vulnerable to disease transmission [1].

The results of the 1996 study of elementary school children in North Jakarta found a prevalence of 59.6% and trichuriasis and ascariasis amounted to 79.64%. The level of disease transmission and trichuriasis and ascariasis is very closely linked to soil contamination by faeces containing worm eggs [1].

In the prevention and treatment of intestinal worms, the government has implemented various worm disease eradication programs, especially at the elementary school age children. These activities include outreach to students, teachers, and parents about the intestinal worms that are transmitted through the ground, including the causes, prevention, and ways of prevention and the provision of de-worming.

VY Belizario, ME Amarillo, WD Leon [2] in 2003 in the study a single dose of Albendazole treatment in primary school children in the Philippines to get Cure Rate for *Trichuris trichiura* 69,7%.

VJ Adam, Lombard CJ, Dhansay MA et al [3], in 2004 in the research use of a single dose of Albendazole 400 mg in primary school children in Cape Town South Africa to get Cure Rate by 23%.

Legesse M, Erko B, Medhin G, in 2004 [4] in the research use Albendazole once daily doses for one day in school children age 6 to 19 years in Ethiopia get the Cure Rate 69,8%.

Sirivichayakul C, Pojjoen Anant C, Wisetsing Pet al [5], in 2003 in the research use of albendazole 400 mg once daily for 3 days, 5 days, 7 days suggested that these of Albendazole 3 days used for mild infections of *Trichuris trichiura*, whereas for severe infection 5 to 7 day.

The report above results indicate that administration of albendazole once a day for 1 day to tackle trichuriasis not provide optimal effect. Based on this fact needs to be investigated how long delivery albendazole once a day to achieve an optimal effect on *Trichuris trichiura* infection control.

The low rate of treatment success (Cure Rate) Albendazole 400 mg once-daily dosing to *Trichuris trichiura* infection. To the above should be compared with the effectiveness of albendazole 400 mg once daily administration for 1, 2 and 3 days.

### 1.1 Objective

The objective of this study was to determine the effective dose of albendazole in preventing worm *Trichuris trichiura* infection in the general population

### 1.2 Hypothesis

There was a difference in the success rate of treatment with albendazole once daily dosing for 1 day, 2 days and 3 days.

There was a difference in intensity reduction worm *Trichuris trichiura* infection by treatment albendazole 400 mg dose once daily for 1 day, 2 days, and 3 days.

### 1.3 Benefits

Getting therapy is more effective and efficient in combating *Trichuris trichiura* infection in the community

Getting optimal drug delivery arrangement and efficient for mass treatment in STH control programs

## 2. LITERATURE REVIEW

Humans are one of the few hospes intestinal worms, most of these worms can cause health problems. Some intestinal worms are partly soil-borne worms called "Soil-Transmitted Helminths" (STH), including *Ascaris lumbricoides*, *Ancylostoma duodenale*, *Necator americanus*, *Trichuris trichiura*, *Strongyloides stercoralis*, and *Trichostrongylus* species [6]. Impact of intestinal worm infection that is transmitted through the soil and its life cycle needs to be studied in order to determine ways of prevention. The spread of infection *Ascaris lumbricoides* and *Trichuris trichiura* almost the same, so that the infection of the two worms above almost always together in the same person. Similarly, the epidemiology of the two worms are almost the same, so it is often seen with a prevalence of ascariasis and trichuriasis always pretty much the same [7]. In endemic areas with a high incidence of ascariasis and trichuriasis, transmission occurs continuously. This transmission is influenced by several things that can benefit the parasite, such as soil and weather conditions are suitable [6].

### 2.1 *Trichuris trichiura*

Humans are the definitive hospes worm and the disease is called trichuriasis. Cosmopolitan distribution of this worm, found mainly in tropical and humid areas in Indonesia and other tropical areas. *Trichuris trichiura* has a whip-like shape with the anterior/head finer than the posterior/tail section. The length of female worms approximately 4 cm by the end of the curved tail, while the female worm has a length of about 5 cm and the tail end of the straight. Adult worms live in the cecum and ascending colon with a smooth anterior part into the villi of the intestinal mucosa to take food and suck blood [8]. Adult female worms will produce as many eggs 3000-10000 a day. Egg size 50-54 microns x 32 microns, oval shaped with 2 knobs on both poles. Relatively thick eggshell, outeryellowish, clear and colored outer. The fertilized egg will come out of the body through the stool hospes. At ground level the egg will mature in 10-14 days depending on climate and suitable environment, such as soil moisture and shade. Humans are infected by swallowing eggs containing larva mature, the egg hatch in the intestine and after the adult worms will move toward the cecum and ascending colon [9]. The time required for the growth from mature eggs are ingested to be a female worm produce eggs that are ready for approximately 30-90 days. In clinical symptoms caused by the adult worms head into the intestinal mucosa and suck blood, there is irritation and inflammation of the intestinal mucosa, which can cause anemia, and easily infected by bacteria/parasites, such as *Entamoeba histolytica* and *Escherichia coli*. Patients with severe and chronic infections, especially in children often show obvious clinical symptoms such as diarrhea are often interspersed with dysentery syndrome and anemia, weight loss, and sometimes accompanied with rectal prolapse, the symptoms can run for many years. Trichuriasis Diagnosis confirmed by the eggs in the feces [6].

### 2.2 Albendazole

Albendazole is an anthelmintic with a very broad spectrum, from the benzimidazole group. Benzimidazole pharmacologically inhibits mitochondrial fumarate reductase, thereby inhibiting polymerization of work [10]. In parasitic worms albendazole and its metabolites are thought to act by inhibiting the synthesis of microtubules, thereby reducing glucose making irreversible, resulting in paralysis of worms [11].

With oral albendazole administration will quickly metabolized in the body into albendazole sulfoxide. Three hours after oral administration at a dose of 400 mg, sulfoxide having maximal concentration of approximately 113-367 ng/ml and the plasma half-life of 8-12 hours. Material removed from the metabolism of the body through the bile and urine. Absorption of albendazole will increase up to five times when administered with a fatty meal. Thus if we want to kill the worms that are in the network, the worm medicine is given with food, and if we want to eradicate worms in the lumen of the intestine, the worm medicine is given at the time before the meal/empty stomach. Albendazole can work as larvicidal and ovisid [11].

Albendazole is indicated to treat intestinal worm infection either single infection or mixed infection.

#### 2.2.1 Treatment and dose albendazole

For adults and children used 1 capsule or 10 ml suspension containing 400 mg given as a single dose. For strongly ill and immunocompromised patients given 1 pill or suspension containing 400 mg given for 3 consecutive days. Treatment does not require fasting or laxative use. Side effects of Albendazole are usually mild and temporary. Gastrointestinal disturbances, headache, dizziness, fatigue, and insomnia may occur in some cases.

### 2.2.2 Contraindicated

Pregnant women and women who are breastfeeding. Caution when used in patients with impaired hepatic function and impaired renal function. Albendazole should not be given to children under 2 years of age [11].

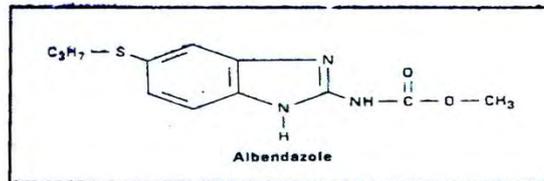

Figure 1. The chemical structure of albendazole

## 3. METHODS

This study was a prospective Clinical Trial with one group pre and post test design [12]

### 3.1 Time and place of research

The study was conducted for two months in Sekolah Dasar No.067230 Tembung Medan.

### 3.2 Criteria for inclusion

1. Willing to take medication
2. Trichuris trichiura eggs found in the feces
3. Fill out the informed consent
4. Meets protocol, prepared for stool examination at a specified time researchers.
5. No other comorbidities

### 3.3 The exclusion criteria

1. Eat anthelmintic drugs within the study period
2. Eating anthelmintic drugs two weeks before the start of the study
3. Arising side effects to the anthelmintic drugs
4. Not willing to fill the informed consent
5. Had diarrhea
6. The existence of comorbid infectious diseases that can weaken the evaluation of treatment in the study

### 3.4 Estimate the Sample [13].

$$n_1 = n_2 = n_3 = \frac{\{Z_\alpha \sqrt{2PQ} + Z_\beta \sqrt{P_1Q_1 + P_2Q_2}\}^2}{(P_1 - P_2)^2} \quad (1)$$

-  $P = 1/2 (P_1 + P_2)$

-  $P_1$ : proportion decreased cure rate of trichuriasis by Albendazole

-  $P_2$ : proportion decreased cure rate of albendazole trichuriasis by the

be expected (*clinical judgment*)

-  $P_1 = 0.542$        $P_2 = 0.825$

-  $P = 0.684$        $Q = 0.316$

$Q_1 = 1 - P_1 = 1 - 0.542 = 0.458$

$Q_2 = 1 - P_2 = 1 - 0.825 = 0.175$

$Z_\alpha = 1.96$        $Z_\beta = 0.842$

From the above calculation, the samples of each group = 41.17

The number of each treatment group are set = 42 persons

### 3.5 Work methods

Stool examination at primary school children grade 1 to grade 6 using the KATO-KAZT. All children with positive *Trichuris trichiura* eggs included in the study participants. Declared negative stool examination, stool examination 3 times if the same is not found worm eggs. Calculated density of eggs in the feces with a count of Egg Per Gram (EPG). In accordance with WHO recommendations preparations were examined based on the volume of faeces taken from thick cardboard hole diameter of 1.37 mm and 6 mm weighed 41.7 mg and the result is multiplied by 24. Classification of the severity of the patient based on guidance from the WHO are as follows:

- Light : Number of eggs 1 - 999 eggs per gram
- Middle : Number of eggs 1000 - 4999 eggs per gram
- Weight : Number of eggs more than 4999 eggs per gram [14].

Stool examination carried out at the beginning of the study and 2 weeks after administration of anthelmintic first day, with the same method.

### 3.6 Treatment group

The study consisted of 3 treatment groups as follows :

1. The group who received albendazole 1 tablet containing 400 mg given orally once daily for 1 hari.
  2. The group that received 1 tablet of albendazole 400 mg orally once daily for 2 days.
  3. The group who received albendazole 1 tablet containing 400 mg given orally once daily for 3 days.
- In this study, the data are not grouped in the intensity of infection in proportion.

### 3.7 Variable

- Independent variable : Albendazole 1 day, 2 days dan 3 days
- Dependent variable : Eggs Per Gram (EPG), Cure Rate (CR)  
 Eggs Reduction Rate (ERR)

## 4. STATISTICAL ANALYSIS

1. To see the difference in the average number of worm eggs in the treatment group for 1 day, 2 days, and 3 days at the beginning of the study population tested Anova if the same variant. If not the same variant was tested by Kruskal-Wallis.
2. To see the difference in treatment for 1 day, 2 days, 3 days, before and after treatment using paired t-test if the data were normally distributed, while the data were not normally distributed with the Wilcoxon test.
3. To see the difference in the average number of worm eggs in treatment group 1 day, 2 days, 3 days, before and after treatment using paired t-test when the data were normally distributed, while the data were not normally distributed with the Wilcoxon test.
4. To see the difference in the average change in the number of worm eggs due to the administration of drugs in each group were tested with Anova.

## 5. RESULT

From the number of students from Grade 1 to Grade 6 Elementary School District No. 067240 Tembung Medan 559 students, only 374 (66.91%) students who are willing to check their stool. While 185 students do not check their feces. In the first stool examination for 374 students before giving medication found 273 (73%) suffer from intestinal worm infections of 4 different types of intestinal worms among others, *Trichuris trichiura*, *Ascaris lumbricoides*, Hookworm, and *Hymenolepis nana*.

Table 1. The prevalence of intestinal worm infections before treatment

Parasit	Number of samples n ( % )
<i>Trichuris trichiura</i>	237(63.37 %)
<i>Ascaris lumbricoides</i>	174(46.52 %)
Hookworm	2(0.53 %)
<i>Hymenolepis nana</i>	2(0.53 %)
<i>T.trichiura</i> + <i>A.lumbricoides</i>	136(36.33 %)
<i>T.trichiura</i> + <i>A.lumbricoides</i> + Hookworm	2( 0.53 %)
<i>T.trichiura</i> + <i>H.nana</i>	2(0.53 %)
<i>T.trichiura</i> single infection	97(25.94 %)

After giving albendazole 400 mg daily dose for all patients with intestinal worm infections by the number of days according to treatment group taken at random, found these side effects such as mild headache to two students in the group of drug delivery is 3 days and the symptoms disappeared on the fourth day without drug delivery.

Two weeks after the treatment given to three groups of subjects performed a second stool examination, there were 273 students who have intestinal worm infections provided stool for the second examination, and only 165 stool students who meet the study requirements. From the results of stool examination were performed, 273 (73.00%) children suffer from intestinal

worms of various types of intestinal worms. Prevalence of *Trichuris trichiura* worm has the highest prevalence compared with other intestinal worms (63.37%), followed by *Ascaris lumbricoides* (46.52%), hookworm (0.53%) and worms *H. nana* (0.53%). Found a mixture of intestinal worm infections such as *Ascaris lumbricoides*, *Trichuris trichiura* with 136 (36.33%), *Trichuris trichiura* with *H. nana* 2 (0.53%), *Trichuris trichiura* with *Ascaris lumbricoides* and hookworm 2 (0.53%), while the number of single infections of *Trichuris trichiura* 97 (25.94%) (Table 1).

Table 2. The characteristics of the samples based on treatment group

Characteristics	1 day n(%)	2 days n(%)	3 days n(%)	Total n(%)
<b>Sex</b>				
Female	22(27.8%)	23(29.1%)	34(43.0%)	79(100%)
Male	23(26.7%)	30(34.9%)	33(38.4%)	86(100%)
Total	45(27.3%)	53(32.1%)	67(40.6%)	165(100%)

165 students who are the subject of research, found 22 (27.8%) and 23 female students (26.7%) male students for a one-day treatment group amounted to 45 students. Treatment group of students two days 53 people there are 23 (29.1%) female students and 30 (34.9%) male students. While on a three-day treatment group numbered 67 people there are 34 (43.0%) female students and 33 (38.4%) male students (Table 2).

Table 3. Characteristics of patients with trichuriasis before treated

Characteristics of the subjects	1 day n = 45	2 days n = 53	3 days n = 67	p
The number of worm eggs (Egg-1)	1276.36 ± 1435.66	789.06 ± 96.38	993.69 ± 1389.37	0.168

Test distribution is normal

The average number of eggs in a single day treatment group 1276.36+1435.66, a two-day treatment group 789.06+96.38, and a three-day treatment group +1389.37 993.69. There are differences in the average number of eggs a day treatment group with a two-day treatment group and three treatment groups 3 days, but it was not statistically significant (p=0.168) (Table 3).

Table 4. The intensity of infection in the treatment group before treatment

Intensitas	1 day n (%)	2 days n (%)	3 days n (%)	Total n (%)	p
light	25(22.3%)	41(36.6%)	46(41.1%)	112(100%)	0,137*
moderate/middle	17(36.2%)	12(25.5%)	18(38.3%)	47(100%)	
weight	3(50.0%)	0(0.0%)	3(50.0%)	6(100%)	
Total	45(27.3%)	53(32.1%)	67(40.6%)	165(100%)	

\* Chi-Square Tests

In observation of the intensity of worm infections before drug treatment is seen in the treatment group of the day there were 25 (22.3%) students with mild infection, 17 (36.2%) students were infections and 3 (50.0%) students of severe infections. At the two-day treatment group consisted of 41 (36.6%) students with mild infection, 12 (25.5%) students with moderate infection and found no severe infections. While the three-day treatment group found 46 (41.1%) students with mild infection, 18 (38.3%) students with mild infections, and 3 (50.0%) students with severe infections (Table 4)

Table 5. The average number of eggs in stool before and after treatment in the treatment group

Group	Before treatment	After treatment	ERR	P
1 day N= 45 Light Moderate/middle Weight	383.04 ± 222,94 1862.35 ± 879,85 5400.00 ± 392,90	10.40 ± 7,27 322.82 ± 197,08 1712.00 ± 121,17	97.28 % 82.67 % 68.30 %	0.001
2 days N= 53 Light Moderate/middle Weight	368.49 ± 209.26 2226.00 ± 901.57 -	15.80 ± 8,96 252.25 ± 199,96 -	95.71 % 88.50 % -	0.001
3 days N=67 Light Moderate/middle Weight	287.91 ± 196.95 2002.67 ± 895.06 5304.00 ± 197.05	1.04 ± 0,49 37.33 ± 12,08 240.07 ± 42,08	99.64 % 98.14 % 98.49 %	0.001

\*Wilcoxon Signed Rank Test

From the results of stool examination before treatment, at a day treatment group the average number of eggs in mild infection 383.04 ± 222.94, moderate infections 1862.35 ± 879.85, severe infections 5400.00 ± 392.90, and after given treatment, the average number of eggs changed, mild infection 10.40 ± 7.27, moderate infections 322.82 ± 197.08 and severe infections 1712.00 ± 121.17

At the two-day treatment group, the average number of eggs in light infection 368.49 ± 209.26, the moderate infection was 1862.35 ± 879.85, and severe infections are not found eggs. After given treatment, the average number of eggs changed, for light infection to 15.80 ± 8.96, and moderate infection was 252.25 ± 199.96.

For the three day treatment group the average number of eggs in light infection was 287.91 ± 196.95, moderate infection was 2002.67 ± 895.06, and severe infections 5304.00 ± 197.05. After treatment the average number of eggs in light infection 1.04 ± 0.49, moderate infection was 37.33 ± 12.08 and severe infections was 240.07 ± 42.08 (Table-5)

Table 6. Heal-Do not cured by the intensity of worm infection treatment group

Group	Before n (%)	After n (%)	C R	P
One day, n=45 light Moderate/middle Severe	25(55.6%) 17(37.8%) 3(6.7%)	Heal : 21(46.7%) light : 4 (8.9%) Heal : 5(11.1%) Light : 9(20%) Moderate : 3 (6.7%) Heal : 0 (0.0%) moderate : 3 (6.7%)	84 % 29.41 % 0 %	0.0001
Two days , n=53 Light Moderate/middle Severe	41(77.4%) 12(22.6%) 0	Heal : 29(54.7%) Light : 12(22.6%) Heal : 1(1.9%) Light : 11(20.8%) -	70.73 % 8.30 % -	0.0001
Three days , n=67 Light Moderate/middle Severe	46(68.7%) 18(26.9%) 3(4.5%)	Heal : 44(65.7%) Light : 2 (3%) Heal : 5(7.5%) Light : 13(19.4%) Heal : 1(1.5%) Light : 2 (3.0%)	95.65 % 27.78 % 33.33 %	0.0001

\* Chi-Square Tests\* \* Significant

From these results we can see, in the treatment group of the day with a number of 45 people, 25 (55.6%) people is a mild infection, 17 (37.8%) people were infections, and 3 (6.7%) people were serious infections, occur conversion after treatment in

group mild infection, recovered 21 (46.7%) people and 4 (8.9%) were still mild infection, the group recovered five moderate infections (11.1%) people, a mild infection 9 (20%) and those whose infection still was 3 (6.7%) persons, while in the group of severe infections encountered no cases were cured, 3 (6.7%) people to moderate infections.

In the two days of treatment with a number of 53 people, 41 (77.4%) persons were light infections, 12 (22.6%) people are moderate infection and no severe infections, the conversion after treatment, in light infection group 29 (54.7%) people were cured, and 12 (22.6%) the infection remains mild, moderate infection in group 1 (1.9%) people were cured and 11 (20.8%) people are still moderate infection.

In the three days of treatment with a number of 67 people, 46 (68.7%) of light infection, 18 (26.9%) of moderate infections and 3 (4.5%) of severe infection, the conversion occurs after treatment, the light infection group 44 (65.7%) people were cured and 2 (3.0%) people become light infection, moderate infection in group 5 (7.5%) people were cured and 13 (19.4%) people were light infection, severe infection whereas in group 1 (1.5%) people healed, 2 (3.0%) people get a light infection (Table 6).

