From table 3, it is known that the usability level for three categories, which are content, organization and readability; navigation and links; as well as performance and effectiveness are moderate with each usability point respectively are 0.60, 0.59, and 0.58. Meanwhile the usability level for user interface category is good (0.64). For content, organization and readability category, the usability criteria that has the lowest point is "I can easily find what I want in this website" (0.55). The lowest usability point for navigation and links category is for "Placement of links or menu is standard throughout the website and I can easily recognize them" (0.48). For user interface category, the lowest usability point is 0.52 for criteria: "This website's interface design is attractive." For the last category, performance and effectiveness, the criteria that has the lowest

point is “This website always provides clear and useful messages when I don’t know how to proceed.” Based on the above result, none of the four categories have excellent usability level (usability point > 0.8). Therefore improvement is needed to increase the usability point for each category.

### 3.2 Analysis of experiment’s result

Based on the result of WEBUSE questionnaire, 6 tasks are developed to be included in the experiment. All tasks represent the functions which are often used by student when they access the library website. The six tasks are as follows:

1. Find out the information regarding the operational time of the UPH Central Library.  
(Category: navigation and links; criteria: “This website provides useful cues and links for me to get the desired information”)
2. Download an article that has been determined from a specified journal.  
(Category: performance and effectiveness; criteria: ”This website responds to my actions as expected.”)
3. Search for the information regarding the number of room types provided in the library, then go back to the front page and find out the title of book of the month.  
(Category: navigation and links; criteria:” I can easily know where I am at this website.”)
4. Search for and record the status of a book, including call number, published year, and loan status.  
(Category: performance and effectiveness; criteria:” This website always provides clear and useful messages when I don’t know how to proceed.”)
5. Find out the information regarding the total amount of borrowed books and loan duration for undergraduate student  
(Category: content, organization and readability; criteria:” Reading content at this website is easy.”)
6. Search for the main steps required to top-up smart card in order to pay the loan penalty  
(Category: content, organization, and readability; criteria:” I can easily find what I want at this website.”)

The time allocated for completing each task is 3 minutes, based on the previous experiment conducted by Augustine and Greene [5].

In this experiment, there are 3 parameters to be measured, which are the number of task correctly done, time of completion, and the number of clicks needed. According to Nielsen [6], usability test with at least 15 users is needed to discover all the usability problems in the design. The chosen respondents are 20 undergraduate students (5<sup>th</sup> and 7<sup>th</sup> semester) from Industrial Engineering Department. The completion time is measured in second. The number of clicks is observed through CamStudio software.

Based on ISO 9241-11:1998 [7], there are three aspects to be measured in usability testing, which are: effectiveness, efficiency, and satisfaction. In this experiments two aspects are chosen, which are: effectiveness and efficiency.

#### 3.2.1 Effectiveness aspect

In this experiment, effectiveness is measured by giving score for each correct answer (accuracy and completeness). The maximum score for all six tasks is 100, so each correctly answered task is given 16.67 point. From all of the respondents, none has got 100 points. The minimum score is 16.67 (only 1 correct answer) and the maximum score is 83.33. The average score is 51.67 with standard deviation of 17.85. This result shows that the effectiveness of UPH library website is quite low. The number of respondents (in percent) who have completed the task correctly is shown in table 4.

*Table 4: The number of respondents (%) who have completed the task correctly*

Task no.	% respondents that answer correctly
1	95%
2	25%
3	60%
4	30%
5	85%
6	15%

From table 4, it is known that three tasks (number 6, 2 and 4) have very low percentage of correct answers. Based on the observation during the experiment, there are some usability problems faced by the respondents when they tried to do those tasks, as follows:

1. For task number 6 (how to top-up smart card):
  - The location of information regarding top-up smart card is on the bottom side of the home page.
  - The term used in the library website is “cash-card”, whereas students are more familiar with the term “smart-card”
  - Search engine is not functioning well.
2. For task number 2 (download a journal article):
  - There are two sub-menus under the menu “resources”, which are: e-resources and periodicals. E-Resources consist of digital library, online database (for e-journal) and recommended links. Meanwhile the sub-menu periodicals consist of journal (for local and UPH published journal only) and magazine. The term “journal” used only for local and UPH published journal lead to ambiguity.

- The usage of patron barcode as login password to access e-journal. Students are not familiar with their own patron barcodes and the option for getting the password through phone is not practical (see figure 1).

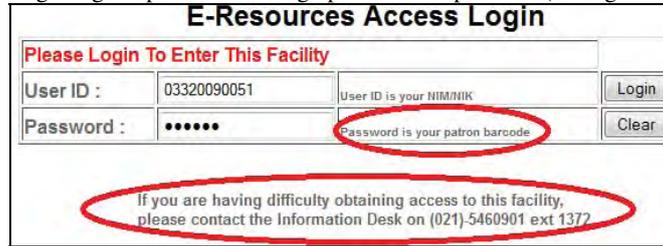

Figure 1: E-Resources Access Login

3. For task number 3 (record for the status of a book):

- Menu “search” at the top right corner of the home page is not functioning.
- The keyword used for searching menu UPH catalog is less sensitive. For example: if the student types the first word of the book title “Goldratt’s”, the result is “sorry no match found.” The result will be different if he types” Goldratt” as the keyword for title.
- Menu “search by subject” is not functioning.

### 3.2.2 Efficiency aspect

In this experiment, efficiency is measured by recording the completion time and the number of clicks required for completing the task. The result of average time as well as expert time for completing each task correctly is shown in figure 2. Expert time is the minimum time needed by the researcher (the person who creates the task) to complete the task.

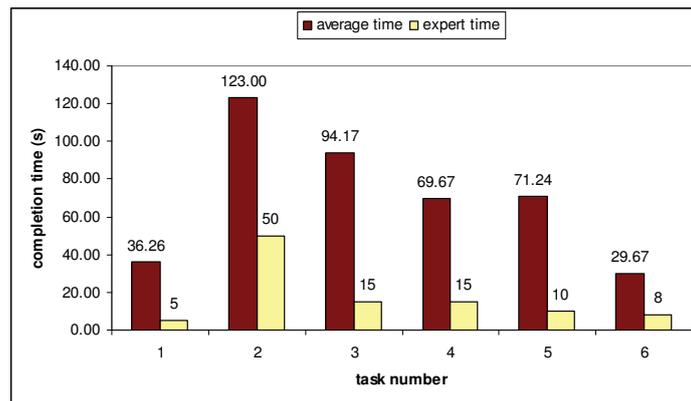

Figure 2: Completion time for each task

According to figure 2, it is known that the average completion time is significantly longer than expert time. The ratio of average time to expert time is about 5: 1. Another measurement for efficiency aspect is the number of clicks required to complete the task. The comparison between the average click and the expert click can be seen in figure 3.

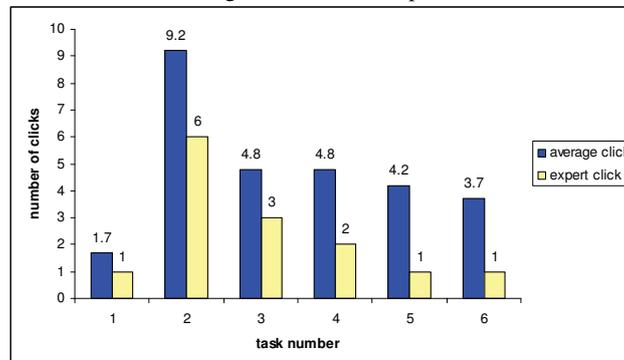

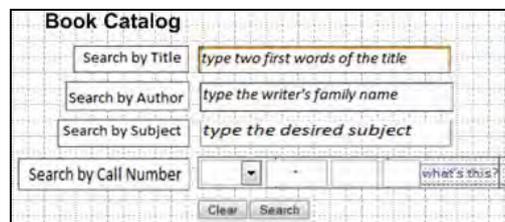

Figure 3: Number of clicks required to complete the task

Figure 3 shows that the largest amount of clicks is for completing task number 2. If figure 3 is compared with the previous one (figure 2), they will show similar trend. It means that the results are consistent. The more the number of clicks it takes, the longer the time of its completion. Based on figure 3, it is also known that there are significant differences between average click and the expert click. The average number of clicks required by the respondents to complete the task is about 2-3 times more than the expert clicks. Both results show that the UPH library website is less efficient.

### 3.3 Suggested improvements

Based on all the problems faced during the experiment, here are some suggestions for improvement:

1. Put the important information such as “how to top-up smart card” on the *navigation bar*. It is better to use more familiar term, such as “smart-card” rather than unfamiliar one (“cash-card”).
2. Make the search engine available on the library website properly functioned. Students usually try to find any information by using search engine.
3. Do not use ambiguous term, such as “journal” for local published journal only, since the published international journal is called “journal” as well. It is better to use the term “periodicals” for all paper- based journals, to differentiate them from e-journal (electronic journal).
4. If possible, use more familiar password for accessing the e-resources (such as: birth date) instead of patron barcode. If it is not possible to use another password, provide any other means for obtaining the password, for example through e-mail.
5. Add some hints to use the catalog search. An example of catalog search hints can be seen in figure 4. Besides adding hints, make sure that all the search option is functioning properly.

The image shows a search interface titled "Book Catalog". It features four search options, each with a text input field and a hint: "Search by Title" with the hint "type two first words of the title", "Search by Author" with the hint "type the writer's family name", "Search by Subject" with the hint "type the desired subject", and "Search by Call Number" with a dropdown menu and a "what's this?" link. At the bottom, there are "Clear" and "Search" buttons.

Figure 4: An example of catalog search hints

## 4. CONCLUSION

Based on the results of processing the WEBUSE questionnaires for 234 respondents, it is known that the usability level of UPH library website for category: content, organization and readability (0.60); Navigation and links (0.59); as well as Performance and Effectiveness (0.58) is moderate. For user interface category, UPH library website is assessed to have good usability level (0.640). Experiments are carried out to determine the usability problems directly, by observing 20 respondents completed six tasks using UPH library website. Based on the experimental results, it is known that the respondents are still facing difficulties to use some features available on the UPH library website. This can be known from the low effectiveness of UPH library website, since the average task score is 51.67 out of 100. The experiment results also showed that the average completion time is 5 times longer than the expert time and the average number of clicks required is 2-3 times more than the expert click. These measurements indicate that some functions in UPH library website have low efficiency. Some of the problems found are the search function that does not work, the location for important information is on the bottom side and there are some uncommon names of menus or less likely to represent the content.

## ABSTRACT

As Introduction, Brain research has reached and contributed to Engineering, and Social Sciences in term of Strategic Management. This paper limits its research discussion in term of i. Neuro Strategy, and ii. Industrial and Systems Engineering for enhancement of Human Life and Environment. Furthermore, as Problem, there is the need to balance between the Systems and the Human Consideration, specially form Neuro Strategy. Then, as methodology through Malcolm Baldrige Criteria and Strategic Choice, this paper relates the concept, theoretical aspects and managerial implications of Neuro Strategy, Industrial and Systems Engineering that refers to Malcolm Baldrige Criteria 2011-2012 toward Performance Excellence, Innovation and Sustainability Perspectives. As the Result of analysis and calculation of equations, this paper emphasize on the importance of Sustainability, and refer to the Future Research of Decision Making Implementation through Neuro Strategy. In term of Neuro Strategy, Powel, T.C (2011) in his paper examines the potential fit pertaining between Neuro Strategy in term of Neuroscience and Strategic Management. Both executive judgment and decision making are indispensable to i. Proceed to Performance Excellence, Innovation and Sustainability; ii. Revisit Psychological foundations of dynamic capabilities, Hodgkinson and Healey (2011), iii. Elaborate Unit of Analysis according to Rumelt, Schendel, and Teece, 1994 as scholars in term of the question in strategic management whether processes within the individual brain can really inform research that take the firm and industry as its primary unity of analysis. In term of Systems Engineering, the paper of Smartt and Ferreira (2011) indicated that The strategic application of systems engineering can lead to sustained competitive advantage for an organization.

### Keywords

*Neuro Strategy, Industrial and Systems Engineering, Malcolm Baldrige, Performance Excellence*

### 1. INTRODUCTION

The philosophy of Strategy can be related to the Brain Research. Furthermore, it is indispensable to relate Psychological Foundations of Strategic Management toward the mentioned Brain Research. Brain research has reached and contributed to Engineering, and Social Sciences in term of Strategic Management. This paper limits its research discussion in term of i. Neuro Strategy, and ii. Industrial and Systems Engineering for enhancement of Human Life and Environment. This paper relates the concept, theoretical aspects and managerial implications of Neuro Strategy (NS), Industrial and Systems Engineering (ISyE) that eventually refers to Malcolm Baldrige Criteria 2011-2012 (MBC 2011-2012) toward Performance Excellence (PE), Innovation (INNO) and Sustainability (SUST) Perspectives, that is abbreviated as Performance-Innovation-Sustainability (PIS).

NS and ISyE constitutes the building block for MBC and its PIS. First, In term of NS, Other than MBC and its PIS, The highlighted discussion refers to the Decision Making and Approximate Decision Programming to make better Decision Making, according to Powell, W. B. (2009, p.239) as relate to available approaches using Operations Research solving the a. Simulation Optimization, b. Rolling Horizon Procedures, and c. Dynamic programming. The focus on this paper pertaining the Decision Making and Approximate Decision Programming (ADP). In term of Dynamic Programming, the equation (1) refers to the Markov Decision Processes using standard form of Bellman's Equation of

$$V_t(S_t) = \max_{x_t} \left( C(S_t, x_t) + \gamma \sum_{s' \in S} p(s'|S_t, x_t) V_{t+1}(s') \right) \quad (1)$$

and Equation (2) of its expectation form of Bellman's Equation of

$$V_t(s) = \max_{x_t} (C(S_t, x_t) + \gamma \mathbb{E}\{V_{t+1}(S_{t+1}) | S_t = s\}) \quad (2)$$

, where where  $S_{t+1} = SM(S_t, x_t, W_{t+1})$ , and the expectation is over the random variable  $W_{t+1}$ .  $V_t(S_t)$  is the value function (in control theory this is represented by  $J$  and is called the cost-to-go function) which gives the expected value of being in state  $S_t$  at time  $t$  and following an optimal policy forward, according to Powell, W.B (2009, p. 240). Second, In term of ISyE, Other than MBC and its PIS, The highlighted discussion refers to discussion of Industrial and Systems Engineering and Its Analysis by Blanchard and Fabrycky (2011) and General Framework for Systems Engineering Strategy by Smartt and Ferreira (2011).

## 2. LITERATURE REVIEW

### Neuro Strategy

In term of Neuro Strategy, Powell, T.C (2011) in his paper examines the potential fit pertaining between Neuro Strategy in term of Neuroscience and Strategic Management. The mentioned Strategy Management is about the strategic management interest in executive judgment and decision making and in the psychological foundations of strategy practice according to Hodgkinson and Healey (2011). Both executive judgment and decision making are indispensable to i. Proceed to Performance Excellence, Innovation and Sustainability; ii. Revisit Psychological foundations of dynamic capabilities, Hodgkinson and Healey (2011), iii. Elaborate Unit of Analysis according to Rumelt, Schendel, and Teece, 1994 as scholars in term of the question in strategic management whether processes within the individual brain can really inform research that take the firm and industry as its primary unity of analysis.

### Industrial and Systems Engineering

In term of Systems Engineering, the paper of Smartt(2011) indicated that The strategic application of systems engineering can lead to sustained competitive advantage for an organization. Furthermore Smartt and Ferreira (2011) refers to the framework that defines a state-based model for systems engineering strategy. States are grouped by organization, environment, product or service, and systems engineering process characteristics. These characteristics provide an extensive set of considerations for making a strategic decision related to systems engineering. Smartt and Ferreira (2011) explicitly mentions that decision makers are able to apply the framework to make more informed choices that ultimately will lead to an organization's long-term survival, which is known in this paper as Sustainability.

## 3. METHODOLOGY

Several steps of the Methodology in this paper comprises the 1. Clarifying the Research Questions; 2. Research Design Strategy ( Data Collection Design and Sampling Design); 3. Data Analysis and Interpretation, 4. Research Findings and 5. Decision. Methodology and Discussion through several steps in this paper emphasize on generalized concept and scope of the problem, this paper has research questions toward the Antecedent, Behavior and Consequences of all discussion about Neuro Strategy, Industrial and Systems Engineering, Performance Excellence, Innovation and Sustainability. As scope of objectives, this Methodology and Discussion in this paper emphasize on generalized concept of Neuro Strategy, Industrial and Systems Engineering to support the Malcolm Baldrige Criteria 2011-2012 to reach the goals. The mentioned goals refer to the Performance Excellence, Innovation and Sustainability Perspectives of its unit of analysis. In this paper, Confirmatory Factor Analysis (CFA) was utilized to investigate constructs' reliability and validity, while Structural Equation Modeling (SEM) were utilize to examine relationship among constructs that relate the effect of Neuro Strategy, Industrial and Systems Engineering. Second, the mentioned effect refers to the Malcolm Baldrige Criteria toward Performance, Innovation and Sustainability.

## 4. DISCUSSION AND ANALYSIS

### Neuro Strategy

In term of Neuro Strategy, Powell, T.C (2011) in his paper examines the potential fit pertaining between Neuro Strategy in term of Neuroscience and Strategic Management. The mentioned Strategy Management is about the strategic management interest in executive judgment and decision making and in the psychological foundations of strategy practice according to Hodgkinson and Healey (2011). Brain research has reached and contributed to Engineering, and Social Sciences in term of Strategic Management. It is indispensable to relate Psychological Foundations of Strategic Management toward the mentioned Brain Research and the following Dynamic Capabilities in Table 1.

### Industrial and Systems Engineering

In term of Systems Engineering, the paper of Smartt and Ferreira (2011) indicated that The strategic application of systems engineering can lead to sustained competitive advantage for an organization. In Figure 1, Smartt and Ferreira (2011) refers to the framework that defines a state-based model for systems engineering strategy. Subsequently, various references enriched the mentioned Smartt's Framework in Table2, pertaining the Systems Engineering Process Characteristics.

Table 1: Psychological Foundations of Dynamic Capabilities Revisited

Capability	Extant psychological foundations	Indicative supporting literature(s)†	Revised psychological foundations	Indicative supporting literature(s)
<b>Sensing and shaping</b>	Opportunity discovery and creation originate from the cognitive and creative ('right brain') capacities of individuals, requiring access to information and the ability to recognize, sense, and shape developments	Entrepreneurship literature; organizational search (e.g., March and Simon, 1958; Nelson and Winter, 1982)	Identifying and creating opportunities through searching, synthesizing, and filtering information stems from the interaction between reflexive (e.g., intuition, implicit association) and reflective (e.g., explicit reasoning) cognitive and emotional capabilities	Social cognitive neuroscience research on the interaction between reflexive and reflective systems (Lieberman, 2007)
	Recognizing, scanning, and shaping depend on individuals' cognitive capabilities and extant knowledge	Knowledge-based view of the firm (e.g., Grant, 1996); organizational learning (e.g., Levinthal and March, 1993)	Recognizing, scanning, and shaping depend on the capability to harness emotion to update mental representations (e.g., dissonance recognition) and skilled utilization of intuitive processes to synthesize information and form expert judgments	Cognition and capabilities literature (Gavetti, 2005); affective processes in learning (Lieberman, 2000)
<b>Seizing</b>	Seizing innovative investment choices requires managers to override 'dysfunctions of decision making'	Classical behavioral decision theory (e.g., Kahneman and Tversky, 1979)	Seizing opportunities requires the fostering of appropriate emotional reactions to new directions	Neuroeconomics: immediate emotions shape choice (Loewenstein <i>et al.</i> , 2008)
	Overcoming biases requires a cognitively sophisticated and disciplined approach to decision making	Classical behavioral decision theory (e.g., Kahneman and Tversky, 1979)	Cognitively effortful processes can exacerbate bias—alleviating bias and inertia requires both cognitive and emotional capabilities	Self-regulation (e.g., Ochsner <i>et al.</i> , 2002) and affective routes to de-escalation of commitment (e.g., Sivanathan <i>et al.</i> , 2008)
<b>Reconfiguring</b>	Top management ability to coordinate and execute strategic renewal and corporate change	Organizational structure and design and strategy and performance literatures (e.g., Bartlett and Ghoshal, 1993; Chandler, 1962)	Reconfiguration requires management of the transition and repeated redefinition of social identities by alleviating implicit bias and self-regulating emotional responses to identity threats caused by major change	Research on the neural basis of self and social identity processes (e.g., Derks <i>et al.</i> , 2008)

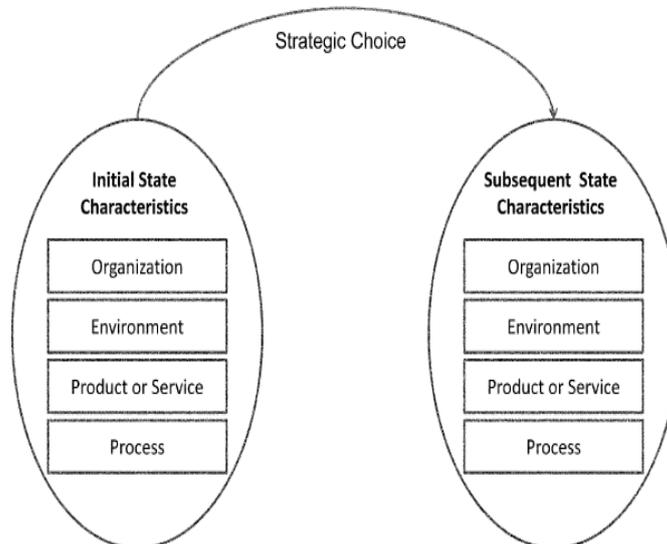

Figure 1: Overview of Framework for Systems Engineering Strategy

Table 2: Systems Engineering Process Characteristic

Characteristic	Definition	Sources
Level of quantification in control	The degree to which quantitative schemes are employed to monitor performance and exert control over a particular systems engineering process.	[Boehm and Turner, 2004]
Level of documentation generated	Overall level of documentation generated related to a specific systems engineering process.	[Agile Manifesto, 2001]
Portion of process completed	Portion of a specific systems engineering process completed before subsequent processes can begin. For example, how much of the architecture definition must be completed before developers begin writing software or creating hardware?	[Boehm and Turner, 2004]
Maturity of process	The maturity of a particular process that is being applied.	
Level of usage of information technology	Degree to which an organization utilizes information technology (databases, formal requirements management tools, formal system architecture tools, etc.) in support of a specific systems engineering process in engineering a system or service.	[Hansen et al., 1999]
Formalization of policies and procedures	Degree to which policies and procedures are formalized for a specific systems engineering process within the organization.	[Lai and Guynes, 1997]

**Malcolm Baldrige and Performance Excellence**

Generalized concepts of Malcolm Baldrige and its seven criteria, in Figure 2, are referring to three pillars in Business, Health Care and Higher Education. Furthermore, posterior to the mentioned generalized concept, specifically the result of this paper conveys discussion on the Malcolm Baldrige Criteria for Business that generates beneficial aspects for theoretical development and managerial implication in Indonesia. Data collection pertaining Company’s Malcolm Baldrige Criteria and its Performance Excellence, is conducted using both Primary and Secondary Method. For Primary Method, the interview process is conducted, along with the survey that relate to the Management of The Company. For Secondary Method, the analysis is referring to the Annual Report from the listed company in Jakarta Stock Exchange ( www.idx.co.id ). Other information is originated from the Indonesian Quality Award Foundation ( IQA ) www.indonesianqualityaward.org that since 2006 has conducted and provided the Indonesian Quality Award.

Figure 2: Malcolm Baldrige 2011 – 2012 Criteria

**Innovation and Sustainability Perspectives**

Prahalad, Nidumolu and Rangaswami (2009) raise question and discuss why sustainability is now the key driver of innovation.

The same question and discussion constitute the ground for this paper, incorporating the Innovation and Sustainability, with the holistic discussion of NS and ISyE toward MBC and its PIS. The further focus of discussion refers to Decision Making and Approximate Dynamic Programming.

### Decision Making and Approximate Dynamic Programming

Decision making constitutes important elements in the discussion of this paper, as previously the discussion refers to NS and ISyE that are related to the MBC and its PIS. Precisely, in term of Strategic Choice in Figure 1, as refer to the Innovation and Sustainability. In term of that Strategic Choice; It is deemed indispensable to be aware of the Initial State Characteristics prior to move forward to Subsequent State Characteristics that require careful assessment in term of Decision Making and its Systems Engineering Process Characteristics, as illustrated in Table 2. Malcolm Baldrige and Performance Excellence are deemed as holistic approach as this MB and PE, not only refer to the Results but also refer and carefully assess the Process that lead to the intended Results. The state does not stop to any result, but also proceed subsequent level that lead to the Innovation and Sustainability.

Prior Equations (1) and (2) respectively constitute the baseline for further discussion on the Decision Making. The first equation refers the Markov Decision Processes using standard form of Bellman's Equation and the latter equation refers expectation form of Bellman's Equation. Both Equations are beneficial to tackle Decision Making that involves Uncertainty. Powell, W.B (2009, p. 239) indicates that there is a wide range of problems that involve making decisions over time, usually in the presence of different forms of Uncertainty. By Analogy in operations research, the consideration is that system as being in a state  $S_t$ , from which take an action  $x_t$  and observation of new information  $W_{t+1}$  lead to a new state  $S_{t+1}$ . The Policy Representation for making a decision is using the function  $X^\pi(S_t)$ . The assumption is that there is a transition function  $S^M$ , known as the "system model" or merely "model" which describes how a system evolves from  $S_t$  to  $S_{t+1}$ . Powell, W.B (2009, p. 239) mentioned that The dynamics of problem can then be described using

$$x_t = X^\pi(S_t), \tag{3}$$

$$S_{t+1} = S^M(S_t, x_t, W_{t+1}). \tag{4}$$

Powell, W.B (2009, p. 239) assumes that there is a choice of decision functions  $X^\pi$  where  $\pi \in \Pi$  designates a particular function or policy and use decision function and policy interchangeably. Posterior to making a decision  $x_t$ , it is assumed cost is given by  $C(S_t, x_t)$  which usually depends on the state. Several contribution about  $W_{t+1}$ , in which case it would be written  $C(S_t, x_t, W_{t+1})$ . The ultimate goal is to find the best policy  $\pi \in \Pi$  that solves

$$\sup_{\pi \in \Pi} \mathbb{E} \sum_{t=0}^T \gamma^t C(S_t, x_t) \tag{5}$$

where  $\gamma$  is a discount factor. The form of an expectation is needed, because the information variable  $W_t$  is random, at times before time  $t$ .

Further elaboration in term of theoretical approach and managerial implication on Decision Making pertaining Approximate Dynamic Programming (ADP) approximate dynamic programming (ADP). Powell, W.B (2009, p. 240) refer to the available references in form of book that are represented by three dedicated topics. First, *Neuro-Dynamic Programming* is a primarily theoretical treatment of the field using the language of control theory; Second, *Reinforcement Learning* describes the field from the perspective of artificial intelligence/computer science; and Third, *Approximate Dynamic Programming* uses the language of operations research, emphasizing on the high dimensional problems that typically characterize the problems in this community. Judd (1989) provides a nice discussion of approximations for continuous dynamic programming problems that arise in economics, and Haykin is an in-depth treatment of neural networks, with a chapter devoted to their use in dynamic programming.

### 5. CONCLUSION

The philosophy of Strategy can be related to the Brain Research. Furthermore, it is indispensable to relate Psychological Foundations of Strategic Management toward the mentioned Brain Research. Brain research has reached and contributed to Engineering, and Social Sciences in term of Strategic Management. This paper limits its research discussion in term of i. Neuro

Strategy, and ii. Industrial and Systems Engineering for enhancement of Human Life and Environment. This paper relates the concept, theoretical aspects and managerial implications of Neuro Strategy (NS), Industrial and Systems Engineering (ISyE) that eventually refers to Malcolm Baldrige Criteria 2011-2012 (MBC 2011-2012) toward Performance Excellence (PE), Innovation (INNO) and Sustainability (SUST) Perspectives, that is abbreviated as Performance-Innovation-Sustainability (PIS).

In term of NS and ISyE, further discussion pertaining Decision Making need to be elaborated toward Decision Making Uncertainty and Decision Making Biases. The first, has been discussed by Powell, W.B (2009, p. 239) as relate to the Approximate Dynamic Programming. The latter, has been discussed by Smith and Bahill (2009, p. 130 ) pertaining attributes substitution in Systems Engineering. Furthermore Smith and Bahill (2009, p. 130) mentioned that Cognitive biases affect decision making in systems engineering (SE). Daniel Kahneman, 2002 Nobel laureate for his pioneering studies of cognitive biases in economic decision making, describes many disparate cognitive biases as abstractly belonging to one higher-level bias, that of attribute substitution.

Other than NS and ISyE, as relate to PIS and other than Decision Making Uncertainty and Decision Making Biases; it is indispensable to highlight the discussion on Sustainability. According to Smith and Bahill (2009, p. 136) Sustainability refers to the potential for a system to be supported materially and technologically over an extended period of time. Yet, in this paper the Sustainability need to be viewed in wider thinking, across the Systems Engineering and include all aspects of Cognitive Thinking in NS and ISyE that relate to Strategic Management.

As Future Research, Prior to have Sustainability, It is indispensable to consider the Decision Making Implementation. Not many existed paper discussed this Implementation, along with the NS and ISyE that relate to PIS and eventually Strategic Management. Thus, It is indispensable to elaborate in more thorough discussion and consideration this aspect of Implementation. Yet, it is important to differentiate the implementation in Neuroscience in experiments versus in firms, according to Powell, T.C (2011, p.1498). Precisely, Powell indicated that In Neuroscience experiments, the choices are often difficult, but implementation is trivial; In firms, implementation is usually more difficult than decision making, requiring motivation, resource mobilization, and major project implementation. Strategic decisions are often implemented partially, unsuccessfully, or not at all.

### ABSTRACT

*Ergonomics interest is more focuses on the human quality of life; therefore, it is very important to apply it in any kind activities, included in production process. But unfortunately, industries put on ergonomics mostly for product design or the product user only and forgot about the designer or the workers during the engineering design and construction processes. The main objective of this paper is to define how important is comprehensive ergonomics for all workers during engineering design and construction process. The proposed framework and data processing approach comprised of three major stages: 1) literature gathering and screening (textbooks, articles-journals, and the previous researches), 2) data analyzing, and 3) writing the literature review by providing an arguments. Data analyzing divided into four main aspects: a) workers characters (age, gender, and fitness), b) task (work load, man-machine interaction, and work station), c) physical environment (microclimate, noise, dust, vibrator, and lighting), and d) organization (work-rest schedule, nutrition, and information system), both for design and construction process. Result showed that for engineering design process, the ergonomics problems are mostly about work station especially human computer interface, lighting, work-rest schedule, nutrition, and working behavior. Furthermore, the most problem for construction process are physical work load, man-machine interaction, working posture, physical environment (heat stress, noise, vibrator, and dust), and work-rest schedule. This paper provides the basic ergonomics concept that should be considered in design and construction processes to protect the workers from ergonomics hazards, especially in the developing countries where ergonomics has not well known yet, such as Indonesia. It is also emphasize that applying ergonomics could provide safety, healthy, comfort, efficient and productive work condition that finally increase the welfare and quality of life, both for the workers and management.*

Keywords: *Comprehensive ergonomics, design, construction, processes.*

### 1. INTRODUCTION

Nowadays, Industry becomes the most important sector of economy in the world. Many strategic plans were obtain and all efforts were focused to support this sector. High technology has been imported and applied to meets it goal, but unfortunately, the consideration in building the program, including the system, mostly about economics and technology only, and less consideration about human factors or ergonomics point of view, especially in developing countries such as Indonesia. However, it has become more and more popular. Many products have been designed with ergonomics consideration, but industries put on ergonomics mostly for product design or the product user only and forgot about the designer or the workers during the design and construction processes.

Ergonomics (or human factors) is the scientific discipline concerned with the understanding of the interactions among humans and other elements of a system, and the profession that applies theoretical principles, data and methods to design in order to optimize human well being and overall system [1]. It means that ergonomics interest is more focuses on all aspect of human activities. Furthermore, Marras and Allread [2] reported that application of ergonomics in an occupational environment can have a positive impact on the safety and health experience of the facility, the production process, as well as the quality of the product or process engaged in. Therefore, it is very important to apply ergonomics in any kind activities, included in

engineering design and production processes. The main objective of this paper is to define how important is comprehensive ergonomics for all workers during engineering design and construction process.

## **2. THEORETICAL BACKGROUND**

### **2.1 Domain of Ergonomics**

The International Ergonomics Association (IEA) council describes the domain of ergonomics including physical, cognitive, and organization ergonomics [1].

#### **2.1.1 Physical Ergonomics**

Physical ergonomics is concerned with human anatomical, anthropometric, physiological and biomechanical characteristics as they relate to physical activity. The relevant topics include working postures, materials handling, repetitive movements, work-related musculoskeletal disorders, workplace lay out, safety and health.

#### **2.1.2 Cognitive Ergonomics**

Cognitive ergonomics is concerned with mental processes, such as perception, memory, reasoning, and motor response, as they affect interactions among humans and other elements of a system. The relevant topics include mental workload, decision-making, skilled performance, human-computer interaction, human reliability, work stress and training as these may relate to human-system design.

#### **2.1.3 Organizational Ergonomics**

Organizational ergonomics is concerned with the optimization of socio-technical systems, including their organizational structures, policies, and processes. The relevant topics include communication, crew resource management, and work-design, design of working times, teamwork, participatory design, community ergonomics, cooperative work, new work paradigms, organizational culture, virtual organizations, tele work, and quality management.

### **2.2 Total Ergonomics Approach**

Total Ergonomics approach which is consists of SHIP approach (Systemic, Holistic, Interdisciplinary, and Participatory) and applies appropriate technology promotes the whole disciplines, opens participation, respects and gathers the new technology systematically and holistically with long-term gains and sustainable development [3][4]. A Systemic means that the plan should be analyzed through a system. Holistic means that every team works always interrelates with other team works, so it is analyzed through existence system and non- system holistically. Interdisciplinary means that analyzes should be utilized with all related and significant disciplines as tools; Participatory means that all relevant and significant parties take apart on it [5] [6]. The main goal of total ergonomics approach is to attain human and sustainable work system [7] [8].

There are four aspects that should be considered in ergonomics observation, evaluation, and problem analyses: 1) subject characters, including age, gender, fitness, and experience; 2) Task, including work load, man-machine interaction, and work station; 3) physical environment, including microclimate, noise, dust, vibrator, and lighting; and 4) organization, including work-rest schedule, nutrition, and information system.

### **2.3 Engineering Design and Construction Process**

It is important to recognize the close relationship between design and construction as an integrated system. Design is a process of creating the description of a new facility, usually represented by detailed plans and specifications, while construction is a process of identifying activities and resources required to make the design a physical reality or the implementation of a design envisioned by architects and engineers. Ertas and Jones describe the engineering design process as a multi-step process including the research, conceptualization, feasibility assessment, establishing design requirements, preliminary design, detailed design, production planning and tool design, and finally production [9].

Based on the theoretical background, the design and construction processes could be described as Figure 2. For engineering design process which is consist of basic concept, two and three dimension visualizes, the ergonomics consideration is more focuses on cognitive and organizational, while for construction process, it is more focuses on physical and organizational process. In engineering design process, the ergonomics problems are mostly about mental workload, decision-making, skilled performance, human-computer interaction, human reliability, work stress and training as these may relate to human-system design. Furthermore, the most problem for construction process are working postures, materials handling, repetitive movements, physical workload, work-related musculoskeletal disorders, workplace lay out, safety and health.

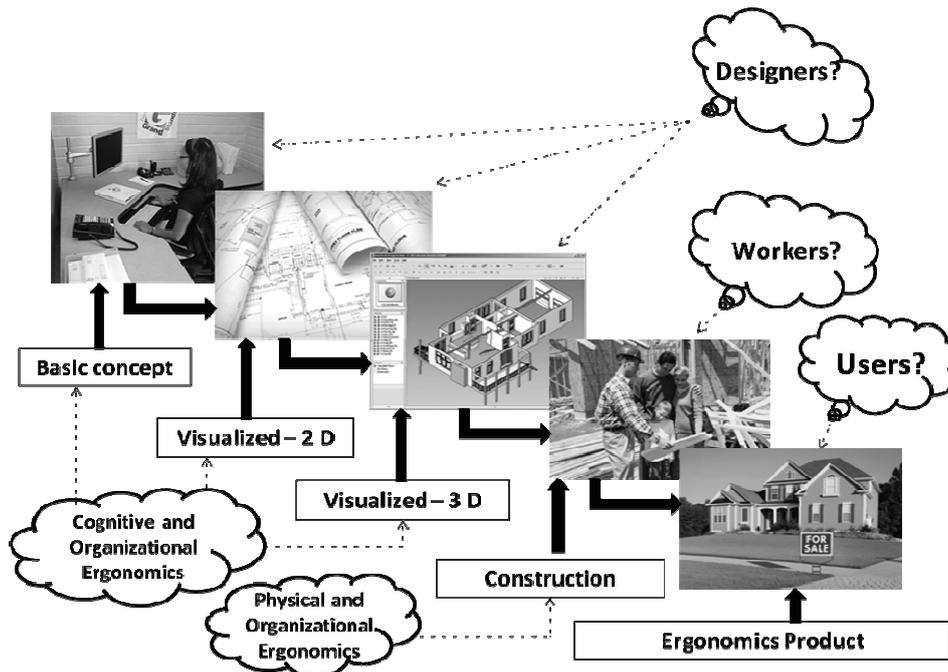

Figure 1: Ergonomics Focuses on Engineering Design and Construction Processes

### 3. RESEARCH METHOD

This paper is literature study with framework and data processing approach comprised of three major stages: 1) literature gathering and screening (textbooks, articles-journals, and the previous researches), 2) data analyzing, and 3) writing the literature review by providing an arguments. Data analyzing divided into four main aspects: a) workers characters (age, gender, and fitness), b) task (work load, man-machine interaction, and work station), c) physical environment (microclimate, noise, dust, vibrator, and lighting), and d) organization (work-rest schedule, nutrition, and information system), both for engineering design and construction process.

### 4. RESULT AND DISCUSSION

#### 4.1 Workers Characters

##### 4.1.1 Age

Many studies Show a positive relationship between age and physical activity, cognitive function, and productivity. Huxhold et al reported that in single and dual-task conditions, older adults showed lower postural control performance and lower cognitive performance than young adults [10]. In addition, Gelderblom reported that the pattern of the relationship of age and productivity is increase at younger age, but decrease at older ages. He also reported that the pattern of age with wages is rather different, namely rising wages with increasing age. At older ages, wages stabilize more [11]. Moreover, Avolio et al and Skirbec stated that the relative capability and productivity level increase gradually and reached the maximum value between the early 20s and the end of 30s [12] [13]. Patrick Aubert and Bruno Crépon found out that productivity increases with age until 40 to 45 and then remains stable after this age. Workers aged 40 and more are roughly 5% more productive than workers aged 35-39, while workers below 30 are 15% to 20% less productive [14]. Furthermore, Aubert dan Crepon [15] reported that the maximum productive age for physical work such as in manufacturing was 35 to 39, and 45 to 50 for services work.

Refers to the overview of age, engineering design workers which tent to do cognitive work have wider range of productive age start from 20 to the maximum productive age between 45 to 50, while the maximum age for construction processes is between 35 to 39 years old.

#### 4.1.2 Gender

Discussing about the gender differences has become not popular already, but however, there are biologically differences between male and female that influent both physical and psychological performance. There were many studies of gender and endurance performance reported by North West Runner Magazine in 2001 as follows:

- 1) The average VO<sub>2</sub>max is about 33 milliliters of oxygen per kilogram of body mass per minute for sedentary young women and around 42 ml/kg/min for sedentary young men [16].
- 2) Elite female distance runners can sometimes reach VO<sub>2</sub>max readings of 70+ ml/kg/min, whereas elite men can attain values in the 80s [17] [18]
- 3) men to be significantly more economical than women [19] [20]

Refers to the research above, men have more capacity for physical activities, however, another researches reported that women seem to score slightly better on tasks that involve cognitive task including visual memory, word and landmark recall and math calculations [21] [22]

Based on the overview of gender, women better than men in engineering design task, while men have more capacity in construction process.

#### 4.1.3 Fitness

A study commissioned by Medibank Private reported that healthy employees are nearly three times more productive than unhealthy employees; unhealthy employees take up to nine times more sick leave than their healthy colleagues; poor employee health and absenteeism is costing Australian business \$7 billion annually [20]. Another research identified higher levels of independent components of fitness may positively influence employees' productivity, job satisfaction and absenteeism [23]. Some indicators that influent the individual fitness level including body weight that performed by Body Mass Index (BMI), hemoglobin levels and blood pressure. Widiastuti reported that BMI and hemoglobin levels have significant correlation with productivity [24]. In line with this research, Wattles and Harris reported that the fitness level has strong correlation with productivity [25].

Refers to the overview of empirical studies on the workers characters (age, gender, and fitness), in designing and construction processes, it is importance to promote it as one of the consideration in designing humane and sustainable work system that meets the potencies and limitation of the workers.

## 4.2 Task

#### 4.2.1 Workload

Workload defines as the amount of work assigned to or expected from a worker in a specified time period. The level of workload is depending on the task demand. Workers mostly employ muscle power such as during construction process tend to exposure by physical workload, while workers use brain power such as in engineering design process tend to exposure by mental workload. Most people stress because of an overload at work, but some job demand too little effort also causes work stress. A very simple method to assess the workload level is by counting the heart rate during work. Heavier workload needs higher the energy requirements and the more blood flow. To attain more blood flow, the heart must produce higher output which is achieves by increasing number of heart beats per minute. Based on the variety of heart rate, the level of workload differentiate into light work (< 90 beats/minute), moderate work (90-110 beats/minute), heavy work (110-130 beats/minute), very heavy work (130-150 beats/minute), and extremely heavy work (150-170 beats/minute). Both overloaded and under loaded caused work stress. Overloaded caused early fatigue; decreases the work endurance, vigilant, and consistency. Under loaded leaves workers idle, bored and their capabilities underuse. Both over and under load finally decrease the productivity [4][26]. In engineering design process, the workload level tend to under load and lead the workers exposed to mental workload, while in the construction process, the workload level tend to heavy, even up to extremely workload that lead the workers exposed to physical workload.

#### 4.2.2 Man-machine/tools Interaction and Work Station

Ergonomics design of man-machine interaction and workstation depends on proper and comprehensive consideration of several aspect, including work task, work movements, and work activities. It must be designed based on the dimension of body size of the workers (the height, width, maximum reach limit, and the clearance). Unsuitable man-machine interaction to the body size of the workers forces awkward postures that caused overexertion, musculoskeletal complain, early fatigue, increase the workload and finally decrease the productivity [26] [27]. Some research showed that ergonomics intervention on man-machine interaction and work station increased the productivity up to 20 %, decreased the score of musculoskeletal complain and fatigue up to 15 % [28] [29] [30].