## 5. DISCUSSION

From table-1 we can see whipworm prevalence of 63.37%. There is a difference with the results obtained Subahar Ret alin 1996 amounted to 79.64%. For roundworm infection prevalence roundworm researchers gain of 46.52%, lower than that obtained by Subahar Ret alin 1996 amounted to 59.60%. Most researchers obtain the prevalence of intestinal worms is lower than previous researchers. This is possible because from time to time increase people's knowledge of health, disease worms, and the worm treatment program in school children.

*Ascaris lumbricoides* and *Trichuris trichiura* has a way of infection, and the optimum growth temperature is almost the same culture, so often occurs in patients with concurrent infection and the prevalence is almost the same. From the results of research conducted in primary school children of primary schools sub-field No.067240 Tembung whipworm found a higher prevalence than the prevalence of roundworm, this is possible because of the government's program provides for regular worming of primary school pupils using the helminthic preparations pyrantel pamoate for 1 day, as we know whipworm pyrantel pamoate less sensitive preparations.

Hookworm infection found in elementary schools in the district of Medan Tembung very low (0.53%), this can be made possible because of the neighborhood and children's playground consisting mostly of students from the cement floor or the ground is solid, less suitable for growth hookworm larvae. Similarly, the behavior of the students in their daily lives are always barefoot, it is difficult to hookworm infection through the skin. From this research we have encountered a mixed infection roundworm and whipworm prevalence is high (36.33%). This is possible because both these worms have properties similar either way infection or optimal breeding temperature.

The number of men and women who participated in each drug group no significant difference. This happens just by chance, due to random sampling (Table 2).

The intensity of worm infection medication groups before treatment is seen in one-day treatment group, there were 25 (22.3%) people with light infection, 17 (36.2%) of moderate infections and 3 (50.0%) of severe infections. In the two-day treatment group consisted of 41 (36.6%) people with light infection, 12 (25.5%) people with moderate infections, and no severe infections. While the three-day treatment group consisted of 46 (41.1%) people with light infection, 18 (38.3%) people with moderate infections, and 3 (50.0%) people with severe intensity. Overall light infection intensity has the greatest number, that is 112 people, as many as 47 people moderate and severe intensity only 6 people from a total of 165 people. Statistically there is no significant difference in the intensity of the number of each group in each drug group ( $p=0.137$ ) (Table 4).

The average number of eggs in the feces per gram students who participated in the study for the treatment of one-day, two-day treatment group, and the three-day treatment group decreased significantly after drug administration ( $p=0.001$ ), both for the group of severe infections, moderate or light infection. Based on the calculation of the ERR obtained for the treatment of 1 day, light intensity ERR=97.28%, moderate intensity ERR=82.67%, and for severe intensity ERR=68.30%. For the treatment of two days, light intensity ERR=95.71%, moderate intensity ERR=88.50%. For the three days of treatment, light intensity ERR=99.64%, moderate intensity ERR=98.14%, and severe intensity ERR=98.49%. From observations decrease the average number of worm eggs a result of treatment, the high ERR above 90% in the three days of treatment for an infection light, moderate or severe infections. As for the treatment of one-day and two-day high ERR only to light intensity, while for moderate and severe intensity ERR remains low (below 90%) (Table 5).

Based on the rate of healing (Cure Rate) as a result of treatment in a group 1-day treatment on the intensity of light is CR=84.0%, moderate CR=29.41%, and the intensity of CR=0.0% by weight. Cure rate (CR) as a result of treatment in group two days of treatment at a light intensity of CR=70.73%, moderate CR=8.30%, recovery rate (CR) as a result of treatment in the three days of treatment at a light intensity of CR=95.65%, moderate CR=27.78% and severe intensity CR=33.3%.

From the cure rate (CR) is seen, the highest value reached above 90% are on medication three days at a light intensity of infection, while for moderate and severe intensity values infection cure rate (CR) is low in both treatment arms one day, two days and three days. Value cure rate in the treatment arm for two days of moderate intensity less than the cure rate in the treatment arm one day of moderate intensity, it is probably caused by technical errors in the field, such as the existence of some students eat at home before taking the medication at school, despite being told by investigators for no breakfast at home (Table 6).

Compared with previous studies, researchers get Cure Rate for treatment day at 55.6%, lower than the research VY Belizario et al, in 2003 amounted to 69.7% and M. Legesse et al, in 2004 amounted to 69.8%. But when compared with the research VJ Adamet alin 2004 in South Africa by 23% for once-daily doses of albendazole treatment. There are differences in numbers for different cure rates obtained VJ Adamet al with the results obtained by previous investigators and researchers, this can occur by different technical field

From the results obtained in all three treatment groups, the treatment of one day and two days having a high ERR for all levels of intensity of infection, but have a low CR rate, especially for moderate intensity of infection and severe intensity. As for the three day treatment group with ERR reached 99.64% and 95.65% Cure Rate in a light intensity of infection, is expected to be effective to address whipworm infection with mild intensity. This is consistent with previous studies conducted by Sirivichayakul Cet al, in 2003, who suggested the use of albendazole for 3 days to cope with whipworm infection light intensity, while for severe infections requiring treatment for 5 days to 7 days.

## 6. CONCLUSION

1. The use of albendazole dose of 400mg daily for 1 day, 2 day and 3 day can significantly reduce the intensity of infection.
2. Use of albendazole worming dose of 400mg once daily for 3 days only effective for the treatment of light intensity trichuriasis, because having high Cure Rate and ERR.
3. Side effects of the drug found in two of the students (0.73%) and mild headache that arise on the third day of drug administration, and lost in 1 day without treatment.

## ABSTRACT

Public awareness regarding the importance of healthy living has become of major concern in recent year. This affect pet owners to be very concerned about animal health. Consequently, the field of animal health business become an important issue and has a good opportunities and prospects. Ipteks bagi inovasi dan kreativitas kampus (IbIKK) program on Car's services for grooming and pet health care has been done for 3 years. This project aims to facilitate the need to increase attention and awareness of healthy living, so that pet owners concerned about animal health. IbIKK program is the unique and professionally managed program that provide mobile grooming van for health care, disease prevention programs (immunization) and animal hygiene programs under supervision of veterinarian, the grooming van always standby and ready for some remedial action even in the case of an acute illness. IbIKK program has opened a new opportunities for entrepreneurship in the field of pet health care and grooming. Based on the performance within 3 years, the analysis of the business was ROI of 36%, BEP 2146 services and RC of 1.52

## Keywords

IbIKK, animal health, grooming, health care

## 1. INTRODUCTION

Public awareness regarding the importance of healthy living has become of major concern in recent year. This affect pet owners to be very concerned about animal health. Consequently, the field of animal health business become an important issue and has a good opportunities and prospects. Pet care may bring a lot of positive impact to the owner including value of responsibility, compassion, comfort and give companionship. Some considerations, however, have to be taken into account especially conditions associated with cleanliness, hygienic and health care because the pets can be a source of disease transmission [3].

Some pathogenic agents causing diseases to pet animals such as Parvo virus, whip worms, hook worms, round worms, Giargia, Coccidia can be found in pet feces [4]. This will cause disease and lead to infection in pet animals that will impact the health of the pet owner. Therefore it is necessary to take into consideration the health-related risks of owning and caring for animals due to public health concern [5]. In addition to the spread of disease pets provide many benefits to humans, including comfort and friendship. Having a pet can be a wonderful and useful for the owner and family. Moreover, it is believed that pets can help their owners, which are psychologically and even physically give life more colorful and feel better. For many people, pets more than just animals, they are like family members.

One attempt to resolve the issue of preventing diseases transmission from the animals is implementing pet grooming. Pet Grooming is an activity related to the hygienic care and clening of the pets. Pet grooming involves techniques on brushing, excerpting nails, eyes and ears care, hair trimming, and hair brush. All these activities should be done perfectly [1]. Groomers work in a variety of locations and environments, including veterinary offices, animal shelters, pet supply stores and even a salon specifically designed for pets [2]. Grooming can strengthen the bond between owner and pet if it is done according to the standard. Therefore the IbIKK program offers pet owners to get closer to animals without the risk of disease transmission.

In order to improve the quality of pet grooming service, it beneficial to provide mobile grooming unit using grooming van. The van equipped with grooming table and storage shelves and a layout inside the van is established that allows for easy access to needed supplies during the grooming process. IbIKK program is the unique and professionally managed program that provide mobile grooming van for health care, disease prevention programs (immunization) and animal hygiene programs under supervision of veterinarian, the grooming van always standby and ready some remedial action even in the case of an acute illness. The pet owner can just order to get a house call services and this program provide quality services in the owner front door. In Malang, especially, there is only few mobile car grooming provided. Therefore, this mobile grooming car is needed and can be of benefit for Malang where are many pet lovers.

## 2. METHODS

Material in this IBIKK project is pet health care and mobile grooming van. This program is executed in three years consecutively. At the first year, the program preparing car for grooming van and promote the program. Year two transform the car into van that is equipped with table, selves and appliances for pet health care, beauty and hygiene services. In this year, the program has a considerable amount of klients and provide services not only for grooming but also for sick animals. Generally the grooming needs depend on the breed and hair types. Basic grooming include hair brushing, nail trimming, ear care and hair cutting. If the pet has fleas, special care should be given usually bathing with a special shampoo for fleas and Tick, and medication.

## 3. RESULTS AND DISCUSSION

The children may be most at risk of developing the disease that transmitted from pet animals, because they play very close to the pets and they just do not understand about the disease that pets may have. Maintaining the health of pet animals become very important in order to prevent transmission of the diseases to family members. Animal Hospital could help provide health services for the animals and reduce spreading of the diseases especially the diseases associated with skin diseases, such as ringworm, scabies and internal parasites. Ringworm (ringworm) is a fungal infection of the skin, hair or nails. These infections can cause hair loss, with or without lesions under the skin. This infectious agent can survive in the environment as spores for long periods of time. People infected with this fungi will show signs of red and circular lesion in the skin.

Ibikk activity program provide health care and grooming services using mobile grooming van equipped with table, shelves, water heater and all appliances needed. Grooming is one of basic needs for pet animals and an important part of pets ownership. All pet animals, just like people, need physical maintenance to look and feel their best. Eventhough pets do not need to bathe as often as people, but it do need to learn how much grooming the pets actually needs and keep it on a schedule. Generally, pets grooming needs depend on the breed and hair type. In some cases of skin, ear or nail condition, it requires veterinarian's instructions regarding grooming the pets. It is also important to use the appropriate grooming tools.

In the third year of this program, the grooming van has been equipped for health care services and pet grooming including standard and basic health care equipment, the examination table, disposable injection, stethoscope, microscope and cage. Equipments for grooming including pet bath sprayer, bath towels, furminator deshedding tool, mat removing tools, nail trimmer, a set of clippers for pet grooming, hair dryer, comb and gloves.

Target market of the program are pet owners who stay at elite estates. Promotions and marketing techniques were done by direct approaching to the consumer, visiting door to door using the mobile grooming car. Social level of the target consumers are from the middle to upper class who have a pet. Product selling prices for health care services is Rp 100,000, -, while for vaccination is Rp 150.000, -. Mobile health care provides vaccine according to the consumers needs, with high standard quality and suitable price. Grooming services based on hair types. Long-haired pet usually require daily brushing to prevent matting and tangling of hair. Medium-haired may be prone to matting and tangles and should be brushed at least weekly. Short-haired can typically go up to a month in-between brushing. The rate for grooming short hair pet is Rp 35,000 and Rp 50,000, - for long hair pets. This include services for bathing, drying and nail trimming. If the klient require additional services the price range from Rp 60,000 to Rp 75,000, -. Based on the performance in the second year, the number of klient obtained both for dog and cat range from 15-20 per month at a rate of Rp 30,000, - per service. From the analysis of the business, it is known that the value of an ROI of 17.38%, BEP is 2.146 and RC of 1.2.

These services also involve students in doing health care and grooming in order to provide benefits and support the teaching and learning process for students of Veterinary Medicine School UB (PKH UB). Services and promotional activities further enhanced by supporting community service work which also involve students and take an active role in the of pet contest organized by PKH UB and the pet lovers. IBIKK activity is perceived outcome mainly by pet owners who have obstacles to bring the ptes to the clinic and for those who have not been accustomed to pet's grooming. To further expand this project, the marketing network has been carried out by doing socialization to elementary school students in collaboration with several elementary schools in Malang. It is expected, this project could improve the understanding and knowledge of the community regarding the importance of animal health care and animal welfare at the early stage of pets. Socialization is accomplished by an active role in the activities of cat shows and dog show organized by a pet lover dogs and cats. In this activity, the group IBIKK assisted by students to do grooming, while health care is assisted by several young veterinarians who are members of PKH UB. Thus, this mobile animal health care program that has been initiated through IBIKK program can be sustained after the project ends.

Fig 6: Promotion activities

#### 4. CONCLUSION

1. IBIKK for Health Care and Grooming car facilitated with mobile grooming van equipped with standard appliances allowing to give qualified and confident services for pet health care and grooming.
2. IBIKK program has opened a new opportunities for entrepreneurship in the field of pet health care and grooming.
3. Based on the performance in three years program, the analysis of the business was ROI of 36%, BEP 2146 services and RC of 1.52

It is suggested to the pet owners for maintaining the health and hygienic condition of the pets in order to prevent diseases transmission from the pets to the family member especially children.

## **ACKNOWLEDGMENTS**

Thank you to DIKTI for providing funding to IbIKK program for 3 years from 2010 to 2012.

# Training of Standard Operating Procedures on Semi Material Recovery Facilities/UPS to increasing its efficiency for officers of Depok Cleanliness Department/DKP-Depok

**Djoko M. Hartono, Irma Gusniani, Gabriel Andari Kristanto**

*Environmental Engineering Study Program, Civil Engineering Departement, Faculty of Engineering, Universitas Indonesia.-Depok.  
Email: djokomh@eng.ui.ac.id*

## ABSTRACT

*The implementation of semi material recovery facilities (named UPS/Unit Pengolahan Sampah) has greatly assisted Depok Cleanliness Department in managing solid waste. During the past five years, capacity of Cipayung landfill has become very limited due to the high amount of waste generated and disposed directly. It is critical that the UPS with their 3R-P Program (Reduce, Recover, Reuse and Community Partnership) will not only minimizing the waste transporting to the landfill but also supporting Depok in managing solid waste in more sustainable way. The objective of this community development is to implement standard operating procedure for Unit Pengolah Sampah in Depok. This standard operating procedure will consists of operational management function, building structure, layout arrangement, equipment, and environmental protection equipment. Standard Operation Procedure of the UPS has been introduced to the UPS workers in 4 (four) separate training sessions. During these activities, around 160 UPS workers and participants were actively involved. These training were not only conducted inside the classroom, but also in UPS University of Indonesia. Several approaches were developed to transfer the knowledge including study group, one day workshop, real experience, and discussions.*

*Community Development, Training, Material Recovery Facility, Standard Operating Procedure, Depok Cleanliness Department*

## 1. INTRODUCTION

Based on Ministry of Public Work Decree Number 21/PRT/2006 on National Policy [1] and Development on solid Waste Management and Indonesia Law Number 18/2008 on Solid Waste management [2], it was stated that the new paradigm on solid waste management has shifted from old paradigm to new paradigm. The old paradigm consists of collect, transport and dispose which was all solid waste collected from the sources of solid waste will bring them to solid waste disposal site as the result solid waste disposal site with the short periode has full their capacity. The new paradigm introduce 3 R, reduce, reuse and recycle in the source of solid waste before collect to the disposal site and as the result the generation of solid waste will be reduced in the solid waste disposal site. City of Depok with population in 1982 was 240,000 population, in the year of 2010 became 1,736,565 and almost 90% of solid waste are in old paradigm. As a result solid waste disposal site in Cipayung Disposal Site will no more longer can handle solid waste generation from the city of Depok. To over come that situation, Mayor of City Depok through Cleanliness Department has build 31 Small Material Recovery Facilities [4] so call Unit Pengolahan Sampah (UPS) in several Sub District (Kecamatan) as well as several housing locations. The main objectives of UPS is separating and sorting organic waste to produce compost and inorganic solid waste by reuse and recycle to become valuable things. Mayor City of Depok has planned to built 12 UPS per year until 2018. However, among 31 UPS that has been constructed, only 18 UPS are still in operation. The rest are not in operation due to the in proper standard operation procedure. One UPS has been built in Campus Universitas Indonesia in cooperation with the City of Depok. Universitas Indonesia allocated space and city of Depok sharing UPS building, see Figure 1., and using as pilot project in implementing the SOP of UPS [3].

Figure 1: UPS in Universitas Indonesia

## 2. METHOD.

The method to conduct this community development is divided into 2 parts, (i) material preparation and (ii) training.

(i). Material preparation.

Material preparation is collecting since 2010, the first grant received from Directorate Research and Community Development Universitas Indonesia.

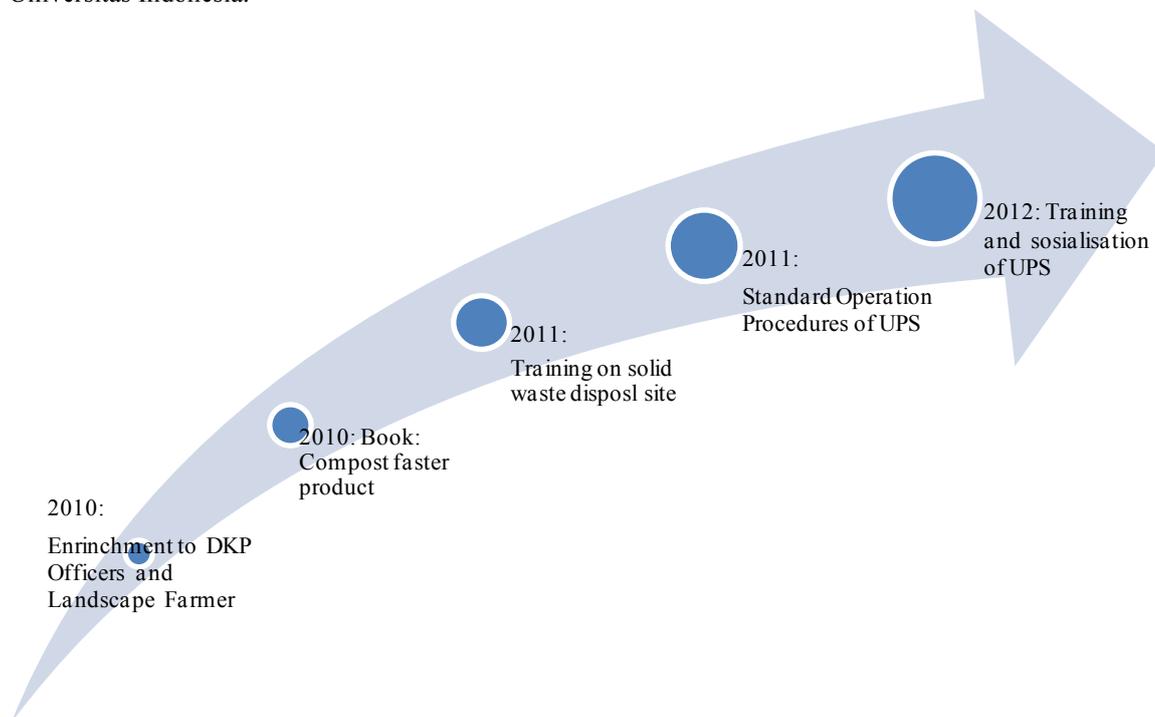

Figure 2: The processes in setting up SOP

As can be seen in Figure 1., the processes in setting up of standard operation procedure was begun in the year 2010 which trained small farmer and solid waste officers and followed by making a handbook on composting method. In the year 2011, received grant on training of solid waste final disposal. Finally by studying almost all 31 UPS in the City of Depok, succeeded in producing guidebook for standard operation procedures. This standard operating procedure will consist of operational management function, building structure, layout arrangement, equipment, and environmental protection equipment [3].

(ii). Training.

There are 4 stages in conducting training which were held continuously, 1<sup>st</sup> stage from 11-18 July 2012, 2<sup>nd</sup> stage on September 18, 2012, 3<sup>rd</sup> stage on October 30, 2012 and November 7, 2012. Several approaches were developed to transfer the knowledge including study group, one day workshop, real experience, and discussions.