In this information technology era, the main problem for engineering designers is human-computer interface, while for the workers in construction process is human-machine/tools interface. The ergonomics aspects in human-computes interface focuses in sitting work posture, requirements of eye on the screen and hand on the keyboard. The best way to set up a computer

work station is by understanding the concept of natural body positioning. Working with the body in a neutral position reduces stress and strain on the muscles, tendons, and skeletal system and reduces the risk of developing a musculoskeletal disorders (MSDs). The following are important considerations when attempting to maintain neutral body postures while working at the computer workstation [31] [32].

- 1) Monitor should be set at a height that keep a straight neck
- 2) Hands, wrists, and forearms are straight, in-line and roughly parallel to the floor.
- 3) Head is level or bent slightly forward, forward facing, and balanced. Generally it is in-line with the torso.
- 4) Shoulders are relaxed and upper arms hang normally at the side of the body.
- 5) Elbows stay in close to the body and are bent between 90 and 120 degrees.
- 6) Feet are fully supported by the floor or a footrest may be used if the desk height is not adjustable.
- 7) Back is fully supported with appropriate lumbar support when sitting vertical or leaning back slightly.
- 8) Thighs and hips are supported by a well-padded seat and generally parallel to the floor.
- 9) Knees are about the same height as the hips with the feet slightly forward.

Sedentary sitting posture for prolonged periods is not healthy. Therefore, changing the working position frequently throughout the day is recommended. The best way avoiding the static sitting posture could be done as follows:

- 1) Make small adjustments to the chair or backrest.
- 2) Stretch the fingers, hands, arms, and torso.
- 3) Stand up and walk around for a few minutes periodically.

Following the engineering design process, the ergonomics aspect of man-machine interface in construction process is more complicated. Construction for one product uses many kinds of machine and tools, start from the very simple and manual to the high technology. Regarding to the product characters and the production system, workers should perform the task in sitting, standing, even both sitting and standing postures. Recommended sitting and standing posture perform at Fig.2 [33]

Standing posture is more tiring. Standing requires ~20% more energy than sitting. Prolonged standing at work causes the additional load and also increases the risks of varicose veins and accounts for more than one fifth of all cases of working age. So standing all day is unhealthy. The performance of many fine motor skills also is less good when people stand rather than sit. Different task needs different level working space. Precision work, such as writing or electronic assembly – 2 inches above elbow height; elbow support is needed. Light work, such as assembly-line or repetitive movement is about 2-4 inches below elbow height [34]. Standing puts greater strain on the circulatory system and on the legs and feet. Consequently, in industry we provide employees with ergonomic anti-fatigue to stand on, with anti-fatigue footwear, and with chairs to allow them to sit down during rest breaks [35].

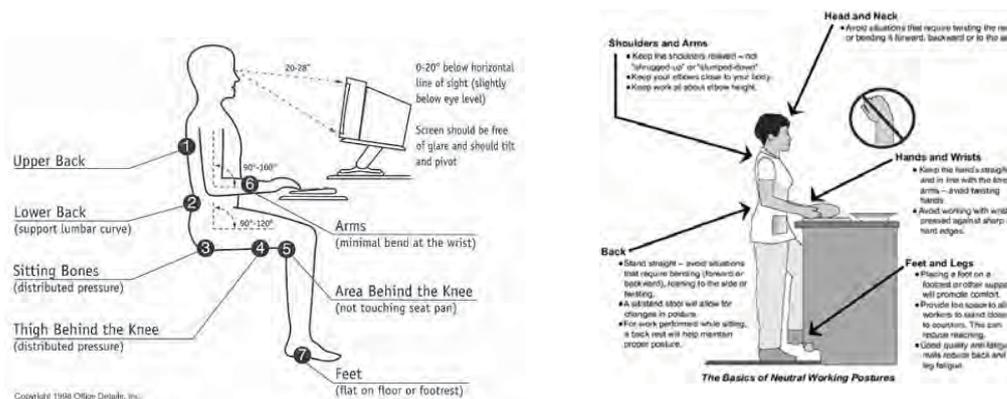

Figure 2: Recommended Sitting and Standing Posture  
 (Resource: available from [www.nismat.org](http://www.nismat.org) for share [33])

The goal of ergonomics approach on working postures is to provide the natural, safe and comfort position and organizes the work so that the usual operations are done within easy reach; avoid the awkward posture that causes over exertion and early fatigue.

### 4.3 Physical Environment and Organization

Study of physical environment including microclimate, lighting, noise, vibrate, dust, and dangerous materials. The main problem for office work such as for engineering design are about micro climate and lighting, while for construction process are mostly all of physical environment aspects. To provide the comfort work condition, all physical environment aspect must be control under threshold limit. It could be done through engineering redesign or organizing the work-rest schedule. For example: controlling noise hazard could be done by partition between noise resource and the workers or by organizing work-rest schedule based on threshold limit. For more than 85 dB (A), the noise exposure should be a quarter hour maximum or by providing the ear plug or muff as personal protection devise [36]. Hence, to protect the workers from the physical environment hazards, it needs the proper safety signs/symbol, training, and alarm system [26]. The exposure of physical environment up than threshold limit will give additional workload; workers got early fatigue that lead to the health impairment and the decreasing of productivity.

## 5. CONCLUSION

Based on the overviews both theoretical background and articles, it could be describing some important conclusion as follows:

- 1) The comprehensive ergonomics approach should be implemented in all human being activities to provide the safety, healthy, comfort, efficient, and productive work condition that lead to the better quality of life both for the workers and the industries.
- 2) The ergonomics aspects that must be considered for designers are the individual designer's characters, human-computers interface, and physical environment exposure.
- 3) The ergonomics aspects that must be considered for workers in construction process are the individual worker's characters, human-machine/tools interface, and physical environment exposure.

## 6. RECOMMENDATION

This study is general overview of comprehensive ergonomics aspects. For further study, it is recommended to conduct more indebt research to build a model of ergonomics approach for engineering design and construction processes that meets the potencies, capabilities, and limitation of both designer's and the workers.

## ABSTRACT

Comfort and safety of passengers are main concerns in a flight. When a plane crashes and the main door is unable to be accessed, it is vital to have accessible and ergonomic emergency exit doors. This research studies the ergonomic aspects of a medium-range twin-engined transport plane emergency door design. The purpose of this research was to evaluate the design of an actual emergency door of such aircrafts and to determine the most ergonomic configuration using door height and width as primary consideration. As the result of this research, four configurations were made and analyzed. Those configurations were analyzed by using Jack 6.1 software. Posture Evaluation Index was used to integrate the analysis from three methods: Lower Back Analysis, Ovako Working Analysis System, and Rapid Upper Limb Analysis. The result of this research suggested that minor modification is necessary from original design.

## 1. INTRODUCTION

Ergonomics is a discipline concerned with interaction between humans and other elements in a system. Furthermore, ergonomics is a science that contributes to the design and evaluation of a job, task, product, environment and systems in order to make these things fit the needs, capabilities and limitations of humans. Therefore, ergonomics is a science that is very important in the design of a product. Ergonomics can be applied in various fields of industry. One of them is aircraft industry.

Indonesia already had an aircraft industry in late 1940s. It was expanded from the Indonesian Air Force facility. During the 1970s, capitalizing money from natural resources sales, Indonesia built a full-sized aircraft industry. This industry had successfully developed several aircrafts. One of these aircrafts is a medium-range twin-engined transport plane that was jointly developed by Spain and Indonesia. Its primary roles include maritime patrol, surveillance, and air transport.

As in other medium-range transport aircrafts, this plane is obliged by regulation to have an emergency exit door for evacuation. The door has to be designed in particular ways so it can comply with safety regulations. This has implications on accessibility, accuracy, number of injured passengers and time to evacuate all passengers. This study analyzes the ergonomics aspect of the door. Research was conducted in virtual environment using software Jack 6.1, in particular the Posture Evaluation Index (PEI). PEI is a formula that consists of Low Back Analysis, Ovako Working Analysis System, and Rapid Upper Limb Assessment. Adjustments have been made on emergency exit design to obtain the ideal configuration.

## 2. BASIC THEORY

*Virtual environment* is a representation of a physical system generated by the computer. This representation allowed users to interact with a synthetic environment, which is similar with real environment [1]. A good simulation of virtual environments must be able to represent a virtual human model within the designed system/environments.

*Virtual human* is an accurate biomechanical model of the human figure. This model fully mimics human movement hence researchers might simulate the flow of work processes, and see how the workloads are received by the model when doing a certain job series.

Jack 6.1 is one of the ergonomic software that simulates how a human model can interact with virtual objects and environments, as well as getting the right response back from the object being manipulated. Jack is one of world's leading applications in ergonomic analysis software.

## 3. METHODOLOGY

The first step in this research was data collection. There are three types of data used in this research, namely the anthropometric data of Indonesian and American people, the size and shape of the actual emergency exit door, and evacuation posture

of passenger during emergency exit. For Indonesian anthropometric data, we used the latest data that has been published in prominent ergonomics scientific journal [2]. The data for the Americans were taken from ANSUR. Data specification of emergency exit was taken from direct measurements of the aircraft.

The second step, data processing, was performed by simulating evacuation posture on the Jack 6.1. It was started by creating the virtual environment. The virtual environment was created using NX. Jack and NX are developed by one company, so the translation/insertion of the environment model from NX to Jack was done seamlessly. The next step is to create a virtual human model. Furthermore, the human model was simulated in the virtual environment. From initial simulation, we determined design configuration for the emergency exit (see Table 1).

Table 1 : Configuration of emergency exit

Configuration	Height	Width	TYPE
1	91,5 cm	50,8 cm	ACTUAL
2	91,5 cm	55,8 cm	REDESIGN
3	96,5 cm	50,8 cm	REDESIGN
4	96,5 cm	55,8 cm	REDESIGN

Figure 1: Virtual Environment and Virtual Human

Moreover, we analyzed simulation results using Jack Task Analysis Toolkit. This toolkit calculates values like LBA (Lower Back Analysis), OWAS (Ovako Working Posture Analysis), and Rula (Rapid Upper Limb Assessment). These three calculations are then combined into PEI (Posture Evaluation Index), which is the value of the overall ergonomics of the human posture [3].

$$PEI = I_1 + I_2 + I_3 \cdot mr \quad (1)$$

$$I_1 = \frac{LBA}{3400N} \quad I_2 = \frac{OWAS}{4} \quad I_3 = \frac{RULA}{7} \quad (2)$$

#### 4. RESULTS AND DISCUSSION

The results of the simulation are shown in Table 2. Focus was given to configuration 1, 2, and 3 where the value of OWAS equals 3. This high number indicates that the current working posture significantly harm the human musculoskeletal system. Regarding RULA, high numbers exist in configuration 1 and 2. Moreover, results on LBA also show the very same pattern.

Table 2 : Recapitulation of PEI Result

CONFIGURATION	Sex	Percentile	LBA (N)	OWAS	RULA	PEI
1	Male	95	1232 N	3	7	2.532
	Male	5	641 N	3	6	2.157
	Female	95	1160 N	3	7	2.511
	Female	5	455 N	3	6	2.101
2	Male	95	1085 N	3	6	2.286
	Male	5	490 N	1	5	1.408
	Female	95	1026 N	3	6	2.269
	Female	5	359 N	1	5	1.370
3	Male	95	960 N	3	5	2.047
	Male	5	439 N	1	4	1.191
	Female	95	913 N	3	5	2.033
	Female	5	326 N	1	4	1.157
4	Male	95	466 N	1	4	1.199
	Male	5	427 N	1	3	0.984
	Female	95	464 N	1	4	1.197
	Female	5	319 N	1	3	0.952

Figure 2 is a graphic comparison of the PEI entire configuration of emergency exit design for 5th and 95th percentile for male and female. Our simulation shows that the initial design (configuration 1) poses high injury risk. Our proposed design (configuration 2, 3, and 4) delivers better ergonomics performance.

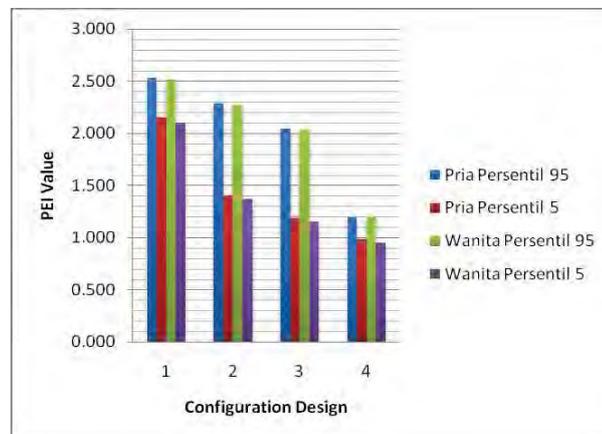

Figure 2: Value Comparison Graph of PEI

#### 5. CONCLUSION

Good human-machine interface will deliver better system performance. In aircraft design, ergonomics play major factor in determining, not only system performance, but also system safety. By using virtual environment, we can conduct ergonomics analysis during design phase. This will affect system performance and safety while keeping the development cost relatively low, since we do not need to construct a full mock-up in early design phase. Though that the design case was simple, this research gives us basis means to conduct further ergonomics study in aircraft design.

### ABSTRACT

A recognition test was conducted on the most commonly used Chinese characters in the Ming, Kai, and Li styles, measuring the minimum visible size of each character in each style. A total of 120 college students participated in the experiment. Each character was initially displayed on a PC screen at its minimum size and enlarged gradually until the participant could recognize it. Analysis of variance showed that character style and number of strokes both have a significant impact on the legibility threshold. Ming is the most legible among the three styles, and Kai is also significantly more legible than the Li style. A regression equation for predicting the legibility threshold based on the number of strokes in a character indicates that an increase of an additional stroke in a character must be compensated for by an enlargement of the character size of approximately 0.25 min of arc to maintain the same legibility.

### ABSTRACT

The current study collected matching accuracy, matching time, and matching sequence data on 95 icons of a vehicle. The ninety-five icons were divided into four different formats: image-related, concept-related, arbitrary, and text, to compare their matching performance. Forty participants with a university education took part in this experiment. Half of the participants had intensive driving experience while the other half had no driving experience. The results showed that the experienced drivers had significantly better recognition accuracy on all icon formats. However, all participants chose to match image-related icons before icons of the other three formats. With about the same recognition accuracy, the image-related format is recommended for use in the design of vehicle icons. Based on its high ratings on subjective design features, textual format can be used for functions describable using simple English and for users with English reading ability.

### Keywords

*image-related, matching test, icon design features*

### 1. INTRODUCTION

As the number of functions in the driving environment increases, icons that are compact and international (language)[1] are often used in a vehicle to convey information to the driver [2]. Effective icons can provide the driver with quick and complete understanding of information [3] to ensure driver safety. However, designing comprehensible icons was not a simple task. Saunby et al. [4] showed that only 16 of 25 car icons tested could be matched correctly by a minimum 75 per cent of experimental subjects.

An icon maybe comprised of border, background, symbol (consisting of graphical elements), and textual labels (Figure 1) [1], [5] although not all these components will be present in it. Each icon component can add meaning to an icon in its own way. Borders can make icons appear more consistent; background can help to group icons; and graphical and textual elements convey the main meaning of the icon[6].

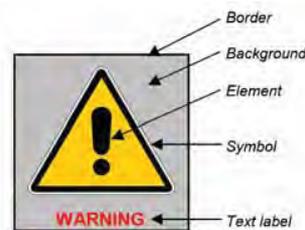

Figure 1: Key components of an icon [5]

To provide a useful framework for icon design and evaluation [7], icons can be classified into image-related (pictorial), concept-related (analogy), or arbitrary based on how far the graphical elements in an icon (Figure 1) resemble their referents. Image-related icons are typical pictorial representations of the object or act [8]. Concept-related icons attempt to visualize a concept that is not far but separate from the concrete image. Arbitrary icons have no obvious reference to their intended meaning but become meaningful only through convention and education [7], [8]. Goonetilleke et al. [8] added a fourth format: the use of text.

Prior researches compared the advantages of using each of the icon formats. Image-related icons have been considered the most effective for fast and accurate recognition response [9], [10], [11]. Educating people to associate arbitrary objects and their referents requires a considerable amount of funding and time, thus, arbitrary icons should be avoided[1]. Regarding textual icons, the general conclusion is that recognition of pictorial images has been found to be superior to that of text for

recall and recognition accuracy [12],[13] while text has been better for reaction time[14]. Thus, Muter & Mayson [15] and Egidio & Patterson [16] advocated the combining of graphical and textual elements to promote association and improve comprehension accuracy.

Most of the above statements seem to suggest that imaged-related icons combined with text would be the most effective. However, if we review the commonly used ISO standard icons, we will find that not all of the icons are image-related because for some functions or contexts, it is difficult or impossible to find a real object to represent the referent when creating image-related icons. Besides, most previous studies only compared three types of graphical icons[17], [18] or graphical vs. textual icons[3], [10]. Therefore, the current study categorized the existing icons used in a newly built vehicle into four different icon formats and compared the comprehension performance of the participants as they responded to the different formats.

Icons can be classified easily into graphical or textual formats based on the existence of textual/graphical elements. However, more caution is needed in classifying graphical icons into image-related, concept-related, or arbitrary formats. Icons will be classified as image-related if the graphical elements are highly pictorial representations of the object or act they represent [5]. The following icons were classified as image-related: , , , , , , , , , , , and . The above icons reveal that objects can be portrayed more easily than action.

Icons will be classified as concept-related if they attempt to visualize a concept that is not far but separate from the concrete image[7], [8]. For example,  (high beam) and  (front fog light) were classified as concept-related since the parabolic shape was used to denote the headlamp while the parallel straight and angled lines in front of the headlamp were used to denote the light beam. Both graphical elements were shape-related but somewhat different from the real image. The position of the lines relative to the parabolic shape indicates whether it is a front light or a rear light. Meanwhile, the wavy curve cross over the parallel lines tilted downward symbolized the fog. For icons containing both graphical and textual elements, the textual information can be ignored and they will be classified based only on the graphical elements. The lane departure warning system  is classified as image-related by ignoring the textual information LDWs+. Also, without clear standards, icons would be classified as concept-related if they are composed of image-related objects and concept-related actions such as air flow control  and recirculated air . In such cases, the arrow is a symbol used to denote air flow when presented together with a real object such as a car or a human being. There are similar examples for windscreen defrosting and demisting  and rear-window defrosting and demisting . Also,  (stability control system indicator) can be classified similarly because the action is the critical part that makes a difference. There was some confusion about classifying the car key reminder indicator  as either image-related or concept-related because of its poor image quality. Since image quality was not an attribute used for the classification of icon format,  was classified as imaged-related. Lastly, graphical icons will be classified as arbitrary if the graphical elements do not resemble the object or action they represent, e.g.,  for power on/off. Textual icons can be easily identified including alphabetical words/abbreviations, numerals or mathematical operators. Table 1 shows the classification of the 95 icons tested in the study.

Table 1: Icon classification

Icon Format	Icon list
Image-related	           
Concept-related	         
Arbitrary	        
Text	P P R D N + - 4WD FAIL TCS OFF TC OFF ESC CRUISE CRUISE ON/OFF RES/+ SET/- SNOW SNOW SOS P/B ON L R UP DOWN BACK MODE ENTER CH+ CH- SEEK ENTER VOL CD/DVD RADIO SET1 BAGLEV NIGHT VISION NAVI AFS ON/OFF A/C A/C TEMP AUTO OFF

Since subjective rating scales are easy to administer, at times they can be more sensitive than objective measurements [19], so these 95 icons would also be evaluated based on some subjective design features [20] such as familiarity, concreteness, visual complexity, and semantic distance. Each will be defined in the following [21], [22]. The subjective rating features can help to explain why some icons could be better recognized than others.

Familiarity reflects the frequency with which icons have been encountered. Concrete symbols tend to be more visually obvious and easier to use [23] because they depict real world objects and actions. Design guidelines typically suggest that icons should

be kept as simple as possible [23] meaning low visual complexity or not containing a lot of details. Semantic distance is the closeness of the relationship between what is depicted on an icon and what it is intended to represent. Among the four differential formats of icons (image-related, concept-related, arbitrary, and textual), all four subjective design features can be used to evaluate the first three graphical formats. However, for textual icons, besides evaluating semantic distance, participants were also asked about whether they understood the meaning of the word or abbreviation in an icon.

The education level (with university education vs. without) [21] and experience [8], [24] of the respondents were found to have significant effects on comprehension performance. Our experiment chose to test participants with at least a university-level education and divided their driving experience into having no driving experience and having intensive driving experience.

Geiser [25] divided the interactive tasks in a vehicle into three classes: primary, secondary and tertiary tasks. A primary task is about maneuvering the vehicle, secondary tasks are setting turning signals and activating the windshield wiper to increase driving safety while tertiary tasks serve the entertainment and information functions [26]. Based on Geiser [25], Tonnis et al. [26] classified input devices into primary, secondary, and tertiary devices and assigned them to specific locations in the car. For example, both primary and secondary devices are arranged close to the driver so that they are easy-to-reach. Secondary devices are often mounted on the backside of the steering wheel while tertiary devices are often placed in the center stack [26]. Therefore, the 95 icons were copied from the dashboard, steering wheel, and center stack of a newly built vehicle and presented on three task screens respectively. Participants will match each icon with the most appropriate referent name. The subjective design features would be rated for each icon after the matching test.

Ninety-five icons of a newly-built vehicle were categorized into four different formats to compare the matching accuracy, time, and sequence produced by the participants. The results obtained for the different icon formats on these performance measures can be used to perfect the ISO standard 2575 published by the International Organization of Standardization to facilitate the design of new icons for new contexts or applications, e.g., car panels.

## 2. METHODOLOGY

### 2.1 Participants

A matching experiment was designed to collect comprehension performance data on 95 icons followed by subjective ratings of their design features. The comprehension performance was measured by the matching time, matching sequence, and the percentage of participants who matched the icon correctly with its functional name (matching accuracy) [6]. Forty participants aged between 23 and 53 years old (mean = 30.4 years) took part in this experiment. All participants are students and staff members of National Taiwan University of Science and Technology with at least a university level education. They consisted of two different groups: those having driving experience (having driven at least once a week) and those without any driving experience (not having a driver's license and never having driven a car). Prior to the experiment, all participants were screened for visual acuity abnormality and color blindness. They were briefed about the experiment goal, and practiced the matching test routine. After the matching test, each participant was asked to give ratings on each of the subjective design features.

### 2.2 Equipment and Computer Programs

Two experimental modules were conducted on two Lenovo Think Centre A70z computers equipped with 19" screen monitors, i.e. the matching test and subjective rating evaluation. In the matching test, icons were displayed on a car dashboard layout to give context as suggested by Vukelich and Whitaker [27] and Wolff and Wogalter [28]. Since context delivers ecologically valid cues that limit the possible referents and the matching performance scores would certainly be raised by providing the testing context [28]. Hence, there may not be enough sensitivity in the matching accuracy. The matching sequence of each icon was retrieved from reviewing the videotape as an index of the matching difficulty.

Ninety-five icons were divided into three task screens - dashboard, steering wheel, and center stack - according to the icons' relative positions on a newly-built vehicle. In other words, the icon format was nested within the task screen [29]. The three task screens would be shown to each participant in random sequence to minimize the learning effect. One example of the task screens is depicted in Figure 2. Participants were asked to click on what they thought was the most appropriate referent name for a specific icon and drag it to the answer box. Each participant was allowed to revise her/his answer during the experiment without time limit. The computer program would collect the name of each icon and the time it took to match it. If the matching result had been altered in any way, all previous matching results would also be recorded.

In the subjective rating of design features, participants were asked to rate each icon in accordance with how much they perceived the icon to be familiar, concrete, simple, and strongly related to its referent on a 1-7 scale [30]. Figure 3 shows the test screen for subjective ratings of design features. Unlike the matching test where icon formats were nested in three separate task screens, in this subjective rating test screen, each icon was evaluated on an individual basis.

Performance Measures		Image-related	Concept-related	Arbitrary	Text
Matching accuracy	ND	76 ± 23%	68 ± 15%	66 ± 27%	67 ± 26%
	D	84 ± 17%	85 ± 12%	82 ± 18%	82 ± 22%
Matching Sequence	ND	11.8 ± 5.5	18.9 ± 7.0	17.1 ± 6.4	18.8 ± 6.6
	D	13.8 ± 5.3	18.5 ± 7.0	18.0 ± 9.0	18.0 ± 7.2
Matching Time (s)	ND	15.2 ± 3.3	13.5 ± 1.9	13.2 ± 1.5	12.5 ± 3.8
	D	18.2 ± 5.8	18.2 ± 5.1	23.6 ± 5.8	17.3 ± 5.8

## 3. RESULTS

### 2.3 Analysis of Variance

Table 2 summarizes the matching accuracy, matching sequence, and matching time for each icon format and for participants with and without driving experience. The nested Analysis of Variance (ANOVA) was performed on matching accuracy, matching sequence, and matching time to examine whether icon format and driving experience had a significant effect on the recognition performance.

The nested ANOVA result indicated that the task screen had a significant effect on all three performance measures (see Table 3). The result also indicated that driving experience had a significant effect on the matching accuracy ( $p < 0.01$ ). Participants with driving experience had significantly better recognition accuracy than participants without driving experience. On the other hand, icon format had a significant effect on matching sequence ( $p < 0.01$ ). For each task screen, image-related icons had significantly smaller means than all other icon formats, indicating that image-related icons were recognized faster. No significant difference was found in matching sequence between participants with and without driving experience.

Table 2: Mean performance measures for each icon format

Note: ND refers to subjects without driving experience; D refers to subject with driving experience

Table 3: ANOVA results of comprehension performance measures

Source	df	Matching accuracy		Matching sequence		Matching time	
		F	Sig.	F	Sig.	F	Sig.
Driving experience	1	12.70	<b>0.00</b>	0.05	0.83	64.69	<b>0.00</b>
Task screen	2	5.57	<b>0.00</b>	34.98	<b>0.00</b>	8.16	<b>0.00</b>
Icon format (Task screen)	9	1.74	0.08	3.31	<b>0.00</b>	2.59	<b>0.01</b>
Driving experience x Task screen	2	1.29	0.28	0.13	0.88	2.88	0.06
Driving experience x Icon format (Task screen)	9	0.29	0.98	0.35	0.96	1.69	0.09

Icon format and driving experience had a significant effect on the matching time. Arbitrary icons took significantly longer than all three other formats for experienced participants. Quite unexpectedly, participants with driving experience took significantly longer than those inexperienced participants. However, reaction time can be affected by the number of unmatched icons left (Hick-Hyman Law).

Image-related icons did not produce better matching performance than other icon formats. This could be because the half of the icons followed ISO standard or common practice, so they can be recognized reasonably well irrespective of their design format. Besides, all participants had a university-level education and basic reading capability for English text. As a result, the study revealed that participants without driving experience had a 100% recognition rate for  (snow mode switch and indicator) and , and an above 90% recognition rate for , , , , , , , and .

For the icons presented on each task screen, the reaction time was supposed to be affected by the number of unmatched icons and can be predicted by the Hick-Hyman Law [31] rather than by perception difficulties. However, after reviewing the videotape and the reaction time vs. the matching sequence curve, it was found that several icons matched last had the longest reaction times (see Figure 4). The matching accuracy had been raised to 70% for those without driving experience and 80% for those with experience because of there being very few possible referents left [28]. Under such conditions, matching sequence is more sensitive and reliable than matching accuracy, and the sequence indicated that participants chose to match image-related icons before icons of other formats. This has very important implications because the duration of any given glance during driving should be relatively short (shorter than 0.8 seconds), with there being about 3 seconds between glances [32]. Thus, those icons that had a high recognition rate but were matched at the last minute should not be used during driving.

#### 2.4 Subjective Rating on Icon Design Features

The means of the subjective ratings for each design feature are listed on Table 4. The analysis of variance was conducted to analyze whether icon format and driving experience have a significant effect on each design feature. Since each icon was evaluated individually without the task screen context, factorial ANOVA was conducted on subjective ratings of design features [29]. The ANOVA result (Table 5) indicated that experienced participants provided significantly higher ratings for all design features. Icon format had a significant effect on all subjective ratings except for familiarity. Concept-related icons had lower ratings on all design features compared to the other icon formats. Image-related icons were expected to have higher ratings on concreteness, simplicity and semantic distance than concept-related icons. However, arbitrary icons had even higher ratings on some of the design features because some arbitrary icons have been used in other contexts such as power on/off  and hazard warning  which are used in electronic devices and road signs, respectively. Besides, all participants had a university-level education and could read English. Thus, textual icons were perceived to have higher semantic distance ratings compared to image-related icons. Meanwhile, almost all concept-related icons were related to functions specific to vehicles, such as front fog light indicator  and engine coolant temperature indicator , which could explain why novice participants gave relatively low ratings on most subjective rating scales. Based on the subjective rating scales, textual icons could be a good choice for icons that can be described using simple English and for users who have some level of English reading ability.

Significant inter-correlation and the higher ratings perceived the by experienced participants proved that subjective rating scales are not diagnostic; they only provide an overall sense and indicators of what we intended to measure [19]. They can be more sensitive than objective measurements [33], [34]. Besides, different researchers have suggested distinctive criteria based on different application domains or data collection methods. For example, [33] suggested qualified computer icons should incorporate the following design criteria: styling, message quality, meaningfulness, locatability, and metaphor, and which has nothing in common with the current subjective rating scale we used here.

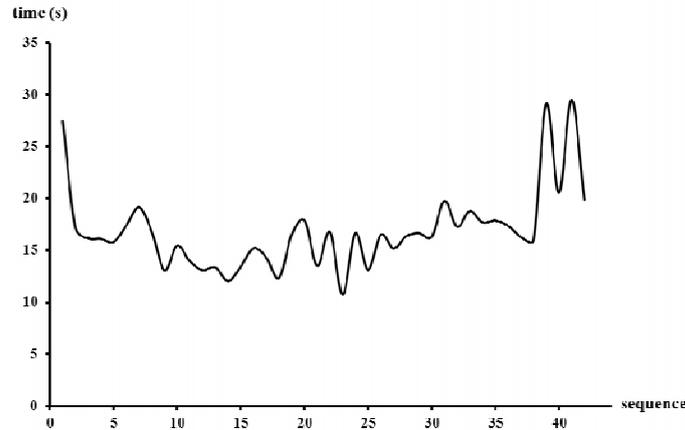

Figure 4: Matching time versus matching sequence for center stack

## DISCUSSION

Kern and Schmidt [35] suggested that designing user interfaces for computer domains where the user pays full attention to the application is totally different from that for cars, where the user's main focus has to be on the primary driving task. However, the current test scenario is more similar to the computer domain. Besides that, Ng and Chan [36] indicated that people with a university-level education or above perform significantly better in symbol comprehension tests than those without a university-level education. This study recruited participants with a university-level education and, as a result, all recognition performance could have been inflated. Also, the recognition performance improves dramatically as a result of learning from the driving experience ([24], [37]). The car manufacturer and interface designers must take notice that a great number of icons tested cannot be correctly recognized with the user's full attention and even worse recognition performance is expected in a real driving situation and in particular for users without a university-level education and without driving experience.

Although Lodding [7] stated that pictorial communication predated text communication and it is more natural to communicate with images, the current study failed to prove that image-related icons have a better matching accuracy than the textual icons. The result can be partially explained by the poor design quality of some of the image-related icons, just as Lodding [7] suggested that image-related icons will be clear and easy to understand when the image bears a close resemblance to a particular object and context is provided. For example, both the car key reminder indicator (🔑) and engine warning light (🚗) had poor recognition rates mainly because both images have poor resolution and do not resemble closely to, the key or engine, respectively. The findings highlighted the importance of the design quality in the resemblance to a real object.

The International Organization for Standardization ISO 2575: 2010 provided a list of standardized symbols for controls and indicators. Among the 95 icons tested in this study, 44 icons came from or were adopted from the ISO standard 2575:2010. If

we divided all 95 icons into the ISO group (n=44) and the non-ISO group (n=51), the t-test result proves that experienced participants had significantly better matching accuracy for icons following the ISO standard (ISO=88%, NON-ISO=79%), but the difference for novice participants (ISO=72%, NON-ISO=67%) was not significant. For conventional functions, the icon should follow the ISO standard since the matching performance was always better than that of the non-ISO for both novice and experienced drivers.

One important implication from the task screen is how many functions can be accessed easily without overloading the user [35]. After seeing the test results and feedback from the car users, designers of the manufacturer company became more cautious in placing too many icons (functions) into their new models. Luckily, some control functions can be replaced by automatic sensors or redundant coding. For example, the automatic induction light system can relieve the driver from having to turning on the beam light; the turning signal seldom relies on the visual sense but more on the sense of feel or touch. Above all, the most important issue here may not lie in the icon design itself but in the system design stage to determine what functions need to exist to meet the system objective and performance specification [38].

## 5. CONCLUSION

The current study evaluates the matching accuracy, response time, and matching sequence for 95 vehicle icons in four icon formats (image-related, concept-related, arbitrary and text). Two groups of participants, with and without driving experience, took part in this experiment. The results showed that driving experience had a significant effect on matching accuracy while the matching sequence was affected by the icon format. All participants chose to match image-related icons before other icon formats. Evaluating icon design features using subjective rating scales lacked diagnostic ability for improving the evaluated icon design. Incorporation of new icons (functions) should be carefully reviewed at the system design stage and be limited to minimize the visual and information processing load of a driver.

## ABSTRACT

There are several environmental ergonomic factors that can affect the learning process of a student such as acoustic and lighting condition of the room that is used. At universities, auditoriums can be used as lecture rooms for lectures that have a large amount of participants. This research is focused on discovering the acoustic and lighting condition of auditoriums used as lecture halls at University of Indonesia. The result of this research that based on two auditoriums at University of Indonesia shows that these two auditoriums have not met the acoustic and lighting criteria set for supporting learning process.

## Keywords

*Environmental ergonomics, acoustic, lighting, auditorium, reverberation time*

## 1. INTRODUCTION

The effectiveness of the learning process can be maximized by a variety of ways, one of which is to consider the convenience of students as teaching and learning activities taking place. A student can go through the learning process in various ways: one is to see and hear. Knowing these facts, classroom facilities, site of learning activities should be able to help the human senses of sight and sound to work optimally [1].

The designer should consider that classroom environmental factors influencing the teaching-learning process in the classroom [2]. Designer in terms of classrooms, classroom factors ergonomics are a factor of major concern where the acoustics and lighting condition (audio-visual) is the physical environmental factors that influence the success of learning a student [3]. A study was also conducted by Caldwell that discussed the physical design of a university classroom to the student learning process and give estimates that the design and maintenance of a poor classroom can cause a decrease of student performance as much as 10-25% [4].

The state of the acoustics of a classroom is less well able to make the teaching-learning process. This is due to the difficulty of students to hear the material being conveyed verbally teaching, where the majority of teaching and learning activities using this communication medium. In addition, according to Burke and the Burke-Samide [5], lighting is one important element that affects the ability of students in learning. Obviously, the level of lighting in classrooms should be maintained so as not excessive [6]. This light source can be derived from artificial lighting, such as lamps and natural lighting, such as bright sky. Although much research focuses on the importance of natural light, the need for integration of natural and artificial lighting is widely accepted [6].

Although it has been known to influence of environmental factors on the performance of students in the learning process, the state of learning spaces for different levels of formal education in Indonesia is still very alarming. According to the Ministry of Education, at least 153.000 elementary school classrooms and middle schools in Indonesia are heavily damaged. In addition, there are also several classrooms at the University of Sam Ratulangi that are considered unsuitable because of the narrow room which causes learning activities not being carried out effectively. Both of these shows formal education classrooms still exist that have not been considered to support the study process and raises the question whether the University of Indonesia already has facilities that support classroom learning activities.

There are two types of commonly used classrooms at the University of Indonesia which are regular spaced classrooms and auditoriums or lecture halls. Both spaces are distinguished from the size and capacity. Regular classroom has a smaller size of the auditorium and has a capacity of 30 to 50 students. The auditorium has a size larger than regular classrooms, which can have a capacity of 100 to 300 students.

In fact, an auditorium space can indeed be said to be a space that has a variety of functions. Larger size and capacity of people to make the auditorium is used not only as a space for the implementation of college with a large number of participants, but also as a place to organize special events. However, based on research conducted by [7] on the acoustic design of a multifunctional auditorium, most auditoriums have problems with the background noise level required to affect the acoustic performance of the auditorium. Given the existence of the auditorium is a priority in the academic environment as a venue for the lecture by the number of participants, it must be noted whether the existing auditorium space can support the performance of students in learning activities. Therefore, the auditorium at the University of Indonesia needs to ensure decent enough condition to support the performance of students in learning activities, where the performance of students is one of the important role towards the success of students to compete in the global era and naming the University of Indonesia as a "World Class Research University".

## 2. METHODS

For this study, two samples taken are auditoriums at the University of Indonesia which is used for school activities. Both the auditoriums are located at the Faculty of Engineering and Faculty of Economics, where the auditorium is used not only for routine college activities that have attendees of more than 100 people, but also for student affairs and academic events. Acoustic parameters used to assess the condition of an acoustic space are:

- background noise level
- signal-to-noise ratio for speech intelligibility parameter space
- Reverberation time which is the time required by the source of sound that is stopped immediately (impulse noise) to step down in intensity by 60 dB from the initial intensity

According to the American Speech-Language-Hearing Association (ASHA), signal-to-noise ratio can be calculated by subtracting the intensity of sound that occurs with noise levels at the same location [8]. In addition, the parameters of reverberation time or reverberation time can be determined by conducting experiments with simulated impulse noise in a room or estimated by the Sabine formula. The Sabine formula is as follows:

$$RT = \frac{0,161V}{A} \quad (1)$$

Where:

RT = reverberation time in seconds

V = volume of space

A =  $\alpha \times S$ . Total absorption in the space obtained of the absorption coefficient of each surface coating material multiplied by the breadth of space.

$\alpha$  = absorption coefficient of materials

Lighting parameters used to evaluate the lighting conditions is the level of illumination (in lux) that occurs in areas of work in that space of each lecture seat. To take this research data, the devices used are a Larson-Davis Soundtrack Sound Level Meter for acoustic data as well as Smart Sensor AR-823 Digital Lux-meter. This device meets the normal specification indicated to measure the level of data noise and lighting for a work area. Before taking data, tools to be used should be calibrated prior to data obtained are accurate.

Acoustic parameter measurements are performed with two conditions; when unoccupied and when room is being used for lecture activity. Measurements made with the condition of room lights on; windows and doors closed. The instrument used for measuring is the sound level meter with a measurement scale with slow response. This is done to equalize ear hearing device with the human condition in general. Measurement points used in each auditorium can be seen in Figure 1 and Figure 2. Measurements are carried out for 30 seconds at a height of a normal human when sitting at each point.

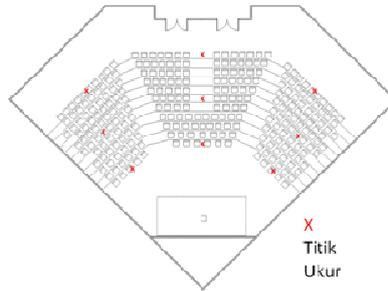

Figure 1: Measurement Points at Auditorium S. Soeria Atmadja (Faculty of Economics)

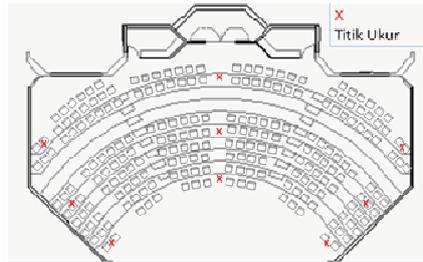

Figure 2: Measurement Points at Auditorium K301 (Faculty of Engineering)

The results of acoustic measurements using a sound level meter can be seen in Tables 1 and 2.

Table 1: Acoustic Measurement of Auditorium S. Soeria Atmadja

Row	Wing	Unoccupied (dB)	During Lecture Activity (dB)	Signal-to-Noise Ratio
1	Right	48.9	70.5	21.6
	Middle	46.8	70.1	23.3
	Left	49.1	70.6	21.5
6	Right	48.9	67.9	19
	Middle	47.2	67.3	20.1
	Left	49.1	68	18.9
11	Right	49.1	62.6	13.5
	Middle	48.2	61.2	13
	Left	47.2	62.9	15.7

Table 2: Acoustic Measurement of Auditorium Auditorium K301

Row	Wing	Unoccupied (dB)	During Lecture Activity (dB)	Signal-to-Noise Ratio
1	Right	54.8	65	10.2
	Middle	48	71	23
	Left	54.8	65.3	10.5
4	Right	48.9	61	12.1
	Middle	48	64.4	16.4
	Left	50.8	61.2	10.4
8	Right	53	56	3
	Middle	48.7	55	6.3
	Left	51.1	56.2	5.1

In this study, the parameters of reverberation time are done through estimation using the Sabine formula. To do this, a survey is conducted for both of the auditoriums to find out the inner surface material contained in the chamber and its area of each material. Tables 3 and 4 show the recorded material contained in both auditorium. After recording the materials, reverberation time is calculated in three frequencies, namely 500, 1000, and 2000 Hz. For estimation of reverberation time on speech auditorium, Acoustical Society of Acoustics says that it is essential to focus on the estimation at frequency 500, 1000, and 2000 Hz.

Table 3: Auditorium Inner Surface Material

Auditorium S. Soeria Atmadja		Auditorium K301	
Material	Area (m <sup>2</sup> )	Material	Area (m <sup>2</sup> )
Carpet	588.03	Wooden Panel	133.68
Concrete	17.75	Wooden Stage	28.3
Glass Door	72.96	Glass Door	3.8
Ceramic Tile	307.23	Chair	30.2
Wooden Panel	14.98	Gypsum Wall	36.48
Wooden Stage	52.37	Ceramic Tile	141.63
Light upholstery Chair	83.4	Concrete	233
Wooden Border	1.93	Muslin	143
		Gypsum Ceiling	306.9

For lighting measurements in auditorium, measurements are conducted using a lux-meter done on each lecture chair in the auditorium. This measurement is carried out in state where all lights were turned, where there are only sources of artificial lighting in the auditorium space.