### 3. RESULT

On the 1<sup>st</sup> stage training which was held in UPS Universitas Indonesia from 11-18 July 2012, were follows by around 150 participant during the training period. Every day training, the participants consists of staffs of Cleanliness Department, Universitas Indonesia staffs, teacher and student from Faculty of Engineering and other guest from other UPS management.

Figure 3: Participants on the 1<sup>st</sup> Taining

On the 2<sup>nd</sup> stage training on September 18, which was held in Chevron Room Dekanat Building of Faculty of Engineering. This one day workshop carried out with Technische Universitat Darmstadt, Germany with Master Program Environmental Engineering, Civil Engineering Department, Faculty of Engineering Universitas Indonesia, with 110 list of attendants from various discipline.

Figure 4: Speaker in One Day Workshop on the 2<sup>nd</sup> Training

On the 3<sup>rd</sup> stage training on October 30, 2012, which was held in Chevron Room Dekanat Building of Faculty of Engineering, Universitas Indonesia. The participants are consisting of UPS officer, Cleanliness Department, lecturers and students

Figure 5: Facilitators in the 3<sup>rd</sup> Stage Training

On the 4<sup>th</sup> stage training November 7, 2012, which was held in UPS Universitas Indonesia, was implementing standard operation procedure for UPS and as the result some correction to be done to improve SOP

Figure 6: Implementing Standard Operation Procedures in UPS UI

#### 4. CONCLUSION

The volume of solid waste to be processed in the UPS should be limited to maximum of 12 m<sup>3</sup> so that the objective of UPS clean and aesthetics will be accomplished. The officers of UPS should be completed with uniform, masker, hat, worker shoes and other equipment for environmental protection such as fire extinguisher and other. Compost should also be analyzed regularly to get the best quality. Although UPS construction is template with other UPS in Depok, the lay out of UPS UI should be redesign so that can cope with efficiency and effectively of UPS as can be seen on Figure 6. The residu of composting process should also be disposed to solid waste disposal site in TPA Cipayung.

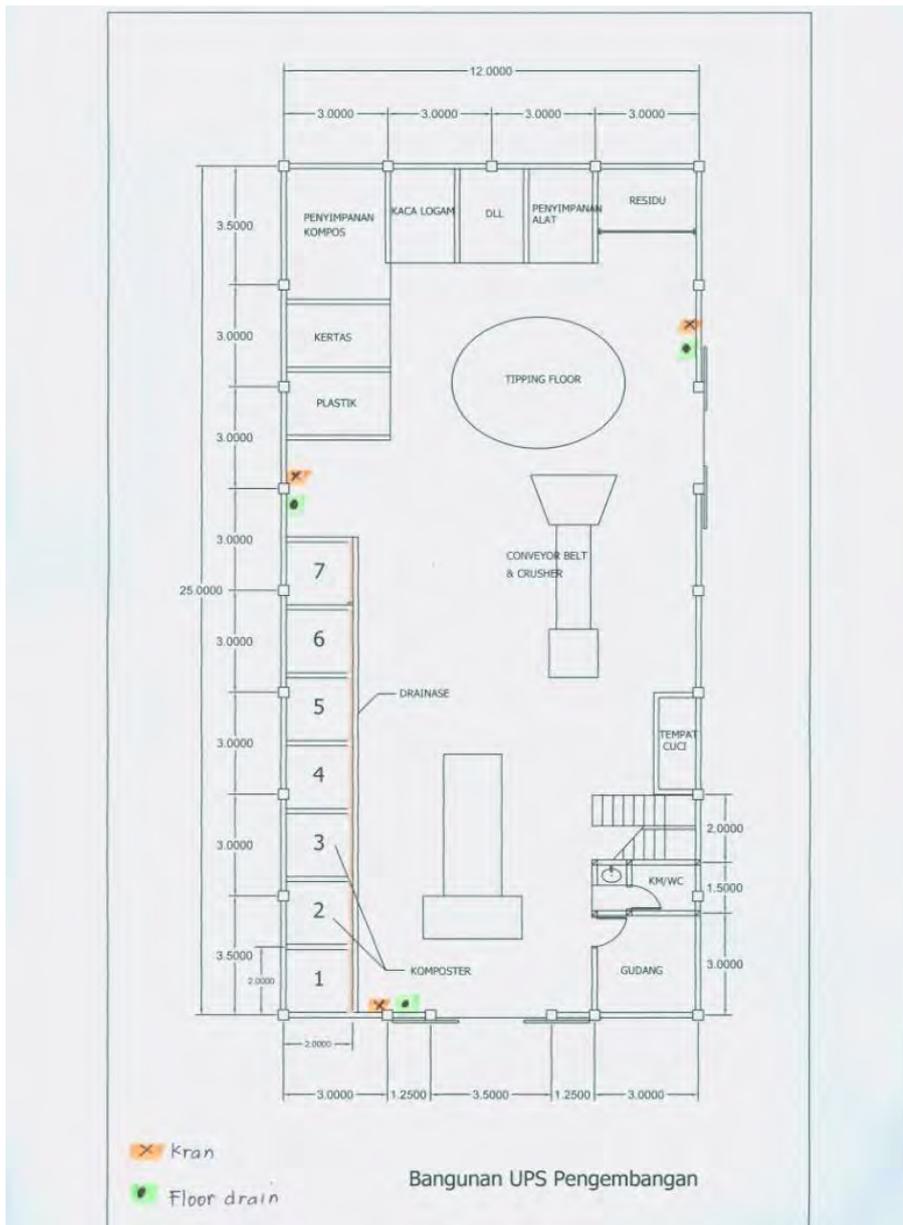

Figure 7: Proposed Lay out UPS UI

# Future Welfare of Neglected Children: Empowerment or Community Development

**Chairun Nasirin**

College of Health Sciences (STIKES) Mataram  
 E-mail : chairun\_nasirin@yahoo.com

## ABSTRACT

*This paper explores the quality of social policy that implication to the neglected children welfare. The neglected phenomenon is real social problem in Mataram nowadays due economic and urbanization. The neglected happens for a child who has no capability to empower themselves and welfare condition as economic is one of important variable in policy formulating process. Despite this problems, social problem of neglected children seen not only in Indonesia, but also happens in all part of the world. Data from statistic bureau (2012) in figures shows that the number of social issues in West Nusa Tenggara (301.153) and 2 % from the total numbers of neglected children needs special attention from the government and community. The phenomenology analysis appropriate to remark the issues of neglected children's in the city of Mataram as they are related to the setting of social phenomena. From this study can be concluded that core message of existing program for neglected children in Mataram should be evaluated the quality of social services and government need to create the regulation to implement the legalizing program for neglected children in the future. This study found that the social welfare policies, needs to be developed continuously to create the conductive situation and condition to the children development, which a constitution mandate to educate the life of the nation can build a better future.*

## Keywords

*Empowerment, Community Development, Neglected Children*

## 1. INTRODUCTION

The problem of neglected children is a main phenomenon that faced by social department in nowadays. The phenomenon is not only happens in Indonesia, but it also in the other part of the world. The social phenomenon of neglected children is a real faces in Mataram, that can't be avoid in the society life, especially to people who lives in the urban area due the poverty. Those phenomenon is an offspring of the modern urban environment, represents one of humanity's most complex and serious challenges. The problem of these neglected due they don't have a settled home to live, homeless family and their parents can't afford to buy a house for their family. This is may also happened in country which has wide region like Indonesia that needs an effective social government system. This system is not just as a mean to execute all kinds of government's programs for all local area but it is also for local community to develop their own area. On the other hands, the strengthen of local social institution is the way of social development to carried out the root problem in local community that increasing the capability of local social institutions.

Data shows in 2010 there are 78.96 million children, ages between 7-18 years old (35,5 %) lives in urban area and need attention to government to achieve the goals in overcoming social problem as neglected children and able to create programs to developed children in the future. The neglected children occur due to the family can't support to increase the family welfare as low paying jobs or no settled job. According to the Crittenden (1992), says that A neglected child is a social phenomenon in part of the world which effect children's life in their growing period and also the neglected children problem occurs due a manifestation from a deep anxiety during child's growth, therefore family's social relation is an important part to a children's life. The establishment of family's social policy it was usually emerged from politics and government intervention dealing with social problem. Therefore, Roditti (2005) suggest that the approaches to overcome the children's problem, as: (a) emotional support (b) informational support and (c) concrete services.

The social issue of social protection as neglected children was highly effective of local government to improve the social welfare for the population in the region through the services, empowerment and public participation as well as government efforts in addressing social problems. This strategy is an effort that directly point to the root of problem that is by increasing the capability of all kinds of local social institutions. Dasgupta & Serageldin (1999) stated that as social progress from a group of society, that can be a strengthen factor in supporting the success of social welfare development in an area.

In accordance with the social policy of neglected children in Indonesia, as outlined in the law number 12/2008, the local government has authorities to self-organize and self-manage their government in aiming to accelerate the realization of public welfare through the improvement, services, empowerment and public participation as well as government efforts in

addressing of social problems. The processes of social governance in Indonesia social welfare development were considered three main components. First, private sector which establishing a working relationship with government. Second, the civil society that interaction in local community in various forms of social life in the society and the local government itself to protect the social life the neglected children. From the point of view of social welfare, Martinussen (1997) considered that the government official should implement the correct economic policies. The change from traditional local government to a more complex network of agencies involves in 'local government' is no longer theory (Goss, 2001). This means that the policy of local government appropriate critical consideration to achieving the social problems as neglected children phenomena. This also approach provides a theoretical justification including neglected child problem, unemployment, to improve health and to reduce crime and to build communities in society. For Ryan, 1999, social action determined the goals (often politicians) were often deemed dependent on technically competent (generally bureaucrats) to flesh of neglected problems. Essentially, Williams (1989) looks at social welfare that the mainstream concept was in economy crisis, whether it had lost legitimacy not simply amongst social policy but amongst the public in large. Thus, the decentralization adds importance of local government institutions to hold government in autonomous regions. Beyond the classical definition of Smith (1985), decentralization is widely regarded as a necessary condition for social, economic and political development.

## 2. METHODOLOGY

This descriptive study uses phenomenology to illustrate the local governments to improve the pattern of relation between local government with community empowered and stakeholders in running the government functions. Details of the design the governments need to create regulation in form of local regulation to legalizing the neglected children, therefore the local government functions can running optimally. To understand how the local government functions of social welfare for neglected children empowerment in the of Mataram, as they are related setting of social fenomena requiring comprehensive study. Figure 1 shows the system model to empowered the neglected children model in Mataram.

The issues related to local government of social welfare regarding the neglected children in Mataram is very complex. In so doing, the study stressed at on to three specific issues of each case. This study analyzed by qualitative inquire and employs several method of data collection to explore the data sources. To gain the information regarding the empowerment of neglected children in the city of Mataram, depth interview is conducted. Yet it is acknowledged data analysis used Miles and Huberman (1994) character. Basically, to understand local government function of neglected children in Mataram, three main substances that related to this study as: [1] neglected phenomenon, [2] local government policy in the empowerment of neglected children and [3] the function of government of neglected children involving the private area and public sectors.

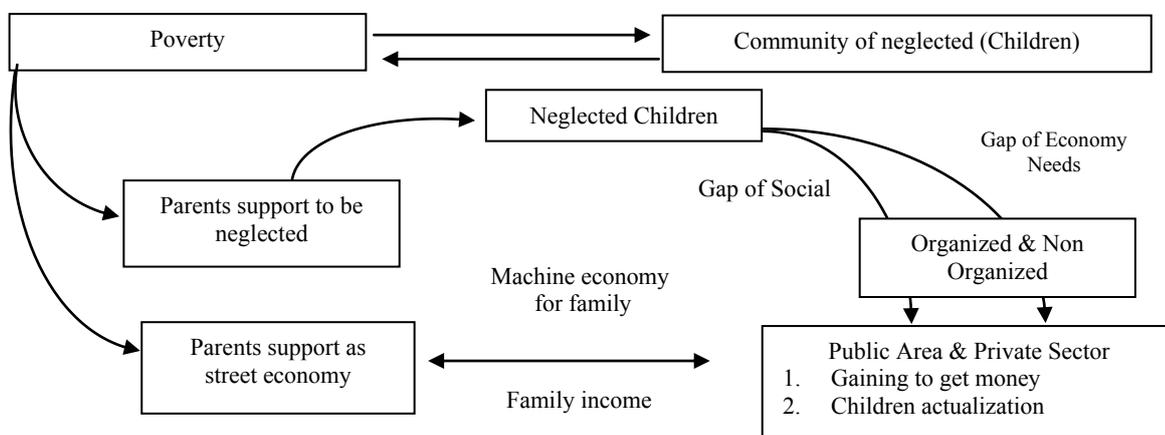

Figure 1: System model to empowered the neglected children model in Mataram.

## 3. DATA

To collect further information on the formulation, data were collected from Mataram statistic bureau between 2009 and 2011 that the number of issues in this province as 262,159 number of neglected children throughout both regency and municipalities. To ascertain views on the neglected child, the researcher conducted investigations and depth interview regarding the children phenomenon. Neglected children interviewed were audio-taped and transcribed. The data shows that the large number of children living without their parents for various reasons and indeed need special attention from the government and society.

Data were analyzed with a focus on describing the essence of neglected child life experiences and factors related to be neglected.

The majority of neglected children interviewed, both male or female which reflected in the participating. The ages ranged between 8-15 years old with the majority of the child interviewed is street worker participants in different places or locations in the city of Mataram. The interviewees were provided with an open-ended questions asking them to identify any areas where they doing their activities or who organized the neglected child community. Internal validity on the other hand, by having third party check decision made throughout the analysis process to bias minimized.

#### **4. DISCUSSION**

A neglected child is real phenomenon of social problem in the world. Although it is difficult for government to overcome that social problems, this study were based on neglected children's real life experiences of how they managed and struggle their life even as street working children that mostly living on the street.

The Research findings describe and underlying proportions from this study were based on these neglected children's real life experiences of how they managed their life economy. These description not only provide a clear and substantial concept of neglected children as a real social problem, but also provide the local government regulation for social department conceptual both regency and municipalities in West Nusa Tenggara Province. Indeed, the implementation of local government functions in administrating the government social welfare affairs, including the empowerment of neglected children in general [1]. Adherence to the rule, the principle of participation, optimizing the local government authority along with the implementation of decentralization, competence and professionalism of planners, the compliance toward the real problems of society, reducing its dependence on the budget from central government and the success to adjust the budget with the burden that must be resolved through specific programs, [2]. Clarity of policy design, support and coordination between inter-regional bureaucracies' instruments, institutional capacity enhancement, public or community neglected children participation and partnership with various stakeholders.

#### **5. CONCLUSION**

The main contribution of this paper is that present a new approach to overcome the social phenomena problem due neglected. Yet the finding of this study suggest necessary information might be sufficient for the local government to overcome the social phenomenon. The existing implementation and I believed that the concept can be applied to develop the policy of social problem as neglected children.

Neglected children is a root problem that can be underlying the actor occuring in the city of Mataram. Interestingly, how the policy implementation and pcesses can be overcome due the social problem. The paper can be highlight that the neglected and the empowerment of children in Mataram become the priority of social department agenda. The implementation of local government functions in the administration of government social welfare affairs sector, largely determined by the rules, optimization of government authority and the budget from central government.

The conclusion suggests that a neglected child is typified child inadequate care from their parents, less attention from their family, poor family, failure to provide a child with an adequate education in form of enrolling in school, away from home and failure provide needed.

Finally, this study recommendations constructive professional practice in order providing optimal care and solution for neglected children based on these essential research findings. These recommendations may be able to help the local government find formulated and solution regarding the social problem and neglected children social phenomenon. Clearly, as evidenced in this study, social problem of neglected can be formulated as follows: (1) the social department should be redesign of the implementation of local government functions, (2) the need of certain legal instruments supports so that a program should have optimal power, both at the time of planning and implementation; (3) a specific legislation related to the real problems of society is to be formulated; (4) a culture change in local bureaucracy in order not only to adhere to the ethics and morals that have been established in the personnel regulations and central regions, but have also strengthened with the creation and implementation of reward and punishment system, so can encourage the creation of high performance in carrying out the local government functions; (5) the civil community organizations, such as NGOs should conduct institutional reform so as to make active and critical participation and avoid dependence on the Regional Government funding alone.

# The Pre-specific City: A Theoretical Narrative in the Post-Generic Age

Diana Alvarez-Marin

FCL Future Cities Laboratory – Simulation Platform  
 ETH Zürich – CAAD Computer Aided Architectural Design Department  
 alvarez@arch.ethz.ch

## ABSTRACT

During the 20th century, the interest and preoccupation over subjects such as global crisis, scarcities, urbanization or population growth, ended up in a series of statistics and simplifications of reality, which in the urge for efficiency, control and optimized unilateral solutions, didn't take into account their interconnectedness to many other factors. This 100% optimized scenario, ultimately manifested itself in a Taylorisation of the city and by the same tokens into generic space, as the imprint of market economy and globalisation. However, the emergence of networked communication technologies has extended our interaction with the city towards an invisible and complex network of relations and data, embodied through growing interactive platforms such as social media. For the first time in history, we are not only aware of such a degree of complexity surrounding us but also likely to grasp it through a real-time flow of data. Hence, we are no longer constrained to see the city as a limited set of logical assumptions on reality, but as a data platform able to preserve any potential relations. The Pre-specific City is the upgraded space of the any-relations. The Pre-specific City is not exactly definable in geometric terms. In order to locate it, one must consider  $n$ -dimensions, out of which none is correct or false. In fact, all of them coexist simultaneously into one single space-time. Therefore, the Pre-specific City is not a point in space, but rather a point and all its possible trajectories. This non-Euclidian condition, have induced some of its inhabitants into some kind of painful sensation, like the one that persists in an amputated phantom limb. Seemingly, the definition of the city has been stretched towards inconceivable limits, in a desperate try to fit to it what has become the contemporary urban condition. But why does uncertainty seem always so painful, when change is the only certainty we have? This theoretical narrative embeds a double purpose. Firstly, it celebrates the generic condition, inherited from the 20<sup>th</sup> century, through an exploration of its possibilities, and considers its empowerment within the rise of information technologies, through new social phenomena such as the democratization of knowledge, the diversification of identity, the rise of an economy of information and the extension of public space towards more virtual grounds. Secondly, it challenges modern science generalizations and rule-based models, suggesting a shift towards non-linear data driven approaches likely to go beyond mere representation and to provide insight on the rising complexity of the city.

## Keywords

*Pre-specific, city, identity, data, media*

*"If there is to be a "new urbanism" it will not be based on the twin fantasies of order and omnipotence; it will be the staging of uncertainty; it will no longer be concerned with the arrangement of more or less permanent objects but with the irrigation of territories with potential; it will no longer aim for stable configurations but for the creation of enabling fields that accommodate processes that refuse to be crystallized into definitive form; it will no longer be about meticulous definition, the imposition of limits, but about expanding notions, denying boundaries, not about separating and identifying entities, but about discovering unnameable hybrids; it will no longer be obsessed with the city but with the manipulation of infrastructure for endless intensifications and diversifications, shortcuts and redistributions – the reinvention of psychological space. Since the urban is now pervasive, Urbanism will never again be about the new only about the "more" and the "modified." It will not be about the civilized, but about underdevelopment."*

Rem Koolhaas. *What Ever Happened to Urbanism?* (1994)

## 1. IDENTITY DOPES THE GENERIC

### 1.1 Decoupling

Here, is where people live. Yet *here*, is not exactly definable in geometric terms. In order to locate us, one must consider  $n$ -dimensions, out of which none is correct or false. In fact, all of them coexist simultaneously into one single space-time. Hence *here*, is not a point in space, but rather a point and all its possible trajectories. This non-Euclidian condition, have induced some of us into some kind of permanent and painful sensation, like the one that persists in an amputated phantom limb. Seemingly, our definition of the city has been stretched towards inconceivable limits, in a desperate try to fit to it, what has

become our contemporary urban condition. But why does uncertainty always seem so painful, when change is the only certainty we have?

## 1.2 Post-Generic

The curtain goes up. A voice-over opens up the scene: 'I am everywhere and I am no one, therefore, I can contain you all. I potentially could become anything and still be no one'. In the background, a city defined by numbers, functions and performances strictly classified by some general features. A mirage of objectivity. A theoretical scenario for scientific scrutinisation. The Generic is our scenario. Instead of despising it, we celebrated it. We learned how to blend with its motion and –merit goes to its massiveness- redirect the force of its occurrence. The operation, if performed with the dexterity of an aikido master, requires little effort. Grasping the leading of its momentum relies on cultivating the essential elasticity embedded in infrastructures. Infrastructures, the subtract of globalisation, populated the territory with a schematic logic of interconnected elements, providing the framework for an entire structure of developments such as a double life span, literacy levels enhanced by factor 60 and an increasingly global population manifested in global urbanisation, accounting today 7 billion inhabitants out of which more than a half are already urban.

We populated infrastructures beyond their physical configuration, learned to abstract their own logistics by turning things into facts and facts into symbols, crafting the conditions for ubiquitous and mobile computing. The emergence of networked communication technologies has extended our interaction with the city towards an invisible and complex network of relations and data, embodied through growing interactive platforms such as social media, urban computing and crowd sourcing. For the first time in history, we are not only aware of such a degree of complexity surrounding us but also likely to grasp it through a real-time flow of data. Hence, we are no longer constrained to see the city as a limited set of generalizations, but as a data platform able to preserve any potential relations: this is the new surface of our world.

This pre-specific surface can be ossified, fossilized, territorialized, deterritorialized; it can turn stale and rigid, but can never be given nor can be lost. Our universality is not defined by the adaptation of a generalization to any context, but rather by the articulation of any identity in a space of possibilities. Hence, the generic is now occupied, doped, induced into a long term 'cohabitation' of multiple identities. 722000 parodies of Gangnam style. 1 billion combinations of tastes and experiences on Facebook. As many definitions of theory as languages on Wikipedia. Identity is an amalgam of secretly borrowed lives and one's own. No longer surrendered to physics and history, its virtual makeup decouples from geometry or locality, replaces one point by a cloud, explodes one centre into *too many centres*. Social media has opened up a wide space of unexpected encounters, where the combinatorial possibilities between cultural indexes are unaccountable. Identity is paradoxically sameness and oneness, simultaneously what integrates and differentiates. You and I are no longer twofold commuters through this city, but *n-dimensional* identities navigating through as many social spheres as traits we are made of.

## 1.3 Memory

Perceptions of time in the Pre-specific City, and prominently the present, are always too full. Since time has taken the role of space, space is just another index and our presence is continuous, always on. One fraction of our (non-linear) time is compressed and concurrently populated by a myriad of events. 1 minute, 694.445 Google queries, +6.600 pictures on Flickr, 600 videos on YouTube; 695.000 status updates, 79.364 wall posts and 510.040 comments on Facebook; +168.000.000 emails, 320 new accounts in Twitter and 98.000 tweets, 20.000 new posts on Tumblr, +50 downloads of WordPress, 100 new accounts on LinkedIn, +1.600 reads on Scribd. Social media has become an indefinite extension of the manifold social memory. The imminence of this real-time construction has merged past, present and future into an approximation of a single point. Memory is now an ambiguous amalgamation of externalized knowledge and lived experiences. "To write a single line of verse... One must have... Many... Memories... And having memories is still not enough... For the memories are not what is essential. It is only when they become blood within us, become our nameless looks and signs that are no longer distinguishable from ourselves - not until then does it happen that... The first word of a verse rises..." [1]. We extended our memory through incorporation, overlapped the privacy of the diary to a network of real-time chronicles. Even before you go to Paris, an Eiffel Tower already erects in your mind, within the experience of others distributed over a trillion of indexes.

## 2. NOTHING AND EVERYTHING

### 2.1 Information

The Pre-specific City has been the scenario of diverse inversions. Once, we revolted against the absolutism of form because its specificity was incarcerating. Ultimately, form is just one of the too many representations the data embedded in things can be mediated into. Since then, our questions are no longer exclusively about the pure geometrical manifestations of the city (the roman *urbs*?) but thrive on the interactions with subjacent levels of *cityness*. In the Pre-specific City, every fact carries a latent

existence in data, the lowest level of abstraction from which information can be derived, and because of this its abundance is incontestable. Strikingly, our more cherished resource is embedded in *everything*, yet outlandishly close to *nothing*, almost inexistent. This incongruous circumstance only allows it to be described by negation. Information is neither matter, nor energy, has no weight, no body, no meaning. Paradoxically, and unlike *things*, its abundance does not lead to its own devaluation, but rather to a striking condition of discernment. Pedestrians sprawling in the streets, sudden crowd gatherings, Twitter geographies, checking-in at favourite restaurants, multiple daily taxis journeys, or even *likes* on friends' status, are no longer isolated events but clusters of insight. Every second, urban life is being engendered, mediated and interpreted within the very banality of social media.

## 2.2 Articulation

Dealing with the informational make-up of facts has prepared us to the restlessness of the unsettled and the primacy of the exception. For instance, the emblematic image of the Pre-specific City is the wasteland. A heap of meaningless indexes appears in seductive nuances on touristic brochures, which reading is notably demanding for newcomers. The plasticity of the metaphor allows to contain previous slogans of the city: Perfect City, Model City, Machine City, System City, Non-stop City, Generic City. The visitor is hence required to build her/his own story-city, for only when articulated, the indexes are likely to evoke a meaning. This one scenario will be an incomplete, but not untruthful, image of a possible city. We've become rhetoric craftsmen, frivolous storytellers aware of the influence our statements can have the development of events. Sometimes, we imagine we had already accomplished something in order to impose upon ourselves a future out of many others. Once Borges depicted the Pre-specific City: "*This network of times which approached one another, forked, broke off, or were unaware of one another for centuries, embraces all possibilities of time. We do not exist in the majority of these times; in some you exist, and not I; in others I, and not you; in others, both of us. In the present one, which a favourable fate has granted me, you have arrived at my house; in another, while crossing the garden, you found me dead; in still another, I utter these same words, but I am a mistake, a ghost*" [3]

## 2.3 Pre-specific

The Pre-specific City has the encapsulating properties of a Matryoshka doll. On these symbolic grounds, an apple is not just an apple. It is rather an x number of possible declinations of it, spanning from apple pie, raw cider, apple juice, to compote or even the apple tree that is present in it, in its seeds. Something like, the possibility of an apple. Similarly, the territory, the city, the quarter, can no longer be described through the narrow and objectifying supremacy of one single map. Instead, *civitas* and *urbs* are rendered concurrently, by a symbolic surface of indexes, elucidating the world through pictures, tweets, feeds, signals, *likes*. We don't look at things anymore, but things look at us, they surround us. We never talk *about* something but always *around* it.

## 3. FROM DATA TO KNOWLEDGE

### 3.1 New Symbolism

Last information revolutions in the Pre-specific City, one after the other, strengthened the articulation between the virtual and the actual, deepening the mark of its operability over the territory. But please, don't get us wrong, we are no technocrats here. Technology itself gave us the means to see it coming, provided us with a wide sense of self-awareness to think to whom and how it should be useful. We managed to learn from previous revolutions, understand the real stakes of the time. Our efforts were both technical and symbolic: writing, printing, computing, just to name a few, not only changed our relation to technology from syllogistic to logic to logistics but also towards increasingly abstract levels of literacy, from ideography to digitality. Certainly, we still have struggles to think about, but they are based on the terms of our century. We built on the leftovers of preceding times with cheerful opportunism and rediscovered in information technology, not just a means for narcissistic self-promotion and inquisitive morbidity, but also a fabulous tool for the transformation of the world, the struggle against ignorance and the extension of democratic space.

Whereas Industrial revolution produced tools to provide extensions of the body, such as the steam machine or the automobile, information revolution engendered mediums to prolong the intellect. Nevertheless, regardless of their level of abstractions, progress in symbolic coding has been the catalyser of all information revolutions. Computers have been the compelling force of globalisation and market economy: their performance allowed us to access and deal with the growing amount of information. In the Pre-specific City, *computers (...) are not just fast machines of the same kind, as we know them. Computers are abstract machines*[4]. Their abstract logistics form a continuity of transformability through mediation: the conversion of our social memory into different kinds of extensions, images, animations, texts, sounds, music. "*Today we're beginning to realize that the new media aren't just mechanical gimmicks for creating worlds of illusion, but new languages with new and unique forms of expression*"[5]. We see the world symbolically, and this is the sheer essence of our upgraded literacy. Since an early age, we

have developed an awoken interest in diverse modes of translation, an ability to read and write processes. This polyglotism of signification regimes has deeply penetrated our popular culture. Grasping the real significance of the formal is an exercise of backwards gymnastics: it cares about engendering forces rather than crystallized outcomes. Bottom-up or Top-down discussions seem now irrelevant: our literacy is orthogonal to them.

### 3.2 Resilience

Since access to information has been declared an inalienable citizen right --as well as disconnection--information is *res publica*. But you must wonder, how do we approach something, which can be taken by anyone? Education systems have been short-circuited by a reciprocal apprenticeship. What genuinely matters is not what you can learn or its amount, but how resilient your intellect can be: everything you learn becomes already useless by the time you think you are done with learning. Learning is an extended process of learning, unlearning and relearning, over and over. Actually, the only thing we can learn is how much we don't know: once we take a look at how much information we can get, we can't help but considering how much of it we need to ignore. Our capacity to generate knowledge relies on our ability deal with things we are not familiar with, to link information in patterns, find relations and give it meaning into a context. This interference is a desired attribute, at least as much as schizophrenia. Whilst content is obvious, changes are subtle. Information without connective thinking is like a labyrinth with no walls, you can stand in the middle of a vast open space and still not be able to find your way out.

## 4. POLITICS

### 4.1 Spect-actors

Media defined and spread the common sense to come in a clearly unidirectional mode, outlining agendas and frames, the which and the how of stories to be told. Namely, in the Pre-specific City it is not this fundamental role that has changed, but rather the ways in which we relate to it. Trader politicians and political corporations embraced in grotesque family portraits carefully framed by media. A remarkable drama distributed profusely through a single centralized stage to isolated quiet spectators. In the Pre-specific City, an inversion takes place from one central point towards a constellation of information foyers. You cannot say 'it', but you have to get people saying 'it' for you, because we trust more and more friends and networks rather than experts. Social media has reached in no time deeper levels of infiltration into social practices than any other prior physical channels. Evolution in social media mechanisms allowed us to do a proper shift from supply to interaction, from being spectators to become spect-actors. Publishers, producers, distributors or any kind of intermediaries are no longer main actors in the process of dissemination of intellect in the Pre-specific City. Intermediaries are now obsolete because social media provide nodes of power with increased capacity for direct control and mobilization of resources, skills and markets, wherever they happen to be. Collaborative culture is a market outside the market.

### 4.2 Sense of Critique

Millions of mobile phones in the streets at this very moment take pictures, make videos, blog, and post on social networks every single event surrounding them. Nevertheless, the same tools we praise as emancipators have the embedded potential of efficient and massive monopolization weapons, and even more, the potentiality of power and knowledge to control doesn't no longer concern merely the state but also market and even our peers (the multitude!). Hence, what is the use of an independent press, blogs or social networks when there is more data than our memory can store, and more images than our eyes can take in? Just another source of information to choose from, think over, or become indignant about? Yet, the distance we can keep from it is like a lifesaver when drifting away in the ocean, it keeps one's head out and breathing. Indignation, appraisal, elucidation (a new level of critical consciousness!) are the very conditions of a smart abundance. The only thing more painful than a lost sense of critique is the quiet brain's mediocre feeling of contempt.

### 4.3 Critical Mass

Domestic dramas, international crisis, existential speculations, and increasingly diverse points of view, simultaneously populate our social sphere. We have learnt new forms of solidarity, not in order to enforce dogmatic views but to make a bold use of our differences. Either you build models out of matches or have an extremely high sense of justice, your experience will be potentially compelling to someone, or even reach a group of people large enough as to become a critical mass and promote change. Taking over power or replacing one political party for another is just another form of perpetuation. Politics in the Pre-specific City do not revolve around parties or ideologies but are rather based on non-ideological community interests or even on smaller scales. New aspects of direct democracy, such as evaluation of public policies transparency, elaboration of urban questions by citizens and self-organization of local communities, have replaced traditional political structures inherited from the French Revolution, based on delegation and representation.

#### 4.4 Peer-to-peer

The generic emerged as the *phantasmagoria* [6] of a centralized production system: the purely physical translation of its purposely hidden production processes. The measure of its success has only been defined in superlative terms. Higher, bigger, greater, mightier. The scale of the Pre-specific City is universal and tends towards the tremendously small because it manifests within peer-to-peer relations. Non-hierarchical and contingent, their rules are not derived from an external authority but are generated within. “*Last night 40,000 people rented accommodation from a service that offers 250,000 rooms in 30,000 cities in 192 countries. They chose their rooms and paid for everything online. But their beds were provided by private individuals, rather than a hotel chain*” [7]. The pre-specific City is the city released from *laissez-faire* capitalism or centralized economy; it is not defined by a centralized managerial command but by out-numbered social relations.

### 5. CITYNESS

#### 5.1 Hybrid

The Pre-specific City is *the city of the too many centres*. The multiplicity of our identities and their eased diffusion has led us into a state of desired schizophrenia that depicts itself effectively into geographical space. Our practices are no longer exclusively shaped by physical context, but by the different mediations information can go through. Public space is more than a *communal world full of differences* [8]: it not only embraces diversity but decouples through a range of dimensionalities spanning between actual and virtual. This *n-dimensional* space is appropriately describable through oxymoron: manifestly virtual, fundamentally actual, specifically global, comprehensively local, peripatetically static, inertly mobile. Admittedly, social media have provided us with a relational space, open to the active self-mapping of the real and vivid scenario of the spatial practice of contemporary urban life. The Pre-specific City has increasingly extended towards new public and virtual grounds, not through a derealisation of the world but rather through an extension of human abilities. These new territories cannot be described geometrically nor calculated physically because their limits are elastic, flexible, negotiable, constituted by the conduct of its occupants or, rather, by certain minimum elements of their behaviour. In this new urban plane, distinctions between subject and object are blurred in a reciprocal way: every writer is a reader, and every reading is a potential writing.

#### 5.2 Landscape

The Pre-specific City mimics a landscape, any attempt to define it through urbanism is reductive. Urbanisation depicted a transmutation of the city from an agrarian to an industrial setup, unfolding its translation into commodities, production into space and growth into settlements, a *city of stones* where territories have been exclusively defined by the proximity granted by the power of infrastructures. This celebration of urban physicality provides a reductive account of what the Pre-specific City is about. Notably, the Pre-specific City does not have an explicit form, because it embodies something more than what it apparently represents: its level is operational, not representative. Skyscrapers, houses, bus stops, streets, highways, bricks do not look radically different from what they used to be, though they are unquestionably transformed entities. Through *Cityness*, we have been empowered to look above the infrastructural level of things (*Urbs*) and enabled to describe the city as a set of collective narrations, the imaginary of the *city of people (Civitas)*<sup>1</sup>. Information technology decouples from familiar categories or pre-defined conceptions of what urbanity, public space, and private space were meant to be<sup>2</sup>. Westernised formalisations of public space such as the plaza, the square, the park or the street, have been enlarged towards physically decoupled and pervasive cohabitations. There is here a radical inversion: Whereas public space, has been largely seen as a static setup populated by mobile subjects, later on updated as a productive commodity, social media engenders hybrid spatialities where the scenario is never officially defined, and the pre-specific citizen becomes the permanent element navigating through these pervasive centres.

<sup>1</sup> Pier Vittorio Aureli and Martino Tattara define in their essay “The City as Political Form”: *Civitas is the political institution that signifies the collective will of a community to inhabit and coexist in one place. Urbs is the infrastructure that ultimately materially supports this choice* [9].

<sup>2</sup> Robert Venturi describes already in 1966, in *Complexity and Contradiction in Architecture*, the relation American have to public and private space: *The piazza, in fact, is ‘un-American’. Americans feel uncomfortable sitting in a square: they should be working at the office or home with the family looking at television* [10].

### 5.3 Poiesis

The Pre-specific City aspires to the East and to the South, or any other latitude that challenges institutionalisation of use. While centralized urban planning imitates the sense of contingency existent in the multitude, in just a few seconds railways become open-air markets in Lagos and whole domestic realms extends into the streets of Jakarta. The distinction between public access and public space is here blatant: the first one is purely bureaucratic whereas the second, built in the making, entangles poetic and poetic processes. Hence, the Pre-specific City, like a doping platform, exacerbates this engendering condition on a levels decoupled from spatiality and physical proximity.

### 5.4 Population(s)

The Pre-specific City is universal although not totalisable: it cannot grow since all the indexes were already there. Its urban environment enlarges in the same degree that relation and articulations are empowered. In order to gather 50 million of spectators it took to radio 38 years, 14 years to TV, 4 years to Internet while Facebook gathered 200 million members in only 12 months. While you read these lines, the social media community is already the largest country in the world. The nexus of place, blood and identity is no longer relevant: we have found a concept of universality that integrates all the individualities. Are you ready? The Pre-specific City is now, and now, and now.

## Unconventional and Original *Anecdote*: Textual Space Construction in The Dictionary of Obscure Sorrows, a Tumblr Blog

Ratna Erika M. Suwarno

Faculty of Humanities, University of Indonesia, Depok 16424  
 E-mails: erika.suwarno@gmail.com, ratna.erika@ui.ac.id

### ABSTRACT

Within a social media platform tumblr, The Dictionary of Obscure Sorrows (DoOS) stands as a unique blog variety of personal space, offering unconventional textual treats in form of dictionary entries. Textual features and signs within navigable space and within electronic space thus are viewed as textual strategies and construction and exploration of one niche representation of modern identity. Textual construction of electronic text then relates to construction of navigable space within the medium, as it provides more scope compared to printed text. Materiality is re-conceptualized as the interplay between a text's physical characteristics and its signifying strategies, a move that entwines instantiation and signification at the outset. This definition opens the possibility of considering texts as embodied entities while still maintaining a central focus on interpretation. Thus within the culture of global internet, DoOS then offers more than just wild sorrows of textual treats; it creates and presents a valid and accessible free textual space, challenging the conventional ways of producing text and meaning.

### Keywords

*Textual space, social media, production of meaning, dictionary, electronic text.*

### 1. INTRODUCTION

As a medium for social blogging Tumblr was first introduced in 2007 and has experienced a significant growth in popularity among Internet users. Taking the specialty of micro blogging, Tumblr[1] service offers minimalist looks with maximum posting abilities ranging from text, pictures, links, short videos, or other media. These services then become norm in Tumblr, giving the outlook of disseminated pieces of digital content throughout the platform; be it in forms of short quotes, personal picture, screen captures of popular video or even any customized content. Yet, among its the busy hive, Dictionary of Obscure Sorrows (DoOS)[2] stands as a unique variety of forms offering a different treat. Dictionary format adapted by DoOS also plays significant role in this discussion as format to build not only textual form but also imagery and meaning. The format then should be considered as an attempt to provide, in opposite, what is not featured in a conventional dictionary. With self-declared mission "to harpoon, bag and tag wild sorrows", through DoOS John Koenig offers unconventional textual treats in form and layout of dictionary entries. With a background as freelance graphic designer, he has been composing entries in his Tumblr blog for over two years with each of the entries completely made up, both the original words and the lengthy and poignant definitions.

Using Figure 1 below as an example, I aim to show all the features for the specific entries of DoOS that will be discussed in this paper. While the linguistic specifics of entry content will be discussed further in other part of this paper, I would like to draw the attention to the visual information first. Reading the entries in its entirety, starting from the first page of the blog, has given the same impression of reading dictionary entries, albeit not alphabetical.

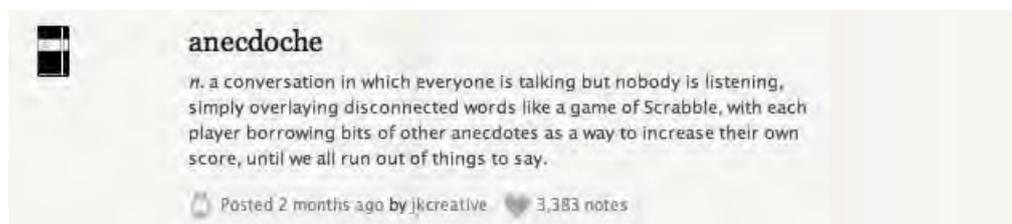

Figure 1: *anecdote* [3]

Lined up in neat rows and entry slots, each word is put forward at the top of the slot in bigger font size, followed by definition of related parts of speech in italics, and the elaborate and relevant meanings last in smaller font size.