### 3. RESULTS AND DISCUSSION

To analyze the condition of both the acoustic and lighting of the auditorium, the acoustics and lighting condition measurements that have been obtained can be compared to that of acoustics and lighting are recommended for the auditorium is used for learning activities. Acoustic parameters suggested by the Acoustical Society of America (ASA) [9] and the American Speech-Language-Hearing Association (ASHA) [8] are as follows:

- The noise level measured at each measurement point along with the average noise level is suggested that space does not exceed 35 dB.
- Reverberation time is suggested to be in the range of 1.0 to 1.5 seconds.
- Speech intelligibility can be determined by the value of Signal-to-Noise Ratio or the ratio S/N, where the ratio S/N are advised not less than +15 dB for the space used for the learning process.
- Parameter lighting for the auditorium used for lectures suggested activities are in category D which is visual task lighting to work with the contrast or large size (based on the Illumination Engineers Society) or a minimum of 250 lux on the working area [10].

#### 3.1. Noise Levels

To analyze the level of noise that occurs on both the auditorium were studied; the results of measurements have been made in terms of each measuring point. This is done to determine the cause of the noise that occurs. The cause of the noise that may occur will be analyzed based on its source is internal noise, or noise emanating from inside the room, as well as external noise, or noise emanating from the outdoor environment.

As can be seen in Tables 1 and 2, the noise levels measured in both the auditorium does not meet the recommended maximum noise level is 35 dB. In terms of external noise, the auditorium is located at a location quite alienated from environmental noise such as noise from transport. The noise level that occurs in both the auditorium can be derived from the internal noise such as equipment that functions in the space (air cooler, lighting equipment, and so on).

#### 3.2. Ratio Signal-to-Noise

To analyze the clarity of conversation in both the auditorium which has been investigated, it can be seen from the data that has been processed in Tables 1 and 2 to get the value of the ratio S / N. In the auditorium of S. Soeria Atmadja, there are seven of the nine points that already meet the standards of the ratio S / N of +15 recommended minimum. Two points which do not meet the standards of the ratio S / N suggested lies in the eleventh row in the middle and right wing with a large ratio of S / N

+13 and +13.5. Given the standard S / N ratio is recommended, both the value of this ratio is less than 2 dB to 2.5 dB in order to achieve good speech intelligibility. To find out the cause of the ratio S / N as well as how to fix it, can be seen from the two major variables that determine the ratio S / N is the noise level and sound intensity that occurs at each measuring point.

The average intensity of noise experienced by the space amounted to 66.8 dB with a fluctuation between the measuring point to 70.6 dB 61.2 dB. Sound intensity in the range of normal conversation in the room was supported by the laying of a sound source speaker as the output of the microphone used by the speaker. Speaker is laying there on both sides of the stage at a height of 5 meters. In addition, the ceiling of the auditorium has a special shape such as stairs. This causes the reflection of sound from the speakers pointed to the location of seat lecture on this space as shown in Figure 3 which shows the reflectance scheme for auditorium sound S. Soeria Atmadja.

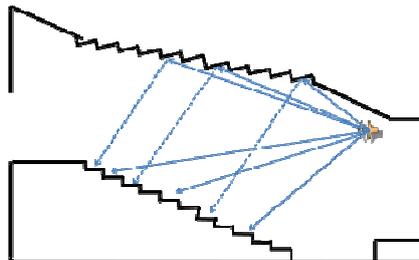

Figure 3: Sound Reflectance Scheme Auditorium S. Soeria Atmadja

In the auditorium of K301, it can be seen that only two points from nine measuring points of the space that meets the minimum value of the ratio S / N of +15 is suggested. The location of the measuring point is located in the middle of the wing first and fourth lines.

The average intensity of noise that occurs in the space of 61.7 dB with a relatively high fluctuation due to measuring point range between 55 dB to 71 dB. This suggests that the spread of the sound is not optimal, although still at the limit of the intensity of a normal conversation is between 50 to 70 dB.

These fluctuations are too large can be caused by the location of sound sources is a speaker that connects to the microphone as a speaker to speaker. The location of the speakers are on the floor in front of the stage space, so the spread of the sound is not optimal. With the laying of the speakers at the venue, the sound coming from the speaker are directed not optimal in terms of distance to reach the ears of listeners in the most remote locations. It can be seen from the schematic reflection sound contained in Figure 4 for this auditorium. Given the auditorium which has a volume of space, especially height, which is larger than the space in general, placement of the speakers should be positioned at a greater height to achieve the sound intensity is still quite enough to seat a distant location.

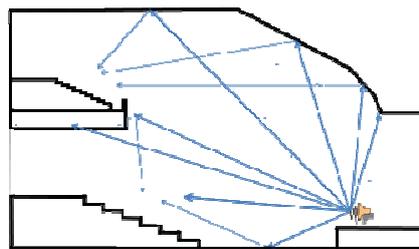

Figure 4: Sound Reflectance Scheme Auditorium K301

### 3.3. Reverberation Time

Reverberation time estimation results for both the auditorium can be seen in Table 4. Based on recommendation by the Acoustical Society of America [9], the RT of an auditorium that is used in an educational facility in the neighborhood suggested in the range of one to 1.5 seconds.

Table 4: Reverberation Time

S. Soeria Atmadja Room		K301 Room	
Frequency	RT	Frequency	RT
500 Hz	1.27	500 Hz	1.88

<b>1000 Hz</b>	1.13	<b>1000 Hz</b>	1.37
<b>2000 Hz</b>	1.02	<b>2000 Hz</b>	1.42
<b>RT<sub>60</sub></b>	<b>1.14</b>	<b>RT<sub>60</sub></b>	<b>1.56</b>

RT60 values for K301 auditorium is at 1.56 seconds is 0.06 seconds in which the value is greater than the upper limit of the recommended reverberation time. The RT that has been estimated at 500 Hz exceeds the upper limit of the recommended reverberation time, while the reverberation time at a frequency of 1000 Hz and 2000 Hz are still in a range of reverberation time recommended. Therefore, the reverberation time in the auditorium of K301 still be controlled to achieve a lower reverberation time for low frequency sound can have a lower reverberation time. To control the reverberation time in the auditorium of K301, can consider the absorbent materials used on the ceiling and the material used as a reflector panel.

RT60 values for the auditorium of S. Soeria Atmadja are within the range recommended reverberation time that is equal to 1.14 second. If you see the results of estimation of reverberation time for each frequency has been calculated that 500, 1000, and 2000 Hz, the estimated reverberation time is still within the range recommended reverberation time.

The results of the measurement data level of illumination at each seat in Auditorium K301 can be seen in Table 5. Standard lighting for a room that is used for learning is based on SNI 03-6575-2001 250 lux. Standard level of lighting can be categorized in the category D is a visual task lighting to work with the contrast or large size. As can be seen, there are still seats on the course of this space that do not meet the lighting standards of workmanship required for the illumination of 250 lux on the task. The number of college seats in this space that meets the standard of 250 lux illumination only two seats.

If viewed from the appropriate lighting levels for the activities carried on in the auditorium is the category D, there are eight seats that meet the lighting for that category. At this auditorium, there were already 152 seats or 69% of the total seats that meet the college level lighting to category C. Lighting levels for category B is owned by a 52 seat lecture or 24% of the total seats in college, while there are still three seats that meet the category A the category of the lowest standards of illumination. Table 4 shows the classification level of lighting in the lecture auditorium chairs S. Soeria Atmadja.

Table 5: Classification of Illuminations at Auditorium K301

Category	Activity	Lecture Seats	
		Amount	Percentage
A	Public place with low-lights illumination	3	1%
B	Temporary place for visit or orientation	52	24%
C	Working place for visual assignment	152	69%
D	Contrast or big scale visual assignment	8	4%
0 - 20	Unstated	5	2%

Table 6 shows the classification of college seats in the auditorium of S. Soeria Atmadja lighting by categories suggested by the Engineering Society Illumination by type of activity undertaken. Standard illumination of 250 lux lighting standards are included in category D, where already there are 30 seats that meet this category. However, the percentage of seats that meet this category only 11%. The highest percentage of seats by 36% to have lighting on the category B, where the lighting category is only intended as a temporary meeting area lighting. In addition, the seat lecture in this room there are those who are in category A which is the category with the lowest total lighting standards.

Table 6: Classification of College Seats in Auditorium S. Soeria Atmadja

Category	Activity	Lecture Seats	
		Amount	Percentage
A	Public place with low-lights illumination	32	12%
B	Temporary place for visit or orientation	99	36%
C	Working place for visual assignment	87	32%
D	Contrast or big scale visual assignment	30	11%
0 - 30 Lux	Unstated	27	10%

#### 4. CONCLUSION

- The acoustic condition of Auditorium K301 located at the Faculty of Engineering, University of Indonesia does not meet the acoustic criteria needed to support learning activities. It can be seen from the noise level exceeds the maximum limit of 35 dB, which exceeds the estimated reverberation time of 1.5 seconds, and the value of the ratio S / N of +15 dB has not met for all parts of the room.
- The acoustic condition of Auditorium S. Soeria Atmadja contained in the Faculty of Economics, University of Indonesia is good enough to meet the acoustic criteria needed to support learning activities. It can be seen that the estimated reverberation time in the range of 1 to 1.5 seconds and the value of the ratio S / N of +15 dB to meet almost all parts of the room. However, the noise level criteria for the auditorium of S. Soeria Atmadja not meet the criteria of a maximum of 35 dB.
- The lighting condition of Auditorium K301 has not fully met the recommended standards of illumination above 250 lux is based on SNI 03-6575-2001 on procedures for the design of artificial lighting systems in buildings and in Category D based on the minimum lighting category for activities in space suggested by the IES (Illumination Engineering Society). It can be concluded from the study 96% of the seats that have not been getting lighting in Category D.
- The lighting condition of Auditorium S. Soeria Atmadja has not fully meet the recommended standards of illumination above 250 lux is based on SNI 03-6575-2001 on procedures for the design of artificial lighting systems in buildings and in Category D based on the minimum lighting category for activities in space suggested by the IES (Illumination Engineering Society ). It can be concluded from the study 89% of the seats that have not been getting lighting in Category D.

## ABSTRACT

*Risk is an inherent factor within any project implementation. In recent decades the number of project risk is increasing over time. Risk management is one the success factors to achieve project goals and to improve the organization overall performance. Traditional theories in strategic management suggest that the higher the level of project risk management the better the organization performance. On the other hand, more recent theories of strategic management suggest that there is no risk management that apply universally. It means that it is necessary to adjust project risk management for different needs and circumstances of the projects. Based on those two conflicting statements it is need a study to empirically assess instrument to measure the maturity level of project risk management compared to the performance of the organization is needed.*

*A valid and reliable instrument to measure the maturity of project risk management has been successfully developed. The instrument was adapted to Indonesia condition and well developed from six existing models that have been carried out by preview researcher through literature review and discussions with experts. The development starts with literature review to build theoretical model with several dimension, sub dimension and items. The study continues with pilot study to test the face and content validity of the instrument. Main survey is conducted to collect data from empirical study , followed by some statistical test. One of the method that being used is exploratory factor analysis. At the final step, model to indicated correlation between level of project risk management and organization performance is build.*

*The result of the research is a valid and reliable instrument well developed with empirical test. The result of empirical studies isa model to indicated the relationship between the maturity level of risk management and organizational performance is delivering with equation  $y = - 93.681 + 58.7x$ . Significance value is 0,00 which mean that there is a significant relationships between independent variables and the dependent variable. R-square value is 0.38, which mean the variation of the variables that form the organization's performance (y) can be explained by the variable level of project risk management maturity (x) by 38 per cent. Hence, this empirical study provides supporting evidence to the traditional theories*

## Keywords

*Project risk management, construction industry, top management*

## 1. INTRODUCTION

Project cannot be separated from risk, it is necessary to identify and analyze risks of the project to maximize positive effects and minimize the consequences of the negative effects. Identify and analyze the risks is called Project Risk Management [2]. Risk management is also a determining success factor of the project at the last few decades. In project risk management, risk of the project will increase caused by increasing unpredictable thing within the project [3].

The traditional theory state that the higher level of project risk management maturity of an organization is the higher value of the organization's performance [6].On the other hand [1]emerging new understanding of contingency theory. Contingency theoryis used to analyze the design and management systems to provide information that can be used by organization for various objectives. [1]states that in theory of contingency, there is no universal control system that always appropriate to be applied to all organizations in all circumstances.

The adjustment between the level of maturity and project risk management to the situation of a project needs to be done considering the trade-off between the level of use of project risk management and the costs to be incurred. [7]stated that the higher level of project risk management applied, the higher costs that may be occurred. Because of this fact, it is necessary to do empirically study, to find out which theory is the closest to the context of the conditions that exist in Indonesia. In the empirical study, an instrument needs to be developed to measure the maturity level of an organization applying their project

risk management. Then the instrument can be used to find the correlation between the levels of maturity of project risk management to organizational performance.

## **2. METHOD**

### **2.1 Research Objectives**

Generally, this study aims to determine the correlation between the level of maturity of project risk management and organization performance. Therefore it is needed to develop instrument that can be used to determine the maturity level of project risk management in the organization. This study specifically aims to: 1. Develop and test an instrument to measure the maturity level of project risk management of the organization. 2. Determine the correlation of the level of maturity of project risk management to organization's performance.

### **2.2 Stages of Research**

At this early stage, the literature study is conducted to obtain alternative variables that affect the level of maturity of an organization or company to apply project risk management. All variables that have been obtained from the study of literature are listed then be adjusted to respondents who are practitioners as contractors in the construction field in Indonesia. After selected significant variables that affecting the level of maturity of the organization then research instruments to measure the performance of the organization is developed. The next step, major surveys is conducted using instruments previously declared eligible by the pilot study, validity testing, reliability testing and exploratory factor analysis. The main survey was conducted using respondents who are practitioners to obtain empirical data.

## **3. RESULTS**

### **3.1 Development of Research Instrument**

#### **3.1.1 Literature Study**

At this stage, literature study is conducted on eight journal literature that discusses about measurement of the level of risk management models. From eight journals reviewed, there were found six different models of risk management maturity level measurement. The next step is to find the intersection from six models to develop a new model that more accurate calculation and efficient in calculating the level of maturity of an organization in the implementation of project risk management. The new model developed is also adapted to the Indonesian context.

Intersection dimension among six previous models are: culture, process, experience and application. All dimensions are used to develop new model in this study. Sub-dimension of each dimension is also developed from previous research studies. After selected the dimension and the sub-dimension the next step is to determine item questions then compiled into a questionnaire. All those things are developed and adjusted with the conditions that existed in Indonesia with a discussion with expert in the field of construction. The example of the item question is, "The project risk management in my organization is standardized", the possible answer are: Very agree, agree, disagree, vary disagree.

#### **3.1.2 Profile Respondent**

Respondents in this study are a practitioner in the construction area. Practitioners are devoted to the management organization who understands the project risk management system of the organization where they work. Respondents in this study must have working experience in the current company at least three years. That requirement is to ensure the accuracy of respondents' answers to be able to give information as closely as possible that reflect the company's current condition. Total of 35 questionnaires were returned, there are two questionnaires could not be used because the respondent has a work experience less than three years.

#### **3.1.3 Validity Testing**

Construct validity refers to whether a scale measures or correlates with the theorized psychological scientific construct that it purports to measure. It is related to the theoretical ideas behind the trait under consideration [4]. In this study validation test is conducted with look at the correlation between the items that are on the same sub-dimension (intra-correlations) than the correlation between the items at different sub-dimension (inter-correlation) [4]. Non-parametric procedure is applied because the data obtained does not fulfill normal distribution so that the correlation is used Spearman correlation [5]. As previously described instrument would be valid if the value of the correlation between the items on the sub dimension (intra-correlations) greater than correlation between items in different sub-dimension (inter-correlation). Items that did not pass the validation test will be removed from the questionnaire. The correlation items question in dimension A is presented in Table 1. Item X1.2, X1.1, X1.8 is removed from the questionnaire

Table 1: Correlation item in Dimension A

Dimension A		Sub Dim 1			Sub Dim 2			Sub Dim 3			Sub Dim 4		
		X1.2	X1.4	X1.7	X1.1	X1.5	X1.6	X1.3	X1.9	X1.11	X1.8	X1.10	X1.12
Sub Dim 1	X1.2	1											
	X1.4	<b>0.077</b>	1										
	X1.7	<b>0.15</b>	<b>.569**</b>	1									
Sub Dim 2	X1.1	0.036	<b>.483**</b>	0.208	1								
	X1.5	-0.076	0.356	0.236	<b>0.291</b>	1							
	X1.6	0.038	0.35	0.295	<b>0.323</b>	<b>.612**</b>	1						
Sub Dim 3	X1.3	<b>-.367*</b>	0.251	0.251	0.017	0.353	0.189	1					
	X1.9	0.062	0.166	<b>.488**</b>	-0.057	0.059	<b>.406*</b>	<b>.407*</b>	1				
	X1.11	0.017	0.274	<b>.539**</b>	-0.013	0.3	<b>.468**</b>	<b>.436*</b>	<b>.741**</b>	1			
Sub Dim 4	X1.8	0.095	0.3	<b>.596**</b>	0.008	-0.022	0.09	0.205	0.323	0.321	1		
	X1.10	0.141	0.285	<b>.635**</b>	-0.008	0.226	0.284	0.206	0.326	0.352	<b>0.308</b>	1	
	X1.12	0.164	<b>.461*</b>	<b>.480**</b>	0.179	0.335	<b>.382*</b>	0.282	0.343	<b>.469**</b>	<b>0.151</b>	<b>.440*</b>	1

### 3.1.4 Reliability Testing

Reliability testing is an index that indicates the accuracy measuring system can be trusted or reliable. Reliability indicates the consistency of a measuring instrument for measuring the same concept. The research instrument is reliable if have Cronbach Alpha above 0.70 [5]. Cronbach Alpha value for each sub-dimension as seen from Table 2, it shows that all Cronbach Alpha values exceeding 0.70. The results showed that all of the items for each sub-dimension are reliable

Table 2: Reliability Testing

Dim	Sub Dimension	n	Cronbach's Alpha	Intepretation
Dim A	Sub Dimension 1	2	0.713	Reliable
	Sub Dimension 2	2	0.818	Reliable
	Sub Dimension 3	3	0.812	Reliable
	Sub Dimension 4	2	0.703	Reliable
Dim B	Sub Dimension 1	2	0.736	Reliable
	Sub Dimension 2	3	0.739	Reliable
	Sub Dimension 3	2	0.798	Reliable
Dim C	Sub Dimension 1	3	0.799	Reliable
	Sub Dimension 2	3	0.799	Reliable
	Sub Dimension 3	3	0.832	Reliable
Dim D	Sub Dimension 1	3	0.774	Reliable
	Sub Dimension 2	2	0.722	Reliable
	Sub Dimension 3	3	0.732	Reliable

### 3.1.5 Exploratory Factor Analysis

Factor analysis is a multivariate method used to analyze the items that allegedly have links with each other [5]. The linkage can be described and mapped or grouped on the right factors. There are 33 items passed the test of validity and reliability. Those 33 items is tested with factor analysis. Test KMO (Kaiser-MeyerOlkin) conducted to determine the appropriateness of the factor analysis performed. Based on Table 3, it can be seen that the assumption of feasibility and adequacy of the data has been met, because there is not any value of KMO MSA less than the threshold value 0.5. Barlett Test is a statistical test to examine whether the items included in the one-dimensional cross-correlated [5]. The null hypothesis (Ho) is no correlation between the items, while the (Ha) is the correlation between items. Base on the calculation can be seen in Table 3 the significant 0.000. So Ho is rejected and Ha is accepted, it means there is an inter-item correlation

Table 3: KMO and Barlett test result

Dimensi	Kaiser's Measure of Sampling Adequacy	Barlett Test Sig.	Interpretasi
---------	---------------------------------------	-------------------	--------------

A	0.660	0,000	The data is correlated
B	0.517	0,000	The data is correlated
C	0.785	0,000	The data is correlated
D	0.571	0,000	The data is correlated

Determining the number of factors is based on Eigen value of a matrix of inter-item correlation. Factor analysis process will be terminated when the Eigen value is 1. Grouping described in detail in Table 4

Table 4: Total factor with eigenvalue calculation

Component	Total Eigenvalue			
	Dim A	Dim B	Dim C	Dim D
1	<b>4.023 (44.6%)</b>	<b>2.682 (38.3%)</b>	<b>4.607 (51.2%)</b>	<b>2.921 (36.5%)</b>
2	<b>1.448 (16.1%)</b>	<b>1.66 (23.7%)</b>	<b>1.568 (17.4%)</b>	<b>1.738 21.7%</b>
3	<b>1.198 (13.3%)</b>	<b>1.07 (15.2 %)</b>	0.801	<b>1.153 (14.4%)</b>
4	0.713	0.547	0.588	0.814
5	0.546	0.494	0.419	0.5
6	0.466	0.391	0.339	0.436
7	0.285	0.156	0.32	0.242
8	0.204		0.235	0.197
9	0.117		0.122	
	<b>3 factor</b>	<b>3 factor</b>	<b>2 factor</b>	<b>3 factor</b>

The extraction method used was principal components to distribution the items of the question in factor analysis. The division of the items into groups is based on a comparison of certain factors loading. Table 4 shows that the dimension A from nine items proposed is formed in to three factors. Component 1 had a total value of initial eigenvalues of 4.023 or 44.6%. It can be interpreted that factor one can explain 44.6% of the total factors that will influence the level of organizational maturity on the dimension of A, the dimension of culture and leadership, as well as for other dimension.

### 3.2 Correlation between Project Risk Management Maturity and Organization Performance

#### 3.2.1 Organization Performance

This section is talk about the effect of project risk management maturity level of the organization to their organizations' performance. The organizational performance is calculated based on the reduction of 100 percent (perfect condition) with a percentage of the discontinued projects, the percentage of projects that over-budget and late , the percentage of projects that experienced over budget but not delayed, the percentage of projects that are not delayed but over budget. The data of project value in organization can be collected from questioner.

### 3.2.2 Project Risk Management Maturity Level

Project risk management maturity level is obtained with factor score method. Factor score calculation is by assigning weights to each of the items that make up the sub-dimension. The weight is obtained from the value of the largest factor loading of each item in the sub-dimension. The weight is multiplied by the value of each item and then calculated as the average value of each item on the sub dimension. Distribution of the data calculated by the method of factor scores can be seen in Table 5 [5].

Table 5: Factor score calculation

	Dimension A	Dimension B	Dimension C	Dimension D	Total
Max	3.2	3.4	3.2	3.1	3.0
Min	1.8	2.1	1.7	1.9	2.0
Avg	2.7	2.7	2.5	2.4	2.6

### 3.2.3 The Model of Correlation between Project Risk Management Maturity and Organization Performance

Before performing linear regression analysis, there are some assumptions that must be met, including autocorrelation test, normality and nonheteroscedasticity error. Test the assumptions made and the data obtained that qualified to do linear regression

After linear regression assumptions are met then do a linear regression analysis. Linear regression is used to develop models to determine the correlation between maturity level of project risk management and organization performance

Table 6: linier regression result

Model	Unstandardized Coefficients		Sig.
	B	Std. Error	
(Constant)	-93.681	34.397	0.011
X	58.702	13.236	0

From the table 6 can be seen the significance value below 0.05 which means that there is significant correlation between the independent variables to the dependent variable. The regression equation can be interpreted that if the project risk management maturity level increases by one the organization's performance increased by 58.7 times with the constants value -93.681. The variable x has positive value which means that the higher the level of project risk management maturity, the higher the performance of the organization. The model is

$$y = -93.68 + 58.7x \quad (1)$$

## 4. CONCLUSION

An instrument to determine the maturity level of project risk management in the organization has been developed and have passed the test of validity and reliability. Instruments developed with reference to six similar models that have been developed by previous researchers. Instrument can be used to measure the maturity level of organization implementing project risk management adapted to the conditions that exist in Indonesia. Correlation between maturity level project risk management to organizational performance can be seen by the equation  $y = -93.681 + 58.7x$  with a significance value 0.00 and r-square 38%, which means there is a significant relationship between the independent variables and the dependent variable, in addition, the variation organizational performance variable (y) can be explained by variable levels of project risk management maturity (x) by 38%. In addition, there is a positive correlation between (y) and (x) so that it can simultaneously support the statement of [6] who said that the higher level of risk management maturity is the higher value of organization performance.

### ABSTRACT

The project has unique and temporary characteristics. These characters are not only found in construction projects, but also information technology (IT) projects. In the competition to win a project, contractors must carry out competitive bidding. The winner is often a contractor who offers the lowest price. Since the winner provides the lowest bid, it prones to small profit or even losses. Conversely, if the contractor expects a higher profit, then the chance of winning tender will be decreased. This is a trade-off in determining the offering price of the project.

The contractor performs the calculations by using intuitive judgment. The use of intuitive judgment sometimes produces biases. In this study, the risky behavior of bidders when determining profit margin is studied. The experiment was administered to 15 respondents from the IT solution provider companies (IT contractors). Scenarios were used in this experiment by referring to the orthogonal array (OA) of the Taguchi method. The experimental results were analyzed by using ANOVA, ANCOVA and t-test analysis then compared to the theoretical framework based on prospect theory.

Results showed that the experimental data only partially support the theory. ANOVA concluded that the scenarios tested on the respondent do not affect the respondent's decision in determining the profit margin. The analysis is continued by considering the influence of risk attitude toward profit margin. It was found that risk attitude dominates the decision determining the risk attitude profit margin as indicated in ANCOVA. The profit margin high when respondents are risk averse and risk is low when the respondents are seeking.

### Keywords

*Project, information technology (IT), bidding, experiment, prospect theory*

### 1. INTRODUCTION

According to the Project Management Institute [1] a project has two main characteristics namely temporary and unique. The project is unique based on the availability of historical data which is very limited. The limited data lead project practitioners, such as contractor, face the difficulties to make cost estimation.

In globalization era, challenges for the company to survive become much greater. One of the competitive strategies to increase the company's value is the implementation of information technology. Information technology (IT) becomes a business strategy for the company to maintain information's flow inside and outside organization. This opportunity used by the IT contractors to develop their business.

In Indonesia, bidding system that frequently used is contractors who offer the lowest price of the project will become the winner. Since the winner provides the lowest bid, it prones to small profit or even losses. Conversely, if the contractor expects a higher profit, then the chance of winning tender will be decreased. This is a trade-off in determining the offering price of the project. [2].

According to Hartono [3], there are four major components in the calculation of the project price estimation: project costs, overhead costs, contingency budget and profit margin. The profit margin determination is deemed crucial and complex from a contractor's perspective. It has a direct bearing toward contractors' well-being in the long term business. But, determining an accurate profit margin is not easy. The goal of maximizing the expected project profit was not always the case in project bids. The profit margin determination strategy might be driven by various motivations such as a strategic concern, resource capacity, and number of competitors and so on.

The fact that a profit margin determination was performed mostly by senior management by using subjective judgment that leads to human error [4]. The limited mental processing capability of human decision makers may cause errors in judgment which could eventually lead to less than accurate results (biases).

## 2. METHOD

### 2.1 Research Objects

This study will use primary data in the form of data samples to be obtained through the experimental method using a questionnaire as a research instrument. Respondents expected in this research are the senior/mid-level managers in IT contractor (IT solution provider) which has a direct involvement in the decision-making process of project bidding.

The sample size required in a study depends on the type of statistical analysis methods used. Statistical methods will be used in this study are t-test, ANOVA and ANCOVA. Field [5] says that one of the assumptions of the t-test, ANOVA and ANCOVA is normally distributed. When the data were normally distributed, the data considered sufficient. This study used 15 respondents for each scenario.

### 2.2 Stages of Research

In general, the research stage is divided into three phases, namely the development of a theoretical model, instrument development and implementation of the main experiment. Development of a theoretical model refers to one-reason decision framework developed by Hartono [3].

After the theoretical model established, the scenarios for the development of research instruments developed. The research instrument was a questionnaire form consists of several parts, namely respondent and company profiles, analytical scenarios and risk attitude measurement. Measuring risk attitude using decision analysis theory with the case of change orders that are familiar to practitioners of the project.

Before the questionnaires distributed, a pilot study conducted to validate the research instrument. Validation of the survey instrument is conducted qualitatively by the pilot study respondents to assess the design of the survey instrument. Pilot study respondents were coming from the project management student to the respondents with experience in IT projects.

## 3. RESULTS

### 3.1 Development of Theoretical Models

#### 3.1.1 Prospect Theory and Framing Effect in a Profit Margin Determination Context

The model was built following the principles of parsimony and based on relevant theories and supported by previous studies. In the development of theoretical models, the first step is to elaborate the variables that affect the determination of the profit margin in this study. Secondly, described the relationship of each variable with the determination of the profit margin. Relationship between variables past financial performance ( $X_1$ ), project backlogs ( $X_2$ ), project strategic importance ( $X_3$ ) and contractor size ( $X_5$ ) is based on research Hartono [3]. While the risk attitude variable ( $X_4$ ) is based on Kahneman and Tversky [6]'s research. Prospect Theory and Framing Effects by Kahneman and Tversky [6] are used to explain the beginning theory of the decision-making by practitioners in determining the profit margin.

In this study, the practical definition of risk was applied. Risk was related to possible downside effects on the profit margin determination. In this sense, contractors would see a profit margin determination which leads to a failure as riskier alternative. Conceptually, there are two possible competing conceptions regarding to what constitutes risky bidding, namely (a) not getting the contract; (b) getting the contract but eventually earning profit less than the aspiration [3]. The two competing conceptions are presented in Table 1.

*Table 1: Two Competing Conception on Risky Bidding*

No.		High Profit Margin	Low Profit Margin
1	The chance of NOT getting the project	Higher chance (riskier)	Lower chance (less risky)
2	The chance of earning	Lower chance (less risky)	Higher chance (riskier)

profits LESS than aspirations	
-------------------------------	--

So the hypothesis can be made as follows:

*Bidders who view their company's performance as being below aspirations tend to engage in risk seeking behavior by providing a low profit margin. While bidders who view their company's performance as being above aspirations tend to engage risk averse behavior by providing a high profit margin.*

### 3.1.2 Relationships between Past Financial Performance and Profit Margin Determination

Decision-makers in determining the profit margin consider the financial state of the company in the previous period as the aspiration to measure the level of risk. According to Prospect Theory [6] when the financial company is in the negative frame or below expectations, the decision makers will generally behave as risk seeking and provide the relatively low profit margins. This suggests an aggressive stance to increase the likelihood of winning the tender. Conversely, when decision makers see the state of the company as above expectations, the level of need for new projects is low, so the decision makers set a high profit margin. In accordance with Hartono [3], the hypothesis can be made as follows:

*H<sub>1a</sub>: Bidders who view their own companies' prior performances as being below aspirations (in terms of company-level rate of returns) tend to engage risk seeking behaviors by providing low bid markups;*

*H<sub>1b</sub>: Bidders who view their own companies' prior performances as being above aspirations (in terms of company-level rate of returns) tend to engage risk averse behaviors by providing high bid markups.*

### 3.1.3 Relationships between Project Backlogs and Profit Margin Determination

Project backlogs will reflect the company's performance in the future. When the project backlogs above company expectations, the decision makers would think that the company does not require additional project, so the motivation to win new projects will be low. Besides, if it wins a new project, it will have an impact on the need for extra capacity and will incur additional costs [7]. This will affect the decision of determining the profit margin, where the decision will set a high profit margin. And vice versa.

From this analysis, the hypothesis can be made as follows:

*H<sub>2a</sub>: Bidders who view their companies' project backlogs as being below aspirations tend to engage risk seeking behaviors by providing low bid markups;*

*H<sub>2b</sub>: Bidders who view their companies' project backlogs as being above aspirations tend to engage risk averse behaviors by providing high bid markups.*

### 3.1.4 Relationships between Project Strategic Importance and Profit Margin Determination

A project can be considered to be of strategic importance for the company, so the motivation to win such a big project. For instance, the decision maker knows that the winning project, the opportunity to get similar projects in the future more wide open. Winning projects can provide benefits to the company in the long run. From the motivations, decision-makers will act in risk seeking to determine risk low profit margins in order to win the tender project.

Conversely, if the project according to the decision maker does not provide a strategic advantage for the company, the profit margins are higher because the project is not so exciting to win. From the analysis of Hartono [3], the hypothesis is as follows:

*H<sub>3a</sub>: Bidders who view the projects as having high values of strategic importance tend to engage risk seeking behaviors by providing low bid markups;*

*H<sub>3b</sub>: Bidders who view the projects as having low values of strategic importance tend to engage risk seeking behaviors by providing low bid markups.*

### 3.1.5 Relationships between Risk Attitude and Profit Margin Determination

When associated with the determination of the profit margin, the risk factors will affect the attitude of a decision maker (estimator) in determining the profit margin of the project by ignoring the uncertainty; do overestimates or underestimates in the calculation and assessment without any clear basis [8]. Decision makers' risk behavior will be consistent with their risk propensities [8], the hypothesis is as follows:

*H<sub>4a</sub>: Risk averse bidder will provide a high profit margin*

*H<sub>4b</sub>: Risk seeking bidder will provide a low profit margin*

## 3.2 A Contingency Framework to Explain and Predict Profit Margin Determination

Hypotheses H<sub>1</sub> through H<sub>3</sub> shows the effect of each independent variable to the determination of the profit margin. Just look at their relationship when standing alone cannot represent the determination of the profit margin when all the variables that appears in the process of determining the profit margin.

Contingency approach is needed in this study to see how these three variables in the scenario of the past financial performance ( $X_1$ ), project backlogs ( $X_2$ ) and the project of strategic importance ( $X_3$ ) calculated and combined in the process of determining the profit margin.

One Reason Decision Model [9] used in this study, where a decision maker will ultimately make a decision based on one excuse after observation and a review of some of the information could potentially be a factor that influenced the decision. One Reason Decision Model consists of the priority rule, stopping rule and decision rule [9].

Initial allegations to the order of priorities in this study followed Hartono's research [2] is project strategic important ( $X_3$ ) in the order of priority. Second are project backlogs ( $X_2$ ). Last is the past financial performance ( $X_1$ ). Some of the scenarios in Table 2 were created for the show One Reason Decision Models in this study.

Table 2: Contingency Framework of Profit Margin Determination

Scenarios	$X_1$	$X_2$	$X_3$	Predicted Y Profit Margin
	Past Financial	Backlogs	Strategic	
Scenario 1	Not relevant	Not relevant	H	L
Scenario 2	Not relevant	A	L	H
Scenario 3	At least one of the three variables is B		L	L

Note: A: above aspiration, B: below aspiration, H: high, L: low

The first scenario ( $S_1$ ): decision-makers focus on the project strategic importance. In this scenario, a bidder perceives that the project strategic importance ( $X_3$ ) of a project being observed is 'high' and disregards the values of other determinants. Referring to the hypothesis  $H_3$  is when decision makers see the strategic side of a project gives high value to the company, the decision-makers will be set low profit margins to increase the probabilities of winning the project.

The second scenario ( $S_2$ ): decision makers shift his/her attention to the project backlogs. This is due to the decision makers do not see the project delivering strategic value to the company. In this scenario, the state of project backlogs companies is above expectations. This information is a stopping rule for decision-making. Referring to the hypothesis  $H_2$ , then when the project backlogs above expectations, decision makers will set a high profit margin.

The third scenario ( $S_3$ ): decision-makers shift their focus on the company's financial condition. When the financial condition of the company in the previous period below the expectation, then the decision will set a low profit margin to win the project. This scenario refers to the hypothesis  $H_1$ .

### 3.3 Instrument Development and Evaluation

Conjoint Analysis Methods or Design of Experiment (DoE) was used, using three factors (past financial performance, project backlogs and project strategic importance) and two levels. Then the full-factorial experimental design was adopted in part by using standard orthogonal array of Taguchi method.

Taguchi method was chosen because this method does not require a lot of mathematical calculations to figure combination scenario, unlike fractional factorial. In addition, by using a standardized method of Taguchi experiments, so that for the same problem is expected to provide similar results although done by different researchers [10]. Design  $2^3$  has an orthogonal array for each variable are shown in Table 3.

### 3.4 Data Processing

#### 3.4.1 Analysis of Variance (ANOVA) and Analysis of Covariance (ANCOVA)

ANOVA and ANCOVA analysis was conducted to see if the covariate risk attitude ( $X_4$ ) and the size of the contractor ( $X_5$ ) have a significant influence on the decision of determining the profit margin in IT projects.

Before the main analysis of the data, Levene's homogeneity test was conducted. Levene's test results showed that the *Sig.* > .05, It can be said to be a variant on the covariates is the same scenario that is not affected by stimulus experiments, thus meeting the assumption of independence.

Table 3: Description of Each Scenario with Taguchi Orthogonal Array

Profile#	Description		
	Level:		
	$X_1$ (past financial performance)	$X_2$ (project backlogs)	$X_3$ (project strategic importance)

1	Negative	Negative	Low
2	Positive	Negative	High
3	Negative	Positive	High
4	Positive	Positive	Low

When the model including only the three main variables that past financial performance ( $X_1$ ), project backlogs ( $X_2$ ) and the project of strategic importance ( $X_3$ ) the corrected model (SSM) is obtained 111,679. After a variable risk attitude ( $X_4$ ) is entered, corrected model (SSM) rose significantly to 529,088 by contribution risk attitude variable ( $X_4$ ) of 417,408. Is said to be a significant covariate seen from sig. processing results with SPSS,  $F(2.54) = 4.75$ ,  $p = 0.013$ , whereas the  $p$ -value  $< 0.05$ , it can be said to be a significant variable affecting the model.

Then ANCOVA analysis performed by including a contractor size ( $X_5$ ). Corrected model (SSM) ride, but not too significant, namely a 530,425 with contributions from risk attitude variable ( $X_4$ ) of 365,992 and a variable sized contractors ( $X_5$ ) of 1338. Judging from the size of the contractor's significance insignificant seen from  $F(1.53) = 0.030$ ,  $p = 0.863$ , while the risk attitude variable ( $X_4$ ) is still significant, namely  $F(2.53) = 4.090$ ,  $p = 0.022$ .

The conclusion of this analysis is the risk attitude variable ( $X_4$ ) deserve inclusion in subsequent analyzes because it proved to have a significant effect on the model. Contractor size ( $X_5$ ) does not need to be included in the analysis because it does not affect the model significantly.

### 3.4.2 Scenario's Result Based on Theory

By using one-reason decision-making determination of the approximate profit margin of each scenario can be seen in Table 4.

Table 4: The decision results from the Profit Margin Determination Theory One-Reason Decision

Scenarios	Profile Descriptions			Profit Margin
	Level of:			
	$X_1$ (past financial performance)	$X_2$ (project backlogs)	$X_3$ (project strategic importance)	
1	N	N	N	L
2	P	N	P	L
3	N	P	P	L
4	P	P	N	H

Note: P: positive, N: negative, H: high, L: low

### 3.4.3 Grand Mean Calculation

This study uses four scenarios; each scenario has 15 data from respondents. The data include respondents expected profit margin and profit margin estimates for each scenario respondent. The calculation of the average in the study using the relative profit margin ('Yhat'), which estimates the profit margin profit margin expectation reduced respondents. Grand mean calculation results are shown in Table 5.

### 3.4.4 Comparison of Results Based on average and Grand Mean Each Scenario

From Table 5, it can be interpreted that the scenario has an average below the grand mean would result in a decision determining the low profit margins. While the scenarios that have above average grand mean will result in a decision determining the high profit margins.

Table 5: The calculation results of average and Grand Mean (n=60)

		Mean (Standard deviation)	The grand mean (Standard deviation)
Yhat	Scenario 1	1.12 (8.35)	-0.54 (7.01)
	Scenario 2	-1.55 (6.27)	
	Scenario 3	-2.18 (5.88)	
	Scenario 4	0.45 (7.46)	

The decision determining the profit margin from the results of comparing the average of each scenario with its grand mean was then compared with the theoretical profit margin in Table 4. The results of the comparison are shown in Table 6.

Table 6. Profit Margin Scenario Comparison and Theory

	Theory	Yhat
<b>Scenario 1</b>	L	H
<b>Scenario 2</b>	L	L
<b>Scenario 3</b>	L	L
<b>Scenario 4</b>	H	H

Note: H: high profit margin, L: low profit margin

Table 6 shows the correspondence between the decision determining the profit margin based on the theory and experiment. Most of the experimental results fit with the theory, which are in Scenario 2, Scenario 3 and Scenario 4. While in Scenario 1, there is a mismatch between theory and experimental results.

Scenario 1 is the scenario in which all variables are negative (below expectations). Based on the theory of one-reason decision, should decide on Scenario 1 produces low profit margins. From the experimental results, Scenario 1 apparently resulted in the decision set a high profit margin, contradicting the theory.

### 3.4.5 T-test Analysis

Analysis of t-test conducted to prove the comparison of the average of each scenario with the grand mean and to see the effect of stimulus scenarios on decisions determining the profit margin

Analysis of t-test were used in this study is a one-tailed t-test. These selections were due early predictions against experimental results, which is based on theories that have been described previously. T-test analysis was performed using SPSS 16.0 software, which the adjustment to the calculation of significance using the analysis of two-tailed t-test, so as to know the sig. one-tailed t-test should be halved in advance as shown in Table 7.

Table 7. T-test Results Each Scenario (n=60, df=14)

		Standard Error	t	Sig. (2-tailed)	Sig. (1-tailed)
<b>Yhat</b>	Scenario 1	2.16	.769	.455	.228
	Scenario 2	1.62	-.623	.543	.272
	Scenario 3	1.52	-1.080	.298	.149
	Scenario 4	1.93	.515	.615	.308

From Table 7 it can be seen that the value of sig. from the Yhat's calculation are  $> .05$  so  $t$  is not significant. Each t-test calculations have a confidence level (confidence level) of 95% for the difference in the average. So, if it is assumed there are 100 samples, 95 samples will have an average value of between -4.90 to 6:28. Interval values gives the average probability is zero which means that both the average group compared samples did not differ (same), thus indicating the samples come from the same group.

The conclusion that can be drawn from this analysis of the t-test is that the sample for each scenario comes from the same population. Scenario experiments designed to manipulate variables thought to affect the determination of the profit margin, did not significantly affect the decision of the respondent in determining profit margins.

### 3.4.6 Subgroup Analysis with Entering Risk Attitude ( $X_4$ )

It has been in the ANCOVA analysis that risk attitude variable ( $X_4$ ) worth taken into account as it significantly affects the corrected model (SSM) model. In this section will analyze the profit margin ratio determination theory with experimental results which consider risk attitude held by the respondent.

The theory underlying the determination of the profit margin from the perspective of risk has been elaborated in Prospect Theory [6] that when a person has a risk-seeking nature it will be aggressive to win the tender in a way set a low profit margin. Conversely, when a person has a risk averse nature it would be conservative to maintain the peg profit margins high.