Just as any blog entry, located below it, there are also information of metadata providing information of time, date and author of the entry posted. As shown by the wristwatch icon, the entry was posted two months before the time of retrieval and authored by jkcreative, as abbreviation of John Koenig and as one of Tumblr features, a heart mark functioning as link for #notes is displayed at the end of each entry. If you hover your cursor upon it, you can click the link and are led to a list of Tumblr users that has both 'like'-d or 'reblog'-ed the entry to be posted on their own blog. These sets of visual information enable us to obtain information on 1) basic time and date of posting to limit the range of this discussion; I only consider a selection of entries within the last two years for this discussion and, most importantly, 2) since I believe re-blogging feature promote authorship by retaining the author's metadata, we can see how many #notes, and by extension, how popular each of the entries is.

I will fully dissect five of the most popular entries, categorized by the number of #notes received by respective entries retrieved at the same span of time. This decision was made as an attempt to effectively show the flexibility of spatiality, a quality of electronic texts of the original DoOS text for discussion—instead of temporal category of most recent entries if we follow the order of posting time or another temporal category based on timeline archives. Then I will briefly analyze the meaning and how the word origin is linguistically constructed before proceeding to a detailed exposition of how then meaning is encoded and decoded by the author for the readers [4] to show process of shaping meaning as “a much more public and collaborative act.”[5] Readers that went through the act of consuming and constructing meaning consciously are then relating themselves toward the meaning provided and being aware and conscious of their own constructive participations they will have been actively participating in the process of reproduction of meaning. The notion of reproduction then is linked with Gumbrecht's idea of production of presence (2003), the idea of “specific moment of intensity, the specific appeal that such moments hold for us and what...it [is] that fascinates us in the objects of aesthetic experience” [6].

## 2. INTENSE PRODUCTION OF MEANING

Thus how the experience of reading DoOS, of consuming meanings and words, of connecting (obscure) sorrows relates to production of meaning and textual space? After the attempt to show how verbal content and dictionary format in form of electronic text are employed to construct the form of the blog, how it then form a base of materiality within the realm of electronic text and how readers formulate response toward the textual treats, the new meanings—all the visual and textual signifiers—are taken as free re-assembled meanings within familiar code of given quotidian referential. Code familiarity, as dominating result of encoding/decoding process, is perceived as a sign of both production *and* consumption of words, of “language” that “gives a value to things (in this case, words), acquir[ing] a social existence when they are named, denoted and systematized”[7]; a *conversation*.

### 2.1 Inexplicable *Mauerbauertraurigkeit*

English language based readers would find it difficult to directly relate themselves with the word *mauerbauertraurigkeit*; which is partially the reason of I wanted to start with this entry (and another, and more compelling this being the fifth entry with the most #notes). With the unfamiliar word as code, how then process of encoding/decoding works? This entry in particular provides what I believe a display of dominant process of decoding—a process when the readers took more effort on breaking the code of communication yet grasping the meaning at the end. Definition comes purely from the entry, setting the platform of referential on an “inexplicable urge”.

Figure 2: *Mauerbauertraurigkeit* [8]

Without reference to any other image, the *mauerbauertraurigkeit* is attempting to define itself with another set of quotidian referential, directly taking stance of communicating with “you”. The explanatory clauses added explication to what starts as unfamiliar by delivering some codes of familiarity, defining the word in moments “as if all **your** social tastebuds suddenly went numb, leaving **you** unable to distinguish cheap politeness from the taste of genuine affection. (bold represents my emphasis).” All the referential then are referred to “you”, enabling “us” (as plural form of “you” as addressed in the entry and

“us” readers in general) to define the abstract “urge” as indeed “inexplicable”, unable to be explained, just as the urge *mauerbauertraurigkeit* tried to embody.

In this paper #notes are taken as a general representation of how many times this entry received nods from the reader. Over the choices readers have for every entry, they could merely read the entry without contributing anything, giving their simple acknowledgement and ‘like’ the entry or ‘reblog’ the entry entirely with or without additional comments, as seen in example of screen capture below:

Figure 3: Mauerbauertraurigkeit [9]

Figure 3 shows variety of notes accumulated by the entry of *mauerbauertraurigkeit*. A tumblr user, for example *pretentiouslimericks*, and *Iwayout*, can ‘like’ the entry without adding anything else. Other options would be to ‘reblog’ the entry with comment, tumblr user *nakedpineapple* shown in figure above, as an expression toward the entry, or simply without, tumblr user *usernamesbugme* shown in figure above. Tumblr user *usernamesbugme* also perform an act of ‘reblog’ not directly from DoOs, but from another user who has previously ‘reblog’-ed the entry.

These number of #notes accumulates all the ‘like’ and ‘reblog’ action each entry gain and, in my opinion, express sense of decoding the reader has performed upon the entry. Readers then grasped the meaning at the end of the code mapping; putting the quantity of readers in numbers, there are 15,156 #notes and counting for this entry. With *mauerbauertraurigkeit*, the moment of intensity, the inexplicable urge the entry pointed out, is then somehow recognized through the quotidian referential that was presented. At the end, the original word *mauerbauertraurigkeit* holds what I see as explicable number of #notes, showing participation and by extension also the level of decoding. Readers then has collaboratively participated in mapping the urge by acknowledging the “inexplicable” as related, eliminating the sense of conditional in “as if—”, and, by extension, explicating an urge, “the inexplicable urge”.

## 2.2 Spatial Kenopsia

*Kenopsia* also starts with an unfamiliar code even if it has vague relations toward a blur image we have on the back of our mind and in particular provides another dominant process of decoding. The platform of definition as “the atmosphere of a place” is thoroughly modified and described by the adjectives “eerie” and “forlorn”. Unlike the previous word, *mauerbauertraurigkeit*, and the rest of the entry I am going to discuss, definition of *kenopsia* operates in slightly different manner. Not only that it provides quotidian referential, its main subordinate clause is describing spatial quotidian referential, of specific places, of “a school hallway in the evening”, of “an unlit office on a weekend”, of “vacant fairgrounds”.

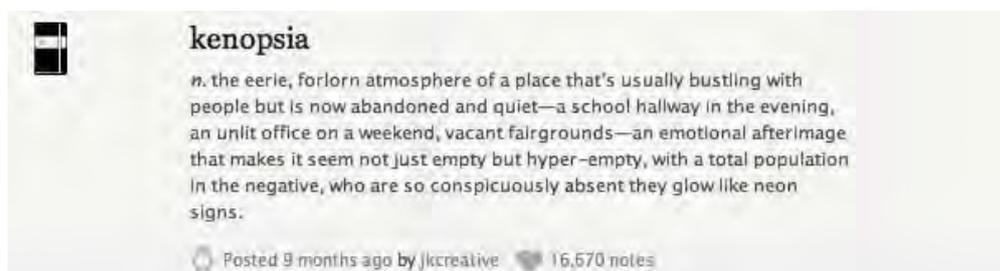

Figure 4: kenopsia [10]

Readers can easily relate to “school” as the symbol of our first stage of our life, “office” as the symbol of our adult life, and “fairground” as the vague symbol of in-between stages—as you generally went to a fairground either when you were a child or when you are already an adult as parents. I consider this attempt of providing spatial concrete referential, instead of emotion/feeling’s abstract ones.

Most of readers also decoded *kenopsia*’s definition through juxtaposing it with references of places they are familiar with.

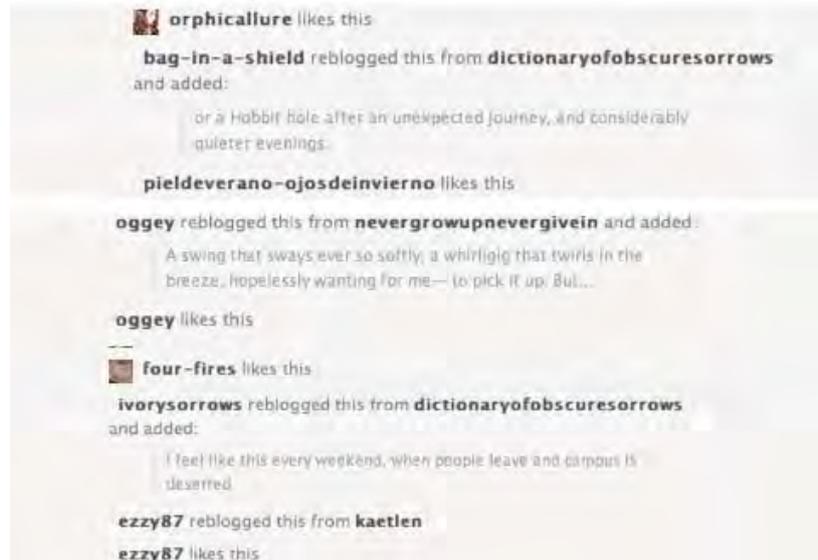

Figure 5: kenopsia [11]

I consider such decoding act as the easiest act among all other acts for definitions on the blog. Naming and identifying specific physical places provide specific connecting tools and at the end simplifying the act of decoding. Readers are guided kindly into embracing the definition by bringing more established and relatable, in terms of intensity, spatial relations. In result the code of *kenopsia* is the most specifically decoded because instead of explicating the “*atmosphere* of a place”, the code operates along with “a place”, a range of places, a range of *specific* physical places.

### 2.3 *Xeno* Connection

Opposite to the previous two, the word *xeno* does strike a sense of familiarity and we immediately connect both the similarity of spelling and pronunciation to a combining form of *xeno-*. Originated from Greek word *xenos*, the (partial) word was usually combined with other words to give referential meaning of “relating to a foreigner or foreigners”.

Figure 6: xeno [12]

Few readers have voiced their arguments noting that *xeno* has already attached to a certain definition, as mentioned above being a combination form. Yet, DoOS then took the definition into more than combination form but word with attachment. Starting in the platform of solitary moment, of where you only pass strangers, *xeno*, as an independent word in this entry, tries to explain the meaning of a single noun that is parallel with, for a start, "the smallest measurable unit of human connection".

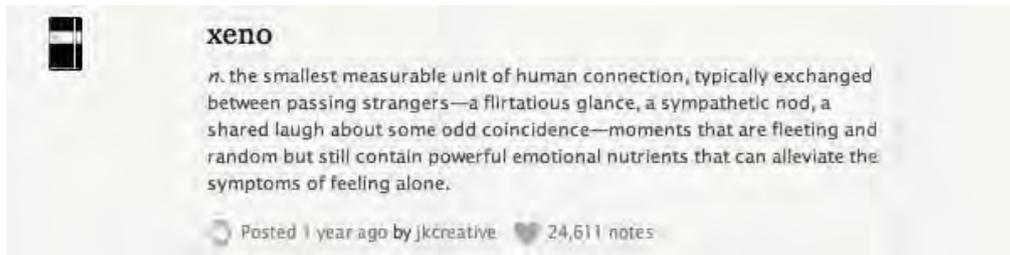

Figure 7: xeno [13]

By not giving any other possible interpretation, the definition was locked on the specific "unit" of meaning that is "the smallest measurable". The definition then was sharpened and detailed in two subordinate clauses "typically exchanged between passing strangers" and the "moments" signifying that there were two detailed definitions given to further explaining "the smallest measurable unit of human connection". Dealing with the "symptoms of feeling alone", *xeno* then mapped several exchanges of people that are "fleeting and random". Connection played as an important signified part of the definition. By explaining the detailed definition of "connection", this entry itself also "alleviate the symptom of being alone".

Reminders that those exchanges with "passing strangers" in forms of glance, nod or laugh (all which are mere and simple contacts with other "human" even if s/he is only "passing stranger") serve as what Stuart Hall [14] referred as stage of "recogniz[ing] that the discursive form of the message has a privileged position in the communicative exchange". I then consider this stage of recognition as important since it then summed the moments of "encoding" and smoothly bridged the discussion to the "relatively autonomous decoding" process within the communicative process as a whole; emphasizing the moments—be it both *xeno*'s "fleeting and random" moment and *determinate* moments of communication process, as a production of meaning.

#### 2.4 Specific *Kairosclerosis*

Meanwhile, dealing with none other than "the moment" itself, *kairosclerosis*' definition process began with employing several of methods that I have discussed above; 1) directly taking stance of communicating with "you" and attaching "the moment" into "you"'s experience by focusing on the moment of realization that belongs to "you" instead of anybody's; and 2) like *xeno*, striking a sense of familiarity with the word *kairos*, again from Greek origin, to give referential literal meaning of "opportunity" and the word *cleriosis* with association of "abnormality" and "excessive".

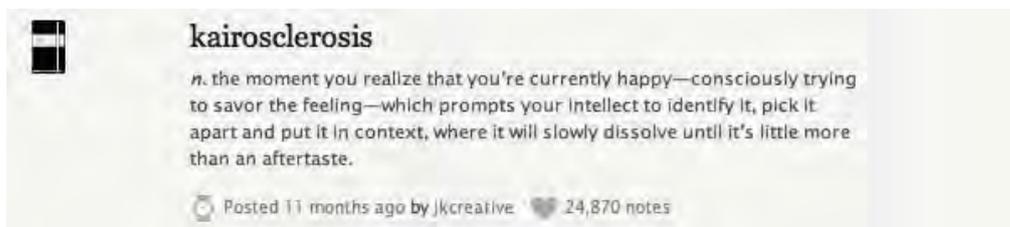

Figure 8: kairosclerosis [15]

But even if it starts within the platform of solitary moment, *kairosclerosis* mapped its definition in further details of mere realization of being "currently happy". There are acts of identification of, "put[ting] in context", and "pick[ing] apart" of feeling. There is also sense of uncontainable from last clause, when feeling "will [eventually] dissolve," turning into *uncontainable* liquid. All these signified that *kairosclerosis* tried to map moments of intensity involved in relating oneself with the specific feelings. This act then is not only taken as "relatively autonomous decoding" process within the communicative process as a whole but also a calculated act of encoding, bringing a specific "appeal that such moments hold for us" [16], for the readers.

#### 2.5 Epic Story of *Sonder*

*Sonder* is the most popular, and one of the entry with the most of number of words within the whole realm of DoOS; open praises, questions of origin and many other compliments have been addressed regarding this particular word through 30,852 #notes and counting for this entry and other avenues. These number of #notes accumulates all the 'like' and 'reblog' action each entry gain and, in my opinion, express sense of decoding the reader has performed upon the entry. I believe dominant

process of encoding is played impressively on this particular code, since *mauerbauertraurigkeit*, *sonder* stands at first as an unfamiliar code. In this particular entry, the author has displayed a great effort in encoding as many details and quotidian referential as possible, so that readers could relate themselves almost seamlessly to the meaning.

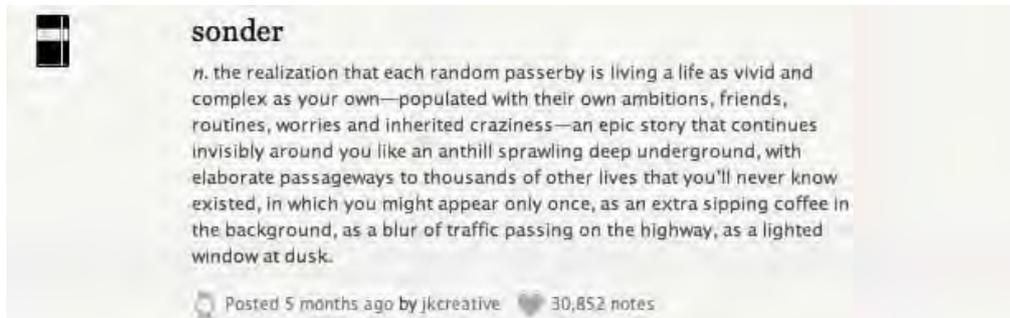

Figure 8: sonder [17]

Not only directing the stance to a possessive adjective for “you”, *sonder* went as detailed as attaching the referential “[own] life” to the definition. It also did not provide any other possible referential relation between “you” and again stranger, like *xeno*, in form of not only one, or two, but “each random passerby.” That being so, considering that both the subordinate clause for attribute for “living” as parallel, *sonder* dealt with the definition of “the realization that each random passerby is living a life” and “is [living] an epic story”. To avoid confusion, I will discuss the first subordinate clause (*sonder* as the realization that each random passerby is living a life) first then the second (*sonder* as the realization that each random passerby is living an epic story) before at the end merging the discussion to map the overall production of meaning.

The first subordinate clause dealt mostly with definition of “life” for both “you” and “each random passerby” being “vivid and complex”. Additional acts of defining “life” are conducted by attaching firm explanations of populating objects for a life to be vivid and complex; i.e. “ambitions, friends, routines, worries and inherited craziness”. The acts signified that first clause of *sonder* tried to map moments of intensity involved in relating oneself with the specific objects and by bringing specific “appeal[s] that such moments [of possessing objects] hold for us” [18], another calculated act of encoding has been accomplished.

To complement the encoding act of the first clause, the second clause was even more encoded in the most explicating manner, employing not only operating codes along with specific places but also specific quotidian referential. Starting with a sense of continuation parallel of “life” operating invisibly, two points of quotidian referential are offered for “anthill” as an object related to life that “[is] sprawling deep underground” and “[has] elaborate passageways”. The quotidian referential then carried the sense of a range of *specific* physical places, a spatial concrete referential.

To further complement the act, extra quotidian referential points were added to “other lives that you’ll never know existed”; at one point further locking the definition on specific “life” while at the other giving the another notch of intensity to the solitary sense of “life”. “You” then is defined as “might appear only one”, “as as an extra”, “as a blur of traffic” or as “a lighted window”, while at the same time just “sipping coffee” and “passing” within, again, a spatial concrete referential of “in the background” and “on the highway”.

With *mauerbauertraurigkeit*, the moment of intensity, the inexplicable urge the entry pointed out, is then somehow recognized through the quotidian referential that was presented. At the end, the original word *mauerbauertraurigkeit* holds what I see as explicable number of #notes, showing participation and by extension also the level of decoding. Readers then has collaboratively participated in mapping the urge by acknowledging the “inexplicable” as related, eliminating the sense of conditional in “as if—”, and, by extension, explicating an urge, “the inexplicable urge”.

*Sonder* had not only attempt to provide abundant spatial concrete referential but also played with detailed emotion/feeling’s abstract ones, forming itself as an epitome of textual treats as it works on almost all identified encoding acts, resulting in “enforce[ing], win[nin]g the most plausibility for and command[ing]...decoding within the limit of dominant definitions in which it has been...signified” [19]; an *epic* textual treat.

### 3. CONCLUSION

As Hayles argues, materiality is re-conceptualized as the interplay between a text’s physical characteristics and its signifying strategies, a move that entwines instantiation and signification at the outset. [20] This definition opens the possibility of

considering texts as embodied entities while still maintaining a central focus on interpretation. Yet debate on considering whether a textual treat from a public blog could be classified as literary text is still a heated argument nowadays. In spite of that the fact that dictionary has become a firm format of DoOS blog I find the exploitation of its medium specificity is important.

I suggest that DoOS should be understood as interplay of content, an attempt to describe the indescribable sorrows of everyday life into words through its materiality as a blog and through interactions with readers signified by the readers' #notes. Such interplay signifies, in my opinion, a distinctive dynamic quality, enabling readers to relate to conceptual content and share collaborative interpretive activities. Textual features and signs within navigable space within electronic space thus are viewed as textual strategies and construction and exploration of one niche representation of modern identity.