Table 8. Comparison of Theoretical and Experimental Results with Risk Attitude (n=60)

	Theory		Yhat		
			Mean	Stdev	Category
Scenario 1	<i>Seeking</i>	L	-0.1	5.366563	L
	<i>Neutral</i>	L	-1.55	2.294014	L

	<i>Averse</i>	L	5	13.43503	H
Scenario2	<i>Seeking</i>	L	-5.1	3.879433	L
	<i>Neutral</i>	L	-2.15	2.42126	L
	<i>Averse</i>	L	2.6	8.876936	H
Scenario3	<i>Seeking</i>	L	-6.1	5.683309	L
	<i>Neutral</i>	L	-1.65	2.713393	L
	<i>Averse</i>	L	1.2	6.906519	H
Scenario4	<i>Seeking</i>	H	-0.1	8.876936	L
	<i>Neutral</i>	H	-2.35	2.73633	L
	<i>Averse</i>	H	3.8	9.176056	H

Table 8 shows the comparison of the average of each subgroup with the grand mean. Can be observed that in Scenario 1, Scenario 2 and Scenario 3 the experimental results are not always the same in accordance with the theory that when respondents are risk averse. Scenario 4 shows the results of the contrary, the experiments with risk averse respondents resulted in the decision of determining the profit margin in accordance with the theory, while the other two risk attitude (seeking and neutral) resulted in a decision that profit margins are not in accordance with the theory.

It can be concluded that the risk attitude of respondents strongly influences decisions in determining profit margins. This is indicated by the overall suitability of the experimental results with the Framing Effect in Prospect Theory [6], the profit margin will be higher when respondents are risk averse and low when respondents are risk seeking.

#### 4. CONCLUSION

Based on the research that has been done, it can be concluded that in addition to the variable past financial performance, project backlogs and project strategic importance, risk attitude also significantly affects the determination of profit margins in the IT project.

From the experiments that have been conducted that analysis results obtained experimental results with a combination of variables past financial performance, project backlogs and project strategic importance only supports some theories. In addition, empirical data can be predicted better by considering risk attitude.

## ABSTRACT

One of the success keys in project implementation is the effectiveness of implementation level of project risk management (PRM). By implementing PRM, many opportunities and risks in uncertainty project can be anticipated immediately. However, the study for capturing condition and PRM implementation in Indonesia is not yet conducted. Therefore, this study aims providing initial representation of implementation risk management project in Indonesia. This study was focused on observing the implementation level of PRM from the organization perspectives. The questionnaire was developed and distributed to 61 top managements in the construction industry with a 57.4% response rate. The questionnaire item developed considered on the study of [1] which is grouped into four dimensions, namely culture, process, experience and application. According to the culture, process, experience dimensions, the PRM implementation in Indonesia can be stated as satisfied. Nevertheless, in the application dimension, the implementation is not yet applied completely. It is depicted on the formal technique in the risk analysis which is rarely used in Indonesia (73%). This result is similar with other countries which is not yet conducted the formal technique of PRM.

## Keywords

*Project risk management, construction industry, top management, implementation*

## 1. INTRODUCTION

Project is indicated by the unique characteristics and the limited project duration [2]. Many companies and organizations conduct project management for many crucial activities such as business process re-engineering [3], change management [4], new product development and infrastructure installation. However, CHAOS report conducted by Standish Group found that in many project performances were below expectation. The trend of project performance in Indonesia is seems to be similar to those studied by Standish Group. A comprehensive study explaining about the project performance in Indonesia is not yet conducted.

One of the success keys in the project is the effectiveness of implement level of project risk management [5]. By implementing good project risk management (PRM), many opportunities and risks in uncertainty project can be anticipated immediately [5]. In addition, reference [6] also stated that the risk in projects will increase when the uncertainty level of project is high. Therefore, good implementing of risk management is prominent in order to obtain the goal of the project.

Many empirical studies had been carried on in many countries to observe actual condition and level implementation of PRM in project. Empirical studies reported that framework, method, and tools related with PRM are rarely applied by practitioner. Therefore, risk management approach has ad-hoc characteristics and not yet to be generalized because of the lack of familiarity [7], the lack of understanding [8], the insufficient knowledge and the experience [9] on applying PRM. On the other hand, time and human resource limitation become another important reason for accomplishing PRM implementation [8]. Reference [9] also argued that technical reason, such as data limitation, essentially influences in risk analysis. Otherwise, the environment factors, such as government policy and business motivation, also affect PRM implementation of industry. For instance in US nuclear power operation development, government policy significantly supported the US industry to adopt advanced PRM approach [10]. However, several empirical studies are conducted only in developed countries as resumed on Table 1. Hence, the study for capturing condition and PRM implementation in developing countries contexts, particularly in Indonesia, are strongly limited and must be conducted immediately.

Table 1: Empirical study in PRM implementation

No.	Author, Year	Domain	Location	Method
-----	--------------	--------	----------	--------

1	Akintoye and MacLeod, 1997	Construction industry	UK	Questionnaire
2	Shen, 1997	Building Contractors	Hong Kong	Questionnaire and Interview
3	Raz and Michael, 2001	Software & High-tech industries	Israel	Questionnaire
4	Wood and Ellis, 2003	Cost Consultant companies	UK	Semi-structured interview
5	Lyons and Skitmore, 2004	Construction Industry	Queensland, Australia	Questionnaire
6	Simu, 2005	Small Projects	Sweden	Semi-structured Interview
7	Tang et al., 2007	Construction Industry	China	Questionnaire, Interview & Case Study
8	Paté-Cornell & Dillon, 2001	NASA	US	[not a formal empirical study]
9	Apostolakis, 2004	Safety	'---	[not a formal empirical study]

Therefore, this study in Indonesian PRM implementation is significantly important because by capturing the actual condition of implementation PRM in Indonesia, the big picture will be used as a foundation for many initiatives related in implementing project risk management. On the other hand, in academic perspective, this overview will be used as future research foundation and framework, method and tools of risk management development in Indonesia.

## 2. METHOD

This research is a part of a series of studies to understand, to develop and to adapt novel PRM methods in Indonesia. Purposing to recognize initial condition of PRM in Indonesia, this research falls under the first stage of “understanding” stage. This research is more focused on observing the implementation level of PRM in organization perspectives rather than project practitioner perspectives. Therefore, to represent the organization perspective, this research used top management in the construction company as respondents. In addition, this research was conducted by empirical approach known as cross-sectional survey with using primary data provided by questionnaire and survey. Table 2 explains about the response rate, in which there were two methods for distributing questionnaire, namely email (26 questionnaires) and survey mail (35 questionnaires). A response rate of 57.4% is achieved with the sample size of 35 respondents.

Several stages were carried out to conduct the research. Firstly, the development of survey instrument was accomplished by adopting question items from literature studies, which was adjusted in Indonesian contexts. Afterwards, the question items were assessed qualitatively, namely face validity and content validity by conducting pilot study. Face validity and content validity are obtained by using the pilot study to six practitioners about their respond on instrument proposed. Subsequently, the instrument would be revised until the numbers of feedback were omitted. Therefore, the proposed instrument could be claimed as valid and ready to use. Finally, the result is assessed by descriptive statistics and compared by the PRM previous study in developed countries.

Table 2: Response rate

Questionnaire Distributed		Response Rate
Email	26	57.4 %
Survey Mail	35	
Total distributed	61	

## 3. RESULT AND DISCUSSION

### 3.1 Profile of Respondent

Having distributed by online survey and mail survey, the questionnaire was returned to researchers with a response rate of 57.4% (35 respondents) showed on Table 2. However by data cleansing, 2 of 35 data cannot be used in the result analysis because of the lack of experience of respondents regarding to Certified Associate in Project Management (CAPM). CAPM stated that the project practitioners can be guaranteed as the experience practitioners when they have experience more than three years. Thus, for preserving accuracy and capturing actual condition, two respondents were excluded because they only have experiences less than three years.

On the other hand, this experiment was focused on the organization perspectives. Therefore, there is required the reliable sample who must understand wholly in term of their organizations. One way to provide the reliable sample is by knowing their background, such as respondent’s position, scale of industry and so forth. Table 3 explains about the current position of respondents, which is divided into three groups, namely top management such as general manager, vice president, project manager and so forth; mid management such as process engineer, engineering staff and project control engineer; and low

management such as technical administration and technical laboratory. Regarding to Table 3, most of respondents are the top management with portion as much as 80%.

Table 3: Descriptive statistics of respondent's positions (n=30)

No	Positions	Total	Percentage (%)
1	Top Management	24	80
2	Mid Management	4	13
3	Low Management	2	7
	Grand Total	30	100

On the other hand, respondents are also classified into their company size. According to *Badan Pusat Statistika* (BPS), there are four types of company size, namely micro enterprise, small enterprise, medium enterprise and large enterprise. The first type of company size is the micro enterprise which has employee less than four people. The second type of company size is the small enterprise which the company has the employee between 5-19 people. Meanwhile, the third and fourth company size regarding to BPS are the medium enterprise which has the employee roughly 20-99 people and the large enterprise which has the employee more than 100 people. Table 4 explains the respondents according to their enterprise scale. Indeed, considering the Table 4, most of the respondents come from the small and medium enterprise.

Table 4: The size of industry based on the number of employee

No	Size of Industry	Total	Percentage (%)
1	Micro Enterprise	1	3.3
2	Small Enterprise	10	33.3
3	Medium Enterprise	14	46.7
4	Large Enterprise	5	16.7
	Grand Total	30	100

As explained before, the respondent background is also described into their experience in project management. There are three types of experience regarding to the time depicted on Table 5, namely 3-5 years, 5-10 years, and more than 10 years. The minimum requirement of respondents is three years experience for securing accuracy to figure out precisely the actual condition in their company.

Table 5: The experience of respondents

No	Experience Time	Total	Percentage (%)
1	3- 5 years	9	30
2	5-10 years	13	43
3	>10 years	8	26
	Grand Total	30	100

According to Table 5, most of respondents had been working for approximately more than five years. Hence, they understand completely in term of the risk management in their industry due to their experiences.

Table 6: The comparison between criteria in each category

Criteria	Current Study	More Successful	Less Successful	CHAOS report 2008
	Mean (%)			
Project Success	58	78.9	37	16
Project Challenged	38.6	20.3	57	53
Project Impaired	3.4	0.8	6	31

Ultimately, the respondent is divided in terms of the accomplishment in completing project during the last three years. Based on CHAOS report developed by Standish Group [11], the accomplishment in completing the project is divided into three criteria, namely project successful, project challenged and project impaired. The successful project is the project completed on-time and on budget with all features and functions as initially specified. Meanwhile, project challenged can be described as the project operated completely yet over-budget, behind schedule and offers fewer features and functions than originally specified;

and the impaired project is the project cancelled at some point during the development cycle. Hence, to compare the study result and the CHAOS report, the study also divides the respondents into three criteria which the same with CHAOS report criteria. However, to make it detail, this study also divides the respondent into two groups, namely more successful and less successful based on their performance to accomplish the project. The more successful group is the respondent having the portion of project success under the average (58%) and vice versa.

Table 6 compares between the portions of project performances of the respondent and CHAOS report. The percentage of project success in this study is more than three times higher rather than CHAOS report. On the other hand, the percentage of project impaired according to CHAOS report is ten times higher than PRM in Indonesia. Briefly, in a glance, the accomplishment level of successful project in Indonesia is better than result of CHAOS report in 2008.

Meanwhile, considering the group of project performance, the more successful group has the highest number in the portion of project success and the lowest number in the portion of project impaired. Meanwhile, compared to the others, the less successful group has the highest number in the portion of project challenged, in which it is similar to the CHAOS report.

### 3.2 Project Risk Management Implementation in Indonesia

The questions item consists of four dimensions considering the previous study conducted by [11], namely culture, process, experience and application. The summary of the comparison of each dimensions depicted in Table 7. Culture dimension is related to the companies' awareness of the important of PRM implementation [6]. This dimension explains comprehensively about the attitude of each company eliminates risk during the project, such as senior manager's response as well as commitment and leadership of the organizations to support the implementation of PRM.

According to the data collected, 90% of respondents are aware to PRM implementation. It is depicted on their commitment that PRM is one of the success keys and a part of sequential efforts to achieve the company's target. Compared to the developed country, such as UK, the companies' awareness of PRM in Indonesia is significantly excellent. It occurred since PRM members in UK are unconscious to conduct PRM due to the lack of familiarity in term of risk management [8]. The top management in most of project in UK did not provide the contribution to conduct the PRM. It is similar to the PRM implementation in Queensland which the most barriers for implementing PM are the top management [7]. Nevertheless, it is strongly different with 96.7% of the top management in Indonesia who always supports and contributes to PRM implementation by being a raw-model through providing the real evidence to other members. On the other hand, 76.7% of the top management also awards an achievement to project member who has the most contribution in PRM.

On the other hand, in order to conduct PRM, not only top management which must aware to PRM implementation, but also all of members related to project. All members must understand the possibility of risk embedded during the project. This behavior to inform and notify the risk to all members had been applied in Israel, Queensland and China. They utilize the brainstorming to identify risk information before the project started. Surprisingly, this behavior to inform risk to all project members is also adopted by 93.3% of construction industry in Indonesia.

The second dimension is process dimension. It highlights about the standard process and the ability of organization in term of dealing with risk [6]. In this dimension, the good risk management is a stepwise procedure composed of several processes whether it can be repeated continuously throughout the project lifecycle. Commonly, the organization which is aware to risk uses the historical data in term of risk in the last similar project in order to become the standard process of the next project. According to the data collected particularly in this dimension, 96.7% of PRM implementation in Indonesia also uses the historical data by collecting the feedback of the last similar project to improve their performance in the further similar project. The other way to improve the performance is conducting the monitoring, evaluation and audit process during the project. This is similar with PRM in Indonesia which 90% of project in construction industries use them for improving the further project. Meanwhile, PRM implementation in China uses another way called joint evaluation in order to assess risk [12]. Surprisingly, the use of PRM is not only applied on the developed countries but it is also implemented other domains, such as US Nuclear project and NASA. US Nuclear project had conducted integration among other PRM processes in order to obtain the effectiveness of project, such as quality management and government policy. Therefore, many project members tried to use the advanced PRM approach in order to accomplish the policy. In line with US Nuclear Power, NASA also used PRM as the routine procedure [10]. Hence, it is not separated from the project implementation itself. However, the implementation of PRM in two instance domains are significantly different with PRM implementation in Indonesia which tends to ad-hoc rather than make PRM as the routine procedure equal to NASA project.

The third dimension is known as experience dimension explaining about how the organization members face the project risk. The goal of this dimension can be achieved successfully when all members can use basic risk management skill in order to support risk management process in the organization. Therefore, the regular training to enhance the skill of PRM members is strongly required obtain the goal of this dimension [1].

Table 7: The comparison between PRM in Indonesia and other developed countries

Point of Interest	Past Studies		Current Study
	Location, Year	Findings	
1. Culture	UK, 1997	Most of PRM member in UK is not aware to conduct PRM because of the lack of familiarity [8]	90% of respondents stated that their company is aware whether PRM is one of success factors and a part of sequential effort in their company
	Queensland, Australia, 2004	Most of PRM barrier is caused by resource constraint [7]	60% of their top management always supports and commits PRM implementation with real evidences. 76.7% of respondents stated that their company always provides an achievement to project member who has the most contribution in PRM
	Israel, Queensland and China	Brainstorming is conducted to identify and provide risk information	93.3% of respondents stated that their company usually notified risk information
2. Process	US, 2001	US Nuclear regulations push the industry to adopt more advanced PRM approach [10]	90% of respondents stated that PRM process in their company is integrated with the other PRM process, such as quality management, government policy and so forth.
	US, 2001	PRM is lagging behind other domains such as NASA in applying risk concepts. NASA has risk standardization, from resistance to routine procedure [10]	Only 73.3% of respondents stated that ad-hoc PRM is usually used in their company
3. Experience	Queensland, Australia, 2004	Most of PRM barrier is caused by resource constraint [7]	73.3% of respondents stated that PRM training is usually conducted in their company
	China, 2007	PRM member usually conduct joint evaluation to analyze risk [12]	86.7% of respondents stated that their company usually uses the evaluation of project as a lesson learning
	UK, 1997	Lack of understanding in PRM [8]	86.7% of respondents stated that project member in their company is understand of PRM concept
	Hong Kong, 1997	Insufficient knowledge and experience on applying PRM [9]	
4. Methods	UK, 1997	The increased availability of computers do not appear to have much impact on the tools being used [7]	90% of respondents stated that their company has operated the computer to PRM activity, for instance cost accounting, database and scheduling.
	Queensland, Australia, 2004	The use of computers was found to be consistently lower in PRM than this in other project applications, such as cost accounting, database and scheduling [9]	
	China, 2007	The use of computers and modeling techniques in risk analysis is seldom used [12]	
	UK, 1997	PRM uses few formal techniques [8]	26.7% of respondents stated that their company rarely used formal technique in risk analysis in PRM implementation

Regarding to the data collected, 86.7% of PRM members in Indonesia are sufficient in understanding of PRM concept. This condition is strongly influenced by the effectiveness and the frequency of training and evaluation which are conducted frequently to urge the PRM knowledge of each member. This strategy, training and evaluation, had been conducted by China

as well for eliminating the probability of risk in the further project [12]. Therefore, surprisingly, it significantly influences the project performance in China.

Dissimilar to China, the project members in UK and Hong Kong have different knowledge of PRM in which the knowledge is not distributed uniformly in each member. Thus, only particular project member understands comprehensively in terms of PRM [9]. Whereas, supporting of all project members in the implementation of PRM is strongly prominent because the commitment of top manager in the first dimensions is not adequate without the commitment of all members as well to accomplish the project goal. Hence, the strategy such as explained before is important to conduct it.

Meanwhile, the last dimension is the application dimension. It provides detail in tools and method required to handle risk. Reference [1] stated that the good project organization in this dimension must identify and analysis risk with integrating and using both quantitative and qualitative methods and tools. Practically, tools and method using in PRM implementation in Indonesia is more advance and sophisticated rather than other developed countries. It is supported by two evidences. Firstly, 90% of respondents have operated the computer to PRM activity, for example cost accounting, database and scheduling. Whereas, many countries in China, UK and Queensland, rarely use computer in PRM activity compared to other countries. Reference [7] stated that the computers for PRM activity rarely use particularly in Queensland. In line with reference [7], reference [12] stated that the use of computer and modelling techniques in risk analysis are seldom utilized in China since the increasing of availability of computers does not affect significantly in the project performance.

Secondly, 73% of respondents argued that simple technique is worthless to prevent risk in PRM implementation. Therefore, PRM practitioner in Indonesia tends to provide advanced method to eliminate risk. Compared to several projects in UK, they only use the simplest model to estimate the risk which will be probably appeared [13]. As the consequences, the tools such as influence diagram, neural network and other complex tools are rarely used in develop countries to estimate the risks.

Nevertheless, though PRM has the excellent on the application of this dimension, the formal technique in risk analysis is rarely used in Indonesia (73%). In line with PRM Indonesia, reference [8] conducting PRM research in UK stated that PRM implementation in UK also uses few formal techniques, similar to Sweden and China.

#### 4. CONCLUSION

According to the result in the previous chapter, explained that most of the dimensions are placed in the pleasant condition. Firstly, PRM implementation in Indonesia is incredibly excellent not only in their member and top management but also in providing risk information in the culture dimension. Secondly, related to process dimension, PRM implementation in Indonesia is conducted smoothly. For instance, it can apply in the routine procedure as other domains. Thirdly, considering on experience dimension, PRM member is categorized as a proficient member because of their knowledge of PRM due to their frequently training. Ultimately, however, in the last dimension, PRM in Indonesia must be improved particularly in term of using the formal technique. In conclusion, by considering on the four dimensions, PRM implementation in Indonesia can be categorized as the good implementation of PRM.

Nevertheless, this study about PRM implementation in Indonesia is not completely explain the detail condition PRM implementation in Indonesia but only provide the big picture of PRM implementation in Indonesia due to three reasons. First, the type of industry used on this study is only construction industry. Therefore, other type of industry such as service, information technology (IT) industry and so forth are not considered. Hence, the further research can be more considering towards other enterprise types in order to represent the detail and the real condition in Indonesia.

Second, this study is conducted on the newest period compared to other PRM study in the developed countries. The last study in the literature review is study conducted by reference [12]. Hence, it might appear the improvement of PRM implementation after five years of Tang's study.

Third, the use of expert judgment as the input of this study does not accurately represent the real condition during the project. Reference [14] stated that the expert judgment can provide the systematic bias when they must estimate. Therefore, to solve this limitation, the further study must be conducted particularly to develop the standard instrument to measure the expert judgments particularly when they must estimate risks which will be appeared.

### ABSTRACT

*Gunaksa harbor is a harbor which provides crossing from Bali to Nusa Penida Island or vice versa. The harbor is located at Gunaksa beach, which has not had access to harbor. Thus, a way leading to Gunaksa harbor needs to be built to ease the accessibility and mobility from and to the harbor. Except being a crossing site, the harbor is going to be developed to be a tourist harbor and a back up for Padang Bai harbor. In addition, at area at the harbor surroundings (the ex of entrenchment) will be developed from a nonproductive land to be a land related to tourism, residence, and other public facilities. To realize road construction to the harbor, a feasibility study of some aspects, including route, environment, economics, as well as financial aspect should be undertaken.*

*Construction of a new road generally requires quite high financial investment and maintenance cost, that aspect of needs and functions for society and its investment feasibility should be considered. Due to the construction plan there are four alternative routes that should be analyzed, including: 1) that with 1.77 kilometers long, 2) that with 2.02 kilometers long, 3) that with 2.05 kilometers long, and 4) that with 2.25 kilometers long. The four alternatives will be analyzed with a number of indicating variables, such as length or distance, congestion rate, land acquisition, travel cost (travel time value and vehicle operating cost), environmental impact and area development using Analytical Hierarchy Process (AHP) method. AHP is a method implemented to analyze a complex multiple criteria to be a hierarchy which is then analyzed using matrix to obtain range of priority based on the criteria. The analysis result showed that access alternative 1 has the highest matrix score or is the 1<sup>st</sup> rank.*

*By operating the access alternative 1, the travel time spent will be 2.655 minutes, the lowest travelling time value is Rp 89,488,813 per year, the lowest vehicle operating cost is Rp 40,325,515 per year. It will result in the lowest travelling cost Rp 129,814,328 per year and the benefit will frequently increase in the future.*

*Analysis on investment feasibility based on criteria used with interest rate 12%, 15%, and 18% showed that the total NPV values was positive; BCR > 1 with the lowest BCR value 1.98. Pursuant to assumption of bank interest rate 18% per year, IRR value was 33.52% which is higher than the interest rate. It indicates that the alternative access investment is economically feasible. Based on sensitivity analysis with assumption of interest rate 18%, that there was increase in cost 20% and decrease in benefit 20%, the analysis also showed that NPV > 0, BCR = 1.5, and IRR = 24,86% which is higher than the interest rate. It indicates that the investment was not sensitive to change of benefit and cost to 20%. It can be concluded that based on all indicators used in this study showed that the construction of alternative access 1 to Gunaksa Harbor is feasible to undertake.*

### Keywords

*Vehicle Operating Cost (VOC) Saving, Travelling Time Value, Net Present Value (NPV), Benefit Cost Ratio (BCR), Internal Rate of Return (IRR)*

### 1. INTRODUCTION

Klungkung regency is located at east Bali. The regency has a major island of Nusa Penida which is separated from the main land of Klungkung and is still under the administration of Klungkung Regency. Seeing from its area width composition, one

third of the regency total width is located at the main land (11,216 Ha) and the rest two third is at the island of Nusa Penida (20,284 Ha). Since 2007 until 2012 the Government of Klungkung had been establishing Gunaksa harbor as the access for crossing to the Nusa Penida island. The harbor construction is intended to smooth sea transportation and accessibility between the two lands, i.e. Klungkung main land and Nusa Penida Island in order to maintain a better, routine, and fast transportation.

Development of sea transportation is closely related to land transportation as a supporting access to the continuity of the harbor operational. To achieve this target, this shall be supported with a good access road to the harbor which connect harbor hinterland and harbor area. The planned construction of access road to Gunaksa harbor is a transportation facility between Nusa Penida harbor with Gunaksa harbor. The access road plays a role strategically and importantly as it is one of knot crossing network of which break the isolation of island outside Bali area and is hoped to enhance economic activities in Klungkung regency particularly and in Bali generally.

In line with the rapid development of economy in Indonesia in general and in Bali particularly, development of access road to Gunaksa harbor is completely needed. In order for them to realize it, study on the best alternative access to the harbor shall be conducted to see its feasibility based on a number of aspects, such as route, environment, economy and financial aspect. The empirical study can be used as a reference for the Government of Klungkung in prioritizing development in that area.

## **2. THEORETICAL BACKGROUND**

### **2.1 Project Feasibility Study**

Feasibility study is a research or study undertaken comprehensively based on some aspects in purpose to analyze a project's level of feasibility. A project's level of feasibility is an important initiating stage of the activity of a set of project cycle. The same case is also valid for projects of transportation. The result of the study is a recommendation whether the project needs to be continued to further stage. In other word, the study of feasibility is intended to analyze to what extent the project's level of feasibility, so that the limited natural resource can be allocated appropriately, efficiently, and effectively. A project shall be executed in the case that it can be accountable economically and financially (Kadariah, 2001). Thus, it is very clear that a project's feasibility study is required as an assistance for a decision making process.

### **2.2 AHP (Analytical Hierarchy Process) Method**

AHP is a decision supporting model developed by Thomas L. Saaty (1994). The model will break down a complex multiple-factor problem or multiple criteria to be a hierarchy. According to Saaty, hierarchy is defined as a representation of a complex problem in a multiple level structure where the first level is purposed, followed by factor level, criteria, sub criteria and further down until the last level of alternative. With a hierarchy, a complex problem can be broken down into its groups, then it managed into hierarchy format so the problems show more structurally and more systematically.

### **2.3 Vehicle Operating Cost (VOC) Saving**

Theoretically, vehicle operational cost is influenced by a number of factors, such as vehicle condition and type, environment, rider habit, road condition, as well as traffic. The cost is estimated for types of vehicle representing their group, and is stated in a monetary per unit of distance (Rp/km). Nowadays, there are various model and method of calculating VOCS, namely Pacific Consultant International (PCI) Capacity Manual, Highway Design and Maintenance (HDM), World Bank, Indonesian Highway Capacity Manual (IHCM), and Central Road Research Institute (CRRI). There are also a number of VOCS counting models in Indonesia. In this research, the vehicle operation cost model which is focusing on vehicle speed by LPM ITB whereas vehicle operation cost is the total of running cost and standing cost.

### **2.4 Travelling Time Value**

Time is a real cost in transportation. Travelling time value or time saving value is defined as the total amount of money willing to spend by someone to save one time unit of journey (Hensher, 1988). In a project's feasibility study, traveling time saving is total travel time deviation with that or with no project. Saving time value per time unit which is usually taken per hour, shall be counting also the time daily saving. The total daily time cost is then converted into yearly time cost and then its result is used to be net value to obtain time cost saving.

## **3. RESEARCH METHOD**

### **3.1 Access Alternative Selection Method**

For the best alternative choosing from a number of existing access alternatives, method of AHP was applied. In this method, some stages were conducted as follows:

1. Defining problems and determining solution used.
2. Making a hierarchic structure preceded by the main goals
3. Making a paired comparing matrix describing relative contribution or the influence of each element to aim or criteria which is at the same level as that above it.
4. Defining paired comparison to obtain the total assessment result of  $n \times [(n-1) 2]$  pieces.
5. Counting value of Eigen and examining its consistence.
6. Rewinding steps 3, 4, and 5 to all levels of hierarchy.
7. Counting Eigen vector of each matrix of paired comparison which is the value of each element for determining priority on the elements at the level of the lowest hierarchy to achieve the goal.
8. Checking hierarchic consistence with consistence risk of lower than the same as 10%.

### 3.2 Economic Feasibility Assessment Method

Some investment criteria will be used to evaluate the project feasibility economically or financially is Net Present Value (NPV), Benefit Cost Ratio (BCR) and Internal Rate of Return (IRR). Economic analysis is based on net economic cost-benefit analysis by comparing economic benefit “with” and ”without” project. The benefit difference between “with” and “without” project development is benefit gained by the project development.

#### 3.2.1 Net Present Value (NPV)

*Net Present value* (NPV) used base point at present. Thus, all inflow and outflow are converted to the present value with interest rate determined. It is then formulized mathematically as follows.

$$NPV = \sum_{n=0}^N \frac{B_n - C_n}{(1+i)^n} = \sum_{n=0}^N \frac{F_n}{(1+i)^n} \quad (2)$$

NPV > 0 investment is considered to be economical

NPV < 0 investment is not considered economical

where:

$B_n$  = benefit accepted in the end of the year n

$C_n$  = cost spent in the end of the year n

$F_n$  = difference between cost and benefit in the end of the year n

#### 3.2.2 Benefit Coat Ratio (BCR)

Benefit cost ratio (BCR) is comparison between benefit and cost at a same point, such as present worth, future worth or annual worth

$$BCR = \frac{PresentWorthBenefit}{PresentWorthCost} \quad (3)$$

BCR > 1, investment is considered economical

BCR < 1, investment is not considered economical

#### 3.2.3 Internal Rate of Return (IRR)

Internal rate of return is interest rate producing NPV equally zero. In IRR analysis we wish to know what “r” is, thus:

$$\sum \frac{B_t - C_t}{(1+r)^t} = 0 \quad (4)$$

Where:

Bt = total of project advantage component in the first year.

Ct = total of cost component in the first year

r = IRR producing NPV = 0

The value of  $r$  making  $NPV = 0$  is then called IRR of the project. Criteria used to determine whether a project is considered feasible is the condition where IRR is bigger than discount rate or  $IRR > i$ .

### 3.2.4 Analysis of Sensitivity

In order to know how sensitive a decision is to factors change that is influencing it, every decision making on technical economics shall be with analysis of sensitivity. The analysis of sensitivity is will contribute to a description to what extent a decision will be strong enough to face factors change or parameter influencing it. In case that the factors change results in change in the decision, the decision is said to be sensitive to the parameter value change (Pujawan, 1995). Analysis of sensitivity was done by changing value of a parameter a time, then we had to see how is it impact to acceptability of an investment alternative. The Parameters which usually change and whose change can influence decisions in technical economics study is investment cost, benefit value, interest rate, and others.

## 4 RESULT AND DISCUSSION

### 4.1 Access Road Alternative Conditions

Road access to Gunaksa harbor is designed with 4 alternatives (figure 1), where the alternatives are designed with the same road class as the figure beneath.

- a. Road Type and class : type II, class I
- b. Functional Class : Primary collector road
- c. Road length : 1.770m (Sta 0+000 to Sta 1+770)
- d. Median : completed
- e. Track number and width : 2 tracks, 4 sub tracks, 4 X 3.5 m
- f. Own Road Width : 30 m wide

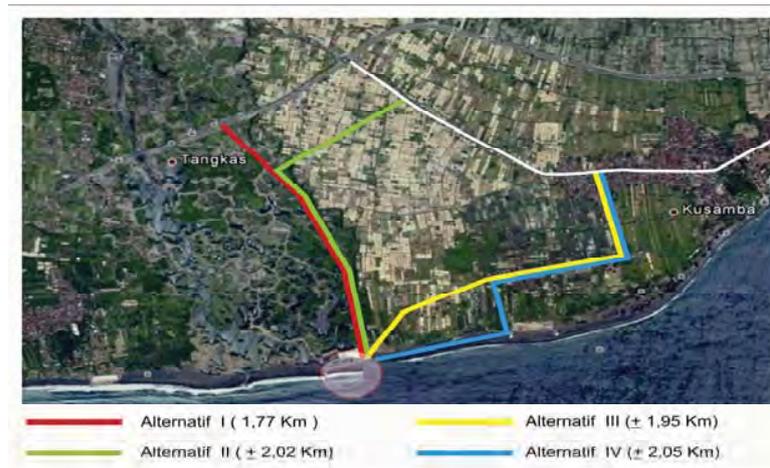

Figure 1: Four Alternatives Route to Gunaksa Harbour

Technical data and Environment for four route alternatives :

#### a. Alternative 1

- Its location is at Gunaksa Village extending from the North (at eastern part of Bridge of Unda River II) to south until the End of Gunaksa Harbor
- Road alignments are made to connect the harbor with the hinterland
- The road alignment site was consolidated by Government of Klungkung. The alignments are made 1.770 m long extending from the highway of Ida Bagus Mantra until Gunaksa harbor.
- Basically, its horizontal alignments can be said to be straight without any sharp turning and its vertical alignments are considered extreme since there are fairly deep entrenchments.
- The topographic condition of the lower road varied where there are a lot of entrenchments ex using power tools and sand suction machine with extremely 15 meters deep. The entrenchments are full of water.
- There are 4 big entrenchments in the site, there are Sta. 0+625, sta. 1+450, sta 1+550, and sta. 1+700. The extremely deepest entrenchment is that of 15dpl at sta. 1+700.
- Apart from the entrenchment there is dry land with topography between 0 until +12.00 dpl. The dry land consists of mound of sand and soil.

- Basically, the land is not inhabited by people. However, some people are fond to do activities of traditional mining.
- There is no wet agricultural land at all.

**b. Alternative 2**

- The site of the second alternative is quite similar to the first alternative, from Kusamba street exactly 500 meter from the High Way cross road going to Kusamba going through rice field area to west part reaching sta. 0 +500 in alternative 1, and extending to the south until the end of the harbor.
- Some of the alignment sites had been consolidated by Klungkung government. The alignments are made for 2.020 meters length extending from Kusamba street until Gunaksa Harbor.
- Based on horizontal alignment, the road alignment is shaped L where there is one quite sharp turning. However, based on vertical alignment, the alignment condition is very extreme because there are ponds and quite deep entrenchments about 1.200 and it is a rice field area of about 800 m long.

**c. Alternative 3**

- Its location is at Kusamba village starting from Gunung Batur street (Batur and Rame sub-village). It is following the existing road to Karangdadi sub-village existing to the west going to the harbor.
- Half of the alignment is using the existing road of 3–5 m wide, and the rest half of the alignment is still a rice field area.
- The alignment is made 1.950 m long extending from Kusamba streets to Gunaksa harbor.
- Based on its horizontal alignment, the road alignments are quite winding, and based on its vertical alignment the condition of alignment is not very extreme because some of the alignment area is the existing area where there are housing and rice field along the road.
- Its topographic condition is quite good since there are not entrenchment as in alternative 1 and 2.
- The area is basically a residing area.
- The wet agricultural activities are still productive at the area since 60% of all citizens are farmers and fishermen.

**d. Alternative 4**

- It is located at Kusamba village, starting from Batur street (Batur and Rame sub village), following the existing road to Karangdadi sub village, and then turn to the south to the Fish Docking Harbor (FDH) of Karangdadi and extending to west to the harbor passing the beach.
- Half of the alignment is the existing road with width of 3 – 5 m. The rest area of the alignment is still in form of rice field area. The alignment is made 2.050 m long extending from Kusamba street until Gunaksa harbor.
- Based on its horizontal alignment, the road alignment is quite winding. However, based on vertical alignment, the road alignment condition is not too extreme as the half of the alignment is the existing street which is still surrounded with residing place and rice field area.
- Some parts of the area is dry sand land as it is located at the beach side of Gunaksa.

**4.2 The route choosing analysis with Analytical Hierarchy Process (AHP) method.**

Diagram of decision making on route maintenance is shown in figure 2 as the basis for making matrix with the following variables.

Choice of Variable:

I = alternatif 1 with distance 1,770 Km

II = alternatif 2 with distance 2,02 Km

III = alternatif 3 with distance 2,05 Km

IV = alternatif 4 with distance 2,25 Km

Variable of comparing Criteria (indicator)

A = distance/length

B = level of density

C = land acquisition

D = travel cost

E = environment impact

F = area development

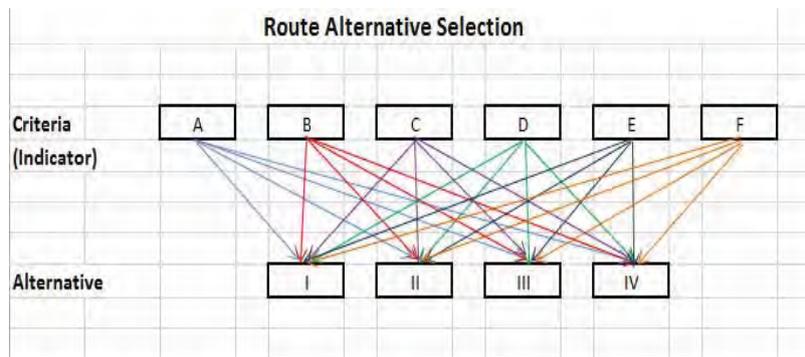

Figure 2: Decision Making Diagram

Based on matrix analysis in some stages with various above mentioned criteria, matrix result is shown as in table 1. The table shows that the one obtaining the highest matrix multiplying score (rank 1) which is considered as the best alternative is alternative access road route 1 whose location is based on the figure 1.

Table 1: Final Matrix on AHP Analysis Result

	A	B	C	D	E	F	MULTIPLICATION MATRICS	RANK ALTERNATIVE
I	0.18	0.24	0.25	0.18	0.10	0.05	0.46	1
II	0.66	0.07	0.58	0.67	0.58	0.10	0.19	2
III	0.17	0.14	0.21	0.17	0.30	0.16	0.17	4
IV	0.13	0.30	0.13	0.12	0.07	0.28	0.18	3
	0.04	0.48	0.07	0.04	0.05	0.47	1	
	1	1	1	1	1	1	1	

### 4.3 Economic Feasibility Analysis

Economic feasibility analysis will be carried out to access road alternative to Gunaksa harbor obtaining the highest rank based on the above mentioned analysis which also has various betterment, that is access road of alternative 1.

#### 4.3.1 Project Cost

Cost component calculated in planning the investment on the access road development to Gunaksa harbor consists of:

1. Investment cost estimation
  - Land procurement cost
  - Construction coast
  - Study, design, and maintenance cost
2. Operational and maintenance cost estimation

Description and amount of the cost component is as follows:

##### 1. Land Procurement cost

Cost for the land consolidation refers to the Tax Object Selling Price (TOSP) per area at the access road which will be built. The cost of land consolidation will generally be decided pursuant to area width and the building, as well as number of utility and plantation that will be removed prior to the construction. Basically, there are not people residing in alternative 1 area. However, there are some people who just work as traditional miners. The wet land or rice field agricultural activities are brushed up. There have been street alignment built and the land consolidation for the harbor done by Government of Klungkung since 2001 and it has been in the 4<sup>th</sup> term with average land width 99.999 m<sup>2</sup>. The amount of compensation is Rp.13.999.860.000,- which is Rp.140.000,- per m<sup>2</sup>. The access road to the harbor procurement cost is Rp.7.434.000.000,- per 5,31 Ha with Rp.140.000 per m<sup>2</sup>.

##### 2. Construction Cost

Construction cost estimation will be determined by calculating quality of each item of work based on pre-planning design and unit price of the work item. The estimated cost includes general cost, drainage work, soil work, street body, graining work, asphalt work, structure work, and other minor work is Rp.90.152.449.000,-. In this study, with yearly inflation 8,49% the construction cost in 2014 will be Rp.124.892.501.899,61.

### 3. Design and Construction Supervising

The planning cost includes cost of study, design and project supervision. In the study, the cost amount is assumed 3,5% of the construction, i.e. Rp.4.371.237.566,49.

### 4. Operational and Maintenance Cost

Operational and maintenance cost is that spent for the routine operational activity and road maintenance including its facilities and the road supporting equipment. The cost is prepared in order that the road condition and its facilities is continuously proper. The operational and routine annual cost starting from the opening of the road in 2016 is Rp.4.036.962.785,15 and the periodically 5 year maintenance is Rp.6.728.271.308,59.

## 4.3.2 Economic Benefit Analysis

The estimated economic benefit of the access road development to Gunaksa harbor will be correlated directly with the harbor operating time as the pair of Nusa Penida harbor. Benefit of the road constructing project based on economic aspect commonly calculated as direct benefit for road user, such as Vehicle Operating Cost Saving (VCOS), Time Value Saving (TVS). The indirect benefit includes multiplier effect in study of road economic development like impact of macro-economic increase like increase of Gross Regional Domestic Product (GRDP) as the result of tourist activity increase, development of area and increase in GRDP of other business sectors upon the new road operation.

#### 1. Vehicle Operating Cost (VOC) Saving

VOC saving is counted from difference VOC prior to project and upon the project where crossing was done at Padangbai harbor with distance of 11.68 km. The crossing through Gunaksa harbor with 1.77 km at land. VOC is counted based on components related to vehicle operation, including some components: 1) use of fuel; 2) oil (lubricant), 3) tire; 4) vehicle repair and maintenance; 5) vehicle depreciation; and 6) interest, insurance, and overhead. The result of analysis show VOC without project is Rp381.208.332 in 2006, and the VOC value with the project is Rp.60.607.792 with the total saving of Rp.320.600.539,-

#### 2. Time Value Saving

The amount of time value for road users is the description of consumer time service given by road to its user. The time value allocated in this study is total time value at land and at sea through Padangbai harbor or through Gunaksa harbor to Nusa Penida. The approach used for time value calculating at land is personal income from GRDP divided by population. Time value of at seat passengers is counted based on the valid tariff for adult passengers crossing by Ferry RoRo from Padangbai. Time Value Saving is counted based on difference between travelling time prior to and upon the project either for the land and sea travel time value. The total time value saving in 2016 after being predicted based on level of growth is 7,19% or Rp.253.593.006.

#### 3. Multiplier Effect of Tourism to GRDP and Regional Revenue (RR)

Concept multiplier in these activities is based on the fact that many sector supporting tourism has relation and is dependent on one local economic community. Thus, each tourism expenses change will affect income, employment, and government revenue. Change ration in each variable above as the result of the change is called multiplier. In other word, multiplier is a risk of change of each variable to tourism expenses change. The number of foreign tourists visit in 2010 in Klugkung regency was 280.871 people and the Nusa Penida was 174.831 people. Upon the project, it is assumed that 45% tourist use the access road to go to Nusa Penida, and their average cost of purchasing is \$45 per day and the assumed average of their visit is 2 day. This results in an effect to multiplier to increase of GRDP and RR

## 4.4 Feasibility Analysis

Feasibility analysis conducted based on some assessing indicators leads in values as shown in table 2.

Table 2: Feasibility Analysis result

<b>Cost</b>	
Land Procurement cost (in year 2013)	7.434.000.000
Construction cost (in year 2014 – 2015)	124.892.501.900
Total of construction and land procurement cost non tax	132.326.501.899.61
Operational and annual routine maintenance cost	4.036.962.785.15
5 yearly routine maintenance cost	6.728.271.308.59
<b>Benefit</b>	
Vehicle operating cost Saving (operational start in year 2016)	320.600.539.76
Travelling time value Saving in operational year 2016	253.593.066.00
Multiplier effect benefit	71.825.034.414.09
Total of Benefit (operational start in year 2016)	72.399.228.019,86

Assesment Indicator		
Interest 12%	NPV	292.015.144.622
	BCR	3,46
	IRR	33,52%
Interest 15%	NPV	185.726.438.290
	BCR	2,76
	IRR	33,52%
Interest 18%	NPV	86.596.726.821
	BCR	1,98
	IRR	33,52%
Sensitivity for the assumed interest rate 18%		
Cost increased 20%, benefit fixed	NPV	100.366.162.799
	BCR	1,89
	IRR	29,68%
Cost fixed, benefit decreased 20%	NPV	75.501.973.939
	BCR	1,80
	IRR	28,49%
Cost increased 20%, benefit decreased 20%	NPV	56.587.192.516
	BCR	1,50
	IRR	24,86%

## 5. CONCLUSION

Based on the above theoretical background it can be described some important conclusion as follows:

1. The best alternative is the alternative 1, located at Gunaksa Village, based on short route, ready site, relatively minor social and environmental problem
2. Investment feasibility analysis based on the used criteria with interest rate 12%, 15%, and 18% showed that all NPV valued positive (NPV > 0), BCR > 1 with the lowest BCR value 1,98 and IRR= 33,52% with the assumed bank rate 18% per year.
3. Seeing from NPV, BCR, and IRR value, economically the access road is feasible to develop.
4. Pursuant to the sensitivity analysis conducted with assumption of interest rate 18%, increase in cost is 20% and decrease in benefit is 20%, consequently, all parameters used showed that the access road to Gunaksa harbor is feasible to develop where NPV = Rp.56.587.192 > 0, BCR = 1,5 > 1 and IRR= 24,86% which higher than the valid interest rate.

## 6. RECOMMENDATION

For further study, it is recommended to conduct activities as follows.

- Synchronization shall be synergized and made to some local development plans at the area of project.
- The more detail study to plan of cross road to harbor and Ida Bagus Mantra high way needs to be conducted.

### ABSTRACT

Presently, information system is increasingly important to support many fields such as business and education. The implementation of good information system also becomes attention improving customer satisfaction. One of some tools to analyze customer satisfaction is SERVQUAL. However, five service dimensions formulated by SERVQUAL are not always able to cover all of service attribute in some different case such as in information system field. Based on this phenomenon, it indicates that adjustment of types and number of dimension are extremely needed in special case. Information system field has different service attribute uniquely used in service performance assessment. In addition, there is also different service dimension between information system for education and for business. However, there are few researches focusing on determining service dimension of information system for higher education field, which become attention in assessing service performance. The importance of types and number of dimension results SERVQUAL evaluation. The scope of this research is determining service dimension for information system in higher education field. This research will be conducted by survey. In detail, the respondent in this research will be user of information system such as lecturer, student and management of education institution. They are stratified based on their accessibility and interest. Collected data of service attribute from this survey will be analyzed by factor analysis. The output of this analysis is service dimension.

### Keywords

*Service dimension, service quality, information system, SERVQUAL*

### 1. INTRODUCTION

Today, service activities are regarded as increasingly important for running the business [1] [2] [3] [4]. Adding service to product can influence customer satisfaction. A kind of service that can be provided by management is the implementation of information system in business system [5]. Business process will be more relatively effective and efficient by using information system. However, the effort to improve customer satisfaction by using information system should be evaluated in order it is able to understand customers' wants and needs. It is very important to understand service given to customers that is meeting with their wants and needs to establish customers' loyalty and to pursue potential customers. This is supported by empirical study that mention qualified service can increase customer satisfaction, then customer satisfaction will build customer loyalty and customer loyalty will give profitability to company [6]. One of some tools to analyze whether service given can meet customers' wants and needs is SERVQUAL. By using SERVQUAL, the performance of service given is evaluated from gap between customers' expectation and customers' perception. Those services given can be grouped into several dimensions based on the equality of function and of impact in satisfaction improvement. There are five dimensions formulated in SERVQUAL that become general model to accommodate much kind of services given. They are tangible, responsiveness, reliability, assurance, and empathy. However, five service dimensions formulated by SERVQUAL are not always able to cover all of service attribute in some different case. Based on this phenomenon, it indicates that adjustment of types and number of dimension are extremely needed in special case. The benefit of this adjustment is to avoid the misleading in understanding and in interpretation of the performance of certain service dimensions due to categorize inappropriate service attribute to certain service dimension. This adjustment had been conducted several times in previous research [7].

Based on background above, the objective of this research is to investigate the suitable service dimension for information system in higher education field. As the fact of the powerful of technology, education field also depends on information system to conduct their activities. Information system in education is like the basic needs and it expedites learning process. However, there are few researches focusing on determining service dimension of information system for education fields, which become attention in assessing service performance. The importance of types and number of dimension results SERVQUAL evaluation.

Generally, the benefit of this research is able to improve users' satisfaction by using wise service dimensions. The scope of this research is determining service dimension for information system in higher education field. This research will be conducted by method of survey.

**2. SERVICE DIMENSIONS IN SERVQUAL**

Over the years management literature has proposed many concepts and instruments concerning how to measure the service quality. Some of them are service quality (SERVQUAL), and quality function deployment (QFD). QFD is commonly used in SEE methodology to translate voice of customer in first phase into technical design in third phase. The use of QFD in process design is straightforward. However, good service delivery is a successful strategy to serve customer. Thus, knowing the gap between customer's expectation and customer's experience is important. QFD cannot record the gap. There are several gaps in service field which consists of following gaps: customers' expectation versus their understanding by manager; managers' perception of customers' expectation versus service specifications; service specification versus fulfillment; information about service versus service that is actually provided; and customers' expectations versus service provided.

Reference [8] mentioned that to evaluate service, SERVQUAL divide attributes of service into five dimensions which consist of follows:

1. **Tangibles** : The appearance of physical facilities, equipment, personnel and communications material.
2. **Reliability** : The ability to perform the promised service dependably and accurately.
3. **Responsiveness** : The willingness to help customers and provide prompt service.
4. **Assurance** : The knowledge and courtesy of employees and their ability to convey trust and confidence.
5. **Empathy** : The caring, individualized attention the firm provides its customers.

In most cases of SERVQUAL, five service dimensions above become general model to evaluate and improve service given. Whereas in some other cases, there are several services those have not been able to be covered by those five dimensions mentioned before. In addition, customer or user is very sensitive to service given selection. Thus, mistake in classifying service attributes into dimension will give bias assessment and misleading interpretation to service performance itself [7]. Obviously, service dimension will influence the assessment of service quality. Service quality of a specific service dimension is defined as the attitude of the customers' perceptions towards the specific service dimension according to their experience of uses at a specific time [9].

In fact, adjustment of the number and the kind of service dimensions is previously done in several researches. Reference [7] gave the chronologies as follow:

*Table 1: The Chronologies of Service Dimension Development*

Year	Proposer	Component/ Dimension	Additional Information
1982	Lehtinen	<ul style="list-style-type: none"> <li>• Interactive Quality</li> <li>• Physical Quality</li> <li>• Corporate Quality</li> </ul>	

*Table2: The Chronologies of Service Dimension Development (Cont.)*

Year	Proposer	Component/ Dimension	Additional Information
1984	Gronroos	<ul style="list-style-type: none"> <li>• Structure-Technical Quality</li> <li>• Functional Quality</li> <li>• Reputational Quality</li> </ul>	
1988	Leblanc and Nguyen	<ul style="list-style-type: none"> <li>• Corporate Image</li> <li>• Internal Organization</li> <li>• Physical Support of The Service Producing System</li> <li>• Staff/ Customer interaction</li> <li>• The Level of Customer Satisfaction</li> </ul>	
1988	Parasuraman, Zeithml and Berry	<ul style="list-style-type: none"> <li>• Tangibles</li> <li>• Reliability</li> <li>• Responsiveness</li> <li>• Assurance</li> <li>• Empathy</li> </ul>	Eventually led to the development of SERVQUAL
1988	Garvin	<ul style="list-style-type: none"> <li>• Performance</li> </ul>	

Year	Proposer	Component/ Dimension	Additional Information
		<ul style="list-style-type: none"> <li>• Features</li> <li>• Conformance</li> <li>• Reliability</li> <li>• Durability</li> <li>• Service</li> <li>• Response</li> <li>• Aesthetics</li> <li>• Reputation</li> </ul>	
1989	Hedvall and Paltshik	<ul style="list-style-type: none"> <li>• Willingness</li> <li>• Ability to Serve</li> </ul>	
1994	Oliver and Rust	<ul style="list-style-type: none"> <li>• Functional Quality</li> <li>• Technical Quality</li> <li>• Environment Quality</li> </ul>	

The other example given for service dimension adjustment is adjustment of SERVQUAL's five dimension in airlines industry. In airlines industry, SERVQUAL's five dimensions are difficult to apply to airlines. This is because the SERVQUAL instrument does not address other important aspects of airline service such as in-flight meals, frequent flyer programs, seat space and legroom [10]. In addition, reference [10] also showed that they adjusted the SERVQUAL's service dimension became three dimensions. Those three dimensions are as follows

- Dimension 1: Reliability and Customer Service
- Dimension 2: Convenience and Accessibility
- Dimension 3: In-flight Service

Regarding the benefits of SERVQUAL itself, reference [11] summarized the benefits of SERVQUAL as follows:

1. It is useful in understanding the opinion of customers regarding a service delivery, for example perception, expectation, and satisfaction.
2. The model alerts management to consider expectations and perceptions.
3. The gaps among different people, and at different time periods regarding expectation and perceptions can be identified,
4. It is useful in identifying specific areas of weaknesses and dissatisfaction.
5. It helps prioritize areas of service weakness to focus effort on.
6. It provides benchmarking analysis for organizations in the same service sector.
7. It can work as a basis for gathering customer requirements to explore further quality improvement analysis.

### 3. SERVICE ATTRIBUTES FOR INFORMATION SYSTEM IN HIGHER EDUCATION FIELD

Presently, organizations continue to increase spending on information technology (IT). The impacts of IT are often indirect and influenced by human, organizational, and environmental factors; therefore, measurement of information systems (IS) success is both complex and illusive [12]. Nevertheless, measurement of information system success related to users' satisfaction is extremely needed.

Users' satisfaction has close relationship with service quality. The determination of service quality is considered as a comparison process between an expected level of service and the service perceived by the user. The relationship between service quality and users' satisfaction is showed by reference [13] as follows:

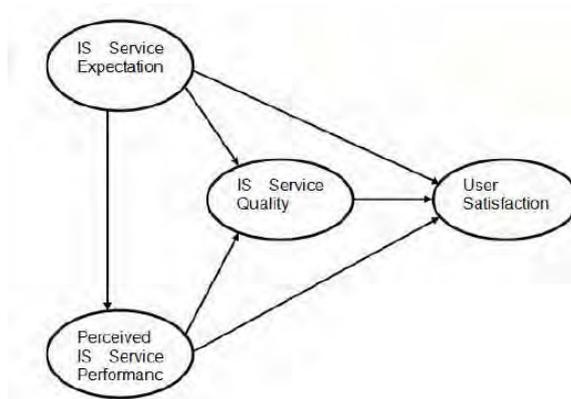

Figure 1: Users' Satisfaction Determination

In order, the measurement of success of users' satisfaction will not be misleading and bias, service dimension determination becomes something crucial [12]. Service dimension is group of some service attributes those have the same function and impact to satisfaction improvement. So that classifying of certain service attributes into inappropriate dimension will cause misleading in interpretation of performance of service dimension itself. Service attributes can be generated by several ways such as based on ISO as a fulfillment of basic requirement standard, based on the same previous research and based on voice of customer as service development indicator. Generally, service attributes used as key of success measurement in information system are as follows:

Table 1: Service Attributes for Information System

No	Service Attribute	Reference
1	Ease of using system	Research
2	Ease of learning system	Research
3	System accuracy	Research
6	Flexibility of system	Research
7	Sophistication of system	Research
8	Integration	ISO, Research

Table4: Service Attributes for Information System (cont.)

No	Service Attribute	Reference
9	Customization of system	Research
10	Consistency of network connection	Research
11	Availability of information	Research
12	Usability of information	Research
13	Understandability of information	Research
14	Relevancy of information	Research
15	Format of information/documents	Research
16	Conciseness of information	Research
17	Individual learning impact	Research
18	Individual awareness impact	Research
19	Individual decision effectiveness impact	Research
20	Individual productivity impact	Research
21	Organizational cost impact	Research
22	Overall productivity impact	Research
23	Improved outcomes impact	Research
24	Ease of accessibility	Voice of Customer
25	Speed of access and operation	Voice of Customer
26	Communication media provision	Voice of Customer
27	Quota of downloading and uploading file	Voice of Customer
28	Green information system	Voice of Customer
29	Protection from virus, spam, worm and so forth	Voice of Customer
30	Broadcasting of latest information (news, advertisement, announcement, so forth)	Voice of Customer
31	Supporting vision organization	Voice of Customer
32	Information security policy	ISO, Voice of Customer
33	Management commitment to information security	ISO
34	Confidentiality agreement	ISO

No	Service Attribute	Reference
35	Independent review of information security	ISO
36	Information classification guideline	ISO

Table 5: Service Attributes for Information System (cont.)

No	Service Attribute	Reference
37	Information labeling and handling	ISO
38	Network control and maintenance	ISO
39	On line transaction	ISO
40	Protection of log information	ISO
41	Clock synchronization	ISO
42	Privilege management	ISO
43	User password management	ISO
44	Review of user access right	ISO

Based on service attributes list above, some service attributes cannot be fitted into tangible, reliability, assurance, responsiveness and empathy. Service attributes mentioned above are service attributes which are commonly used either for information system either in business field or education field. Whereas, there are differences in both business field and education field, especially higher education field. The differences are fundamentally associated with the goal of using information system. So that, it needs to be adapted to use service attributes mentioned before for information system in higher education field. Here are several additional service attributes for information system in higher education field.

Table 6: Additional Service Attributes for Information System in Higher Education

No	Service Attribute	Reference
1	E-learning	Voice of Customer
2	On line-class	Voice of Customer
3	On line-examination	Voice of Customer
4	Cloud computing	Voice of Customer
5	Automatic examination mark calculation	Voice of Customer
6	Restricted web that is visited	Voice of Customer
7	Ease of registration	Voice of Customer
8	WIFI availability	Voice of Customer
9	Ease of device setting	Voice of Customer
10	Quota of cloud computing	Voice of Customer
11	Filtering plagiarism	Voice of Customer
12	Concern to copyright (software, ebook, research, journal and so forth)	Voice of Customer
13	Supporting for student presence, lecturer presence and employee presence	Voice of Customer
14	Paperless data back up	ISO, Voice of Customer
15	Durability of storing file to cloud computing	Voice of Customer

## 4. DETERMINING SERVICE DIMENSION FOR INFORMATION SYSTEM IN HIGHER EDUCATION FIELD

### 4.1 Questionnaire Design and Sample

Data collecting is conducted by distributing questionnaire to respondents that is defined before. The respondent in this research will be user of information system such as lecturer, student and management of education institution. They are stratified based on their accessibility and interest. The given questionnaire contains service attributes list for information system in higher education. Those service attributes are generated as method explained before. Respondents are asked to determine the importance level of those service attributes. Importance level of service is filled based on respondent's expectation toward the importance of certain service. This study adapted the SERVQUAL scale to the specific context of aviation by generating additional quality related measures or items other than the ones already included in the SERVQUAL instrument. This study will change the measurement items and the dimensions to develop a more appropriate scale for measuring service quality of information system in higher education.

### 4.2 Factor Analysis

In this study, factor analysis is used to determine the service dimension based on the importance level of service attributes which have been assessed by respondent. Factor analysis is a method for investigating whether a number of variables of

interest  $Y_1, Y_2, \dots, Y_i$ , are linearly related to a smaller number of unobservable factors  $F_1, F_2, \dots, F_k$ . Variable of  $Y_i$  in this study refers to service attribute and Factor of  $F_j$  in this study refers to service dimension.

#### 4.3 Reliability of Measures

The next step after getting the new service dimension from factor analysis is the reliability test of the new service dimension itself. Reliability test is used to know the internal consistency of service dimension and to know whether the service dimension is able to be credible measurement tools in service evaluation. The first step to do reliability test is establishing the hypothesis as follows:  $H_0$ : questionnaire is reliable;  $H_a$ : questionnaire is not reliable. Decision is taken by comparing Cronbach's alpha and R-value from table. Cronbach's alpha was used to assess internal consistency.

### 5. ANALYSIS

Based on service attribute generation on Table 3.1 and Table 3.2, at glance it can be analyzed that there are some service attributes uncovered by 5 SERVQUAL service dimension. This is probably caused that there are two different respon variable in information system field which have the same importance level in user assessment. Both the variables are related to either system quality or information quality alone. So that, both of the variables should be separately analyzed because they are not the same. In the other hand, analysis conducted by 5 SERVQUAL service dimension is general and tending to system quality in delivering service. Before grouping the attribute by using factor analysis, at glance the attributes on Table 3.1 and Table 3.2 can form dimensions based on D&M model as follows: (1) system quality is the desirable characteristics of an information system, (2) information quality is the desirable characteristics of the system outputs, (3) security is dimension protecting some either information or data, (4) Education support is dimension supporting activities for educational purpose, (5) Assurance is the knowledge and courtesy of employees and their ability to convey trust and confidence, (6) Empathy is the caring, individualized attention the firm provides its customers.

Based on service dimensions above, dimension of information quality, security and education support are uncovered by 5 SERVQUAL service dimensions. In fact, dimension of responsiveness, assurance and reliability in SERVQUAL can be covered by either system quality or information quality. There is interesting point about assurance here. Assurance in SERVQUAL is intended to guarantee and certainty of service given to user meeting with promised service to user. In the other hand, assurance in information system field is more intended to guarantee of confidential of either data or information uploaded to information system. Both of that guarantees are surely different. Therefore, service dimension of security is needed in service evaluation for information system. However, service dimension of tangible and empathy still occur in both of 5 SERVQUAL service dimensions and service dimensions above. This probably shows that tangible and empathy are service dimensions always attracting user's attention and assessment. This dimension looks like being favorite dimension for user so that it is always well provided by provider. It is probably caused by recognition of senses. While empathy is dimension covering service attribute that supports making customer intimacy. Actually service dimensions having formed above can be used for service evaluation not only in information system for higher education field but also in general information system by removing service dimension of education support. Service dimension of education support can be only used in information system for higher education because the function of implementing information system in both of them are different. The implementation of information system in education field must be based on the great value of education and it is not profit or business oriented as the main goal, so there are some service attributes used to limit and support the utilization of information system for educational purpose such as online class, concern to copyright, issue of plagiarism and so forth.

### 6. CONCLUSION

Service attributes for many kind of field are not exactly the same, so that the different field will have different service dimensions too. Based on service attributes which are in line with ISO 27001 and generating idea from voice of customer, service dimensions for information system in higher education field must be unique dimensions. It is because SERVQUAL's five dimension are not exactly fit with and cannot cover all of the available service attributes. The adjustment of service dimension was also done time by time. That adjustment could be done by using factor analysis.

## ABSTRACT

High quality, non-renewable, resource depletion through various consumptive industrial activities, as well as, emissions and wastes during resources transformation have made current industrial systems unsustainable. Industrial symbiosis, coupling economic growth with environment protection, is one of various attempts toward sustainable industrial practice. The literature on industrial symbiosis continues to grow even though the industrial symbiosis practices have been there for quite some time. However, researches on industrial symbiosis are varied and vibrant yet fragmented. This present paper therefore attempts to organize and to review the burgeoning industrial symbiosis literatures by analyzing their state-of-art whether there are gaps. The literature review was based on articles drawn from 13 databases and one internet-based research engine. The literatures are analyzed with respect to evolutions of the concept development and the degree to which material are closed and exchanged, barriers and success factors, performance indicators, and modeling techniques implemented. Research findings are further synthesized to identify direction for potential future research.

## Keywords

*Industrial Symbiosis, Literature Review, Concept Development, Barriers and Success Factors, Modeling Techniques*

## 1. INTRODUCTION

High quality, non-renewable, resource depletion through various consumptive industrial activities, as well as, emissions and wastes during resources transformation have made current industrial systems unsustainable. This will lead that the current resource use dynamics cannot be maintained for existing human populations. Therefore, people are now trying to bring about a change in the way their operation so that the negative impacts towards ecosystem can be stopped or at least minimized. Industrial symbiosis, coupling economic growth with environment protection, is one of various attempts toward sustainable industrial practice. The most famous case study of industrial symbiosis is probably the industrial district at Kalundborg, Denmark. During the development of industrial symbiosis, a number of ways to design and implement industrial symbiosis exist. Moreover, industrial symbiosis has also referred to various names, such as eco-industrial park, industrial eco-system, etc. The literature on industrial symbiosis continues to grow even though the industrial symbiosis practices have been there for quite some time. However, researches on industrial symbiosis are varied and vibrant yet fragmented.

This present paper therefore attempts to organize and to review the burgeoning industrial symbiosis literatures by analyzing their state-of-art whether there are gaps. The literature review is therefore more than a mere description. The paper follows the following methodological approach to conduct the review: building conceptual framework, searching and collecting literatures, analyzing and synthesizing findings from literatures.

## 2. FRAMEWORK

The industrial symbiosis literatures are ranging from the conceptual study to empirical study, from broad-brush exploration to in-depth case study. This present paper arranges the literatures by creating an organizing template for this work. Although several templates are possible, a framework used in this paper is built in such a way to map the literatures based on its context into two streams of research: conceptual development of industrial symbiosis (group 1) and tool used or applied in designing and implementing industrial symbiosis (group 2). The review is shaped around these streams because each of stream has distinct body of research. Group 1 deals with attempts to investigate industrial symbiosis concept, formulate its principles and elements. As a new field, industrial ecology and/or industrial symbiosis literatures are seeking to formulate a set of fundamental beliefs and cohesive concepts that lend a common meaning to all players in the field. These literatures are mainly based on conceptual-grounded work. Group 2 deals with issues and approaches related to industrial symbiosis establishment such as performance indicators, modeling and evaluation as well as barriers and success factors of industrial symbiosis around the world. The papers on this category are empirically grounded results, experiences from practice.

### 3. DATA COLLECTION

Due to the multidisciplinary nature of industrial symbiosis, the literature search was organized so that all the related field of industrial symbiosis was covered so that it could be analyzed in different context. Fields included in the literature research includes engineering, economics, environment, and business. The framework above was applied to all areas. Ten sources from databases, e-journal and internet, most of them containing articles, are explored. The data collection was conducted in four steps following the steps below,

1. Screening of databases, journals, conferences proceedings, etc to find references to publications related to industrial symbiosis
2. All the selected references were coded according to our framework, empirical and conceptual research as well as classified into two groups determined in the framework
3. Investigation of most important/central references
4. Identification of potential research themes

### 4. RESULTS AND DISCUSSIONS

#### 4.1 Literature Description

Judging from the numbers of references, research on industrial symbiosis have not yet got a foothold. As new emerging discipline the literatures of industrial symbiosis are evolving in the same way as is industrial ecology. This section addresses the industrial symbiosis literatures evolution to point the center of attention to identify the potential research agenda as well as to provide innovative routes in changing present unsustainable industrial systems.

The concept of industrial ecology was firstly introduced in 1989 [1]. Figure 1 and 2 illustrate the literatures based on the framework discussed in section 2. Tin the early stage, industrial symbiosis literatures were mainly working on the conceptual definition. With respect to the empirical case, the Kalundborg case in Denmark appeared in 1996 literature was the first working model of industrial symbiosis. Afterwards, the industrial symbiosis concept has been refined and the numbers of case and/or project on industrial symbiosis have been increasing since then. The conceptual literatures have given a baseline for studying the cases while case study literatures have inspired to further distill the concept. Case study literatures also contribute to the development of tools for designing and developing industrial symbiosis. Early study on industrial symbiosis was dominated with the technical and economic perspectives. Therefore, there was unbalance between the social and technology study in the area of industrial symbiosis as sustainability is not only based on technology and economy aspects but also social aspect. Furthermore, Cohen-Rosenthal [2] challenged the reductionist and engineering approaches in industrial ecology in general and industrial symbiosis in particular by stressing the importance of solid understanding of the functioning of industrial network and the role of human resources. Human dimension and inter-organizational issues was then addressed in 2006 literatures. Recent development in industrial symbiosis literatures is an attempt to adopt systemic perspective when designing and evaluating industrial symbiosis.

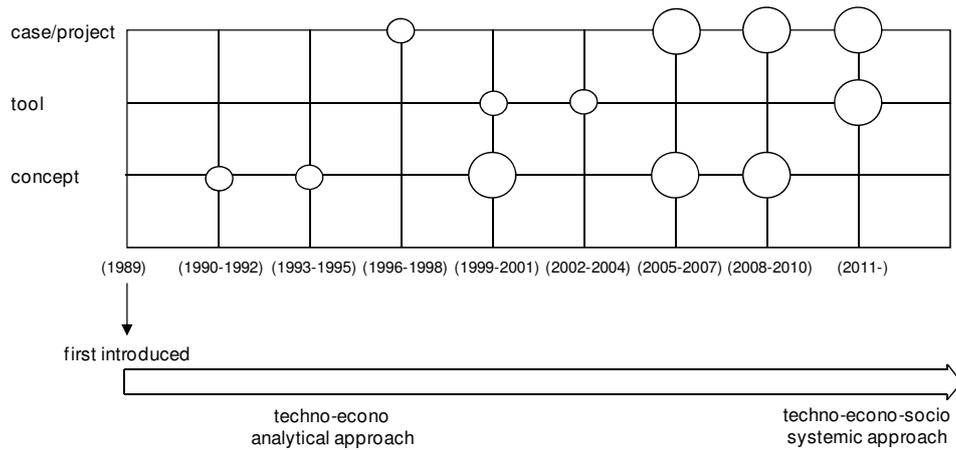

Figure 1: Industrial symbiosis literatures (Note: bigger circles reflect more literatures)

Figure 2 further illustrates that the number of empirical studies are higher than conceptual studies because more literatures presents and explores practices from cases in order to formulate the concept as well as implementing approaches. In turn, the formulated concept will help to learn, design and plan for other cases/projects. The process is however not linear. Theoretical and empirical data collection and generation work is done at the same time.

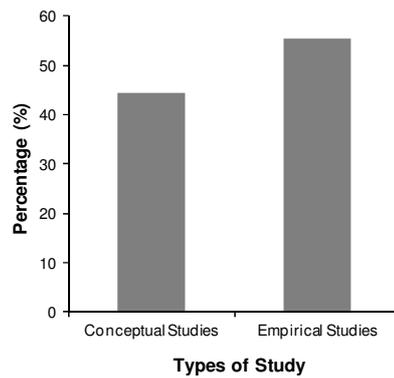

Figure 2: Industrial symbiosis literatures by group based on the framework (Group 1: Conceptual studies, Group 2: Empirical studies)

#### 4.2 Industrial Symbiosis Definition

Industrial symbiosis is perhaps the best-known application of Industrial Ecology principles. There are various definitions of the concept with different implications. Industrial symbiosis normally regards as the exchange of by-products, energy, water, emissions among closely situated firms. There are several terms in the literatures which are used interchangeably. Table 2 provides the terms as well as the definition which develops over time. The early definition is put more focus on trading material, and then it is enriched by the synergy/collaboration within geographic proximity in addition to material exchange. Table 2 also implies that the expressions from different authors are varying depending on the system boundaries, specifics of the project, its management umbrella or geographical location. However, they have one thing in common is that they attempt to create a system by exchanging material/energy with collaboration among companies within region/geographic proximity whose objective to improve economic, environmental, social performance.

Tabel 2: Concepts and definitions in Industrial Symbiosis

Term used	Definition	References
Industrial Ecosystem	In an Industrial Ecosystem, the traditional model of industrial activity is transformed into a more integrated system, in which the consumption of energy and materials is optimized and the effluents of one process serve as the raw material for another process	[1]
Industrial Ecosystem	A community or network of companies and other organizations in a region who choose to interact by exchanging and making use of byproducts and/or energy in a way that provides one or more of the following benefits over traditional, non-linked operations: reduction in the use of virgin materials as resources input, increased energy efficiency leading to reduced	[3]

Term used	Definition	References
	systemic energy use, reduction in the volume of waste products requiring disposal, increase in the amount and types of process output that have market value	
Eco-industrial park	a community of manufacturing and service firms located together in a common property. Member businesses seek enhanced environmental, economic and social performance through collaboration in managing environmental and resource issues. By working together, the community of businesses seeks a collective benefit that is greater than the sum of individual benefits each company would realize by only optimizing its individual performance	[4]
Industrial symbiosis	Industrial Symbiosis engages traditionally separate industries in a collective approach to competitive advantage involving physical exchange of materials, energy, water, and/or byproducts. The keys to Industrial Symbiosis are collaboration and the synergistic possibilities offered by geographic proximity	[5]

The latest definition on industrial symbiosis also takes into account on the common objectives to pursue performance targets. This is quite in line with principles proposed by Korhonen [6], the development of natural ecosystems is driven by roundup, diversity, locality and gradual change, as industrial ecology metaphors.

Table 3: Ecosystem principles applied to natural and industrial ecosystem (adapted from [6])

Ecosystem principles	In Natural Ecosystem	In industrial Ecosystem
Roundup	Recycling of matter Cascading of energy	Recycling of matter Cascading of energy
Diversity	Biodiversity Diversity in species, organism Diversity in interdependency and cooperation Diversity in information	Diversity in actors, in interdependency, and in co-operation Diversity in industrial input and output
Locality	Utilizing local resources Respecting the local natural limiting factors Local interdependency and cooperation	Utilizing local resources, wastes Respecting the local natural limiting factors Co-operation between local actors
Gradual change	Evolution using solar energy Evolution through reproduction Cyclical time, seasons time Slow time rates in development of system diversity	Using waste material and energy and renewable resources Gradual development of the system diversity

Summarizing, the basic concept of industrial symbiosis is attempting to learn and apply ecosystem principles to an industrial system. The ability to articulate and conceptualize industrial symbiosis is crucial because different conceptualizations of industrial ecology suggest different political solutions and different focuses on the environment [7]. Moreover, the principles can be useful either for stimulating creative thinking, innovation, and for providing inspiration for establish industrial symbiosis.

#### 4.3 Barriers and Success Factors

There are two opinions regarding the IS establishment. First, based on the success story of existing IS, the development of IS is *self-organizing* driven by market forces, spontaneously evolved market coordination [8]. Industrial symbiosis is a complex system that is very difficult to intentionally plan, design or manage [9]. However, the second opinion is that the IS development is *planning-based* is that the public planning could foster greater level of industrial symbiosis [10].

There are various barriers and success factors found in the literatures. For example, Ehrenfeld and Gertler [9] found barriers toward industrial symbiosis included lack of technical and economic appeal of continuous sources of feedstock, high transaction costs, small lot sizes, and cognitive domain when wastes have such a long history of being ignored that it is difficult for firms to integrate these output of their activities into their strategic processes. Case study of a Swedish municipality with a developed forest industry results that the greatest barriers were lack of knowledge and resources, attitudes, time frames, development consent and lack of continuity and local power for some companies [11]. On the study of CHP-based energy production in an industrial recycling network, Korhonen [6] identified the barriers are economic barrier, unhealthy dependencies (conflicting interest or diversity of technical requirements), regulation and policy (taxation of fossil fuels), large unit sizes and awareness related to information and know-how. He also discussed on the conditions of success including renewable flow resources as fuels, co-production of district heat and electricity, co-production of industrial heat/steam and electricity, public ownership in related to trust and inability to incorporate as well as local condition that provides market in which this is very much in line with the success factors for Kalunborg due to chemical and other technical compatibility, economic feasibility, organizational arrangements that minimizes transaction cost, regulatory context that is consultative, open and flexible to further reduce emission and adjust prices to make industrial symbiosis economically attractive [9]. Furthermore, case studies of eight eco-industrial park in the Netherlands showed that factors of social cohesion between the partner companies plays, physical and social features as well as the nature of the decision making process determine the degree of success in achieving symbiosis and/or utility sharing in eco-industrial park [12]. Furthermore, the comparative study conducted on six industrial symbiosis projects in the US and the Netherland pointed the factor that essential

to project success is active participation from a number of stakeholders in the planning stages of the project, however, the reasons causing problems or failure is more diverse in nature, ranging from lack of finances, lack of company interest, relatively large distance between companies, different opinions and interest among stakeholders [13].

Summarizing, barrier and success factors on industrial symbiosis project are case-specific; however, there are some commons among the cases. Summarized, the development and functioning of industrial symbiosis depend on the various factors rooted in the different domains [13,14],

- Technical: an exchange is technically feasible in terms of physical, chemical and spatial attributes of in- and output streams, compatibilities between needs and capacities, availability of reliable and cost efficient technologies
- Economic: an exchange might be economically sound or economically not risky from a company perspective in terms of costs of virgin inputs, value of waste and by-product streams, transaction and opportunity costs, size of capital investment and discount rates
- Political/regulatory/legal: caused by the jungle of environmental laws and regulations for example: overarching environmental policies, nature and implications of relevant laws and regulations, relevant fiscal elements (taxes, fees, fines, levies, subsidies and credits)
- Informational: the right people have the needed information at the right time, for example: access to relevant info, availability of timely and reliable information from a wide spectrum of areas to the right parties, continued review of information.
- Organizational and Institutional: the intended exchange might not fit in the current corporate organizational structure in terms of trust, openness, environmental maturity, level of social interaction and mental proximity, local availability of decision-making power, organization history, nature of interaction among industry, policy makers and regulators, social embeddings (degree of familiarity).

#### 4.4 Tools

In order to able to reproduce the success of industrial symbiosis at Kalundborg, Denmark to other places around the world, researchers from different area attempt to develop tools, instruments and/or approaches derived from other different fields. This sub-section will discussed tools and approaches found in the literatures for evaluating industrial symbiosis. Most the published studies on evaluation of industrial symbiosis evaluation is mainly descriptive, leaving out the specific methodology utilized. This section limits discussion by addressing only on performance indicator and modeling techniques of industrial symbiosis.

##### 4.4.1 Performance Indicators

There is very few literatures presenting on the performance indicators of industrial symbiosis. The indicators for evaluating industrial symbiosis should incorporate both environment and economic aspects. Some authors therefore suggest efficiency indicators to measure environmental and financial performances. The study conducted by Biswas *et al.* [15] stated that indicators which reflect environmental, economic, health and safety issues, have been categorized as micro-econometrics and macro-econometrics, and often economic, technical and societal factors are embedded into these measures. The paper however left out specific indicators to measure environmental, economic and social performances.

##### 4.4.2 Modeling Techniques

The primary requirement for establishing industrial symbiosis is that it must be technically feasible. Therefore, the first attempt towards modeling of industrial symbiosis is by modeling the material (raw materials, products, by-products, waste) and energy flow. Tools used for modeling technical aspect are chemical process simulation, linear programming, other operation research tools such as game theory, queue theory, monte carlo simulation, system dynamics, etc. There are many studies that have been done by chemical engineers to seek for the potential linkages among the member in the industrial symbiosis. It can be evaluated using a variety of techniques, such as exergy analysis [16] and emergy analysis[17,18]. They are modeling exergy or emergy flow of the system. This type of modeling tried to model the influence of uncertainty such as market fluctuation, operational uncertainty, etc., using operational research principles, for example game theory [18] and hierarchical pareto optimization [19]. This modeling is to seek the optimal operation of industrial symbiosis economically and environmentally. Moreover, there is industrial ecosystems toolkit developed by Industrial Economics Inc. in partnership with Clark University for the US EPA's Office of Policy, Planning and Evaluation, Urban and Economic Development Division in 1999. It consists of Facility Synergy Tool (FaST), Designing Industrial Ecosystems Tool (DIET), Regulatory, Economic and Logistics Tool (REaLiTy). Other toolkits such as MatchMaker that matches the user specific or generic data, Integrated Materials Exchange Tool that integrates linier programming optimization with a visual GIS map based framework, was also available. The presented modeling techniques seek to model the technical system, on the other hand, industrial symbiosis is not only consisting of machine and money but also man (human) in which poorly addressed. Therefore, the recent proposal for modeling industrial symbiosis is the use of agent-based modeling to facilitate the interaction of stakeholder in industrial symbiosis [20,21], however, the application toward real cases are still lack.

## 5. FUTURE DIRECTION

Extracted from the literatures, this section identifies themes which are crucial to be considered when establishing and developing industrial symbiosis. The themes relate to industrial symbiosis concept, performance indicator, human dimension, linkage to business, as well as, modeling techniques. With respect to the concept of industrial symbiosis, due to various proposed definition, no single consensus, it calls to more further research in order to refine the concept of industrial ecology that is widely accepted and useful as the metaphor to be a source of inspiration and creativity in the transformation of management and strategic visions towards a new sustainability culture. Furthermore, with respect to performance indicator, a set of indicators informing stakeholders on how well the system is working is necessary. The future research could be studying on developing key performance indicators to measure industrial symbiosis performance in terms of economy, technology, as well as, environment.

Based on the previous findings mentioned on the barrier of industrial symbiosis establishment and development, it is seen that, sometimes, other barriers and incentives exist which are not directly linked to whether the investment on industrial symbiosis is profitable or not. Human are unique among species, possessing language and intentionality. There is other factor that important for integration, that is human dimension, i.e., inter-organizational management, human action toward the vision of Industrial symbiosis. It echo to the slogan "knowledge makes it possible, people make it happen". Therefore, research on human dimension toward the industrial symbiosis establishment is also required. The linkage toward business models is also particularly important. More often that not it tends to look at industrial ecosystems, industrial metabolism and industrial symbiosis from a biological and engineering point of view. Business people look things differently and even have different languages. There is a need towards any efforts to try to understand symbiosis using business models. This will allow to make better cases once all of the business benefits are understood. Reducing environmental impacts and even making more efficient use of resources don't appear to be enough to make symbioses happen [22]. It is supported by Baumann [23] emphasizes that different ways of managing industrial production results in different environmental performance. Industrial performance does not depend on solely the technology but also depend on how we manage it.

Since industrial symbiosis is complex system, there is a call for applying the systemic approach to understand the problem. There is a strong need for a systemic approach to better understand the full implications of the choice and its attractiveness in terms of resilience [24]. Moreover, Garner and Keoleian [25] argued that environmental problems from industrial processes are systemic and would need a system approach in proffering solutions to them which would involve connections linking industrial practices to human activities in addition to maintaining environmental or ecological integrity. Most authors believe that a systems approach also provides a holistic view of environmental problems thereby making it possible to see and solve these problems that would in turn create advantages towards achieving sustainable industrial systems. To sum up, there is a strong need to provide the modeling technique that can model the system based on the holistic perspective. The possible contribution towards the knowledge development in the area of industrial symbiosis could be on the development of simulation software, optimization techniques (multi-scale) as well as policy that drives or may hinder industrial symbiosis. At the end, all the mentioned potential research themes would contribute to the building of practical framework to establish industrial symbiosis.

Bandung Institute of Technology, Indonesia*

### **ABSTRACT**

Telecommunication technology is proven able to increase the welfare of villagers. In Indonesia, there are still thousands of remote village which have not been reached by the facility of telecommunication technology. One of the barriers of telephone program in the village is the people's behavior towards the telecommunication technology of cellular phone. The main purpose of this study is to know what variables that can influence attitude, subjective norm and perceived behavioral control as well as to know how the influence of the variables towards the intention of villagers to own and use the telecommunication technology of cellular phone. The research findings which are obtained from double regression analysis are as follows: (1) attitude towards behavior and perceived behavior is the significant variable which influences intention and (2) the variable of perceived behavior control that is not proven significant can change the relationship between attitude and intention as well as subjective and intention.

### **Keywords**

Intention behavior, telecommunication technology, cellular phone

### **1. INTRODUCTION**

The role of Information and Communication Technology (ICT) at present is very vital, especially when the trend of world's economy changed from industrial era into information era, from the resource-based economy into knowledge-based economy (Stiglitz, 2006). Currently, people who have access to the latest information are the ones who can conquer the economy (Yunus, 2007). In many literatures, it was found that the telecommunication technology had an influence to the progress and welfare of a country or community (Hardy, 1980; Hudson, Heather & Parker, 1990; Bayes, 2001; Yunus, 2007). Unfortunately, not all people can enjoy the advanced telecommunication technology. Those who live in the villages and remote area often have no access to telecommunication technology. This leads a bigger gap between life in village and in city. Therefore, the inaccessibility of information also causes lack of knowledge for villagers in health and education sectors. It is common if the information accessibility for villagers became one of points of action resulted in the World Summit on Information Society (WSIS) at the end of 2003. One of the points states that the plan is to connect villages and provide telematics facility, including telecommunication and internet in the late year of 2015.

Researches about villagers' behavior in Indonesia towards telecommunication technology are interesting to be conducted due to several reasons. The first is that there has not been any well implemented village telephone program in Indonesia. From the total of 67,797 villages in Indonesia, there are only 24,000 villages which have already got telecommunication service (Donny and Mudiarto, 2006). The government has failed in implementing the village telephone program which was conducted in 2003 for more than 3,000 villages in Indonesia. From several barriers reported by Department of Communication and Information of the Republic of Indonesia (2007), besides the weak system and technology, there is also an indication that the behavior of villagers in adapting the technology has become one of the problems that cause the program unsuccessful. Therefore, it is needed to undertake a research about villagers' behavior towards telecommunication technology. Moreover, the government plans to provide USO village telephones for more than 40,000 villages in Indonesia in the year of 2007 until 2009.

The second reason in undertaking this research is to emphasize the business model (Godong, 2006; Siswanto, 2006) which is based on the Village Phone Model successfully implemented in Bangladesh and Uganda (USA Grameen Foundation, 2005). Meanwhile the other model has more emphasis on technology and policy of national telecommunication industry (Langi, 2005; Bandung et. al., 2006). In fact, within the telecommunication system, one of the most important issues is the telephone user. Venkatachalam and McDowell (2002) state that the need of telecommunication technology of cellular phone that is now commonly offered to people live in cities is not the same as the one that is needed by villagers. Learning how villagers'

behavior towards telecommunication technology of cellular phone will help policy makers, both the government and the company managers to make the best decision for regulations and marketing strategy of telecommunication service for villagers. Therefore, learning villagers' behavior towards telecommunication technology becomes an interesting topic to study.