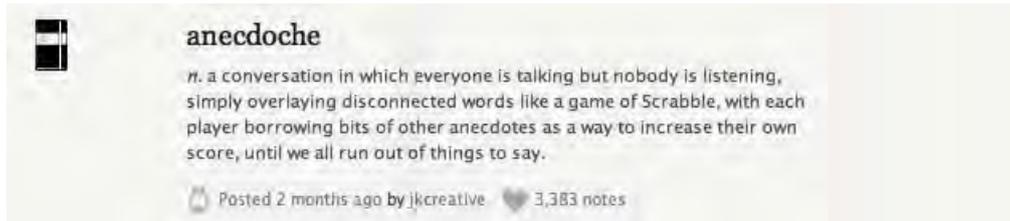

Figure 9: *anecdote* [21]

Thus within the culture of global internet, DoOS then offered more than just wild sorrows of textual treats; it creates and presents a valid and accessible free textual space, challenging the conventional ways of producing text and meaning. Readers were presented with textual treats within their convenient spaces, allowing themselves to connect with specific moments of their choosing, specific appeal to the words and definitions provided. As result, DoOS becomes a navigable space that did not only feature a static temporal text (in form of dictionary) but also dynamic conversations with its readers. Putting aside originality notion, the unconventional space holds important conversation in which everyone (the author and the readers) was "talking, overlaying disconnected words." However even if either the author or the readers are "running out things to say", DoOS will stay as a space where once words, signs, and collaborative interpreting acts hold a conversation; a valid and accessible free textual space produced to defer the temporal meaning of disconnected conversations of a shared collective obscure sorrow.

## ACKNOWLEDGMENT

This paper could not have taken shape without the initial support of Vauriz Bestika, as she has encouraged me to compose the original ideas for this paper, all the way throughout the completion of this draft, and Manneke Budiman who had generously offered his time and support, which I, unfortunately, could not meet due to personal circumstances. I also extend a special thank you to Teti Sumarni for her lightning grammatical proofread. The remaining mistake is mine. Last but not least I would want express my deepest gratitude for John Koenig, the dictionary artist, for his permission to use his blog as research object and to reproduce all the necessary materials; to be able to write this paper on your beautiful literary work has been an honor for me.

## ABSTRACT

This paper investigate the changing of play culture affected by the present of electronic game, have impacts on children's emotions as well as their sense of outdoor place. The study focuses on the voices of small group school-age children and their parents who live in a gated residential community in an urban setting located in Jakarta. The findings reveal that the additional member of family (since the birth of their brother/sister); parental fears and concerns on children independent ability to play outdoors, and electronic game as parent's solution; have caused electronic game shifted the play culture before. This study also reveals that children place two different meanings toward electronic game. First, electronic games are represented as a joyful experience with high sense of positive emotional feeling attached to them. Second, as an unpleasant experience when parental controls toward electronic game take effect. In sum, children connote electronic games as an attachment figure that repetitively lures children inward. Consequently, their environmental range remains within familial space or microsystem. The outdoor space is represented as a fearful and frightening place. Their sense of place is low. There is hardly any outdoor place in them.

## Keywords

*Changing of play culture, children, electronic game, emotion and sense of place*

## 1. INTRODUCTION

Today, children's use of technology has been a common public phenomenon. Research by Jessen [1] confirmed that children's play culture had changed for the last 20 years due to the influence of electronic games and digital media. She [1] distinguished that children's play culture previously were: 1) playing with group; 2) there was good contact between young and older children; 3) young children learned a wealth of games from older children; 4) play was done outdoor; 5) many games involving motion; 6) and playmates are close, well-defined social relationships. Today, children's play culture are: 1) play with fewer groups of children; 2) more organized activities, more school and academic activities; 3) less contact between children of different ages; 4) tend to play only with the same age groups; 5) indoor oriented; 6) and playmates farther afield [1].

One of the causes of the shifting play culture is electronic games. Why? Verenikina & Herrington [2] asserted that electronic games such as computer games allow and gave opportunities for engagement with make-believe play. Product of technology and media provide an unlimited playground for children without have to rely on space and play equipments. In a virtual reality world, children has the opportunities to play and interact with other children without the restriction of space and time [1]. Olson [3] revealed that children's motivations for playing electronic games are various, e.g. for social interaction, joy of competition, opportunities to lead, making friends, young teaching each other, challenge and mastery, experimentation with different identity, expressing creativity, curiosity, discovery and learning.

Researches done mostly in Western society show both negative and positive influences of children playing electronic games. McCarrick's [4] showed positive influences of electronic games on pre-school's social, cognitive, language development and motivation, while Subrahmanyam et.al [5] showed positive influences in the increasing of ability to read, ability in visualize images in three-dimensional space, ability to tract simultaneous images and even contribute to better academic performance. The use of wireless and mobile technology can contribute to the increase of children's awareness towards their environment. On the other hand, there are also negative influences, such as Subrahmanyam et.al [5] indicated the risk of obesity due to lack of physical activities, loneliness, depression, aggressiveness, unable to distinguish real life and virtual reality, while The Henry J. Kaiser Family Foundation [6] reported on violence, addiction, interfering academic performance, and Olson [3] revealed fear of mature content as the negative influences of electronic games.

On the other side, there is a phenomenon called 'shrinking world of child' [7], where children independent access to outdoor environment are limited due to parental fears and social traps [8], children's negative perception on their environment [9], unaffordance environmental factors of children's neighborhood [7, 10] and children's dependency on TV and digital media [11]. These all cause children spatial ability in outdoor environment [12] and the loss of children's sense of place in outdoor

environment [13]. Several researches revealed that factors influenced children's use of outdoor spaces are: family, community and social factors [7, 10], physical factors [10], availability of parks [14] and its amenities [15], including infrastructure [16].

Those reviewed research emphasize on the present of children *in* the city, by investigating how and why they use outdoor places. How the inevitable present of electronic game have impacts on children's emotions as well as their sense of place are still open for investigation. Therefore, my prime interest has been to let the voice of children and parents tell what the meaning of electronic games to them and how it will impact the developing of their sense of place presented by the present of place *in* children. This investigation is essential and significant, because freedom to move and to explore the surrounding are very important for children's physical and mental development [7, 17-19]. Accordingly, a city has to provide amenities and infrastructure that are child friendly [8, 17, 20, 21].

## 2. WHAT IS ELECTRONIC GAME?

Electronic game is a play activity in a virtual setting that can stimulates environment, is implemented by the use of instrumentations like computer, laptop, tablet, mobile phone, game console, TV, etc. Richard Bartle (2004) cited in Walz [22] defined that play has three modalities. They are physical (players, spaces, and objects that are material), imaginary (which is not material), virtual (that which is not material but had the form or effect of that which is material). Walz [22] cited Bartle (2004, p.1) defined "Virtual worlds are places where the imaginary meets the real and Virtual worlds are implemented by a computer – ora network of computers – that simulates an environment" (p.28). According to Walz [22], this notion of virtuality propose a new modality which he called "hybrid: that which is not material but has the form or effect of that which is material mixed with that which is material to the extent that one can no longer be separated from the other without losing its form or intended or emerging effect" (p.28).

In order to understand the experience while playing electronic games, one has to be able to distinguish the difference between game and play. Huizinga [23] defined play as 1) a free or voluntary activity, not a serious activity but a joy and make-believe activities involved with imagination process; 2) not ordinary or real life; 3) its secluded, its limitedness. It is "played out" within certain limits of time and place (p.9) – all play moves and has its being within a playground marked off beforehand either materially or ideally deliberately or as a matter of course (p.10); 4) it creates order and tendency to be beautiful, enchanting, captivating (p.10); 5) all play has its rules (p.11); 6) as a contest for something or a representation of something (p.13). Huizinga [23] perceived play community as an emotional ties which would take player away from reality. He [23] defined formal characteristic of play as "a free activity standing quite consciously outside 'ordinary' life as being 'not serious', but at the same time absorbing the player intensely and utterly" (p.13).

According to Roger Caillois (1961) in *Man, Play and Games* cited in Masters [24], game is a social part of play. Caillois cited in Masters [24] categorized the game as *agon* (competitive play engaged individuals and groups in tests of skill and ingenuity), *alea* (games of chance or luck), *mimicry* (pretense and illusion), *ilinx* (games when individuals pursued vertigo). Huizinga [23] and Caillois cited in Masters [24] definitions of play certainly imply that "part of play's enchantment rests in the pleasure that it provides" (p.860). On the other hand, Mihaly Csikszentmihalyi (1990) in Master [24] asserted that what game players felt are positive experiences. According to Csikszentmihalyi (1990, p.49) cited in Masters [24], this positive experiences occur when the individual acts with "a deep and effortless involvement that removes from awareness of the worries and frustrations of everyday life" (p.860).

In sum, electronic games can be as joy and make-believe activities, not ordinary or real life, attractive and captivating, competitive, has aspect of luck, giving the player an experience and positive emotion which absorb the player intensely and utterly from fear, frustration and daily life problems.

## 3. RESEARCH OBJECTIVES AND METHODOLOGY

The major interest of this research is to investigate whether the outdoor place is *in* children. How the *voices* of children and parents tell what the meaning of electronic games to them and how it will impact the developing of their sense of place presented by the present of place *in* children. The methodology is partial ethnography conducted for about three months (September-November 2012). Ethnography is "the art and science of describing a group or culture" [25]. Ethnography emphasizes on everyday engagement and immersion between ethnographer and "native" for a long period of time, richly contextually, situated in a certain location, in order to grasp in rich and thick description of certain culture [26, 27]. Data was collected through participant observation, in-depth interview with both parents and children. The children and parents were interviewed individually. Participant observation was conducted in a setting accompanied by their parents. To record children's understanding of outdoor place, children were asked to participate in a drawing. Fieldworks were done at four different locations.

The study focuses on the voices of small group of school-age children and their parents who live in a gated residential estate in an urban setting located in Jakarta. There are four children participated in this research. They are Dewi (girl, 11 years old), Dimas (boy, 11 years old), Martin (boy, 9 years old) and Evan (boy, 7 years old). All names used in this paper are pseudonymous. The selected school age children had been intensively used electronic game for 5-6 years. They do not have any academic problem at school and come from middle income family. Their parents are aged between 30-40 years and well-educated. All of the children's fathers are working fathers. Dewi and Martin's mother are career women. Evan and Dimas' mother are house wives. Figure 1 shows the housing estate where the children live, has adequate amenities. There are pathways for pedestrian, open playground, open spaces for activities in various sizes. The environments is also relatively clean, safe and have various environment richness to encourage senses, e.g. smell, sight, touch and feel. Children mobilization to and from school and other activities are carried out by private cars.

## 4. RESEARCH FINDINGS

### 4.1 The Changing of Play Culture

Children's interaction with electronic games are introduced by their own parents. Electronic games, such as Nintendo DS, Play station, PSP, Ipad, PS3, and Nintendo Wii, are bought as gifts and as a sense of sympathy from parents to children. All children have been interacted with electronic games since they were 4 or 5 years old till now. Hence, they have been playing electronic games for about three to six years long. Since then, their play culture have changed. The observed children come from a small family (with 1 or 2 children) and are the eldest in the family. As in the case of Dimas, before he knew about electronic games, he would spend his time with various extracurricular activities, e.g. piano, drawing, singing and cycling. Moreover, according to his mother, Dimas has no impediment problem like today. For the case of Martin, Evan and Dewi, they used to play outdoor with peers, nannies, parents or play individually and they frequently play outdoors, e.g. cycling, soccer, or playing with their neighbor (under their nannies supervision). It means that their play culture before are more varieties, from physical outdoor activity into sedentary indoor activity together with peers, nannies and parents.

The additions of a new member in a family are obviously affecting children's play culture. Their parents have been occupied with the new born sister or brother, caused most children are not having the same attention from their parents as before. Mostly, they are let playing alone with their electronic games and watching TV while their mothers take care of the new born. While for the case of Martin, the attention and the focus of his mother is more towards his young brother who has ADHD syndrome. According to Jessen [1], media and electronic games become important for children because they stimulate the impulse to play (p.8). When parents are occupied with the arrival of new sister or brother in the family, there is also reluctance from parents to allow their children play independently outdoor without supervision. These cause media and electronic games move in and fill in the gaps in greater or lesser extent. Media and digital toys are also becoming good play tools that inspire children to interact socially and play together [1]. The electronic games become a means of social interaction between children, as experienced by Evan's mother, where the electronic games become the fun conversation topic amongst the children.

### 4.2 Electronic Game as Parents' Solutions & Control

Referring to children's daily schedule, it is revealed that parents and children are not too often involve in play activities together. This is because parents are busy with the household chores, their career and occupation. Parents' involvement in

children's activities take place only when helping children with their homework or studying for exams (if necessary) and during Sunday morning (cycling with father while mother busy with household chores). For example, in the case of Martin, he plays his own game, unaccompanied. No maternal involvement during Martin's free time. Moreover, during my observation at Dimas' house, his parents only sat and looked at their children playing and there was no involvement from the parent in engaging play with their children.

Career building, caring for younger sibling(s), caring for school age child, caring for husband and households have been impacting every mother in exhaustion. Based on these reasons, most parents use game as the solution for their child to not overburden their parents. Mrs. Dewi and Mrs. Martin also let their children play games so that they will not 'bother' them. All mothers even suggesting and letting their children play games during their spare time such as waiting time in the restaurant, in the car and before entering the cinema. Although all mothers perceive game as the parent's solution, but all mothers show a firm stand on when their children need to play; to go school; to go for extra lesson outside school; to study; to worship, and others. This was reflected in the daily schedule written by the children's mother. Of the daily schedule, it can be seen that the duration of playing game is relatively long hours (approximately 6-12 hours per week), even longer during school holiday season. Every mother has a strategy in dealing with the emotions and behavior of their children, e.g. in the form of playing time restrictions, reward and punishment's method, control over time spent playing games.

### 4.3 Emotional Ties and Electronic Game

During participant observation, there were emotional and behavioral expressions in the form of pleasure or excitement, skills in using the electronic games and the desire to always touch or play with the electronic games. Emotions and behavior observed are from the face, verbal words, and actions/behaviors. During my participant observation with Dimas, he shouted "... *there is a dragon vale!*" (an Ipad's game) when he saw my son's ipad during a visit to his home. He also seemed very enthusiastic and immediately took the ipad without the permission of my son and immediately played some games (for example 'stickman', 'plant vs zombies', etc.). Similarly, during my participant observation with Dewi, she was very excited in playing games. She laughed and her eyes lit up saying "*yes ... now I can play ipad*", after 2 weeks of being grounded without an Ipad /game. However, during my 2.5-hours observations with Martin and Evan, showed that they had spent intensive time in playing games. They stopped playing games only during the mealtime. Before and after the mealtime both Martin and Evan spent their time in playing games. Martin stopped playing game only when the battery depleted. I observed Martin when the battery was depleted, he just sat sideways, quietly, and looking very confused on what to do next. He obviously bored and did not know what to do. Their eyes and attention of all the children were deeply focused on the game. They did not hear me when I called them because they 'sunk-in' with their electronic game.

The observation revealed that the children have a fun positive experience during their time in playing game. They are very focused and deeply immerse in their electronic game. Children interpret the game as something fun, enjoyment, challenging, exciting, and competitive. Some positive affirmations are delivered from the children such as: "*karena game lebihseru... lebihasikaja. Game itu endless. Pakeotakjuga..bikindulu..challenging...mestimikir...*", explained Dimas. "*simulation..kitamainnyaenakgitu...*" continued Dimas. "*lebih seru aja*" said Martin. "*because it is fun, like super jumping Fin, talking Tom. It's challenging, like PVZ, home sheep home, angry birds...and it's competitive, like racing game...I feel fun...the game is fun...*", said Dewi. In sum, while playing, they become unaware of time, deeply immersed into the games, recognize and familiar with all the characters in the game. Clearly, they are capable of expressing in details which are to be their favorite games. The games are truly *in* them.

The phenomenon of positive emotions and experiences of children in playing reveal that the children are not only feel an emotional ties or absorbing themselves into a condition that was far from reality [23] and positive play experience as asserted by Mihaly Csikszentmihalyi [24]. However, during the participant observation and in-depth interviews with the children's mothers revealed, that there are emotional attachments that arise in children towards their games. This emotional attachment is not shown in the form of a positive experience but rather in a form of a negative experience, such as sadness, anger, jealousy, anxiety, arguments. Dimas and Martin gave sullen expression when they prohibited during game play and refused to download new games. Dimas also separated himself from the crowds of children who were playing games when he wanted to play certain games but were not approved by the other children. At the time when Dewi was suspended for two weeks without a game, Dewi looked envious and jealous with her lucky brother who could play the games. Dewi was in nervous conditions (uncertain with her direction, lying in bed for a while and then get up again), especially when her little brother (5 years old) are playing games (Ipad). She was caught a few times when sitting next to her brother and began to intervene in the game. During the observation, Dimas seen several time intensively argued with his mother. Dimas' argument was about his resentment at her mother, because her mother forbade him to play, limiting what should be played and limiting the playing time.

To understand about what the children thought and felt, then I asked them about what happened if the game was banned by the parents? "*Keselajasamamami...samapapi...ah..tapiudahbiasa*" said Dimas. "*sedih, marasih..*" answered Evan.

“pernahsihdilarang main sama mama, tapilupakarenaapa....kayaknyaseminggudeh, eh...tapi kayaknyangkunginselamaitudeh” said Martin. In addition to the negative emotions and behaviors arise, there are also behavioral desires to be close to the electronic games at any time, especially at a time when the children have already done all the school work and daily activities programmed by parents. According to Dimas’ mother, every day Dimas is always whining to her mother “Can I play Ipad?” Dimas’ whining is done every day after school and after he has done the school’s homework. Martin’s mother also experiences the same thing. According to Martin’s mother, Martin asked the same thing like “PR udahselesai, boleh main game, ya, ma.....” everyday.

The phenomenon of negative emotions when children have been kept away from the game shows some characteristics similar to the characteristics of the phenomenon of human attachment (which is studied by Bowlby [28] and Ainsworth [29] in infants). Characteristics of human attachment by Bowlby and Ainsworth in Giuliani [30], are: 1) relatively long and continuous emotional and affectional bonding; 2) unique characteristics of attachment figure; 3) desire to seek and maintain proximity as well as contact with the attachment figure as a secure base; 4) attempts to get security and comfort with attachment figure. This research revealed that the meaning of electronic games for the children is as an interesting and attractive attachment figure, which lure children to always come closer to the game. Negative emotional attachments that arise when children are separated from game, indicate an emotional tie due to the children have been permitted and allowed to interact with the game for over the years. Although the game itself does not provide real-world realities (e.g. texture, odor, etc.), but the game remains an attachment figure for the child. Since the game can become a “friend”, as a place for self-actualization (providing the ability to act could not be done in the real world) and as a comfortable place, especially during stressful time after doing homework, school & extra curriculum activities that are so pack as well as good academic performances expected by parents.

#### 4.4 The loss of Children’s Sense of Place in Outdoor Space

The changing of play culture from outdoor to indoor, from physical motoric activities to sedentary activities give influence on the crisis of children’s spatial relations in outdoor space [12]. According to Ainsworth [29], since pre-school age (4-6 years), children experience cognitive development, language development, memory, social interaction which oriented in partnership and peers, as well as motoric abilities to run and walk significantly. Then, primary school age children (6-12 years) have the ability to think logically and concretely [31]. Children are capable to thinking inductively than deductively and understand reciprocal relationship. These abilities lead the children to move away from the secure-base area (home) to explore their world widely and interact with others (including strangers and peers). School-age children are independent enough to move around and explore their environment. Their environmental range should be at mesosystem [32] or neighborhood space [33-35]. However, this research found that areas explored independently by the children are remain only at microsystem or familial space (as indicated by Erikson, Porteus, Bronfenbrenner as space explored by children below 6 years old). Children’s environmental range in this case is only inside the house and on the street just in front of their house. Social relations with peers are also showed a strong influence in the emotional ties between children and games. Peers are also becoming the only reason children willingness to explore the neighborhood and playing outside.

Everyone has emotional experience with a place; it can be a pleasant or unpleasant experience. According to Canter [36], place is strongly associated with perception and cognitive knowledge. Children emotional experience in open space show a negative emotional experience, not a positive emotional experience. During my fieldwork with the children, I tried to explore what open space meant for children. Fear to something (e.g. fear of animals, fear to older and bigger children, fear hit by a car on the street, fear of fatigue, fear of pain, fear of falling, fear of heat, fear of sweating) are all negative expression expressed by children. “panas, keringetan...” said Dimas. “Outside is hot...” said Dewi. “Tidak boleh sama mama, main di luar... karena diluar ada jalan raya”, replied Martin, “kejauhan lapangannya” replied Martin and Evan. “Karena dilapangan ada anak-anak yg gede-gede... dantakut digigit binatang... trusngakseru.. dankalaujatosakit...” explained Evan.