## 2. KNOWING INTENTION BY USING THEORY OF PLANNED BEHAVIOR

Researchers have been trying to improve behavior models in order to explain people behavior in all aspects of life. At the early development of the theory of behavior, attitude is believed as the most influential variable towards intention and person's behavior. In 1991, Ajzen added perceived behavioral control variable into a TRA model to accommodate a person's self confidence in behavior with all the limitations. This model is later known as *the Theory of Planned Behavior* (TPB). In this model, there are three factors which influence consumer's intentions, namely: (1) the belief of the possibility of the effect towards certain behavior and evaluation from the effect of that behavior (*behavioral beliefs*), (2) the belief of other people's normative hope and motivation to achieve that hope (*normative beliefs*) and (3) the belief of the existence of the factors which can support or interrupt behavior to happen and how big the influence of those factors (*control beliefs*). Behavioral beliefs create attitude towards the behavior (positive or negative attitude towards the behavior), *normative beliefs* create *subjective norms* and *control beliefs* create *perceived behavioral control*.

In the research conducted to explain behavior of lower-middle business people in Chile in adopting the e-commerce technology (Nasco et. al., 2007), it is found that *attitude* and *subjective norm* are proven have positive and significant influence towards *intention*. However, the constructed *perceived behavioral control* is not proven have significant influence. The research conducted by Nasco et. al. (2007) which states that *perceived behavioral control* (PBC) does not give significant influence to the formation of *intention* is very interesting to be investigated. The insignificant influence of PBC towards *intention* is also found in the research of adopting information technology by lower-middle managers in United States (Riemenschneider, Cyntia et. al., 2003). Referring to that condition, the researchers are interested in investigating the behavior of villagers towards cellular phone technology by using TPB model. In a research using TPB, Celuch et. al. (2007) suggests the next researchers to investigate possibility of variables in TPB whether they have capability to moderate relationship among the variables and *intention*. From the literary study, the researchers put PBC as a moderator variable that will influence relationship between *attitude* and *intention*, and relationship between *subjective norm* and *intention*. Furthermore, the research model can be seen in the following Figure 1.

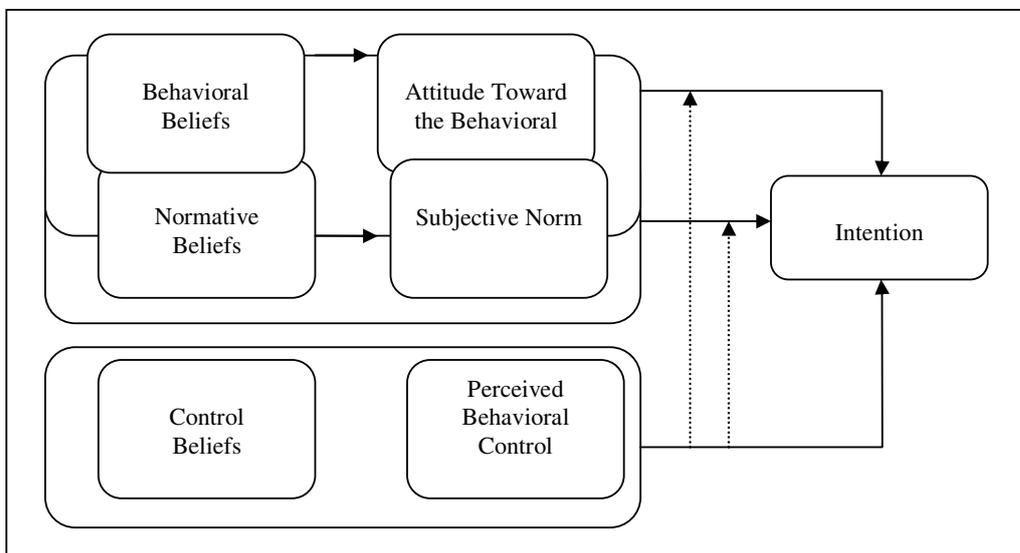

Figure 1: Research Model

## 2.1 Measuring the Construction of TPB

A guideline to elaborate construction of each variable in the Theory of Planned Behavior has been provided by Ajzen. By direct and indirect measurement for emphasizing each measurement must be arranged based on unique behavior of each population which is going to be researched at early research (Ajzen, 2006; Francis, Jillian et. al., 2004). In arranging construction of each variable, an early research was conducted in the form of interview survey to 30 villagers come from Cikadut Village and Mekarmanik Village in Cimenyan Residency, Bandung Region. The early research was conducted to know what factors of the villagers that represent three variables, namely *Attitude towards Behavior Beliefs*, *Subjective Norm Beliefs* and *Perceived Behavior Control Beliefs*. In each proposed question, the researchers have prepared options of answer and let respondents to write down their own opinion. To know the attitude towards behavior of the villagers, the researchers also ask several questions related to advantages and disadvantages felt by the villagers when using telecommunication technology of cellular phone, such as the advantage to be able to communicate easily, to save money and time as well as to increase self confidence. In *subjective norm* variable, the question is related to the closest persons who influence the respondents in making the decision to own and use the telecommunication technology. Meanwhile, for *Perceived Behavior Control* variable the respondents were asked about the factors supporting or avoiding them to use telecommunication technology.

Results of early research about the constructed variables were elaborated more in the form of questionnaire. The answer of the questions which are approved by 75% of the respondents was then written in questionnaire. Total of closed-questions is 46 which consist of 8 questions related to respondents' profile and other 38 closed-questions on Likert scale (ordinal) ranging from 1 until 5 which indicate: strongly agree, agree, no opinion, disagree and strongly disagree. The scoring range is more appropriate to be used for villagers instead of a wide range of scoring that can confuse respondents.

## 2.2 Research Hypothesis

From the background of research it can be described that there is a strong pull to connect all villages in Indonesia with telecommunication network. This is not only the agenda for the government but also the ones for private companies. It can be seen by wider coverage of telecommunication network to small villages by telecommunication operators in Indonesia. Despite the high number of villages in Indonesia which has not been reached by telephone, there are several villages, especially in the island of Java have almost been reached by telecommunication service (Department of Communication and Information of the Republic of Indonesia, 2007).

Referring to general principle of relationship of each variable in TPB stated by Ajzen (2006), the research hypothesis which is arranged based on the relationship between *attitude toward behavior* variable (AB) and *intention* (I) is:

H1: The attitude of villagers towards telephone has positive influence to their intention to own and use telecommunication technology of cellular phone.

The research hypothesis for the relationship between subjective norm (SN) and intention (I) is:

H2: Subjective norm of villagers towards cellular phone has positive influence to their intention to own and use telecommunication technology of cellular phone.

Variable relationship of perceived behavior control (PBC) in this research is investigated by two models, i.e. independent variable (see figure 2.4) and moderator variable. The research hypothesis for independent variable is:

H3.1: Perceived behavior control of villagers towards cellular phone has positive influence to their intention to own and use telecommunication technology of cellular phone.

Meanwhile, the research hypothesis for moderator variable is:

H3.2: Perceived behavior control of villagers towards owning and using cellular phone influences the relationship between attitude and intention as well as the relationship between subjective norm and intention of villagers towards their intention to own and use telecommunication technology of cellular phone.

## 3. RESEARCH METHOD

### 3.1 Arrangement of Research Instrument

Stages of conducting this research are based on the research guideline of TPB proposed by Ajzen (1991). The first stage is to identify population of the research (villagers who have not owned telephones), to determine behavior or intention which are going to be investigated (intention to own and use telecommunication technology), and to undertake early research to reveal specific elements needed in the questionnaire. The early survey was conducted in two different villages in Bandung region.

Referring to the early research, questionnaire that consists of 8 questions which represent behavioral beliefs about the advantage of owning a cellular phone was made. Other 6 questions represent normative beliefs of closest social environment upon having cellular phone and 11 questions represent control beliefs of obstacles to have a cellular phone. Each belief is measured to calculate how big is the value of constructed attitude, subjective norm and perceived behavioral control. The value of attitude towards behavior norm is obtained from behavioral beliefs and outcome evaluation ( $A_B = \sum b_i e_i$ ). Meanwhile, the constructed subjective norm resulted from normative beliefs and motivation to comply ( $SN = \sum n_i m_i$ ) and the constructed perceived behavior control is obtained from control beliefs and perceived power ( $PBC = \sum c_i p_i$ ). Besides the 25 questions above, there are 13 direct questions to measure attitude, subjective norm, perceived behavioral control and intention. The options to answer are measured by 5 Likert scales, ranging from Strongly Agree, Agree, No Opinion, Disagree and Strongly Disagree. Considering that the research population is the villagers in West Java Region, the questionnaire is translated into Sundanese language by a translator in order to ease respondents to understand the questions.

### 3.2 Respondents

Research respondents come from 6 different villages in districts located near the border of Bandung City, West Java. This research uses purposive sampling technique. Technique of obtaining data is in-depth interviewing to the respondents directly. This way is enable the researchers to obtain answer of each question in the questionnaire and also observe the villagers as the research objects directly.

## 4. RESEARCH FINDINGS

### 4.1 Demography

Number of respondents is 143 persons with 76 males (53.9%) as majority. The ages of the respondents are mostly ranging from 17 to 25 years and from 36 to 40 years. Only a few of them have higher education. One person has a bachelor degree (BA) education and another one has a diploma degree. Majority of female respondents are housewives (27.7%), while other professions which also have a high percentage is private employees (16.3%) and business people (17.7%).

### 4.2 Factor Analysis

One of the requirements to operate data by using factor analysis and regression is that the data must be metric with minimum interval scale (Hair et. al., 2006). To fulfill the requirement, data tabulation which come from the questionnaire are changed by using Method of Successive Interval (MSI). By using this method, the data is arranged into order data and analyzed by using MSI program in MS Excel in order to become interval scale to fulfill the basic requirement in analyzing data using factor analysis and double regression. The value of *beliefs* is obtained from multiplication of each comment upon *beliefs* (b) given by the respondents with an evaluation (e).

McCarthy et. al. (2003) in his research about meat consumers' behavior by using Theory of Reasoned Action (TRA) as an early model of TPB, stated that the construction made by the early research that the uni-dimensions should be tested first by using factor analysis. Besides, the reliability of the questions must be seen to measure research construction based on Cronbach Alpha.

Results of the analysis factor can be seen in Table 1. From the table, it can be known that the constructed attitude towards behavior consists of 2 questions in which each question is related to the feeling caused by cellular phone and that the cellular phone is a good gadget. Because there are only 2 questions, the construction of the Cronbach Alpha value is not measured. In the construction of subjective norm, 4 questions are grouped into two factors in which each factor has two questions. The first question is related to the belief upon the influence of friends' opinion in buying cellular phone and the card, while the second question is related to the belief of family in buying cellular phone and the card. Cronbach Alpha used for these questions is 0.821. For the construction of *perceived behavioral control* and *intention*, each has 3 questions with Cronbach Alpha values 0.580 and 0.629.

### 4.3 Regression Analysis and Correlation: Double Linear Regression

To elaborate relationship of variables in this research model, double regression analysis is used as a method. The results of factor analysis which have been done in the following stage are used as a basis of data grouping for each identified variable. By SPSS 15 analysis, it is found in the respondents' histogram that 3 outliers are not included in the analysis. So, the total of analyzed respondent data is 138 persons. This number is still far below the minimum sample of Hair (2006) which mentions

100 samples as a minimum sample for regression analysis, or 5 times bigger than research variables or 15 to 20 times bigger than research variables for a better result.

In this study, the double linear regression analysis is conducted for four times. The first is the relationship that influences attitude (AB). It is found that the people's belief to benefits of telephone is to save the time (AB2) is the most significant predictor ( $\beta = 0.278$ ,  $p < 0.05$ ) comparing with the people's belief that the phone allows them to communicate easily (AB1) and save the cost (AB3). This also shows that villagers believe strongly that the telephone help them save time needed to give information than their belief that the phone can allow them to communicate easily and save the cost. Meanwhile, the positive correlation between AB2 and the attitude can be interpreted that the more convince the villagers to the benefits of cellular phone in saving time, the better attitude they have towards the cellular phone.

Table 1: Loading factor and reliability of each construction

The Components of TPB Model	Loading Factor	Cronbach Alpha*
<b>Attitudes toward behavior</b>	1	
Telephone creates happy feeling	0.819	
Telephone is a good thing	0.819	
<b>Subjective Norm</b>	1	0.821
Belief to the influence of friends' opinion in buying telephone card	0.910	
Belief to the influence of friends' opinion in buying cellular phone	0.839	
Belief to the influence of family's opinion in buying cellular phone	0.808	
Belief to the influence of family's opinion in buying telephone card	0.746	
<b>Perceived Behavior Control</b>	1	0.580
There is no barrier to have a telephone	0.828	
Having a telephone is an easy thing	0.755	
If you want to have a telephone, then you must own it	0.623	
<b>Intention</b>	1	0.629
Efforts to have a telephone	0.831	
Commitment to have a telephone	0.757	
Intention to have a telephone	0.682	

\*The calculation of Cronbach Alpha is only for constructed variables with minimum three questions

The second double linier regression is conducted in the beliefs that it can influence subjective norm (SN). The analysis results show that the villagers have a belief that friend (SNF1) and family (SNF2) influence them in buying cellular phone and the card. These two factors show positive influence to subjective norm, i.e. the higher their belief to their family and friends, the higher their subjective norm will be. Meanwhile, by the double linier regression to see relationship on the perceived behavioral control (PBC), it is found that only one belief which is proven significant ( $\beta = -0.233$ ,  $p < 0.05$ ), i.e. the belief to long distance to buy and use cellular phone (PBC4). The other 5 beliefs are not significantly proven. The long distance that the villagers have to buy cellular phone and the cards has a negative influence to their self confidence (PBC) to have cellular phone. It can be inferred from the relationship that the more convince the villagers to get cellular phone and the cards, the less their self confidence will be to buy and have cellular phone.

To test the TPB model, the double linier regression is conducted in the relationship between *attitude toward behavior* (AB), *subjective norm* (SN), *perceived behavior control* (PBC) and *intention* (I). This study found that the villagers' intention is significantly influenced by their positive attitude towards cellular phone and their self confidence to have cellular phone. The influence of surrounding environment towards the villagers' intention to have cellular phone is not significantly proven.

Besides testing the TPB model, there is also a test to know the relationship of villagers' self confidence that can change the relationship between attitude and intention and the relationship between *subjective norm* and *intention* (PBC as a moderator variable). It was found in the test that *perceived behavior control* cannot influence the relationship between *attitude* and the *intention* to have cellular phone. The only relationship that can be changed by adding the villagers' self confidence factor (PBC) is the relationship between *subjective norm* which come from the influence from friends and the intention. Before *perceived behavior control* is used as a moderator variable, friends' opinion has positive influence to the intention to have cellular phone. After the self confidence factor is added into the model, the influence of friends' opinion becomes negative. This is interesting to be analyzed because when the villagers are more confident to be able to have cellular phone, in fact friends' opinion becomes a factor that can weaken the intention to have cellular phone.

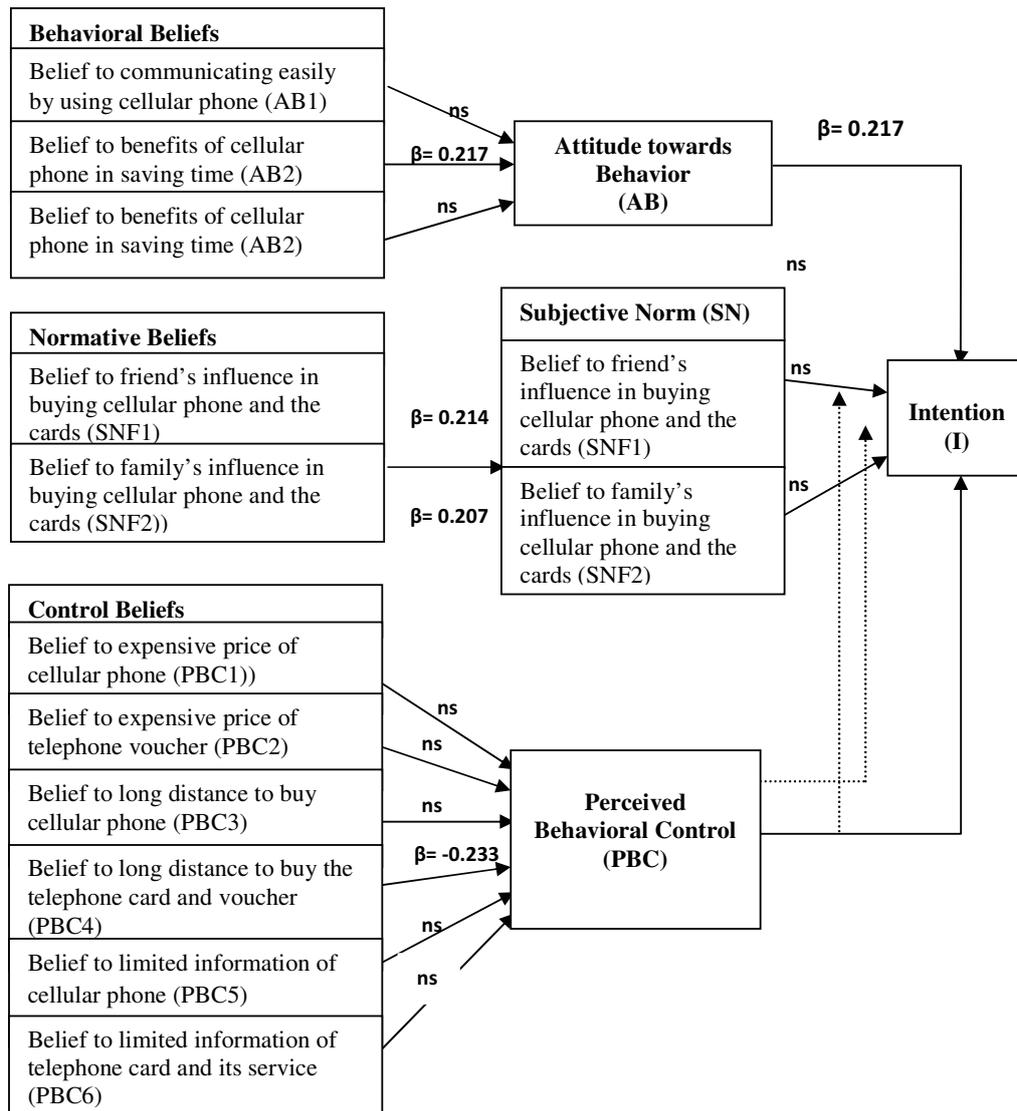

Figure 2: Final results of double regression

The researchers use relationship limitation that can be found possibly due to the inaccurate parameter. Consequently, the respondents tend to be confused in interpreting the proposed questions. The bias or confusion of the concept of PBC variables is also mentioned by Armitage and Conner in Nasco (2007). Therefore, the conclusion is not very convincing.

On the practice, this study can be an input for Indonesian government, especially Department of Communication and Information which become the policy makers in telecommunication sector to have an approach to attitude and self confidence of the people to village telephone. By concerning the factors which are proven having influence, the government is expected to arrange a policy that can accommodate the wants and behaviors of villagers.

## 5. CONCLUSION AND SUGGESTION

It can be inferred from figure 2 that the results of analysis using double regression can explain the variants of TPB model which is an enhancement of TRA model as follows: (1) 16% intention variants of villagers to buy and use telecommunication technology of cellular phone, and other 84% is caused by other factors. Even though it is significant, the intention variants have not been able to be explained yet; (2) the differential of the model consists of several *beliefs* variables which does not have a significant influence to explain the latent variables (figure 5.1). This is because the TPB model is an advanced model of

TRA which is included in multi attributes group. Therefore, this model possibly has problems in a situation where the dimension analysis is used by discrete data.

In previous researches on benefits of technology (Nasco et. al., 2007, Riemenschneider et. al., 2003), it is found that PBC does not significantly influence *intention*. So, in the case of villager's intention to buy and use village telecommunication technology, the SN dimension does not significantly influence intention. In this case study, it is also proven that the suggestion from Celuch (2007) to investigate further on the moderator relationship among variables cannot be proven. In other words, proposed hypothesis is rejected.

Findings of the study are still not optimal yet. It is expected that there will be an advanced research on villagers' behavior by using the same theory and model. In spite of the fact that the study still needs to be continued, there is a finding shows that there is a moderator relationship between PBC variable and SN, though the influence is not very significant. These findings are beneficial as an early point for further investigation in the next researches.

### ABSTRACT

Communication among doctors in addressing a disease that involves the same disciplines and involves a wide range of different disciplines plays a very vital. Significant aspects of influence in the advancement of medical science are knowledge sharing activities as a form of follow-up communication activities. This study will examine knowledge sharing activities in the 5 (five) department in a teaching hospital in Indonesia. The method used to conduct surveys directly to the doctors who are selected as respondents by random sampling. The number of questionnaire were distributed to respondents as many as 200 pieces, while the questionnaires were returned and processed fruit totaled 192 with a net responses rate of 96%. This study shows that of the five hypotheses, there are three hypotheses supported. The conclusion of this study is that management support has no effect on intention to share knowledge, that doctors are mostly internal-driven, i.e. they share their knowledge because they enjoy doing it, not because management support this, and not that the knowledge involved is useful. This points to the difficulty of promoting knowledge sharing, that is, top management support or leadership may not be that effective (since the results show that management support has no effect) in driving knowledge sharing. Maybe what management can do is to ensure that they select doctors who are intrinsically motivated and like to help people.

## 1. INTRODUCTION

Health conditions in Indonesia had a very significant development in recent decades. For example, the infant mortality rate fell from 118 deaths per thousand births in 1970 to 35 in 2003, and life expectancy increased from 48 years to 66 years in the same period. This displayed a developmental impact of the expansion of the provision of public health facilities in 1970 and 1980, and the impact of family planning programs [1]. Indonesia's health ministry has improved although some remained problems and new challenges continue to increase [1]. The progress achieved including reduced infant mortality and increased life expectancy, but maternal mortality and child malnutrition remains a major problem. Demographic and epidemiological transition accelerated by rising incomes and an aging population. This shift resulted in a rapid increase in health care demands more and better. Indonesia's health system must answer this demand by improving the quality of services and diversified its funding of health [1]. Public health in Indonesia was influenced by many factors. These factors not only from the health sector such as health care and availability of health infrastructure, but also influenced by economic factors, education, social environment, heredity, and other factors. Public health situation can be reflected through morbidity, mortality and nutritional status [2].

Seen from the side a more micro level hospitals, there are several things that can affect the process of integration of health information systems in Indonesia and in other countries, namely concerning the relationship between the readiness of policymakers in the hospital, the patient data documentation system is good (medical record), human resources directly involved both doctors, nurses, midwives and pharmacists as well as other resources that are not directly involved as well as other supporting infrastructure such as server systems and the process of defining all business processes that occur in a hospitals [3]. To realize all of the above, then one of the factors that play a role is communication, direct communication

between all actors involved in the health world with emphasis on the sharing of useful information and knowledge (information and knowledge sharing) as well as through its medium well it software or hardware with respect to effective strategies in implementing information and communication processes for knowledge sharing [4].

## 2. LITERATURE REVIEW

The implementation of knowledge sharing can take place not only in the formal order, but also in the form of non-formal order is precisely the process of knowledge sharing can be run more effectively [5]. The process of knowledge sharing in the medical world especially among doctors is needed. This happens especially when a doctor with specific expertise found patients with a special case and is not in accordance with the area of competence, then the doctor will naturally consult other doctors are more appropriate competence. These conditions can be considered as the beginning of the process of knowledge sharing. The other thing is when a patient requires treatment not only by a doctor but by a team of physicians, the knowledge sharing process is in progress for this condition.

Previous research focused on the process of knowledge sharing in the field of health, among others References [6] with emphasis on the implementation of decision-making at a health clinic. References [7] discuss the role of information technology in changing society's view of health care. References [8] explained that more than the ability to see the role of knowledge management in healthcare to alter the characteristics of organizational capabilities and human resources, the quality of infrastructure and the decision making process. References [9] described the knowledge sharing behavior of physicians in a hospital. References [10] used deductive databases and database ontology in information integration process and the implementation of knowledge sharing in health care. References [11] using the media storytelling as knowledge sharing media treatment of a disease. References [12] emphasizes the importance of interdisciplinary science in solving problems in health care in particular a hospital. References [13] utilized bioinformatics and centralization-based health services in the process of knowledge sharing.

References [14] further highlight case studies of autism as the main chart roadmap to generate knowledge sharing specifically for people with autism. References [15] described the results of an investigation into the application of knowledge management system for the classification of disease. References [16] designed a process of knowledge sharing after the SARS outbreak. References [17] described the knowledge sharing behavior of consumers in an inter-organizational healthcare community. References [18] conducted research related to knowledge sharing in the hospital more specific. References [19] raised the issue of ease of access and reuse the knowledge and the knowledge sharing process with a case study on the health sector in the Caribbean region. References [20] developed a model of knowledge sharing for pediatricians using a Web 2.0 framework. References [21] stated that the community of practice (CoP) is the best solution in the process of sharing knowledge specific to the case in Kuwait. References [22] used statistical methods and perspectives from existing experience to improve the process of knowledge sharing.

References [23] conducted an analysis of knowledge management mechanisms that occur in health care portal. References [24] described the main factors that influence health professionals to adopt knowledge management. In the end references [25] provide brilliant idea, called the future of healthcare knowledge sharing, where there are several key trends that knowledge ownership, endorsment of informal channels, specialized communities, real-time knowledge sharing, consumer-generated knowledge, Mandated sharing of the "collective intelligence ", and improved access to knowledge.

From a full explanation before, we could conclude that with the increase in the number and type of disease in this world requires a qualified medical treatment. To produce high quality medical treatment, the required increase in the quality of research related to medical treatment. However, the increasing amount of research is not enough to be followed also by improving the quality of research that is not directly in dire need of good quality communication between physicians specializing in the dissemination of research results related to medical treatment. One of the main requirements to allow the dissemination of research results can be well established is the need for the process of knowledge sharing among doctors that would lead to the need to improve the effectiveness of the base of knowledge sharing among doctors.

This study tried to look at the relationship level interplay of intention to share knowledge that has been developed by several previous investigators through the Theory of reasoned Action (TRA), the Theory of Planned Behavior (TPB) and Technology Acceptance Model (TAM) with Knowledge Sharing Attempt (KSA) which is a positive contribution of references [26]. Some of the factors that have significant influence based on the analysis of the previous studies on intention to share knowledge are management support, enjoyment helping others, perceived usefulness and the interaction frequency. Broadly speaking, this research can be concluded has 4 (four) direct effects on intention to share knowledge, as well as the intention to share knowledge (ISK) is assumed to affect knowledge sharing attempt (KSA). There we propose the following hypotheses:

*H1. Management support is influenced to intention to share knowledge*

*H2. Enjoyment helping others is influenced to intention to share knowledge*

*H3. Perceived usefulness is influenced to intention to share knowledge*

*H4. Interaction frequency is influenced to intention to share knowledge*

*H5. Intention to share knowledge is influenced to knowledge sharing attempt*

Further explanation of the conceptual model of this study can be seen in figure 1 below.

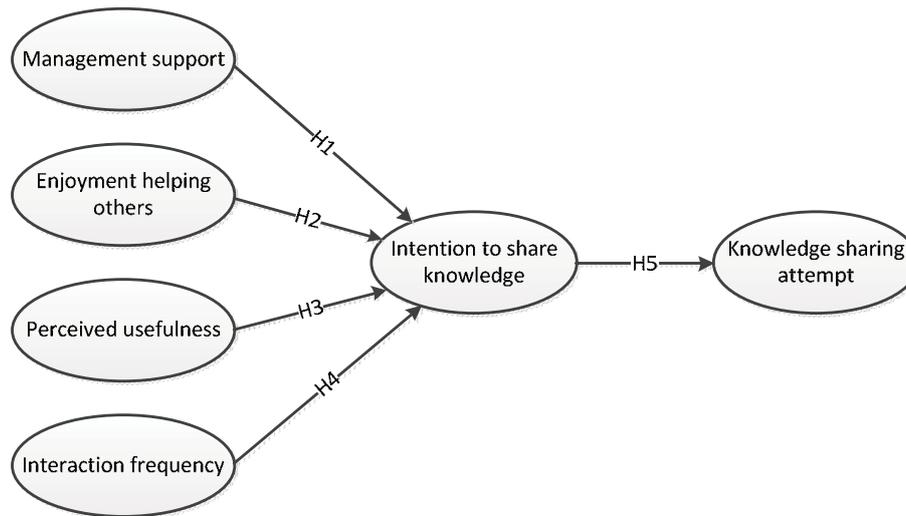

Figure 1: Conceptual Model

### 3. METHODS

In this study we used the survey method, this is caused by this research work was the focus of the current situation, and then shape the research questions about of who, what, where, how much / many, and does not require control over behavioral events [27]. This research questionnaire using closed questions. The main requirement of the respondents who would fill out this questionnaire is a medical specialist candidate (resident), specialist doctors who are continuing to be the consultants and specialists are a faculty member in the Faculty of Medicine and minimal working together in a hospital for at least 2 (two) years, the reason is that respondent assumed to be representative of the actual conditions in terms of knowledge, skills and experience they have in doing medical treatment. In addition to these criteria, the doctor is concerned with the doctor already knew each other well in the same part or different parts but has a level of interdependence is high especially in dealing with a problem of the patient as a team.

The survey was conducted by the method of paper-based questionnaire distributed directly to the respondents. The main part of the questionnaire in this study was a closed question that contains a list of questions with answers that are available and choose the answer that the respondent lived there [28]. The answer to a closed question questionnaire will be validated using appropriate statistical methods both in terms of descriptive statistics to multivariate statistics. The processes of distributing the questionnaire can only be done after the issuance of a certificate of ethical escaped examine the Health Research Ethics Committee Cipto Mangunkusumo Hospital/Faculty of Medicine University of Indonesia Jakarta. This is a major requirement in the field of health research in Indonesia can be implemented. The certificate is valid passes the review of conduct during the period of 1 (one) year and applied nationally in all hospitals located within the jurisdiction of the Republic of Indonesia. The questionnaire study using the 5 likert-scale with the explanation that the value of 1 indicates strongly disagree and a score of 5 indicates strongly agree. The respondents are sampled both of resident doctors and consultants from 5 different departments in teaching hospitals in Indonesia are Pediatrics, Obstetrics & Gynecology, Anesthesia, Radiology and Clinical Pathology. By using proportional random sampling method, a total of 200 pieces of research questionnaire is given directly to the resident and consultant. The number of questionnaire were returned as much as 199 pieces and questionnaires that can be processed as many as 192 pieces with a net response rate of 96%.

This study shows the following profile of the respondents, aged respondents consisted of 81 people (42,19%) aged under 30 years, 83 people (43,23%) between 31-45 years old, 24 people (12,5%) between 46-60 years old and 4 people (2,08%) aged over 60 years. By sex as much as 82 people (42,7%) were male and 110 (57,29%) were female. The respondents of this study is dominated by the resident with a total of 153 people (79,69%), the staff of as many as 9 people (4,69%), a fellow by 2 people (1,04%), 18 people (9,38%) consultant, head of division by 4 people (2,08%), as well as the professor as 6 people (3,13%). While the composition of the respondents from the five departments under study shows the results of 38 people (19,79%) came from the department of clinical pathology, 40 people (20,83%) from the department of pediatrics, radiology department of 39 people (20,31%), 37 people (19,27%) from the department of anesthesia, as well as 38 people (19,79%) from the department of obstetrics & gynecology. Meanwhile, recent information shows that 142 people (73,96%) have experience of 2-6 years as a doctor, 21 people (10,94%) experienced for 7-10 years, 11 people (5,73%) experienced for 11-15 years, and each group of 9 people (4,69%) for respondents with 16-20 years experienced and above 20 years.

#### 4. RESULT AND DISCUSSION

After all data was collected through the paper based questionnaire with a total of 192, performed the processing and analysis of data using the rules of PLS-SEM with using Smart PLS 2.0 software. The use of software Smart PLS 2.0 is not without controversy, in which the most basic things a matter of debate on the expert was mentioned that when using PLS Smart PLS 2.0 or other software, it cannot be measured Goodness-Fit Test [29]. But if we set aside the controversy beforehand, the actual use of PLS is quite helpful for the research that has little data, because the main rule of the PLS-SEM does not specify a minimum sample size that can be processed [29]. PLS-SEM also has the flexibility in the distribution of population, as well as formative and reflective structure has the power in the process of exploration [29]. The other thing that supports the use of PLS-SEM in the processing and analysis of research data is optimized PLS-SEM on prediction accuracy, and can maximize the value of the variance in the construct variables [30].

The next stage after it is determined that this study will use Smart PLS 2.0 for processing and analysis of data is test reliability. Indicators are widely used by the researchers for this is Cronbach's alpha [29]. Cronbach's alpha values of these will range from 0 to 1, where references [31] explained that the minimum of a variable is said to be reliable 0.7 for the early stages, but in its development some researchers suggest that the minimum is 0.8 or 0, 9 with the aim to increase the confidence of researchers that research instrument used is really reliable. Meanwhile, references [29] suggested that the threshold for each variable is said to be reliable at 0.5. Indicator test reliability than Cronbach's alpha this is a composite reliability or part of research called Dillon-Goldstein's Rho, its value is at least equal to Cronbach's alpha or possibly larger [29].

Indicator reliability used results of the calculation of loadings for all observed variables [29]. The main purpose of the indicator reliability is to check whether there is one or more observed variables of a variable construct that has no reliable indication [29]. The minimum value that can be said reliably is of 0.7 [29]. In the next stage is to test the validity of particular convergent validity, which would be a valid indicator of whether or not a variable is used indigo AVE (average variance extracted). AVE measures the amount of variance that is on variable constructs (latent) in relation to random measurement error [29]. Its value ranges from 0 to 1, and the minimum acceptance amounted to 0.5 [32]. The explanation can be seen in table 1.

Table 1: Indicator reliability

	AVE	Composite Reliability	R Square	Cronbachs Alpha	Communality	Redundancy

References [32] describes for discriminant validity verification can be done by using the value of the root of the AVE (average variance extracted) and replace the value 1 in the calculation of correlations between variables constructs. In principle, the value of the root of the AVE should be greater than the value of the correlation between variables and construct the other just said that the variable is valid constructs [32]. Table 2 shows the correlation values for all variables of the same construct was greater when compared with the value of the correlation between different variables.

In this study to test the hypotheses on each direct antecedents we used SmartPLS 2.0 software with the generation of data through a bootstrapping procedure [33] & [34]. This research used the number 500 for each time bootstrapping run, there is no definitive reason to choose this 500 number. Previous researchers suggested that the amount of bootstrapping run as many as 500 shows a fairly optimal result for a study specifically related to behavioral research [35]. All tests of this hypothesis using a two-tailed (two-way), on the grounds that all the hypotheses are designed not made to have a tendency towards the positive and negative effects, but rather focus on the exploration of the relationship between the levels of one variable with another variable. Detailed descriptions of the results of hypothesis testing are in Table 3 and Figure 2.

Table 3 Hypotheses test result

## 5. CONCLUSION

Based on the hypothesis test for the data using the method of paper-based data collection questionnaire with a total sample of 192 pieces, acquired three (3) supported the hypothesis and 2 (two) hypothesis is not supported. Variables that are not declared "relationship" between the antecedents with constructs such as management support and perceived usefulness on intention to share knowledge. This indicates that management support has no effect on intention to share knowledge, that doctors are mostly internal-driven, i.e. they share their knowledge because they enjoy doing it, not because management support this, and not that the knowledge involved is useful. This points to the difficulty of promoting knowledge sharing, that is, top management support or leadership may not be that effective (since the results show that management support has no effect) in driving knowledge sharing. Maybe what management can do is to ensure that they select doctors who are intrinsically motivated and like to help people.

### ABSTRACT

*Hand stamping and hand writing in Batik industry is a famous culture characterized by Indonesia. The traditional Batik industry may hold great potential to boost economic growth. Most of the industry consists of generally small but labor-intensive firms. Unfortunately the development of technology and policy changes in the last 40 years have threatened their existence. Many of the traditional Batik firms are not able to compete with the Batik printing industry, and at the end they closed down their business. It happened especially in Laweyan, Solo, one of the central area of traditional Batik production of Central Java.*

*The objective of the study is to revive the traditional Batik industry in Laweyan back to its existence from its long time gone through an investment model of traditional Batik home industry. It will be proven that a small capital funding from banks is quite enough to rebuild profitable home industry Batik firms that make Laweyan regain its Traditional Batik Kingdom in Indonesia. The result of the study shows that the business model of Batik traditional home industry yields positive investment criteria. Industrial conditions mapping also indicates that a cluster model of the Batik industry has a potential of growing.*

### Keywords

*Traditional batik, feasibility, engineering economics, investment criteria, IE Matrix*

### 1. INTRODUCTION

Writing and stamping Batik by hand in a traditional way is putting special pattern with melting wax on “mori”, white fabric material, using tools called “canting” and “stamp”. Writing Batik with “canting” or stamping with “stamp” has been known since the ancient kingdom of “Majapahit” and currently recognized worldwide as Indonesian traditional cultural heritage; many of us believed this kind of technology has to be preserved rather than abandoned. During 1950-1970, traditional Batik became a mainstay of Indonesia textile products both locally and internationally, when the industry was growing rapidly. However when the government began to introduce a capital-intensive textile industry in 1970s, and the printing industry is allowed freely to exploit the traditional Batik patterns in the printing to produce similar products, called the printing Batik, which much faster and cheaper, then the traditional Batik industry began to collapse. The existence of Batik printing reduces much of the market share of traditional Batik [4].

Laweyan, a small village in Surakarta City suburb, is known as one of the central area of traditional Batik production in Central Java. Formerly there were 170 traditional Batik firms in 1980, but currently only 27 traditional Batik firms are left and those are small-and medium-scale enterprises (SME). In micro-economic level, the SME of a traditional Batik industry contributes as a source of income for craftsmen and small entrepreneurs; while that on a macro level, it may expected to contribute to the output production and employment in Indonesia [5]. However, uncertain economic conditions, such as imperfect competition, currently embrace, cause financial problems for the purchase of materials, for the production capacity and for the payment to Batik craftsmen of the industry.

References [3] added that SMEs in Indonesia faces many problems, mainly: (1) lack of technological knowledge; (2) lack of marketing know-how; (3) lack of managerial capacity; and (4) poor access to formal financial resources. It is difficult for SMEs, especially the traditional Batik industry, with its limited skill of human and financial resources to develop markets and arrange financially by themselves. Therefore, a special effort to provide source of funds for new investment and working capital to the traditional Batik industry has to be arranged and developed, to rebuild the industry back on its foot into the Great Laweyan of 1960s. Banks are effective in providing external resources for new and innovative activities, because banks can credibly commit in making additional funding available as the project develops [1].

Based on the reasons above, the issues in this study is of traditional Batik industry that has high economic and cultural value, but its existences is threatened by an imperfect market situation. Therefore, what is needed is designing a model of investment in the traditional Batik industry, where banks as capital funders are attractive to invest.

## 2. METHODOLOGY

This study uses the traditional Batik industry in Laweyan, Surakarta, as an object. Several firms that have been closed, some others which are still producing with very low capacity, and big firms which produce both the printing Batik and traditional Batik are studied and used to create a model. The analysis is done through descriptive qualitative and quantitative methods which are in the form of primary data and secondary data collected from owners of the firms. The study also collects data from the SME Industry Regional Department in Surakarta; and information from some Batik literatures.

This research approach involves several key steps:

Step 1: determine an economies scale of Batik firm, which will be used as representative model in this study, assumptions to be used, and input data in form of costs to be incurred.

Step-2: calculate cost of fixed asset and working capital required for investment in the model

Step-3: calculate annual production costs, including product price, and its annual sales projections.

Step-4: modeling a financial scheme through bank loans, including interest rate and debt service payments.

Step-5: arrange projected sources and uses of funds statement to see where and when an amount of funds to be placed

Step-6: calculate feasibility analysis using the techniques of financial analysis

Step-7: make sensitivity analysis to know how sensitive the business due to changes of factors

Step-8: draw a map of traditional Batik industry in Laweyan, based on internal and external environments.

Financial feasibility analysis of the model is based on some investment criteria [2], such as: Net Present Value (NPV), Benefit Cost Ratio (BCR), Discounted Payback Period (PBR), and Internal Rate of Return (IRR).

Net Present Value (NPV) is ratio between PV of net cash flow and PV of investment (capital outlays) over the life of the investment. NPV is as indicator of the feasibility of an investment: If the NPV >0, the investment is feasible to be implemented; if NPV <0, the investment is not feasible to be implemented. The NPV formula is as follows:

$$\text{NPV} = \sum_{t=1}^t \frac{CF_t}{(1+i)^t} - I_0 \quad (1)$$

Where:

CF<sub>t</sub> = annual cash flow in period t (Rp)

I<sub>0</sub> = initial investment in year-0

i = discount rate used to find the present value (%)

t = duration of investment (year)

IRR is a discount rate at which the net present value of costs of the investment equals the net present value of the benefits of the investment. It also used in capital budgeting to measure and compare the profitability of investments in a rate of returns. Generally IRR is compared with rate of capital or MARR, the Minimum Attractive Rate of Returns: If the IRR >MARR, the investment is feasible to be implemented; if NPV <MARR, the investment is not feasible to be implemented. The IRR formula is as follows:

$$IRR = i_1 + \frac{NPV_1}{NPV_1 - NPV_2} \cdot (i_2 - i_1) \quad (2)$$

Where:

NPV1 = net present value at a discount rate i1

NPV2 = net present value at a discount rate i2

i1 = discount rate first experiment

i2 = discount rate second experiment

Discounted Payback Period (DPP) is the number of periods (years) required to cover all capital expenditures incurred using proceeds of the net cash flow. If the discounted payback period is less than the maximum attractive period the project is acceptable, and vice versa. The DPP is calculated as follows:

$$DPP = \frac{I_0}{DCF} \times 1 \text{ years} \quad (3)$$

BCR is ratio between discounted of benefits and discounted of costs of an investment project. If the ratio is >1 then the investment means profitable; likewise, if the ratio is <1 then the investment is not profitable. The formulation of BCR is as follow:

$$BCR = \frac{\sum \text{Benefit}}{\sum \text{Cost}} \quad (4)$$

The SWOT Map of the condition of the traditional Batik industry in Laweyan Cluster is determined based on internal and external environments that can be generated to support the model of the traditional Batik home industry to be sustainable. Internal and external environmental factors are analyzed using internal factor table (IFAS) and the external factor table (EFAS) by the use of weighting and rating. The weighting is based on the relative strengths of other factors; where as the rating is based on the actual condition of the industry in response to those factors. Furthermore the results of matrix IFE and EFE assessment is mapped into IE matrix, a schematic diagram which is divided into 9 cells to determine the appropriate direction of the industry strategy

### 3. RESULTS AND DISCUSSION

#### 3.1. The Business Model of Traditional Batik Home Industry

The assumptions behind the model of the traditional Batik home industry are follows:

- The Model of traditional Batik firm is derived from a traditional Batik of small-scale industry in one of the Batik industry cluster in Surakarta
- The total area of land of the Model is about 500 square meters; with the building area is about 350 square meters. The building area mainly consists of area for both writing and stamping Batik; there are 10 work stations for writing Batik and 5 work stations for stamping. There are storage for materials, and workshop for repair and maintenance.
- Outside the building, there are several pools of 2 x 1.5 meters, to colorize the just waxed written and stamped cloth: usually two brown pools and one black pool. Other two or three pools with hot water are used to wash the wax out-of the cloth. Another area, outside the building, is use to dry-up the nearly finish Batik product, before each of the Batik product is ironed, folded and packed.
- The model produces both stamped Batik and written Batik; the maximum capacity production of which is 30 pieces per month for written Batik and 200 pieces per month for stamped Batik.
- There is a showroom inside and in front part of the building, 5x5 meters, for individual customers to visit, see and select the Batik product.
- Projections carried out for 10 years.