Place attachment development depends on positive cognitive responses received by the children, and generally positive responses occur in places that are considered important or special by children [7, 37, 38]. However, the positive response of children on the environment is not revealed in this study. Repeated experience and direct as well as the social meanings attached to the children and other people (such as parents, teachers and peers) have a tendency to influence the development place attachment [7]. The Children also do not connoted the open space as a place of social interaction, except for Evan who connoted the street in front of his house as a place for social interaction and play with his peers. To find out if outdoor place is in children, I asked the children to participate in drawing a map of their neighborhood. Of 4 children interviewed, only Martin who refused to participate. The drawings appeared on figure 2 show that their knowledge about the environments is limited. Their body movement in place either individually or collectively with peers are also very limited. Therefore, their knowledge about their outdoor places is higher formed by their abstract knowledge than emplaced knowledge [39].

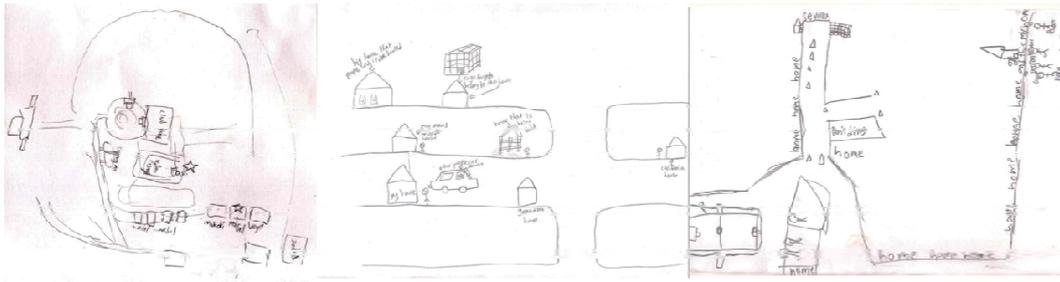

Figure 2: Children's environmental cognition by Dimas, Dewi & Evan (left to Right)

This study revealed the lack of children movement in place, resulted in the low level of children's sense of place of their neighborhood and the low knowledge of outdoor place in children. Sense of place is a specific experience that people experienced [40]. Referring to Shamai's seven levels of sense of place [41], observed children show second level of sense of place, i.e. awareness of their presence in the outdoor space, could identify several places located in the outdoor space, but they do not show any emotional feelings associated with open space. The outdoor space is represented as a fearful and frightened place. The low level of children's sense of place in outdoor space is also caused by parent's social traps that affect children's freedom to move [8] and these several unsupportive environmental factors [7, 10].

The study also shows that there are two different parental perspectives regarding to their neighborhood. Dimas and Evan's mothers explicitly stated that they always encourage and not worry about the safety of their children playing outside. While Martin and Dewi's mothers severely restricted outdoor play activities for their children. All parent's view are relevant when placed in the context of their neighborhood. Evan's and Dimas' home environment are more closed, less crowded and more secured with security guard. According to Martin's mother, her neighborhood was not safe due to direct frontage with major roads. Due to these conditions, Martin's mother was never allowed her children to play outside. Meanwhile, according to Dewi's mother, the neighborhood was quite busy with passing vehicles and parking, especially on the main road. There is a playground nearby, but not too appealing. Playground is generally used by toddlers and their nannies in the afternoon. To reach the playground they need to walk across the main road.

In sum, negative meaning towards the outdoor space by the children and parents result in lesser movement of children in outdoor space. Their environmental range remains within familial space or microsystem. The Negative meaning contributed to the low level of children's sense of place in outdoor space. Consequently, their emplaced knowledge of place in them is very low (limited). There is hardly any outdoor place in them.

## 5. CONCLUSION

This research finds that the addition of a family member (the presence of a new brother/sister), parental fear and concerns on children's independent ability to play outside, have caused electronic games move in and fill in the gap and shift the play culture before. Electronic games become a tool that inspires children to socially interact and play together. Parents perceive electronic games as parenting solution (not be bothered by their children). However, parents also make an effort to control when to play and when to study, limiting the playing time and impose a system of reward and punishment.

This study also reveals that children place two different meanings toward electronic game. First, electronic games are represented as a joyful experience with high sense of positive emotional feeling attached to them. It makes the children become very focused and deeply immersed in the game and keep them away from reality [23, 24]. Second, as an unpleasant experience such as sadness, anger, jealousy, and arguments, when parental controls toward electronic game take effect. In sum, children connote electronic games as an attachment figure that repetitively lures children inward. These negative emotional indicate an emotional ties caused by children attachment to electronic games over the years. There is also observed behavior of the children having desire to maintain closeness to electronic games at any time, especially at a time when the children were already doing all the school work and daily activities programmed by parents. The phenomenon of negative emotional experiences shows similarity to the characteristics in human attachment. Electronic games become a safe and secure attachment figure that repetitively lures children inward. These emotional feelings towards electronic games are not revealed in outdoor places. Shouldn't outdoor places also become a safe and secure attachment figure for children that will also repetitively lures children toward them?

Consequently, the electronic game also affects the low level of children's sense of place in outdoor space, i.e. awareness of their presence outdoor environment, can identify a few places, but they do not show significant positive emotion associated

with the outdoor space. The outdoor space is represented as a fearful and frightening place. Their environmental range remains within familial space or microsystem. Peers are also the only reason children willingnessto explore their neighborhood and playing outside. The low level of children's sense of place is also caused by parental social traps and different parent's views of security and comfort of an outdoor space environmentthat affect children's independent to move and explore their neighborhood [8]. At the end, there is hardly any outdoor place in them.

The findings of this study suggest that the design of children's environment especially home's environment, should take serious considerations on how the outdoor place can be a safe and secure attachment figure for them and their parents. Although their neighborhood is considered as a well-designed gated community, nevertheless their outdoor environment is still not served as an attachment figure for the children. The inevitably impacts of electronic games clearly confine the children into just familial space. They have almost never moved beyond their secure familial space. Policy makers and developers should consider outdoor place for children is not only playground. But how outdoor space should be designed as attractive and fun place as electronic games, so it will lure the children repetitively to move, to explore and to play for the benefit of their physical and mental development.

## ACKNOWLEDGMENT

This research was conducted as part of ethnography research coursesupervised by Ms. SurayaAffif, Ph.D. I would like to express my appreciation to all children and parents who give consent for me to do this research; and to my advisor Ms. ParamitaAtmodiWirjo, Ph.D. for her encouragement for me to revise this paper for the conference.

## ABSTRACT

The research is focused on green cities and how the digital media has formed the basis for the development of corporate sponsorship of high tech green cities currently under construction like Masdar in Abu Dhabi, Songdo in South Korea and PlanIT Valley in Portugal. The urban imaginary of virtual green cities is directly linked to an ecological cyberspace which promotes futuristic images of green cities such as Vincent Callebaut's Hydrogenase (2010), which is a transport hub for an algae farm and biohydrogen airships. These images of sustainable green cities pose a challenge to define ecological civic space and green architecture in order to allow for the transformation of Jakarta into an eco-architectural hub that balances social, economic and environmental issues. The role of Google Earth and digital maps are not be underestimated in digitizing the 'bytes' and realizing design scenarios of the 'bricks' for green cities, including those options related to traffic planning simulations, water catchment scenarios, disaster planning and flooding as well as social media simulation for crowd control and governance issues.

### Keywords

*Civic space, glocal, green architecture*

## 1. INTRODUCTION

The phenomena of social media are focused on the Hotel Indonesia Roundabout (*Bundaran HI*) as an urban accupressure point for the promotion of civic space. Worldwide social media has promoted spontaneous flash mob dancing inspired by the South Korean singer PSY with his Gangnam style in an almost Elvis Presley or for the current generation Michael Jackson craze for public street galloping and dancing in a *glocal* celebration of globalization and localization in civic spaces from New York City to Jakarta. Besides being a media hub for cultural expression (Gangnam Style Flash Mob 9 Sept. 2012), the Hotel Indonesia Roundabout is also a contested political territory whose various designs have celebrated the emergent nation state of Indonesia with the Welcome Statue (*Tugu Selamat Datang*, 1961), built during the Sukarno era as one of the national monuments and a landmark to herald the ASEAN Games IV. (Kusumawardhani & Kurniawan, 2013) After the Reformation Era, (1997-present) the Welcome Statue at the Hotel Indonesia Roundabout was modernized in 2002 with a fountain as a way to reclaim security and police control over what had become a contested site for various political and social demonstrations during the emergence of democracy after the handover of the Suharto government. As a civic proponent for the vitality of the democratic process Jokowi's (Joko Widodo) successful election campaign for Governor of the DKI Jakarta (October 2012) included the massing of supporters wearing checkered shirts. Yet, even such a powerful national and international symbol of the central business district of Jakarta as a global megacity is not immune to the effects of climate change, flooding, and natural disasters, as witnessed by the January floods in 2013 that inundated the Hotel Indonesia Roundabout and shut down the main corporate and commercial boulevards of Thamrin and Jalan Sudirman.

Recent plans for the new Mass Rapid Station (MRT, 2013) suggest that the positive civic space will become instead an urban void leading to the new underground mass rapid station and commercial mall, further underscoring the need for additional green space in the urban streetscape. In its most recent permutation the civic space at the Hotel Indonesia Roundabout will be celebrated as part of a modern mass transit hub connecting the city of Jakarta with the suburbs of the megacity in South Jakarta, thus expanding the access for social media penetration and mass gatherings. Whether the realities of mass transport planning are able to accommodate the infrastructure required for the MRT, possible relocation of the main traffic arterials, additional drainage infrastructure, plus an allowance for an expansion of 30% open space and the provision of civic space to allow for festivities, street markets, and New Year's celebrations remains as a challenge for Jakarta's architects, planners, politicians, and citizens. One example of how 'bytes' or information technology can improve the physical structure or the 'bricks' of a city is the Boston Transport system (2010) that used real time data simulation to synchronize its bus lanes. The necessity of 'bricks' as well as 'bytes' to solve Jakarta's transport infrastructure and civic space will undoubtedly converge at the Hotel Indonesia Roundabout as Jakarta becomes one of the megacity hubs for ecological green architecture.

The paper follow a tripartite sequence: first, realizing the imaginary of green cities and the metaphors of bricks and bytes are analyzed in the context of three case studies of green cities under construction with high technology components, namely Masdar in Abu Dhabi, Songdo in South Korea and PlanIT in Portugal. Second, the role of the social media in relation to local and global phenomena is considered relative to the balance between eco-social and eco-technological issues in urban planning and green architecture, specifically at the Hotel Indonesia Roundabout as a contested civic place in central Jakarta. Third, in comparing the virtual reality of green cities with the actual realities of civic space, traffic congestion and climate change, the Hotel Indonesia Roundabout and plans for the MRT are analyzed in the context of realizing a mandatory increase of 30% in open space, providing civic space, and implementing a mass rapid transport system. In conclusion, a visionary design competition entitled “Architecture Triennale 2012: Architects For People - Towards Jakarta 2045,” sponsored by the Indonesian Institute of Architects (IAI), shortlisted ‘Jakarta Xcavated’ in the professional category. The design allows for the addition of green parks above and underground commercial and transport facilities below the city as one alternative to realize the connection between bricks and bytes.

## 2. REALIZING THE IMAGINARY OF VIRTUAL GREEN CITIES

Generally speaking, computer-generated virtual realities are based on bytes that are units of digital information in computing and telecommunications composed of 8 bits, a term coined by Werner Buchholz, a German computer scientist in 1956 for the design of the IBM 701, a defence calculator introduced in 1952 as IBM’s first commercial scientific computer and IBM 7030 Stretch computer, (Wikipedia, 2013). A byte is used to encode a singular character of text and in that sense is comparable to a brick in tectonic architecture as being the major component of a wall. The catch phrase ‘bricks and mortar’, is a metonym, a figure of speech associated with two concepts, related to traditional building materials. In banking terms ‘bricks and mortar’ are related to investments in buildings as securities. In e-commerce ‘bricks and mortar’ refers to a business with a physical presence and face-to-face communication as opposed to online shops with electronic communication such as Amazon, etc. The computer language metaphors overlap between computer architecture and building architecture, resulting in the dissemination of virtual realities.

Social media web sites like YouTube and specific websites on green cities promulgate the idea of virtual green cities. Hydrogenase by Vincent Callebaut (2010), (Figure 1), is a virtual reality project based on hydrogen powered airships. This fantastic idea literally fuels the imagination and provides the precedent for green cities based on alternative energy from algae farms coupled with high technology. To paraphrase M. Christine Boyer (1996), what the machine was to modernism, the computer was to postmodernism and what the social media is to hypermodernism, YouTube is to spontaneous hyperconnectivity. The computer or the information age involved Boolean logics, a series of logics denoted as true or false, 0 or 1 as a series of binary syntaxes to organize data into worlds of artificial intelligence and cyberspace. The metaspaces or the hyperspace often imposes a bird’s eye view, a level of reality that allows for a collective imaginary about cybercities that combines globalization and localization into a *glocal* experience. Boyer (1996) defines CyberCities as:

“This unwieldy mixture of urban dystopia and cyberspace – here called CyberCities – turns the reality of time and place into an imaginary matrix of computer nets electronically linking together distant places around the globe and communicating multilinearly and non-sequentially with vast assemblages of information stored as electronic codes.”

Figure 1: Vincent Callebaut, Hydrogenase, (2010), Permission Pending <http://www.inhabit.com>

With their philosophical and intellectual roots in cybercities, technological variants of green cities like Masdar in Abu Dhabi, Songdo in South Korea and PlanIT in Portugal rely on technological sponsorship and linkages with computer companies and high technology as tangible evidence of the realization of cybercities into sustainable ecocities. Indeed the city itself is managed and controlled by sophisticated computer programmes consuming terabytes of data, providing smart grids, smart traffic and transport and smart waste and water management, a genuflection to the fact that reducing our consumption of resources is as much about management as it is about the technology. The sponsors are keen to promote connected smart communities and their particular management solutions to achieving them, as smart cities are seen as the drivers of the next

technological revolution underpinning future revenue streams; whilst cyberspace focuses more on technology to realise utopian visions.

Masdar, as a global hub for emergent technologies, is a sustainable city under construction, (Figure 2). It is scheduled for completion in 2025. Designed by Foster + Partners, Mott MacDonald, and Sheppard Robson International, Masdar is estimated to cost US\$18-19 Billion for 40,000 residents and 50,000 commuters on a 6 km<sup>2</sup> site. Masdar is based on a pedestrian city with a modular transportation system of Personal Rapid Transport (PRT) and Freight Rapid Transport (FRT) as well as electric cars. Technology and development partners include Siemens, Mitsubishi Heavy Industries, GE, Schneider Electric, BASF, and Bayer MaterialScience among others.

Figure 2: Masdar City Master Plan, Foster + Partners (2007), Permission Pending, <http://www.bustler.net>

Designed by Kohn, Pedersen and Fox, Songdo International Business District (IBD) at Incheon in South Korea is under construction with a completion date of 2016 for 65,000 residents and 300,000 commuters at a construction cost of US\$35 Billion on a 1,500 acre (6.07 km<sup>2</sup>) site, (Figure 3). The buildings are expected to receive LEED ratings and there will be 40% green space in the city with sustainability designed into the master plan. In partnership with Cisco, the city includes state-of-the-art communications, broadband connectivity and smart meters in each home to monitor electricity and water consumption. The model of an instant city is applicable to meet urban infrastructure needs. The instant city has a potential market beyond Songdo. "According to a study by an investment bank CIBC World Markets, governments are expected to spend US\$35 Trillion and public works projects in the next 20 years," (Johnson, 2010). In terms of the 'City of the Future,' Cisco cites ABI Research with estimates that US\$39.5 Billion will be spent on smart city technologies in 2016, (ABI Research, 2013). The technologies include smart transportation pricing, Internet connectivity to all homes and schools, demand alert response for energy consumption, medical facilities, and patient coordination as well as electronic offices.

Figure 3: Songdo Master Plan, Kohn, Pederson and Fox (2009), Permission Pending <http://www.archleague.org>

PlanIT is a model city and sustainable community being developed by the Municipality of Paredes near Porto in Northern Portugal for a population of 225,000 people on a 1,700 hectare (17 km<sup>2</sup> or 4,000 acre) site for €10 Billion (US\$14.1 Billion) with a targeted completion date of 2015, (Figures 4 and 5). The co-founder, Steve Lewis of PlanIT in Portugal, was formerly the General Manager of Market Development at Microsoft. According to Quintain, a London based property developer, they are joining "...Microsoft, Buro Happold, Cisco and Formula One suppliers McLaren as partners in the Living PlanIT concept to develop a "smart" city, where built-in sensors measure occupancy, temperature, humidity and energy production and use." The intention to incorporate technology and computer systems is apparent in the 'Introduction to Future City Technology' as follows:

“Living PlanIT’s Urban Operating System (UOS™) provides essential middleware – built on Cisco infrastructure and Microsoft Cloud platforms – that enables networked sensors and actuators to be deployed at scale, coordinated through a unified and secure real-time control layer which also shares and collects data across the entire urban landscape.”

Based on an UOS (Urban Operating System) and PlaceApps, urban data and monitoring systems form the core of intellectual property. Construction is to be based on mass production principles of automotive and aircraft manufacturing. Besides portraying an image of a digital green city, PlanIT Valley will involve partnerships with Portugal’s national government, universities, and companies in a living technology laboratory.

Figures 4 and 5: PlanIT, Portugal, Buro Happold, Engineers (2010), Permission Pending, <http://jornal.publico.pt/noticia/06-03-2011/planit-valley-quer-ser-a-montra-do-urbanismo-sustentavel-21474643.html> and <http://cdn.controlinveste.pt/storage/ng1153995.jpg?type=big&pos=0>

Each of these green city developments share a strong economic vision and how this integrates with the wider global economy (globally interconnected through bytes). Masdar is branded as a global centre of excellence for renewable and clean technologies and has already recruited the International Renewable Energy Association and Siemens to its hub; however, Masdar has modified its targets as a zero carbon city. Songdo International Business District is co-ordinated by Gale International, United Technologies Corporation and the Hanjin Group; it aims to attract multi-national companies who will make it their regional office for Northeast Asia. PlanIT is marketing itself as a base for companies developing products and services for other cities seeking to develop their green credentials. Neither Masdar nor PlanIT have given serious consideration as to why environmental companies would want to move to either the UAE or to Portugal, save the important agglomeration effects popularised by Richard Florida in his Ideopolis thesis, but which are dependent on a significant mass being achieved (Alusi, A. Eccles, R., Edmondson, A., Zuzul, T., 2011).

Despite all of the green cities expressing a desire to be replicable and replicated, it is likely that only the property-driven Songdo economic model (more bricks than bytes) could be replicated by other aspiring green cities, and presumably only those strategically placed, as Songdo is, between major economic powerhouses (in Songdo’s case between Beijing and Tokyo). The connectivity of their communities seems to suggest a desire that from it will cultivate an Ideopolis-inspired creative class at the forefront of the knowledge economy (more bytes than bricks). Nevertheless, even those cities that could claim the title of knowledge cities have done so in response to global economic forces, more so than through the sort of planning and control that is being integrated within these green cities, (Yigitcanlar, T., Velibeyoglu, K. and Martinez-Fernandez, C., 2008). Indeed, the failure to attract high technology tenants to Serpong’s Science Parks, provide a warning of what happens when well-intentioned plans fail to coincide with global market forces.

In conclusion, digitized images of cybercities and YouTube broadcasts have formed the basis for the imaginary of digitized green cities and the development of corporate sponsorship of high tech green cities currently under construction like Masdar in Abu Dhabi, Songdo in South Korea and PlanIT Valley in Portugal. Their technological solutions are far more than the ‘green wash’ Jakarta’s newer commercial developments have cloaked themselves with, although the application of these technologies outside these ‘experimental’ cities may prove little more than a tool for managing our increasing consumption of scarcer resources (crowding even more cars into Jakarta’s crowded streets).