##### 3.1.1. The Production Process

The production process of making the traditional Batik is as follows:

- |   |   |
|---|---|
| 1. Cutting the cloth from its bundles into pieces of 2 meters long colorizing | 5. Sending to another pool for another colorizing |
| 2. Sending the pieces to work stations for wax writing and stamping           | 6. Sending to pool for washing-out the wax        |
| 3. Sending to pool for colorizing (dyeing)                                    | 7. Sun drying                                     |
| 4. Wax removing   | 8. Inspection and pocketing/packing               |

#### 3.2. Cost of Investment

Investment costs consist of cost of fixed asset investments (fixed assets) and working capital (working capital). This model assumes that the land and buildings already exist and is already owned. The cost additional buildings and facilities incurred are shown in Table 1

Working capital is one of the most important asset elements of the company. Due to the absence of working capital consist of raw materials needed to run the day-to-day production activities. Working capital is defined by entire current assets owned by firm subtracted by its current liabilities; they are shown in Table 2. As usually as it is, payment period of account receivables is 5 days, while for account receivables is 20 days, while for trade payables is 10 days. Inventory storage is given a period of 15 days.

#### 3.3. Annual Operation

##### 3.3.1. Sales Projection

Production adjusted for projected sales. The finish good inventory period is given in this business model is 20 days. Sales projection is assumed increasing 2.5% every year because sales of printing Batik cannot be prevented so as make little growth in sales of traditional Batik. The sales projection is shown in Table 3. Selling price is set for stamped Batik in first year is Rp 100.000 per piece and selling price is set for written Batik is Rp 600.000. There is an increase in price 5% every year.

Table 1: Fixed Asset Investment

Investment Cost	Cost
Building Facility	Rp 28.750.000
Production Equipment	Rp 25.325.875
Showroom Equipment	Rp 3.910.000
Pump and Installation	Rp 4.025.000
Licensing	Rp 1.725.000
<b>Total Investment Cost</b>	<b>Rp 63,735,875</b>

Table 2: Working Capital

Working capital	Cost year-1
<b>Current Asset</b>	
Cash and Account Receivables	Rp 6.666.667
Inventory	Rp 10.678.035
<b>Current Liabilities</b>	
Account Payable	Rp 6.766.785
<b>Total working capital</b>	<b>Rp 10.577.917</b>

Table 3: Sales Projection

Year	Written Batik		Stamped Batik	
	Sales (Unit)	Sales (Rp)	Sales (Unit)	Sales (Rp)
1	248	148.800.000	1.656	165.600.000
2	268	168.840.000	1.711	179.655.000
3	277	183.235.500	1.768	194.922.000
4	286	198.648.450	1.825	211.266.563
5	295	215.144.606	1.883	228.879.827
6	304	232.793.757	1.940	247.598.623
7	313	251.669.961	1.997	267.617.099
8	322	271.851.802	2.055	289.159.137
9	331	293.422.651	2.112	312.038.590
10	340	316.470.956	2.170	336.638.223

### 3.3.2. Annual Cost Allocation

Allocation of annual production costs consists of raw material cost, overhead costs, operational cost and wages that can be seen in Table 4. Both written Batik and stamped Batik have the same raw material, just a different quantity adapted to production capacity. The raw material is mori (white fabric), wax, dyes, Batik chemical and petroleum. There are 51 labor force (5 persons a pattern maker with the wage Rp 70.000/piece, 30 writing Batik makers with the wage Rp 330.000/piece, 10 stamp Batik makers with the wage Rp 20.000/piece, 5 dye workers with the wage Rp 500.000/month, 1 person sales force with the wage Rp 500.000/month) that is used in a business model of traditional Batik home industry.

Table-4: Annual Cost Allocation

Year	Material Cost	Overhead Cost	Operational cost	Wages	Total Annual Cost
1	94.411.865	15.259.928	3.144.000	168.240.000	281.055.793
2	102.533.204	15.722.924	3.301.200	177.266.700	298.824.028
3	116.021.721	16.132.499	3.309.060	186.692.310	322.155.590
4	126.004.827	16.562.554	3.309.453	196.541.579	342.418.413
5	137.028.074	17.014.111	3.309.473	206.840.735	364.192.393
6	147.805.206	17.488.246	3.309.474	217.617.567	386.220.492
7	160.208.100	17.986.088	3.309.474	228.901.520	410.405.182
8	173.178.982	18.508.821	3.309.474	240.723.790	435.721.067
9	186.415.549	19.057.692	3.309.474	253.117.423	461.900.137
10	201.600.090	19.634.006	3.309.474	266.117.424	490.660.994

Overhead costs are costs associated with the operation of the production of Batik such as electricity costs, water costs, maintenance costs, telephone costs, and indirect labor. Whereas operating cost consist of administrative and marketing costs, these costs are incurred for the operation and marketing of the product and is not associated with production activities. Percentage of cost increased 5% per year.

### 3.4. Financing

The source of funds used to finance fixed assets and working capital is from bank loan; the whole assets are used as collateral. For the calculation of the debt service an effective interest of 12% is used, in accordance with the retail investment interest rate in local Bank. The repayment of principal and interest of this business will run for 5 years. Funding projections are shown in the Table 5.

Table 5: Funding Projection

Bank Loan	Rp74.313.792				
Interest Rate	12%				
Period	5 years				
	<b>Year 1</b>	<b>Year 2</b>	<b>Year 3</b>	<b>Year 4</b>	<b>Year 5</b>
Principal Installment	14.862.758	14.862.758	14.862.758	14.862.758	14.862.758
Interest Payment	8.917.655	7.134.124	5.350.593	3.567.062	1.783.531
Total Installment	23.780.413	21.996.882	20.213.351	18.429.820	16.646.289

### 3.5. Sources and Uses of Funds Statement

Source and Uses Funds statement is designed to show how funds are obtained and how they are used. In the start up phase, the source of funds comes from a bank loan amount of Rp 74.313.792 (nearly Rp 75 million) while the use of the fund is to buy fixed assets and finance working capital to support the production process. When the business enters production phase, the source of fund comes from earnings after taxes (EAT) and depreciation. EAT is generated from revenue subtracted by all of costs, depreciation, interest payment and tax. Tax is set in this business at 10%, in accordance with the government regulation. The depreciation method used in this model is a straight line. Another use of funds is to replacement of some equipments. In addition, the funds is also used to repayment of the bank loan. The difference of the sources of funds and uses of funds become surplus by the end of the year and can be used for next year's capital. Table 6 shows the sources and uses funds projection.

### 3.6. Feasibility Analysis

To evaluate the feasibility of the investment of the business model of traditional Batik home industry, some investment criteria such as NPV, IRR, Payback Period and BCR are used. The positive cash flow of the business shown from the difference between the total source of funds and the total uses of funds indicates the yearly operation of the business can be conducted well. With the use of MARR of 14%, regarding a risk of 2% above the rate of interest of 12%, shows that a positive NPV of Rp 169.928.565 (nearly Rp 170.000.000) is reached. At the same time, the IRR of 37% is considered high enough compared to MARR. The BCR of 3.2 means that the business feasible to run. Another indicator showed by the Discounted Payback Period of 4.2 (5 years) compared to an economic operation of the business of ten years is a good indicator that the business may be run well.

### 3.7. Sensitivity Analysis

Sensitivity analysis is used to determine how sensitive is the profit ability of the traditional Batik model to any change on its main variables. The variables include the prices of traditional Batik product, the raw material costs, and the direct labor wage. Basically the selling price of the traditional Batik product and the raw material cost varies, not stable and cannot be controlled, because there are no specific standards; they may increase or decrease according to market conditions and business strategy. Labor wage in this has a great proportion of the production cost; therefore its sensitivity must be examined.

Based on Figure 1, it can be seen, that the business is able to standstill for the decrease of selling price up to 8%. The increase in raw material costs up to 26% still give rise to a positive NPV; while the increase in labor costs up to 17% still bring a positive NPV.

Table 6: Sources and Uses Funds

	Year 0	Year 1	Year 2	Year 3	Year 4	Year 5	Year 6	Year 7	Year 8	Year 9	Year 10
<b>Sources of Fund</b>											
EAT	-	8,857,510	25,156,775	32,459,798	44,410,196	57,117,271	71,628,312	84,867,304	99,634,497	116,078,606	133,076,979
Depreciation	-	14,584,875	14,584,875	14,584,875	14,584,875	14,584,875	14,584,875	14,584,875	14,584,875	14,584,875	14,584,875

### 3.8. Mapping the SWOT of the Traditional Batik Industry in Laweyan Cluster

Traditional Batik Industry SWOT Mapping is conducted to determine the appropriate strategy to support traditional Batik home industries to be a sustainable industry. The Internal and External factors are generated based on observations, interviews and a review of some literatures. The weighting of the factors (from 1.0 for poor to 4.0 for outstanding) is given by 5 business owner of small-scale traditional Batik industry in Surakarta then processed using the calculation method of AHP (Analytical Hierarchy Process) , and the ratings are given by the Head of SME industry Department in Surakarta. rating scale ranging from 4 (outstanding) to 1 (poor) based on the effect of these factors to the current conditions. Rating for strengths and opportunities are positive (if there is a greatest effect of opportunities and strength, given the rating 4, but if the smallest effect factor of opportunities and strengths, given the rating of 1), while providing rating weaknesses and threats are the opposite. Table 7 and Table 8 shows the IFE and EFE matrix of traditional Batik industry.

Table 7: IFE Matrix

Internal Strategy Factor	Weight	Rating	Weight X Rating
<b>Strength Factor</b>			
Having trained and skilled craftsmen	0.1090	4.0	0.4360
Cohesive business management	0.0690	3.0	0.2070
Strong relationship between Batik entrepreneurs	0.0710	3.7	0.2627
Unique patterns and models	0.1600	4.0	0.6400
High quality handmade products	0.0850	3.7	0.3145
<b>Weakness Factor</b>			
Lack of craftsmen regeneration	0.1540	1.7	0.2618
Difficulty getting raw materials	0.0980	2.7	0.2646

Limitation of capital	0.1400	2.0	0.2800
Traditional financial management	0.1140	3.0	0.3420
<b>TOTAL</b>	<b>1.000</b>		<b>3.009</b>

Table 8: EFE Matrix

External Strategy Factor	Weight	Rating	Weight X Rating
<b>Opportunity Factor</b>			
Increasing demand of Batik	0.0678	3.7	0.249
High appreciation for culture	0.0756	3.3	0.252
Market share is still wide	0.0770	4.0	0.308
Support of local government	0.0587	3.3	0.196
Advances in technology and communications	0.1311	3.0	0.393
<b>Threat Factor</b>			
Instability economic condition	0.1506	1.3	0.201
Development of Batik printing industry	0.2143	1.0	0.214
Existence of substitute products	0.0393	2.3	0.092
Global market conditions	0.0929	3.0	0.279
Many Competitors	0.0926	2.3	0.216
<b>TOTAL</b>	<b>1.0000</b>		<b>2.400</b>

Based on the assessment of the weighting and the ratings, the value of IFE matrix is 3.0 and the value of EFE matrix is 2.4. Then the value is mapped into internal and external matrix (IE Matrix), in which the position of the traditional Batik industry of Laweyan is located in position IV of Figure 2, namely a position of “developing and growing stage condition”. This means, that a suitable strategy to support the traditional Batik industry of Laweyan includes intensive strategy that contains market penetration, market development, product development; and integration strategy, both forward integration, backward integration, and horizontal integration.

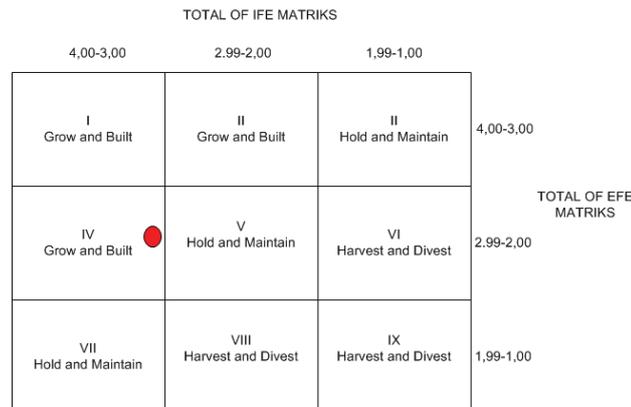

Figure 2: IE Matrix of traditional Batik industry of Laweyan

#### 4. CONCLUSION

From the research results obtained the following results:

1. The value of investment for this business model is nearly Rp 75 million, with capital funding from banks for 5 years and 12% interest rate per year.
2. The results of the projected calculations for 10 years with the amount of MARR is 14%, Show that the business model of Batik home industry is feasible to run, with a value of NPV is nearly Rp 170 million; IRR is 37%, BCR is 3.2; and the Discounted Payback Period is about 5 years.
3. If the government can bring some kinds of financial facilities to the traditional Batik Industry, such as, grace period of two years, tax holiday also for two years, and investment tax credit for at least 10%, better NPV, IRR, BCR and DPP will be reached.
4. The results of sensitivity analysis show that the decrease in selling price of 8% is allowable for a positive NPV; the same thing happens also for the increase in raw material costs to 26%, and increase in labor wages to 17%.
5. Based on the mapping position, Batik Laweyan is in a developing and growing condition. Suitable strategy to survive in this industry is an intensive strategy and integration strategy.

6. To see Laweyan regain its traditional Batik Kingdom in Indonesia a mass investment of 15 to 20 billion Rupiahs are needed.

### ABSTRACT

Various types of goods/services promotion performed by the company to introduce their products, a form of promotion is through advertising. There are several media to place an advertisement, in which newspaper has several advantages than other media. Competition among companies is requiring them to choose an effective advertising. This research focuses on looking at the effectiveness of some of the most popular advertisement in the newspaper-using eye tracking methods. The study was conducted by looking at two factors, size (3 columns and 4 columns) and color factors (color and black & white). Sixty subjects performed four combination of newspaper advertising using Eye Tracker. Every combination is performed by 15 subjects. The next step is used questionnaire to validate the data. This result of questionnaire is similar to results from data viewer software. The results showed that size factor (3 columns and 4 columns) or the interaction between them, do not affect significantly the duration of fixation. The significantly affect the duration of fixation is a factor of color (black & white and color).

### Keywords

*Advertising, Newspaper, Eye Tracking, Ergonomics*

### 1. INTRODUCTION

Along with the progress of time in all areas of life, especially in the field of information and communication technology has caused the development of the media to be very rapid. In the face of future challenges that are very difficult, a clear concept and rigorous competitive strategy are needed and supported by the resources and all the potential owned to be able to deal with it. Marketing strategy which aims to win the competition is needed in order to survive in market. Strategy that can be used by producers in order to market its products is the marketing communications through advertising or advertising program.

Lots of advertising media are well known by people, such as the print media (newspapers and magazines), electronic media (television, radio, computer), and outdoor media (exhibitions, calendar, etc.). In Indonesia, newspaper has an important role for advertisers because nationally, advertising cost of newspaper is second place after television.

Indonesia's leading newspaper is Kompas newspaper. Being a leading newspaper in Indonesia, Kompas has the highest rating among the others. Kompas is one of two Indonesian newspapers which are audited by the Audit Bureau of Circulations (ABC). For advertisers, newspapers rating is a driving factor for choosing them in newspapers where they will advertise their products. Kompas newspaper is one of consumer choice.

Kompas provides advertising rates that is varied according to the type of advertising. The difference of this is caused by its characteristics and value on each type of advertising. Kompas has two types of advertisement, regular and Klasika. Regular has 7 columns and Klasika has 9 columns. Each of it has a type of advertising with sizes, colors, and costs that were different.

The newspaper sells advertising space to advertisers in millimeters column (mmc). An advertisement with a 4-column width and height of 100 mm will have extensive advertising space 400 mmc (4 columns x 100 mm). Thus the cost to be paid advertiser is calculated by multiplying the broad of advertising space based on mmc with advertising rate (rate card) per mmc. The newspaper also provides two alternative colors, namely black and white (BW) and Full Color (FC), which both of them have different prices.

Advertisers who want to advertise their products and services are categorized as display advertising. Size of display advertisement which is favorite by advertisers is 3 columns x 270 mm and 4 columns x 270 mm. The fees are charged for BW at Rp 105,000 per mmc and FC RP 147,000 per mmc.

Because of the high interest of the newspaper advertiser and the fees charged to advertisers, the study was conducted to see the effectiveness of sizes and colors as a recommendation for advertisers using eye tracking. The size and color factor is one of the important factors that determine decision-making of customer so this study focuses on those factors. Small size or larger size of advertising has different purpose. Small space advertisement can be used effectively to build frequency [1]. According to Huang (1993), the color choices made in standardization efforts are integral to industrial product success [2].

The eye tracking methods used in this study are increasingly being applied in the field of marketing and consumer behavior, particularly in advertising [3]. The eye-tracking device has become one of the most important human-machine interfaces in which eye movements are related to the information-processing demands of a task [4].

The size will be in the two trials, display size of 4 columns x 270 mm (color BW and FC) and 7 columns x 115 mm (color BW and FC). Based on the purpose of this study, the title of this paper is Analysis of the Effectiveness of Kompas Newspaper Advertising Based on Size and Color Factors Using Eye Tracking Method.. The research question of this reserach is abut the correlation between size and color of advertising with the visibility of advertising.

## 2. METHODS

### 2.1 Subjects

The number of subjects for the four combinations of newspaper advertisement is 60. Each combination requires 15 subjects. The criteria of the subjects are as follows:

1. Male or female
2. Aged between 18-22 years
3. Subject did not know the theme of the research
4. Subject is not color-blind
5. Subject did not have difficulty on vision, like nearsighted or farsighted and other

### 2.2 Display of Newspaper Advertisement

Newspaper advertisement used in this study is beverage products because it is a general product. There are four combinations of newspaper advertisement, they are combination 1 (black and white advertisement with a small size), combination 2 (color advertisement with a small size), combination 3 (black and white advertisement with large size), and combination 4 (color advertisement with large size). The visualization of these combinations can be seen in Figure 1.

Combination 1

Combination 2

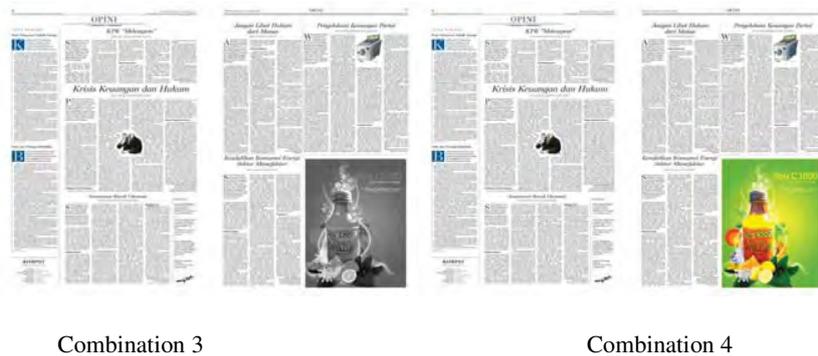

Figure 1: Newspaper Advertisement

### 2.3 Equipments

Eye tracker is a device used to track the movement of eyes. The tracking of eyes movement is needed in order to know whether eyes is doing brief stop (fixation) or rapid movement (saccades) on object seen by the eyes. These two of movement is used to access attention of subject on the picture [5]. This study uses the EyeLink II Head Fixed Eye Tracker. Its main components are EyeLink II Host PC, EyeLink II Display PC, EyeLinkII PCI Card, and EyeLinkII Headband. The eye tracker is combined with Experiment Builder as media execution. EyeLink II Display PC monitor used is a HP 19 "rectangle and CPU. The scope of view of the human eye is limited to 30° so there is a minimum distance between the monitor with the eye, which is 70.53 cm.

### 2.4 Analysis Framework

Data obtained from a combination of 1-4 will be processed using fixation maps, interest area, and statistical tests. Data of fixation map explain about the intensity of the sight of all subjects. Data of interest areas explain about the intensity vision of the respondents in area advertising. The statistical test used to look the factors that significantly affect the dwell time is ANOVA. The interaction between these two factors can be seen in the Estimated Marginal Mean.

## 3. RESULTS

### 3.1 Fixation Map and Interest Area

The colors on the fixation map indicate duration of eye fixations. Duration of fixation is indicated by green, yellow, and red color. Green color indicates the lowest duration while red indicates the highest duration.

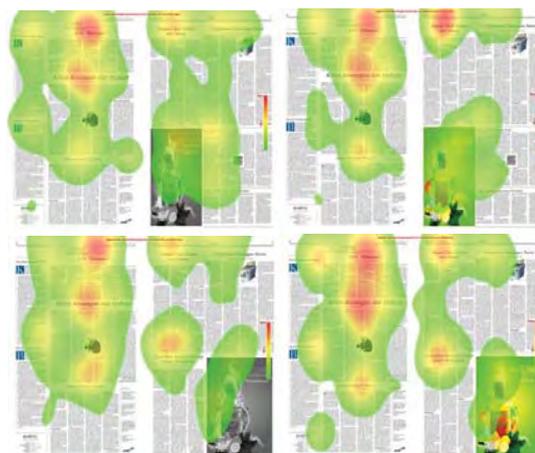

Figure 2: Fixation Map, Combination 1-4

Based on fixation map in Figure 2, the intensity of all subjects' sight can be seen in this figure. Examples of combinations 1, the area of advertisements contains intensity of yellow color that means some subjects see any advertisement in newspapers. Percentage of subjects ever seen in a newspaper advertisement can be seen from the area of interest. This percentage means the

effectiveness of the advertising of newspaper which has been combined. Percentage of subjects ever seen in newspaper of combination 1 is 7.37%, a combination 2 is 7.68%, a combination 3 is 6.01%, and a combination 4 is 7.81%. This percentage shows the time spent by subjects who saw newspaper advertisement than all the time spent to see the entire newspaper.

Based on the results of the data viewer, the value effectiveness of each combination has been obtained. Its value is 7.37% for black and white advertisement in 3 columns type, 7.68% for colored advertisement in 3 columns type, 6.01% for black and white advertisement in 4 columns type, and 7.81% for colored advertisement in 4 columns type. Based on those values, the colored advertisement in 4 columns type has the greatest value of effectiveness, and then the colored advertisement in 3 columns type in second position, black and white advertisement in 3 columns type in third position, and black and white advertisement in 4 columns type in fourth position.

### 3.2 Statistic Test

Before the results of statistical processing are analyzed, it must be ensured that the data processed are Normal. Normally test is conducted to ensure processed data are normal because statistical processing requires normalize data. The test shows that the data is normally distributed (refer to Figure 3).

Normal P-P Plot of Regression Standardized Residual

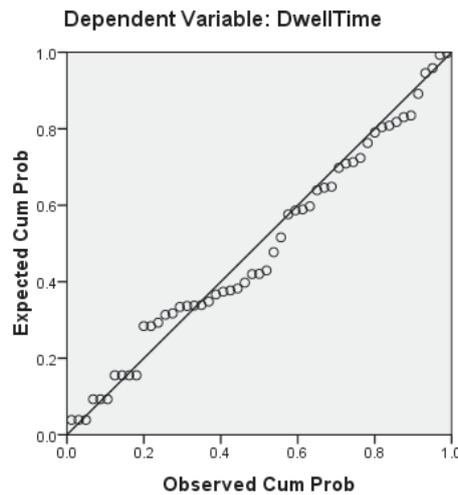

Figure 3: Normal Probability Plot

After the data has passed normality test, further analysis can be carried out to see a significant factor affecting the Dwell Time. The analysis was done by looking at the table of ANOVA and Coefficient table.

**ANOVA<sup>b</sup>**

Model		Sum of Squares	df	Mean Square	F	Sig.
1	Regression	1.328E7	2	6641676.966	4.972	.011 <sup>a</sup>
	Residual	6.679E7	50	1335835.240		
	Total	8.008E7	52			

a. Predictors: (Constant), Warna, Ukuran

b. Dependent Variable: DwellTime

Figure 4: ANOVA Table

F value was obtained 4.972 with a significance level 0.011 (refer to Figure 4). Since the significance level is less than  $\alpha$  (0.05), it can be said that the size and color simultaneously affect fixation duration (Dwell Time).

**Coefficients<sup>a</sup>**

Model		Unstandardized Coefficients		Standardized Coefficients	t	Sig.
		B	Std. Error	Beta		
1	(Constant)	-722.649	698.303		-1.035	.306
	Ukuran	511.913	317.629	.208	1.612	.113
	Warna	870.241	317.629	.354	2.740	.008

a. Dependent Variable: DwellTime

Figure 5: Coefficients Table

Based on the coefficients table in Figure 5, a significance level of size is 0.113, which means the size factor does not significantly affect the level of Dwell Time because the significance level is less than  $\alpha$  (0.05). However, a significance level of color is 0.008, which means the color factors significantly affect Dwell Time. Based on the level of significance of the color factor is lower than  $\alpha$  ( $0.008 < 0.05$ ) then  $H_0$  is rejected.

**Tests of Between-Subjects Effects**

Dependent Variable: DwellTime

Source	Type III Sum of Squares	df	Mean Square	F	Sig.
Corrected Model	1.337E7 <sup>a</sup>	3	4457423.924	3.274	.029
Intercept	9.668E7	1	9.668E7	71.023	.000
Ukuran	3448492.551	1	3448492.551	2.533	.118
Warna	1.006E7	1	1.006E7	7.389	.009
Ukuran * Warna	88917.838	1	88917.838	.065	.799
Error	6.670E7	49	1361282.534		
Total	1.772E8	53			
Corrected Total	8.008E7	52			

a. R Squared = .167 (Adjusted R Squared = .116)

Figure 6: Test of Between-Subject Effects

Based on the Figure 6, the level of significance of the interaction between the size and color is 0.799. The level of significance is much greater than  $\alpha$  (0.05) which means that the interaction between the factors was not significant to the Dwell Time. The lack of interaction can be seen in Figure. 7. Green and blue lines do not intersect which means there is no interaction between the two factors.

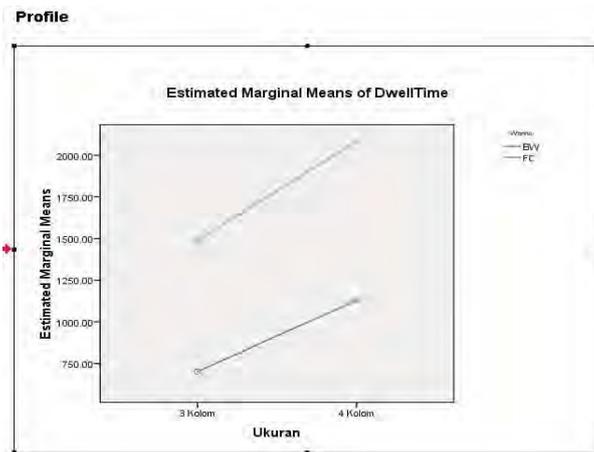

Figure 7: Estimated Marginal Means of Dwell Time

#### 4. DISCUSSION

The purpose of this research is analyzing the effectiveness of sizes and colors as a recommendation for advertisers on the visibility of customers. In combination 1 (black and white advertisement with a small size), some subjects see the advertising and the others see the news or the title. In combination 2 (color advertisement with a small size), most of the subjects see and know about the advertising. In combination 3 (black and white advertisement with a large size), most of the subjects do not see and know about the advertising. In combination 4 (color advertisement with a large size), the result is similar to combination 3.

Based on the values of effectiveness are obtained, most of the subjects' interests to the color advertising and the largest one. Experiment test showed that there is significance effect of size and color of advertisement in newspaper. This finding might justify the higher rate of consumer attractiveness about using color and larger size. Previous study is about advertising using game online [6] which the advertising has a motion together with the game. As the result, there are different factor influences static and dynamic advertising. In game, the advertising must have motion to attract the consumers. However, in newspaper, the static advertising still gives interest for customers. For further study, economy analysis, content of advertising, and type of display advertising can be added as factors to analysis the effectiveness of advertising in newspaper.

## 5. CONCLUSION

Based on the values of effectiveness are obtained ratings from highest to lowest, there are color advertisement in 4 columns type, color advertisement in 3 columns type, black and white advertisement in 3 columns type, and black and white advertisement in 4 columns type. The results of the processing of questionnaire and data viewer have same values. Subjects not only see, but also know what advertisement on newspaper images. The statistical results showed that the interaction between the factor and the size factor does not affect Dwell Time (the time spent looking at the advertisement) of advertisement was significantly. Color factor is the most affecting factor in Dwell Time advertisement. Color factor is affecting the awareness of subjects so it can be an option for advertisers when choosing the type of advertisement in newspapers.

## ACKNOWLEDGMENT

The author gratefully acknowledges the data collection using tools from ergonomic center Universitas Indonesia.

## **ABSTRACT**

Innovation and Malcolm Baldrige Criteria have been indispensable for enhancement of Human Life and Environment. This paper relates the concept, theoretical aspects and managerial implications of Innovation and Malcolm Baldrige for the benefit of Human Life within unit analysis of individual, company and nation toward global benefit. As scope of problem and in scope of a nation, Indonesia, in the last 5 until 10 years, has been experiencing difficulties in competing with other nations. As scope of objectives, Methodology and Discussion in this paper emphasize on generalized concept of Innovation and Malcolm Baldrige to mitigate and eventually has objectives to eliminate scope of the problem pertaining the competitiveness difficulties. Furthermore, in term of generalized concept of innovation of three pillars of Global Competitiveness Index (GCI) and Professor Clayton M. Christensen, and seven criteria of Malcolm Baldrige National Quality Award (MBNQA) in Business, Health Care and Higher Education. In term of Malcolm Baldrige Criteria 2011-2012; in this paper, Confirmatory Factor Analysis (CFA) was utilized to investigate constructs' reliability and validity, while Structural Equation Modeling (SEM) were utilized to examine relationship among constructs that relate effect of Strategic Planning, Customer Focus and Operations Focus toward Result of Performance Excellence and Sustainability.

## **1. INTRODUCTION**

Indonesia in the last 5 until 10 years, has been experiencing difficulties in competing with other nations. According to Global Competitiveness Index (GCI), GCI 2010-2011, Indonesia undergone 10 point increase from Rank 54 into 44. Yet, in GCI 2011-2012, Indonesia undergone 2 point decrease from Rank 44 into 46, that constitute an alert for the incoming years. In this situation, Performance Excellence and Sustainability are deemed Indispensable, not to mentioned the Strategic Planning, Customer Focus and Operations Focus. That relate to Innovation and Malcolm Baldrige. As scope of objectives, Methodology and Discussion generalized concept of Innovation and Malcolm Baldrige to mitigate and eventually has objectives to eliminate scope of the problem pertaining the competitiveness difficulties. The mentioned of generalized concept of innovation of three pillars of Global Competitiveness Index (GCI) and Professor Clayton M. Christensen, and seven criteria 2011-2012 of Malcolm Baldrige National Quality Award (MBNQA) in Business, Health Care and Higher Education. The details of Malcolm Baldrige Criteria is also identified and elaborated by Sadikin (2011) in "Seri Manajemen Mutu Bunga Rampai" and Blazey (2011) in Insights to Performance Excellence 2011-2012. Although the Baldrige criteria and framework are widely accepted in practice, there is surprisingly little theoretical and empirical evidence of their validity (Ford and Evans, 2000). Several studies presented empirical analyses of the original Baldrige Criteria in the manufacturing environment and provided evidence that the performance relationships observed in the Baldrige causal model were supported in US firms. Most recently, York and Miree (2004) examined the relationship between TQM and financial performance, using a sample of Baldrige Award winners; they replicated a second sample of state quality award winning companies with three different sets of financial performance measures. Baldrige quality award winners generally had better financial performance than their peers after and before winning a quality award.

## **2. LITERATURE REVIEW**

### **Innovation**

An innovation is an idea, practice or object that is perceived as new by the entity adopting it, according to Rogers (2003). The concept of innovation implies the idea that something is added to something else that already exists, or that something that exists is given up. The argument is that adding and/or taking away are ways to improve a state of affairs. As indicated by Jalonen (2012), Despite positive connotations associated with the concept of 'innovation', it should be noted that the potential

value integral to innovation may or may not be realised in the future. Fernandes (2012) has further elaborated the value construct that deals with two wide variables: value form and value materialization. The value form varies from tangible to intangible. The value materialization is concerned with the simplicity or complexity of the process utilized to create value. Mehrabani (2012) has further enhanced the mentioned Value Constructs in term of Knowledge Management and Innovation Capacity. Tipu (2011) has further classified the Innovation Management, as entity that consider the i. Process of Innovation, ii. Factors Affecting Innovation, Protection of Innovation, iii. Measures of Innovation, and iv. Types of Innovation. Unlike Tipu, Muscio (2010) has segregated the Innovation according to three big categories, which are : i. Business Innovation Needs, according to Product or Process Innovation, ii. Technology, according to Pure Technology, or Other Technology ( New Materials, Machinery, ICT or Environmental ).

**Innovation and Performance**

Innovation and Performance has been discussed in Scientific Analysis of Entrepreneurship and SMEs (SCALES, 2007, p. 44 and 47). SCALES segregate important determinants of Innovation Input and Innovation Output, that are expressed in the following equations.

Determinants of Innovation Input

$$y_i = \alpha + \sum_{j=1}^J \beta_j x_{ij} + \varepsilon_i \tag{1}$$

Determinants of Innovation Output

$$y_i = \begin{cases} \alpha + \sum_{j=1}^J \beta_j x_{ij} + \varepsilon_i & \text{if } y_i^* = \alpha + \sum_{j=1}^J \beta_j x_{ij} + \varepsilon_i > 0 \\ 0 & \text{if } y_i^* = \alpha + \sum_{j=1}^J \beta_j x_{ij} + \varepsilon_i \leq 0 \end{cases} \tag{2}$$

$$y_i = \begin{cases} \alpha + \sum_{j=1}^J \beta_j x_{ij} + \varepsilon_{2i} & \text{if } y_i^* = \alpha + \sum_{j=1}^J \beta_j x_{ij} + \varepsilon_{1i} > 0 \\ 0 & \text{if } y_i^* = \alpha + \sum_{j=1}^J \beta_j x_{ij} + \varepsilon_{1i} \leq 0 \end{cases} \tag{3}$$

The mentioned equations are discussed in detail in the session of Discussion and Analysis and The above introduction pertaining the Determinants of Innovation, is further elaborated in the overview by SCALES (2007, p. 10) in the following model:

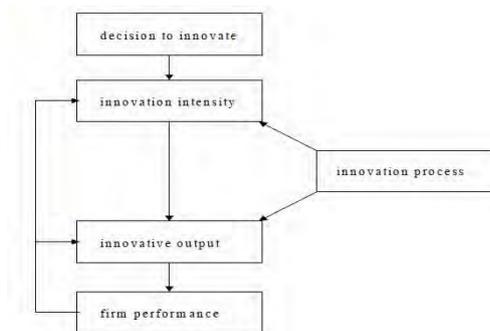

Figure 1 Overview of Innovation Process

**Innovation – Productivity Relationship**

The empirical evidence for Innovation – Productivity Relationship, has been discussed by Hall (2011, p. 11) that provided a detailed review of the studies that have attempted to estimate a quantitative relationship between firm-level productivity and innovation measures explicitly.

In term of Equation, the empirical of evidence has been visualized in the following equation that is resulted from two other equations and its original equation. The mentioned equations are discussed in detail in the session of Discussion and Analysis

$$r_{it} = \left( \frac{\eta + 1}{\eta} \right) (a_{it} + \alpha c_{it} + \beta l_{it}) + \left( \frac{\gamma(\eta + 1) - \varphi}{\eta} \right) k_{it} \tag{4}$$

### Global Competitiveness Index

The *Global Competitiveness Report* ([www.weforum.org/gcr](http://www.weforum.org/gcr)) remains the most respected assessment of national competitiveness, providing a useful portrait of a nation's economic environment and its ability to achieve sustained levels of prosperity and growth. For a portrayal that represents reality as accurately as possible, the World Economic Forum draws its data from two sources: international organizations and national sources, and its own Executive Opinion Survey (Survey). The Survey is a one-of-a-kind tool for capturing vital information that is not otherwise available at a global level. The data gathered thus provide a unique source of insight and a qualitative portrait of each nation's economic and business environment, as well as an understanding of how

it compares with the situation in other countries. The World Economic Forum has conducted its The World Economic Forum has conducted its annual Survey for over 30 years, modifying it over time to capture new data points essential to the Global Competitiveness Index (GCI) and other Forum indexes. It has also expanded the scope of its sample, achieving this year a record of over 15,000 surveys from 142 economies between January and June 2011.

### Malcolm Baldrige National Quality Award

The seven criteria in the MBNQA are hypothesized to have a particular relationship to each other ( Badri et al, 2005, p. 1123 ). Although the Baldrige criteria and framework are widely accepted in practice, there is surprisingly little theoretical and empirical evidence of their validity (Ford and Evans, 2000). Several studies presented empirical analyses of the original Baldrige Criteria in the manufacturing environment and provided evidence that the performance relationships observed in the Baldrige causal model were supported in US firms. Most recently, York and Miree (2004) examined the relationship between TQM and financial performance, using a sample of Baldrige Award winners; they replicated a second sample of state quality award winning companies with three different sets of financial performance measures. Baldrige quality award winners generally had better financial performance than their peers after and before winning a quality award.

Posterior to the discussion on Innovation, there are further discussion based on the title of this paper; Innovation and Malcolm Baldrige: Effect of Strategic Planning, Customer Focus and Operations Focus toward Result of Performance Excellence and Sustainability. The subsequent discussion in Figure 3, convey the further overview aspect of seven criteria within the MBNQA.

Figure 3: Malcolm Baldrige 2011 – 2012 Criteria

### 3. METHODOLOGY

Methodology and Discussion in this paper emphasize on generalized concept of Innovation and Malcolm Baldrige to mitigate and eventually has objectives to eliminate scope of the problem pertaining the competitiveness difficulties. Furthermore, in term of generalized concept of innovation of three pillars of Global Competitiveness Index (GCI) and Professor Clayton M. Christensen, and seven criteria of Malcolm Baldrige National Quality Award (MBNQA) in Business, Health Care and Higher Education.

In term of Malcolm Baldrige Criteria 2011-2012; in this paper, Confirmatory Factor Analysis (CFA) was utilized to investigate constructs' reliability and validity, while Structural Equation Modeling (SEM) were utilized to examine relationship among constructs that relate effect of Strategic Planning, Customer Focus and Operations Focus toward Result of Performance Excellence and Sustainability.

#### Structural Equation Modeling

The literature reviews of this paper are originated from International Journal about SEM (Written in English) and Books about SEM (Written in English and Bahasa Indonesia). The highlighted International Journal among others is **Structural Equation Modeling: A Multidisciplinary Journal**, while the highlighted Books about SEM, among others are authored by Hoyle (2012), Kline (2011), Schumacker and Lomax (2010), Rencher and Christensen (2012), Hair, Black, Babin, Anderson (2010), Ariefianto (2012), Wiyono (2011), Wijaya (2009), and Wijanto (2008). A Multidisciplinary Journal (SEM: AMJ), is the main reference for this project paper. First article on the mentioned journal refers to article of Wu and Kwok (2012) on Using SEM to Analyze Complex Survey Data. Second article refers to Preacher, Zhang and Zyphur (2011) on Alternative Methods for Assessing Mediation in Multilevel Data. Third article refers to Crayen, Geiser, Scheithauer, and Eid (2011) on Evaluating Interventions with Multimethod Data: A Structural Equation Modeling Approach. Books on SEM Concept; this SEM Concept refers to the following discussion on Variables in SEM, Measurement and Structural Models, Measurement and Structural Errors, Mathematical Notation, and Introduction to LISREL 8.8. The books that convey the mentioned discussion are authored by Hair, Black, Babin, Anderson (2010), Byrne (1998) and Wijanto (2008). Books on SEM Procedures; this SEM Procedures refer to the following discussion on Specification, Identification, Estimation, Testing and Re-specification. In addition to the book that is authored by Schumacker and Lomax (2010), The books that convey the mentioned discussion are authored by Hair, Black, Babin, Anderson (2010), Byrne (1998) and Wijanto (2008).

### 4. DISCUSSION AND ANALYSIS

#### Innovation

This paper relates the concept, theoretical aspects and managerial implications of Innovation and Malcolm Baldrige for the benefit of Human Life within unit analysis of individual, company and nation toward global benefit. With the consideration of that unit of analysis, the Figure 1 has indicated the details of that unit of analysis on Know How, in term of Focus Firm, Competitive Environment and Macro Environment Sections and Subsections. Precisely, it elaborates the IT and Organizational Performance from 3 Unit of Analysis. Not to mention the Concept of Disruptive Innovation by *Professor Clayton M. Christensen*.

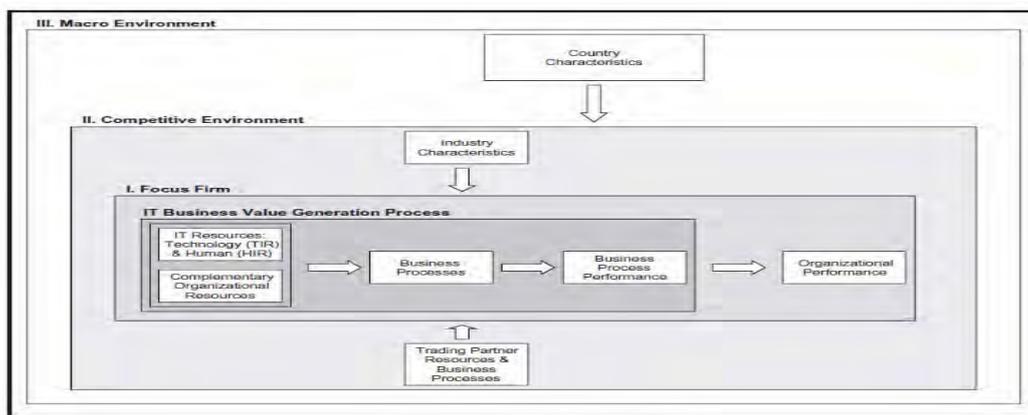

Figure 4: IT and Organizational Performance from 3 Unit of Analysis.