### 3. SOCIAL MEDIA: CHALLENGING THE REALITY OF CIVIC SPACE

The impact of technology on urban development and the allocation of civic space are related to the provision of data from Geographic Information Systems (GIS). In 1972 NASA dedicated its Landsat satellite to mapping natural and cultural resources on land and ocean surfaces in order to classify land use, monitor urban growth and to act as an aid in regional

planning for mapping and transportation networking. The information was and is being used to facilitate transport and power transmission routes. The satellite data analysis is able to predict various urban growth scenarios so that planners can evaluate the spread of urban growth in the context of megacities and their imposition in peri-urban areas on forestry and agricultural lands, (Salkin, 2008).

Figure 6: “The Welcome Statue” at the Hotel Indonesia Roundabout, Permission Pending

<http://www.eazytraveler.com/2011/08/jakarta-jaunt.html>

This grouping together of databases and cartography plus the increased power and usability of computers led to the ability of storing large amounts of data as visual representations with access to websites such as Google and Google Earth. With access to visual mapping, the land use review process is streamlined with the ability to produce accurate maps and three-dimensional views of the city, thus further materializing the city in a virtual way through the Internet and social media access. The ability to manage transport, water, and sewage infrastructure is enhanced as well as the ability to calculate green space areas. Salkin reports that GIS, as a web based, interactive tool is used by local governments for the proposed location of parks.

Besides providing mapping data with access to Google Earth, Internet websites such as Facebook and YouTube provide a social media platform for organizing and communicating with individuals and socio-political groups to arrange for events and demonstrations, thus underscoring the importance of social media and its impact on civic space. One new phenomenon, related more to entertainment than politics (although in Southeast Asia’s case it is sometimes difficult to accurately differentiate, reminiscent of 1960’s youth movements in the west), is the *glocal* phenomena of South Korean Gangnam-styled dancing. However, the occupation of public space by illegal flash mobs also involves the state and security systems to safeguard the peace and security of the city and provide the means for crowd control, specifically in relation to the Hotel Indonesia Roundabout in Jakarta, (Figure 6).

According to Lai Chee Kien at the First Conference on Civic Space in 2010, (Universitas Indonesia and the University of British Columbia), “At the monument at the Hotel Indonesia, demonstrations take over the state space. The people who want to have a say in the civic culture will want to occupy that place. The police also occupy the same space. We have to look at galactic poles with centrally contained power.” This analysis illustrates that space is a contested social process as much shaped by, as shaping, social interaction and power relations as indicated at the WWF-sponsored Panda and Car-Free Day in 2012, (Figure 7).

Gangnam styled dancing derived from songs by South Korean rapper PSY and an illegal flash mob advertised through the social media by the Happy Holiday Indonesia team (a group of video artists inspired by JackAss and Running Man, Korea), resulted in 1,000 people converging at the Hotel Indonesia Roundabout on 9 September 2012 ostensibly to jump in the fountain. Afterwards a 4-minute video broadcast on YouTube generated 336,000 views and 1.4 million comments amongst Indonesian netizens after it was posted on 13 September, (Figure 8). More recently they organized a Harlem Shake (another *glocal* phenomena) on one of Jakarta’s rapid transport buses TransJakarta Busway (BRT), itself a precursor to the MRT.

#### 4. HOTEL INDONESIA ROUNDABOUT: FACING THE REALITY OF GREEN CITIES

“Under a 2007 national law, the city is supposed to dedicate at least 30 percent of its total land area to open green space, but Jakarta has never been able to meet the requirement because of complications in freeing up occupied land and past administrations’ preference for developing open areas into commercial and retail zones rather than parks,” (Tambun, 2012). At the first stage, Jakarta DKI Governor, has targeted an increase in green space from current levels of 9.8% to 20%. Whatever the overall planning target, the fact is that unless there is a radical departure from the use of cars and trucks around the Hotel Indonesia Roundabout or to an extreme measure of road closure, requiring 30% green space would reduce the number of

traffic lanes, (Figure 9). Additionally, the void also presents weather problems during the monsoon season, let alone during disastrous flooding occurrences related to the failure of the canal infrastructure as happened in January 2013 and the potential impact of climate change and urban development on urban water catchment areas (especially around Jakarta's iconic shopping malls, the current substitute for civic space), (Figure 10).

Figure 7: Flash mob at the Hotel Indonesia Roundabout during a WWF sponsored Panda and car-free day illustrating the contested space between City of Jakarta and the public. (2012), Permission Pending, <http://www.hersmagz.com/spotlight/2012/12/flashmob-panda-di-car-free-day-wwf-indonesia-2>

Figure 8: Flash mob and South Korean Gangnam dancing, Hotel Indonesia Roundabout, 2012, Permission Pending, <http://indoboom.com>

Even if the fountain was considered as 'blue-green' open space, the MRT proposal for a void open to the mass transit station and underground shopping concourse and mall produces a negative space, rather than a civic space at ground level, (Figure 11). The potential for use of the urban space for civic events, including festivities, giant digital TV screens, and peaceful political protests would be reduced significantly with the proposed expansion of green space and the MRT void. In fact glass paving blocks, may meet the requirements for the fountain, a skylight atrium and fulfil its symbolic use as public space to be enjoyed by all Jakartans and visitors as a new symbol for an eco-architectural transit hub at the Hotel Indonesia Roundabout.

## 5. CONCLUSION

To a large extent Jakarta epitomises the challenges that most cities will face in attempting to develop their green credentials. Whilst, the conceptual framework, provided by Jabareen, (2008) highlights the enormous task confronting the new Mayor and his administration. These issues include the ethical paradox of balancing sustainability with economic development, the limits to greening and eco-repairing this high-density city (as an extension of its natural capital) and the need for greater equity (political and economic), following a period of spectacularly uneven development, the need for a green architectural forms suited to Jakarta's climate (incorporating passive solar design) and the need to integrate city management (in the ways that the green cities have with their smart grids, transport and traffic). Governor Jokowi's final two challenges of utopianism and global urban political leadership, only serve to highlight the inappropriateness for Jakarta to borrow from distant examples, inspiring Jakartans to devise a unique solution for their tropical megacity. Despite the challenge of new green architectural forms (bricks) and the integration of city management (bytes), these are arguably the easiest of the challenges. Borrowing from David Satterthwaite's (1997) definition of a healthy city, as one which provides a healthy living and work environment, safe water, sanitation, refuge collection and disposal, drains and paved roads, we immediately understand what needs to be prioritised, but the reality of converting bytes to bricks remains the challenge of our times.

Figure 9: Hotel Indonesia Roundabout, Traditional commercial development leaves little room for civic space, Permission Pending, <http://4.bp.blogspot.com/->

Figure 11: Proposed Jakarta MRT with transport system and shopping mall below grade, leaving the main boulevards of Jalan Thamrin and Jalan Sudirman above functioning as commercial traffic corridors with landscaping strips for trees along the perimeter. <http://www.indoboom.com/2012/stories/jakarta-plans-to-build-most-advanced-mrt-system-in-the-world.html>

Although the aspirations for green cities are based on the balance of green space and civic space, the realities of the built-up metropolitan infrastructure require the imbrications of the materiality of the city with its digital management of human, spatial and natural resources. The IAI Architecture Triennale 2012: Architects For People - Towards Jakarta 2045 design competition proposed various alternatives including canals and parks in Jakarta's main throughfares and squares to accept the seasonal inundation caused by flooding and to provide parks and open space with underground facilities, (Figure 12). Besides the vertical expansion of high-rise buildings the potential for green roofs and green architecture with urban agriculture inspires the convergence of the virtual realities with the future reality of green architecture as a *glocal* response in Jakarta, bearing in mind the multiple layers of eco-social, economic, political and social media priorities.

### ABSTRACT

Many believe that video games are part of a popular culture and were created for consumption purposes only. These video games were seen only as a means of entertainment; thus creativity is not usually considered as a quality that can be gained from playing video games. Negative views towards video games came as a result of how people think that the video game player's unable to produce or create new expression from consuming video games. However, there are some users who believe otherwise. These users do not stop at the consumption stage but they venture further. They creatively modify the games for various personal reasons and thus make themselves as the Producer-Consumer. The transition of video game players from Consumer only into Producer-Consumer stage, also happen in Indonesia. Along with the creativity root deep inside cultural traditions, video game player in Indonesia also create their video game modification community. This study tries to identify the relation between creativity and video game modification in Indonesia, and also the purpose of this modification.

### Keywords

*Video Games, User, Modification, Producer-Consumer, Popular Cultures, Creative Contribution*

### 1. INTRODUCTION

The common notion of most people nowadays though see video games as popular media are still thinking that video game created for consumption purposes only. This common perception toward video games comes from negative judgments of the video game players. People tend to look the players as those who are passive and have excessive times. Those judgments lead to conclusion that the players are non-productive people who spend most of their time doing nothing but playing video games. These negative perception often neglecting the other side of playing video games, which also stimulating creativity. In fact, it takes extensive and tremendous talents to make and to play video games, and labeling video games as a non-creative media is simply a simplified misconception since two of the basic elements of video games are creativity and interactivity. In order to play or consume video games, player cannot do it by sit and passively watch thing that happen in screen. Player musttake action and follow the rule, use tactics and logic. It requires the player to interact with the content of video game. Playing video games mean engaging in these creativity and interactivity.

Thanks to the Hacking Subculture, these creativity and interactivity have offered the players some possibility to be a creator as well. There are insatiable players who are not satisfied with the content of the games he/she plays. They would not hesitate to hack or alter the content of the games to optimize their own consuming experience and thus extending the media usage, this activity is known as Modifying or commonly called Modding. For Indonesian players, the modification seen as a way to add local content into popular video game title since the localization of game content is still low. But how exactly video game modification functions as the players' creative contribution in the Producer - Consumer Model of Popular Culture? This is where the research begins.

### 2. PROSUMERMODEL, MODIFICATION, AND VIDEO GAME

Prosumeror Consumer as Producer is a term coined by Dovey and Kennedy in their book Game Cultures: Game as New Media. With theProsumer terminology Dovey and Kennedy try to explain the phenomena of participatory culture where consumer try to accessing, altering, and disseminating symbolic text for further consumption. What happen next is the collapse of distinction between the dominant culture and the subculture [1]. Participatory culture itself is not a new phenomenon in history of media consumption. Long before the digital media emergence people already try to challenge the establish media content producer by making their own content, and distributing it through their own network. The advent of digital media with all its facility accelerate the participatory culture into phenomena that now being accepted as part of modern creativity process.

What people need right now is an idea, time and basic skill to create content, everything else can be provided within the digital media it self. For example a music video that being upload to youtube by prominent musician and being watched by world wide audience, in turn inspiring one of the audience to create his or her own music video. He or she create the video using some of the material from original video, edited it and adding additional material using his or her own laptop. Upload it to youtube have feedback and can have worldwide audience like the video of prominent musician. This may lead to his or her stardom in music industry. The example is just one of many example how the prosumer model in digital media and popular culture context being accepted as modern creativity process.

Prosumer or Consumer as Producer is a term coined by Dovey and Kennedy in their book *Game Cultures: Game as New Media*. With this terminology, Dovey and Kennedy try to explain the phenomena of participatory culture, which is a culture where consumers try to assess, alter, and disseminate symbolic text for further consumption. What happen next is the collapse of distinction between the dominant culture and subculture [1]. Participatory culture itself is not a new phenomenon in the history of media consumption. Long before the digital media emerged, people had already challenged the established media content producers by making their own contents and distributed them through their own networks. The arrival of digital media, and all its facilities, had accelerated the participatory culture into a social phenomenon, which is now being accepted as a part of modern creativity process. Currently, people only need an idea, time and basic skill to create content and everything else can be provided within the digital media world. For example, a worldwide audience is watching a music video, which is uploaded to YouTube by a prominent musician; one of the audiences is inspired to create his or her own music video. He or she creates the video using some of the materials from the original video, edits, and adds their own materials using his or her own laptop. Then, he or she uploads it to YouTube to gain some feedbacks from the worldwide audience, through the same process and the same channel as the video of the prominent musician. This action can lead him or her to his or her stardom in music industry and become a YouTube celebrity. This example is only one of the many examples of how the prosumer model in digital media and popular culture context can be accepted as modern creativity process.

The act of modifying or modding video games at first was seen as an act of altering the content for humorous or parody purposes. Dovey and Kennedy gave the example of people replacing the Nazi enemies in the video game *Castle Wolfenstein* with Smurf character from TV cartoon [2]. As the time goes by, the modification serves different and more complex purposes. If we look at the current video games modifications, we can see at least four types or models of modification, according to Newman [3]:

1. Modding to help finish the game being played.

This model alters the game data or programming codes in order to make the players finish the game easily. For example: editing player's life, or bullet, or time from limited to infinity.

2. Modding to spread or communicate the issue.

This modification alters the data or programming codes by injecting a message, then spread the edited version back to the community. For example: changing the villain character into hero character or vice versa.

3. Modding to convert or extending original material.

This modification alters the data or programming codes in order to extend the playability or converting the original content of the video game into different looks. For example: adding more levels that originally did not exist.

4. Modding to achieve economy benefit.

This modification alters the data or programming code in order to achieve economic benefits by adding new features or services over the previous version. For example: by offering patching or selling downloadable content released by developer.

Few examples of famous modification case are: *Half Life* modding that spawn the *Counter Strike* video game and *Warcraft* modding that create the *Defense of the Ancient* video game, or more known by their abbreviation: *DotA*. Both were modifications, which created new games over the original material, and have became as famous as the original game. At first, video game developers were reluctant and objected the modifications, which were done by the players, due to the nature of video games as software that are licensed to users. But some more independent developers, like ID Software and Valve, encourage players to modify their game contents by providing the players tools for editing. Some of these modding could help developers by providing features that previously not included in the original release. It produces cooperation between the producers and the players, and lately it is being seen as a standard business practice for some developers [4]. In most cases, a modder with adequate technical background could find a way to alter, even if they are not given the tools. The modder often uses this act of modification to gain some experiences in developing a video game before actually involved in video game industry.

### 3. METHOD

This research gathers primary data, taken from visual artworks, records, and online interviews with players from modding communities. These data are analyzed qualitatively using the guidance of the Dovey and Newman's descriptive interpretation approach for Production - Consumer Model. There are some difficulties in gathering data from modding communities, one of it come from the nature of modification activities that sometimes considered as hobby or personal activity. As a result most modification process have unorganized documentation. However, the data gathered from interview and visual artworks captured from the modification video game are adequate to give some information on the creativity process and reasons beneath modification.

### 4. DISCUSSION

Although modding is still in its infancy stage of Indonesia's video games development, there are cases of video game modding that can be used as research objects. One of them is the "Battle of Soerabaja 1945". It is a modification from Close Combat: Invasion Normandy video game that was produced by Atomic Combat. It is a war strategy game which placing the player as the general who lead and command the soldiers to achieve victory in war. [5] Like most war strategy games, Close Combat: Invasion Normandy uses historical event as the background. Thus some elements in the game were created using historical data. The modder uses the same approach for the Battle of Soerabaja 1945. The modder alter the original game data especially the visual artwork of Close Combat game; in order to create visual that closely resemble Battle of Surabaya 1945.

This research uses online interviews, In the interviews the modders being asked about the creative processes they went through and their motives for the modifications of the Battle of Soerabaja 1945. The result shows that the motives behind the modification are to spread and communicate nationalism amongst Indonesian youth through video game. This is a very interesting finding because the modders are independent individuals, not being supported financially or mentally by any government agency. They propagandate nationalism on their own will, which match with model number 2 of modification motive. The game also match with another model of modification, model number 3, where the motive of that model is to convert or to extend the original game that was based on Allied versus Axis on World War II in Normandy France into the Battle of Soerabaja 1945, because it is one of the important battles in the history of Indonesian Independence War. The modders: Dicky Octavia, Gregorius Satia Budhi, and Yusuf T, gathered some historical data from the real event of Battle of Soerabaja for the game [6]. These data consist of: the regiment from the both side, Indonesia and Allied (British Occupation Army) that were involved in the war, their whereabouts during battle, and other relevant data. These data were translated into visual artworks in forms of: uniform, insignia, weaponry, voice, sound, leader, and so on. Some of the contents were fictional, since there were difficulties in finding documented historical data. Some were taken from a movie on the Battle of Soerabaja that was produced in 1990, such as the voice and the sound. The motive for using the voice and sound from the movie for the modification was to enhance the dramatic effects on the players being in the war. Other data, such as regiment insignia and uniform colors, were elaborated from partial historical data. The modders had to recreate them because the original photographs and movie footages from the war period were black and white, and they did not have high quality details. For these efforts, the modders and their modification had gained national media coverage in some news paper and magazine [7].

Figure 1 : Screen Shot of Battle of Soerabaja 1945 video game

Other example of video game modification can also be seen in Indonesia Driving Simulator (IDS). IDS is a video game that modded from the United Kingdom Truck Simulator video game, produced by SCS software. The original game places the player as a driver of big vehicle who have to transport cargo from one city to another city within United Kingdom. A group of Indonesian modders modified this game into the Indonesia Driving Simulator. Similar to the Battle of Surabaya 1945, Indonesia Driving Simulator modification also uses alteration of the data inside the video game. The vehicles were altered into various big local vehicles that were common in Indonesia traffics, such as a truck from national oil company or a bus from local bus company. The modder also alter the environment and map inside the game.

Using similar method like being done for Battle of Surabaya 1945 interviews, the finding for this modification is taken from online interviews and records from the IDS modder community. The community using Indonesian largest forum: Kaskus (kaskus.co.id), for communicating and publish their newest modding. Through these data, it is found that the motives to modify also match modification model 3, which is to convert or extend the original material. The modders want the content of the video game to have local visual look. The modders in this model admit their reasons for doing this alteration are to gain some experiences before they go to the full game development industry as well extend the usability of original game. The most interesting part is that the company for the vehicle and the restaurant that are being used in the alteration and were actually contacted the modder and offered them sponsorship as long as the modder add the 3D model of the vehicle or company building inside the game.

Figure 2 : Screen Shot of Indonesia Driving Simulator video game

## 5. CONCLUSION

From discussion above we can see that the modification content of video game already accepted in video game community as a creative way of producer and consumer model involvement to add value to the content of video game. Although the producer may not provide modification tool to facilitate the user for altering game data, if the user have enough technical skill they still can do the modification. Most modification that has big impact on video game community usually has significant alteration of its content. Either by altering the visual look or extending the level or map so the player can have new experience of playing previous version of the video game title. The video game modifications in Indonesia happen because player-who later become modder-need to add local content that previously not exist in original version of video game. The modification also serve the need to exercise programming skill (hacking) that later could be applied in the real game development business. The popularity of modification also not necessarily depend on the quality of visual artwork, even when the modification can not keep up with current standard of visual technology the game it self can still have wide acceptance. Of course not all of modification of content bring positive side effect there are also negative side effect. One of the example can be seen in the message of nationalism in Battle of Surabaya that being spread, it lacks historical accuracies and fall into cheap propaganda where Indonesia nationalism can only be achieved through war effort. There are also the consequences that the game being modified bring generic visual look in the perception of gamer due to the minimal effort of modder who are not willing to start from scratch when modifying the content. Other problem that can be add into this conclusion related with copyright issue not all of developer allowed user to modifying their game but usually this problem arise when there is a clear copyright violation or the game mods got popular without original developer involvement.

The discussion above shows that the modification of the content of the video games has been accepted in the video game community as a creative way from the players' part to add value to the content of the game; this is seen as the producer and consumer model of involvement. Even though the producer did not provide any modification tool, the modders can alter the games nevertheless, provided they have enough technical skills. Most modifications alter the game's content and this gives big impacts on the video game communities and the game popularity as well. The alteration can be done by either altering the visual look or extending the level or map so that the players renew their experiences. In Indonesia, the modders serve the need to add local contents that did not exist in the original version. They also use modification as exercise of programming skill by hacking the games. Later on, the modders may use their experiences to enter the actual game development industry. Modification of video games does not necessarily relying on high quality visual artwork. A modification can still be widely accepted even if the modification doesn't meet the standard of visual technology. There are some weaknesses, flaws or problems in a modification. In the Battle of Soerabaja 1945, the message of nationalism can be seen as cheap propaganda, due to the lack of historical accuracies. In other modifications, the altered version were so similar to the original ones because the modders only put minimal efforts and did not want to start from basic when modifying the content.