Determinants of Innovation Input, from Equation (1)

SCALES (2007, p. 44) elaborates the mentioned Equation, by stating that The variable of interest is innovation intensity, the total amount of time all employees spend on innovative activities, as a percentage of total available time<sup>1</sup>. The whole set of innovation

and firm-performance variables, including the sectoral dummies, are used as explanatory variables in the innovation equation. With  $y_i$  denoting innovation intensity for firm  $i$  and  $x_{ij}$  the value of explanatory variable  $j$  for firm  $i$ , with  $\epsilon_i \sim N(0, \sigma^2)$ . The explanatory variables that are included in the model are displayed, for which an expected sign is filled. The sectoral dummies are added in the model. A constant term  $\alpha$  is included. Equation (1) could have been modelled as a Tobit model, which takes account of zero shares of innovation input. The standard linear-regression model seems most appropriate to model the innovation-input equation, using ordinary least squares (OLS) as estimation method.

Determinants of Innovation Output, from Equation (2)

SCALES (2007, p. 47) elaborates the mentioned Equation, by indicating that use the share of new products or services in total turnover as innovation-output indicator and dependent variable. Since a number of firms have zero innovative output, simply estimating a linear regression model by OLS leads to biased estimates. Tobit models are better suited to model such a dependent variable (Greene, 2000; Franses and Paap, 2001). We consider two types of Tobit models, named type-1 Tobit model and type-2 Tobit model (Amemiya, 1985). For the type-1 Tobit model, a latent variable  $y_i^*$  is introduced. It takes a value of 0 if firms have no innovative output, and 1 if firms have innovative output. This latent variable is used in the model according to Equation (2).

According to discussion by Hall (2011, p. 11), The Equation (5) is deemed as the original equation, while Equation (6) and (7) are the building block for Equation (4).

$$Q = AC^\alpha L^\beta K^\gamma \tag{5}$$

$$q_{it} = a_{it} + \alpha c_{it} + \beta l_{it} + \gamma k_{it} \quad i = \text{entity}, t = \text{time} \tag{6}$$

$$q_{it} = \eta p_{it} + \phi k_{it} \quad \phi > 0 \tag{7}$$

Hall (2011, p. 7) mentioned that What is meant by the term “productivity” is fairly easy to understand although difficult to measure: it is the quantity of output that can be produced using a given level of inputs. If productivity is to be used as a measure of innovation, there is an implicit assumption that increases in output not accompanied by increases in inputs are due to innovative activity. Equation (5) constitutes relationship between output and the level of inputs using a production function. Hall (2011, p. 7) indicated that  $Q$  is output,  $C$  is the level of capital stock, and  $L$  is labor (and potentially other noncapital inputs).  $A$  is the overall level of productivity which may vary across entities. That is, because of organizational differences, frictions, or other constraints, entities with identical levels of  $C$  and  $L$  may not be able to achieve the same level of output  $Q$ . By algorithm mechanism, then the Equation (5) is transformed into Equation (6), and eventually is rewritten according to the shifted demand. Precisely, Hall (2011, p. 7) mentions the following reason: much of innovative activity is directed towards new products and product improvement, it is useful to rewrite the demand equation to allow the knowledge stock to shift the demand curve facing the firm. Assuming that the knowledge stock has a positive coefficient implies that the effect of increased knowledge or innovative activity is to shift the demand curve out by making the firm’s products more attractive to its customers, at a given price.

Equation (4) is obtained based on the equation for revenue. Hall (2011, p. 11) indicates that this equation shows that knowledge stock  $K$  is likely to contribute to revenue and therefore to measured productivity growth via two channels: directly by increasing the efficiency of production and indirectly by shifting the demand curve for the firm’s products outward (note that  $\eta$  is negative so that  $-\phi/\eta$  is positive). It is usual to think of these two channels as process and product innovation. For full identification of the system implied by equation (4), it would be desirable either to have data on individual firm output prices to allow separate estimation of  $\eta$  and  $\phi$  or to have some information on the components of  $K$  that might be directed toward processes and/or products. At the simplest level, one can gain some idea of the relative importance of the two types of innovation for productivity using the innovation dummy variables available from the various innovation surveys. An implication of the foregoing model is that process innovation will have ambiguous effects on revenue productivity, whereas the effect of product innovation is likely to be positive.

### Global Competitiveness Index

Figure 5 in term of Indonesia’s Stage of Development, is an indispensable aspects to be considered in order to maintain and improve Indonesia’s Stage of Development of Stage 2: Efficiency driven. Furthermore, it is indispensable to consider the GCI, According to Global Competitiveness Index (GCI), GCI 2010-2011, Indonesia undergone 10 point increase from Rank 54

into 44. Yet, in GCI 2011-2012, Indonesia undergone 2 point decrease from Rank 44 into 46, that constitute an alert for the incoming years.

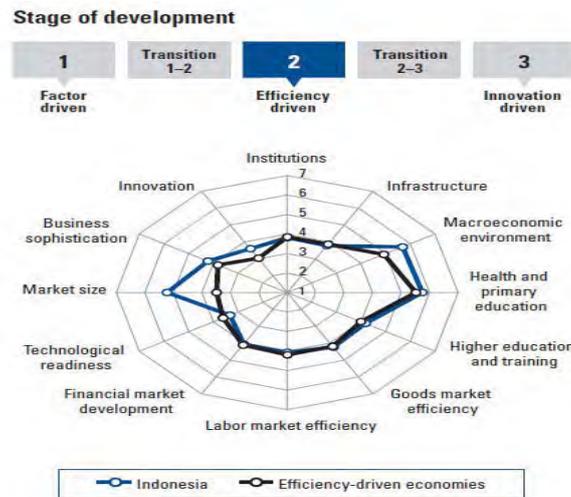

Figure 5: GCI 2011 – 2012 and Indonesia’s Stage of Development

### Malcolm Baldrige National Quality Award

Referring to Figure 1 pertaining the overview of Innovation Process, then Malcolm Baldrige is important to be considered, in any unit analysis that has been mentioned in the aspect of, theoretical aspects and managerial implications of Innovation and Malcolm Baldrige for the benefit of Human Life within unit analysis of individual, company and nation toward global benefit. Precisely, the Malcolm Baldrige refers to Effect of Strategic Planning, Customer Focus and Operations Focus toward Result of Performance Excellence and Sustainability. Data collection is conducted using both Primary and Secondary Method. For Primary Method, the interview process is conducted, along with the survey that relate to the Management of The Company. For Secondary Method, the analysis is referring to the Annual Report from the listed company in Jakarta Stock Exchange ( [www.idx.co.id](http://www.idx.co.id) ). Other information is originated from the Indonesian Quality Award Foundation ( IQA ) [www.indonesianqualityaward.org](http://www.indonesianqualityaward.org) that since 2006 has conducted and provided the Indonesian Quality Award, including the Recent Award in November 2012; Indonesian Quality Award VIII 2012. The highlighted discussion is referring to the “Growth” for both category of institution.

Excellent “Growth” for Middle Level Institution

1. **PT Krakatau Medika** Bronze Award ( Early Improvement )
2. **Universitas Bina Nusantara** Silver Award ( Early Improvement )
3. **PT Krakatau Engineering** Gold Award ( Good Performance )

Excellent “Growth” for Big Level Institution

1. **PT Aneka Tambang ( Persero )** Bronze Award ( Good Performance )
2. **PERUM PERUMNAS** Silver Award ( Good Performance )
3. **PT Semen Tonasa** Gold Award ( Early Improvement )

Innovation and Malcolm Baldrige, and its relations with Effect of Strategic Planning, Customer Focus and Operations Focus toward Result of Performance Excellence and Sustainability are deemed indispensable. Precisely, the Growth that has been shown in by both Middle and Big Institution. SCALES (2007, p. 31) specified the Innovative Activities that lead to the Growth.

### 5. CONCLUSION

An innovation is an idea, practice or object that is perceived as new by the entity adopting it , according to Roger (2003). The concept of innovation implies the idea that something is added to something else that already exists, or that something that exists is given up. The argument is that adding and/or taking away are ways to improve a state of affairs. It is indispensable to refer to the Figure 1 Pertaining Overview of Innovation Process, not to mention the determinants of Innovation Input and Output, and eventually the Innovation – Productivity Relationship, along with their Equations from Equation (1) until Equation (7). Referring to Figure 1 pertaining the overview of Innovation Process, then Malcolm Baldrige is important to be considered,

in any unit analysis that has been mentioned in the aspect of, theoretical aspects and managerial implications of Innovation and Malcolm Baldrige for the benefit of Human Life within unit analysis of individual, company and nation toward global benefit. Precisely, the Malcolm Baldrige refers to Effect of Strategic Planning, Customer Focus and Operations Focus toward Result of Performance Excellence and Sustainability. Figure 5 in term of Indonesia's Stage of Development, is an indispensable aspects to be considered in order to maintain and improve Indonesia's Stage of Development of Stage 2: Efficiency driven. Furthermore, it is indispensable to consider the GCI, According to Global Competitiveness Index (GCI), GCI 2010-2011, Indonesia undergone 10 point increase from Rank 54 into 44. Yet, in GCI 2011-2012, Indonesia undergone 2 point decrease from Rank 44 into 46, that constitute an alert for the incoming years.

Although the Baldrige criteria and framework are widely accepted in practice, there is surprisingly little theoretical and empirical evidence of their validity (Ford and Evans, 2000). Several studies presented empirical analyses of the original Baldrige Criteria in the manufacturing environment and provided evidence that the performance relationships observed in the Baldrige causal model were supported in US firms. Most recently, York and Miree (2004) examined the relationship between TQM and financial performance, using a sample of Baldrige Award winners; they replicated a second sample of state quality award winning companies with three different sets of financial performance measures. Baldrige quality award winners generally had better financial performance than their peers after and before winning a quality award.

# Partnership Strategy to Build Technopreneurship as a Mean to Achieve the Entrepreneurial University

**Tiena Gustina Amran**

*Faculty of Engineering, Magister Program of Industrial Engineering Department,  
University of Trisakti, Jakarta 11440  
Tel : (021) 5663232 ext 8177. Fax : (021) 5605841  
E-mail : tiena\_amran@yahoo.com*

## ABSTRACT

The Entrepreneurial university achievement goes together with community's development in social, economy, politics, environment, and national defense in the Indonesian society. Commitment made by the faculty heads are a priority in achieving vision and missions which resulting in contributions from the qualified lecturers and creative students of the Industrial Engineering Department. This continuous improvement was done in each semester in the form of modules. From the academic side, students are assigned a manufacturing industry planning project for 4 semesters, consisting of 30 modules like industrial planning, production process, and real business development. Maira Technopreneurship Business Incubator (MTBI) is created to accommodate students' products and help them market and manage their business by creating a business incubator. Partnership is conducted with business innovation center focusing on developing business network with regards on professional ethics and legal aspects, as well as social towards other parties like the small and medium enterprises. The innovation center also connects university with researchers and industrial professionals so that this partnership not only developing knowledge, but also developing business products. Based on this partnership and tests, product development and innovation can be obtained and students will obtain an experience of working in the real business environment before their graduation day.

## Keywords

*Entrepreneurship, business plan, industry, partnership*

## 1. INTRODUCTION

University graduates dominate the number of unemployed in Indonesia. The workspace available just could not absorb the annually growing number of university graduates because some of them were not ready to be involved with "the real" job. Based on the Statistical Bureau (*Badan Pusat Statistik*)'s data on August 2012, there are 7.2 million open unemployment with Open Unemployment Rate (*Tingkat Pengangguran Terbuka/TPT*) of 6.12%. The university graduates dominated this rate by 12.12% consisted of 6.21% college level and 5.91% undergraduate level. The rate for vocational school graduate was 9.83%, high school graduate was 9.80%, junior high school 7.76% and elementary school and below 3.64%.

Another reason is the uneven balanced between the number of university level workers needed compared to the number of university, both public and private. The growing number of students in a university did not always mean the increasing quality level of its graduates. This also one of the reasons why there was an increasing number of unemployment of the university graduates. The university party stated that the industry did not put enough trust to recruit science and technology graduates with high grades, and they were placed as operators. The university believed that this underestimated their position. The Ministry of Employment explained the necessity to prepare ready to work graduates as well as those with entrepreneurial spirits. University graduates were in great needs to be ready to get into work both in hard and soft skills from their logical reasoning to their entrepreneurial and leadership skills. Therefore, the graduates did not always need to depend on the industry's employment needs. Nation wise, the ratio of entrepreneurs to the Indonesian people has only reached the 0.18% from the targeted 5%-7%.

Trisakti University consisted of 9 Faculties, 36 Departments, Graduates and Doctoral Programs with around 30 thousand student's body in several campus locations in Jakarta. In its vision, it was stated "To become one of the leading international quality universities in developing knowledge, science, technology, and art as well as entrepreneurship to increase the living quality and culture that pay respect to the diversity and local wisdom of Indonesia."

As a result to that challenge, the Industrial Engineering Department created an organization to accommodate students' products and help them market and manage their business by creating a business incubator called Maira. The aims of this business incubator are:

1. To be an organization where students with entrepreneurial spirits can gather and discuss with each other.
2. To gather individuals with business ideas.
3. This business incubator was supported by the industry, alumni, government, and the non-profit organizations.
4. To create more employment to reduce the unemployment rate.
5. University-related incubator. This incubator aimed to commercialize science, technology, and intellectual rights of the researches' findings. The Industrial Engineering Business Incubator offered beginner companies an access to the department's laboratory, computers, library, and professional services in Industrial Engineering or other subjects.
6. This incubator was directly supported by the department in collaboration with other entrepreneurial concerned parties.

### Maira Technopreneurship Business Incubator (MTBI) Model Development

University-Based Incubator assisting the growth of spin-off firms through a dedicated facility providing subsidized space, consultation and other help to encourage entrepreneurship is a worldwide phenomenon. MTBI will have relationship and cooperation with the following parties:

1. Various Majors in the Trisakti University environment

MTBI gives and shares inputs on the expertise of academic staff and support to a variety of departments in Trisakti University, especially faculties, RICE, alumni, small medium Industries. It also creates synergy with Community Development and other units in Trisakti University which will act as "knowledge forum developer/manager."

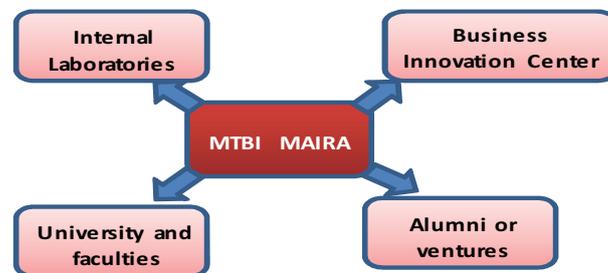

Figure 1: Trisakti University Industrial Engineering Dept. MTBI Model

2. Business Innovation Center (BIC)

BIC was built on 2008 and placed under the Indonesian Ministry of Research and Technology (RISTEK). This center holds the same mission as Ristek in building, promoting, and motivating the use of local generation's innovations through the synergy between A-B-G-M Academics, Business, Government and *Masyarakat* (People); so that in its turn, will pose a strategic role in the development of the national competitiveness in the global economic era. BIC will pose as an organization for innovators, researchers, academicians, and professionals to create a commercial and practicability outlook for their innovations. BIC will act as a bridge between the commercial and researcher party so that they are ready to positively synergize. Until today, BIC has published 510 products. The partnership between the Industrial Engineering Department and BIC involves the act to pro-actively supporting and inviting students, lecturers, and researchers to build the Indonesian competitiveness and independence through successful innovations.

3. Internal Laboratories

In the early stages a number of laboratories in the Industrial Engineering department run on their own based on their own modules. Now, MTBI acts as an integrator in the Manufacturing Industrial Design/MID (*Perancangan Industri Manufaktur/PIM*) throughout the laboratories like the production system, simulation and computation, statistics and quality engineering, design and work analysis, plant layout, and organizational design lab. A synergy with other faculty and department like the Art and Design Faculty, Electrical, Mechanical, and Informatics Engineering Departments were also conducted to design an ICT system that will expand the coverage of the Industrial Engineering student's product.

4. Outside parties

To play the role in creating a relationship between technopreneurs and other agencies such as SMI from the Ministry of Industry and Trade, the Ministry of Cooperation, Financial organizations and organizations like PNPM Mandiri, BPPT, Ristek, etc that are directly involved with the development of technopreneurs in the country.

### The Entrepreneurial University

Incubation is part of a global model for the management of knowledge and technology in regional development, with the university as an entrepreneur. The university has potentially flexible resources, giving it the ability to take on new missions, especially in times of crisis. The former exemplifies incubation as a strategy to revive a declining industrial region; the latter an instance of developing a 'green field' site, a region largely lacking in industry. Ideally, the incubator is part of a broader

strategy of academic and regional co-development and a web of informal and formal university–industry ties. Such ties can be initiated through creation of a formal structure, such as an incubator or a liaison office, or may arise from continuing relationships between professors and former students. In either case, the most productive regime of university–industry relations will comprise both elements (Henry Etzkowitz, 2002).

University is a natural incubator that sometimes plays an informal entrepreneurial role in the incubation of companies. Institutions in each sector (academy, government and industry) play hybridized roles that seem to move them away from classical understandings of each, for instance, entrepreneurial academics, academic industrialists, business strategy in government, and so on.

## 2. METHODOLOGY

### Manufacturing Integration Design

In the university level, the development towards becoming an entrepreneurial university was determined through the annually assessed Strategic Plan as a part of the Operational Plan. The success indicator in each faculty and major can be measured from the laboratory’s performance and the students’ practicum modules. In the Industrial Engineering Department, the MTBI integration to the MID was conducted as followed:

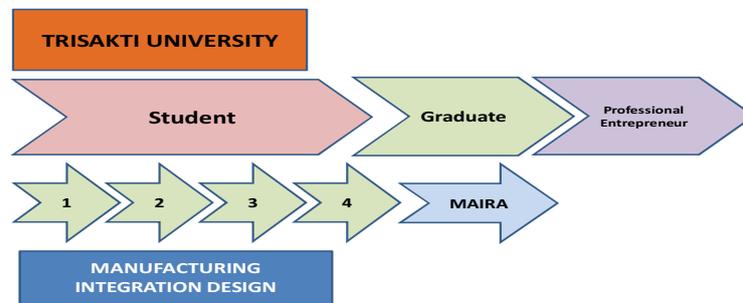

Figure 2: Manufacturing Industry Integration Design

Table 1: Integration between MID and MTBI

Characteristics	MID1	MID2	MID3	MID4 and Industrial Business Fair (IBF)	MTBI
Length of module	6 modules	9 modules	8 modules	7 modules 3 workshop	Selected products
Project/task	Design and report	Design and report	Design and report	Product and Business Plan Design	Enter the incubator
Scope	Shop floor	Shop floor	Factory facilities	Campus and public markets	Public potential market
Timeframe	6 months	6 months	6 months	6 months	Depend on the market
Learning	Supervised with room	Supervised with room	Supervised with factory	Supervised with room for self - development	Self-directed
Resources	Readily available within the department			Obtained on own initiative	joint venture
Credit unit	2 credit	2 credit	1 credit	2 credit	
Deliverables	Structured assignments, interim and final assessment by intensive department			Structured periodic reviews, final report and presentation	Project outcome, final report and presentation
Team	Six students per modules with same scopes	6 students per modules with same scopes	6 per modules with same scopes	Six students per modules with differences scopes	Maximum 4 per team
Supervision	Lecturers and assistants as member of laboratory	Lecturers and assistants as member of laboratory	Lecturers and assistants as member of laboratory	Facilitated by 7 lecturers, 3 practitioners, with 3 possible mentor	Facilitated by two lecturer with consultants

### 3. RESULTS AND DISCUSSION

#### 3.1. Industrial Engineering's Body of Knowledge in PIM Practice

##### 3.1.1. Experiential learning

Students in their small groups were tutored by several laboratory assistants in every stage:

- MID 1 stage: conducting the Product and Process Design (need identification, sketching, quality planning, and process mapping)
- MID 2 stage: conducting Operation Planning (work system improvement using experiments, forecasting, production planning, production main schedule, machine and operator requirements).
- MID 3 stage: conducting the facility planning design and cost calculation.
- MID 4 stage: conducting the business planning beyond the campus scope.
- Industrial Business Fair (IBF) & Maira TBI: developing business by involving the elements of Business, Academics, Government, and the Society.

##### 3.1.2. Outcomes focus approach

The result of MID 1 will be an input for MID 2, and same goes for MID 3. In MID 4, a business plan was prepared to see the market's opportunity for the idea that was developed based on the group's interest and guided by the supervisors from the academic, professional, corporate, and BIC party.

##### 3.1.3. Assessment of Tasks

The following section will highlight the advantages and benefit of the tasks assessment.

##### a. The product chosen is a manufacture project, even though service is also allowed

- Real life: to dig an idea from daily activities and needs.
- Problem solver: to provide a new solution inspired from creative idea brainstorming.
- Environment: to consider the environmental moral and ethics as well.

##### b. Encourages active learning

Shopping idea to find the inspiration, the idea and the implementation product or service as a problem solution in the society based on the MID knowledge in campus. Conduct discussions with professionals and academicians to develop shopping idea into mapping some alternatives solution.

##### c. Develop autonomous learning skill (4L)

Learn, analysis of the information will be collected to identify patterns and insights

Look, observe people to discover what they do rather than what they say

Ask, enlist people's participation to elicit information relevant to the project

Try to create simulation to help empathizes with people and to evaluate proposal design

##### d. Opportunity for self-assessment

1. Value proposition: value created by product or services
2. Customer segment: reason of existence for an organization, no business last without loyal customer behinds them.
3. Customer relationship: clearly define the type of relationship that the customers desire
4. Key partners: customers are the network that help a business model to be effective
5. Channels: the way to engage in product and service relationship function with the customer with quality, cost, delivery, after sales service and flexibility in mind
6. Key activities: the most important activity for an organization to run its business model
7. Key resources: consists of 4 points which are human, physical, intellectual, and financial resources
8. Cost structures: describes the implementation of the key activities by utilizing key partnership which definitely need cost
9. Revenue stream: a series of activities which seek for value so that the customer is willing to pay and also to accommodate the preferred paying method by the customer

##### e. Learning through feedback

1. Point Of Sales as revenue and result
2. Free market demand is the demand from the customer after Industry Business Fair (IBF) event to be marketed. At the time, the students are expected to start to process their company's legal entity

##### f. Selection and Nurturing

MTBI invited professionals, consultants, ventures, and those who were attracted to the product or prototypes to develop the products.

- Market demand
- Product function
- Future product technology
- Product continuity
- Capital aid
- Networking aid
- Information Computer Technology
- Company's Legal Status

### 3.1.4. Results and Improvement

From 2006 to present, 6 IBF has been conducted and in 2011 2 batches of the students, consisting of various teams, who have created 2 products (the poncho jacket and alarm pillow) was obtained.

Table 2: Summary of the project.

Origin	Platform	Number
Self-initiated	Web	1 alarm pillow
Partnership with industry		1 Rain coat

## 4. CONCLUSION

The MTBI Program in Trisakti University is an effort to support its vision and mission as an entrepreneurial university. Challenges and beyond, there are some obstacles: rare individuals with enough passion, those who are not only after academic tasks and valuing them as something to get an employment before graduation, the low importance of intellectual rights in the university, the large number of failure in the product's integral aspects that differ from their initial aims, unsuccessful in the commerce world.

## ACKNOWLEDGMENT

Industrial Engineering Department Trisakti University that sponsored to the International Seminar Quality in Research 2013.

## ABSTRACT

The planned mass rapid transit development in Jakarta as a huge public infrastructure project must balance between massive cost investments with every possible sources of income opportunity. In order to do this, early on in the design, the MRT Jakarta Company with the Government of Jakarta must exploit the presence of each MRT station. This is because each station will bring a significant impact to the surrounding area, especially at walking distance radius. This Transit Oriented Development (TOD) perspective must be able to capture the value added to the area around the station and provide opportunities for additional revenue, especially the non fare box (NFB) revenue for the company. However, it is not clear how the causal relationships between MRT station development and NFB revenue generation. This paper offers a conceptual model of this relationship that would help the shareholders and stakeholders understand these important relationships and devise an appropriate strategy.

## Keywords

*Mass Rapid Transit, Urban Planning, Transit Oriented Development, Conceptual Model.*

## 1. INTRODUCTION

Public Infrastructure with massive investment would require income opportunities from different sources possible. Revenue from public infrastructure comes from usually three sources: income from ticket fare, income from subsidies, and non fare-box (NFB) revenue. NFB revenues are advertisements, property rent, kiosks and other income not linked directly with ticket sales (fare-box or FB). Finding factors that could affect the income dynamics between these three sources of income would provide more understanding on how all three are actually related.

All public infrastructures in general may affect the development and the value of property in an area, which open up the opportunities of NFB. Grass (1992) indicates that public infrastructure has a profound influence on the pattern of urban development and spatial distribution of urban property values [1]. The existence of a station in general would provide benefit to the surrounding environment within walking distance radius, which is known as part of the Transit Oriented Development. PT MRT Jakarta (MRTJ) must capture this predicted growth of NFB income opportunities. MRTJ is the state owned company who has the responsibility of developing, operating and maintaining this first urban rail-based mass rapid transit (MRT) line in Indonesia.

Understanding this relationship between station and NFB growth is important for determining the long term corporate financial strategy of MRTJ. In order to attract more passengers, the ticket price must be affordable. This would require subsidy from the city government. There is not yet clear contract agreement regarding this between Jakarta Government and MRTJ. This agreement could greatly affect the cost structure managed by both parties. For MRTJ this could significantly alter their corporate strategy.

Conceptual modeling, which would be based on system dynamics methodology, could show qualitatively the complexity of variables on this issue. This paper offers a conceptual model of this relationship that would help the shareholders and stakeholders understand these important relationships, and have a common understanding as the background on developing an agreement for MRTJ and Jakarta's City Government.

## 2. LITERATURE REVIEW

The impact of railway station proximity on property value has received wide attention in the economic literature. Several empirical studies tried to quantify this effect. However, the Conclusions are not uniform (Debrezion, 2004) [2]. The presence of a station in an area, will give a great impact of surroundings environment. Naturally, railway stations have an effect on both land value and land use patterns (Ferguson et al, 1988) [3]. The pattern of the effect can be seen as volcano shaped, shown in Figure 1.

Figure 1: Volcano Shaped Value Pattern of Land Value and Station Location

Source: (Steer Davies Glee, 2011) [4]

All public transportation infrastructures in general may affect the development and the value of property in an area. Public infrastructures produce pattern of urban development and spatial distribution of urban property values. This happens because the infrastructure is providing accessibility to an area so that residents from other areas far away can have access to reach the site.

Public transportation infrastructure that provides accessibility definitely impacts an area such as sewer, highway, bus station, train station. Damm then capitalized these services into urban property values [5]. With the accessibility, a place said to be interesting. As a location becomes more attractive, as a result of certain characteristics, demand increases. This results in increase of price

Another effect of the station is also influenced by any of the facilities provided by the station, as said by Bowes, The number of parking lots in or near the station and the proximity of the railway station to the Central Business District also increase of the impact of the station on property value [6].

In addition to the increase in terms of value, the presence of a station also provides other effects. When some of the development of property often focused on area besides highway road, or when on the sides there are fancy and dense commercial buildings, but behind on the second layer would be found lots of underprivileged housing on a way different scale from the first layer from the roadside. The theory on land prices and settlement that indicates a higher accessibility of a location leads to a dense settlement [2]. Area on station's walking distance provide place that has great accessibility for both commercial commuter use and residential use. Naturally, railway stations have an effect on both land value and land use patterns [7].

Station that gives access to a particular area would give movement of passengers in large numbers, especially when the particular area provides great money flow activities. High population movement would create a development of retail activities but at the same time may attract criminality [6]. This indicates that definitely a station would provide a growing retail area.

[8] The center for Transit Oriented Development (TOD) in Berkeley identified several ways that station location, transit accessibility can benefit land owners, improve marketability of new residential units, office and retail space, open up valuable new sites for development, prompt up zoning and higher density development, command higher sales prices and rents, making higher density construction more financially feasible, encourage cities to support new infrastructure and public facility. The development of station area can grow naturally with a possible threat of unstructured sprawling areas. The other better alternative is by orientating the development along the transit stations through regulation, rights allocation, and incentives by the government. This concept of development is known as Transit Oriented Development TOD [9]. The keywords from TOD definitions are mixed-use development, pedestrian walking, multimode interchange access, high density, and transit stations [10]. The TOD initiatives must be adopted by the MRTJ early in the development of the project to make sure that they could capture the business opportunity created by future growth of the surrounding MRT stations.

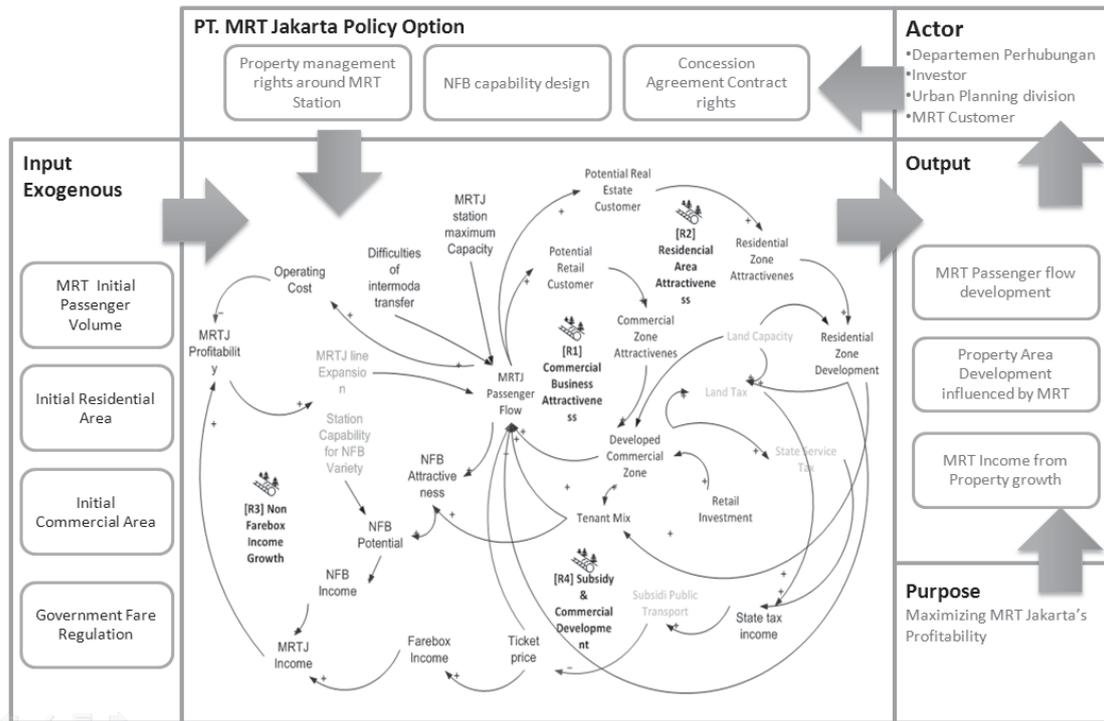

Figure 2: System Diagram

Using MRTJ Company is the primary actor in this analysis, this research identifies the purpose of the conceptual model is to gain insights on how to maximize MRT Jakarta’s profitability, especially from NFB business development. Based on shareholders' interviews, there are three outputs needed to accomplish this goal: passenger flows, property area development and property growth. The actor represents the interest of major stakeholder that could influence the MRTJ policies. Some of the possible explanation of variables interaction.

Figure 3 shows that the presence of the MRT station would affect development of two major area types: commercial area and residential area. Commercial area includes office, retail shopping, dining or leisure. In this conceptual model, the primary focus for area development is the passenger flows. The bigger the passenger flow, the area surrounding the station would be more attractive for development. At the same time, more developed area would attract more people to visit hence increasing the passenger flow, creating a positive feedback loop. The commercial area and retail area loops are R1-Commercial Business Attractiveness reinforcing loop. R2-Residential Area Attractiveness represents the reinforcing loop feedback for the development of residential area.

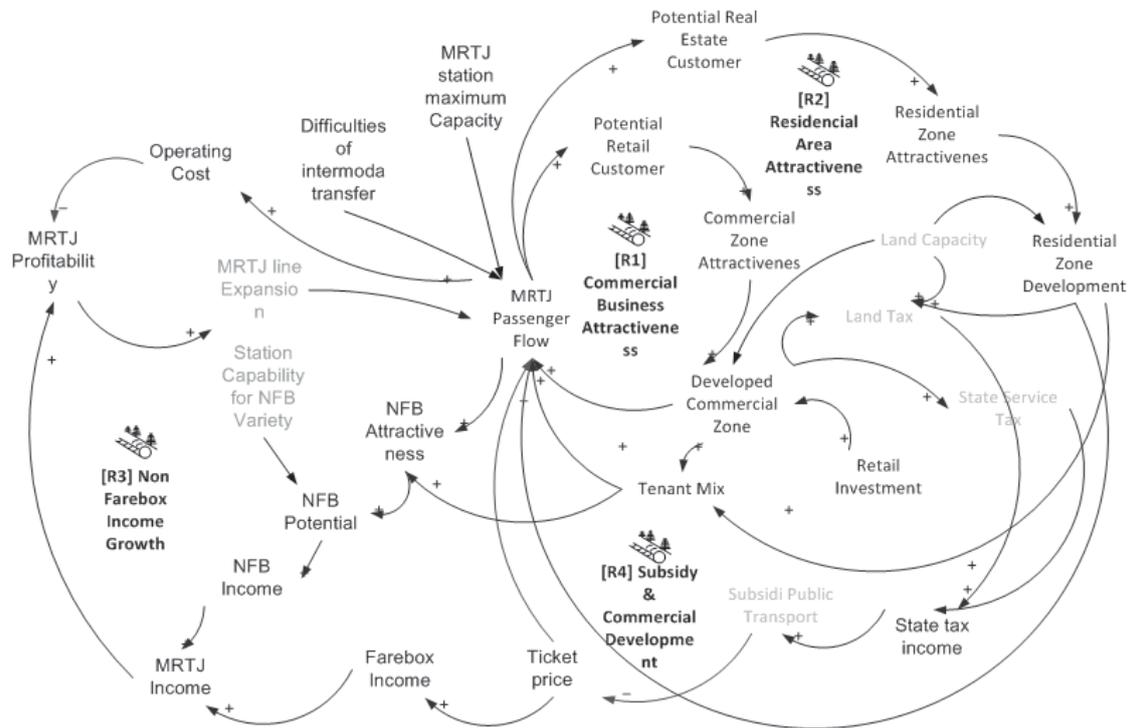

Figure 3: Causal Loop Diagram of TOD Impacts to NFB Income

However, all shareholders agree that with current state of building development in Jakarta and land availability, they would choose an integrated multi use area. Therefore, finding the right tenant-mix-ratio in the surrounding area of the station between commercial (including retail) and residential area would be the key for developing the NFB business. Each area types would have different dynamic effects on increasing passenger flow.

With the increase of passenger flow and influence by tenant mix, MRTJ can capitalize by developing the NFB business and increase their NFB income, shown as R3-NFB income growth. The increase of passenger flow would also increase the operating cost and could reduce MRTJ profitability.

The existence of MRTJ stations would benefit the government of Jakarta from an increasing state various tax, which includes land building tax and service tax. These increase tax along the MRT corridor will support the city government on providing affordable transportation cost to public by giving subsidy to passenger (R4-Subsidy & Commercial Development). The city government will be pressured by the public to make the ticket price as low as possible for the public, usually well below the normal price to cover the operational and investment expense. In addition, the amount of NFB income could never cover the lack of fare-box (FB) income required for breakeven, without government subsidy. This relationship provided the means for MRTJ on negotiating the amount of ticket price subsidy from the city government.

Using the conceptual model, the source of subsidy is shown clearly with the increase annual tax revenue from the development of areas surrounding all the future 15 MRT stations. This would make easy for MRTJ to negotiate the subsidy and create a more complete corporate strategy.

## 5. CONCLUSION

Public transportation development is always in constant pressure to provide affordable price to increase the accessibility of the general public. Greater mobility would be good for the city economy in the long run. However, the feasibility of this development will be questionable if there is a limited income available to cover the expenses. Using the transit development oriented perspective; the conceptual model developed in this paper could show the interrelationships of variables that open up the possibilities of NFB income growth. This growth came from the increasing economic value effects of MRTJ stations.

As part of an ongoing research, this conceptual model is the basis of a system dynamic model. The future final model combine with a financial model, would analyze the most influential variables in maximizing the profitability of the MRTJ. However, the current conceptual model could easily be use as a tool for explaining the positive impact loop of MRT stations development, passenger flow, government subsidy and the growth of NFB business. This would help MRTJ to prepare its corporate strategy in the long run.

# An Inventory Model on Damaged Product with Calculating Crashing Cost and Variable Lead Time

**Inaki Maulida Hakim**

*Department of Industrial Engineering,  
Faculty of Engineering,  
University of Indonesia, Depok 16424  
E-mail : inakimhakim@ie.ui.ac.id*

This paper about an inventory model especially on items had deterioration. Company has a policy to always fulfillment customer demand with specified service level. High technology product is one of single item for final product ordered from suppliers that have a number of requirements, inventory total cost and different lead time where this paper explain lead time have a pattern are variable lead time. Company always have inventory planning with exceeded product to anticipation product rejects caused decreased function product or damaged and had passed product life time. This paper developed an inventory model for high technology product to determine lot size optimal caused reject and damaged. To solve this problem, the first step is developed a mathematical model based on reference's model, and then solve the model analytically. Finally an inventory model for high technology product by calculating damage cost and variable lead time was derived by this research.

## **Keywords**

*Variable lead time, deterioration, high technology, crashing cost.*

## **1. INTRODUCTION**

Inventory item is one that is often done on every company and almost every company to do so. As the manufacturing industry supplies often found in the form of raw materials, semi-finished goods and finish good product. One of is the reason the company must maintain and exercise control over inventory is physically or economically impossible to get the goods immediately upon existing demand. Without the supplies then led to the waiting customers, while the real condition of the customer does not want to wait too long. For this reason the company felt the need to keep inventory to meet customer needs in unexpected ways (Hadle and Within,1963).

Good inventory system can be seen from the performance or the performance of the system inventory on hand. There are two main criteria to measure the performance of the inventory system are: (1) a high level of customer service (service level) and minimum inventory costs (Fogarty,1991). The emergence of inventory in the system is the result of a mechanism to meeting consumer demand. Consumer demand can't be met immediately at the time it depends on the stock. If inventory does not exist then consumers have to wait, as a result consumers are looking for companies to be able to meet the demand of consumers. As a result the company into profit shortfall, therefore, management becomes important. Deterioration product is defined as a commodity that is damaged or lost most of the value of quality as a result of declining utility or benefits when compared to the initial conditions. Wholesaler can be faced with a potential market but in the environment of uncertainty associated with the purchase price, expiry age and level of demand as a result of deterioration. This condition encourages wholesalers to take the right decisions related to inventory policies specifically how much needs to be ordered and when ordered back in order to get the maximum benefit.

In this paper refer to the previous paper Kee Chen Kuo and Ching-Ter Chang (2007), entitled Inventory model with seasonal demand with variable lead time and resource constraint, then developed taking into account the presence of defective single item in the product from the supplier, items referred to reject goods. As a result, the damaged goods inventories, the total cost will change by considering the cost of the damage. For the development of this paper refers to the model of Wu and Ouyang (2001).

## **2. THE PROBLEM FORMULATION**

This model is intended to address issues concerning the phenomenon of how many companies need to be able to meet the demand from customers so that the company can earn a profit and inventories to minimize the total cost of the measure of performance in this study.

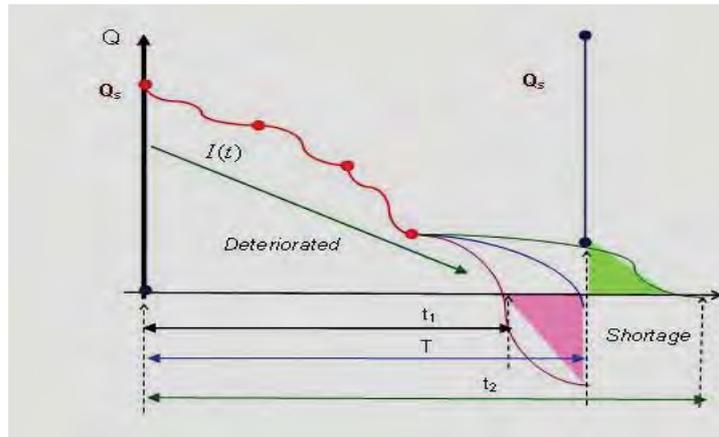

Figure 1 Inventory System Model For Deterioration Product

In the real side conditions if the inventory system is applied then there is the cost of inventory. General cost inventory for items that are not damaged consists of purchase cost, ordering cost and holding cost. Although on defective items (perishable items) on the total cost of inventory to add the cost of damage items. Due to the perishable items usually have life time so that the product caused the loss of value due to quality out of date, damaged and so the result of deterioration.

Decision variable in this model are :

1. While ordering lot size (Q)
2. when ordered (r) and
3. safety stocks (ss)

Assumption was used in this paper are :

1. Demand during planning time horizon is probabilistic and normally distribution.
2. Reorder point calculated from demand expectation during lead time plus safety stock (ss). When safety stock calculated from k multiplied demand deviation standard during lead time. When k as safety stock factor. Then r shown in formula 1.

$$r = DL + k\sigma \sqrt{L_i = L_{\max} - \sum_{j=1}^i (b_j - a_j)} \quad (1)$$

3. Number of items damaged on lot size Q is random variable binomial with parameter Q and p, when  $(0 \leq p \leq 1)$  is probability damaged items. When order coming to all item was inspection and each damaged items will be return to supplier and item sent on next lot size.
4. When process on in control condition assumptions not produce damaged items or number of items damaged = 0.
5. Set up cost and deterioration not calculated.

6. Lead time has n component when  $(L_{\min} = \sum_{i=1}^n a_i \leq L \leq \sum_{i=1}^n b_i = L_{\max})$ . (2)

Each first component has duration minimum ( $a_i$ ) and duration normal ( $b_i$ ) and crashing cost each periode unit ( $c_i$ ).

Crashing cost and lead time component will be shown Table 1.

Table 1: Lead time Data

Component of Lead time	Normal Duration (Day)	Duration Minimum (Day)	Crasing Cost (IDR/Day)
1	16	2	0.40
2	16	2	1.20
3	10	3	5.00

7. Annually demand following normal distribution with average D and deviation standard.

8.  $L_i$  = Long of lead time each component 1,2 .....I where  $L_i = L_{\max} - \sum_{j=1}^i (b_j - a_j)$

and crashing cost given as  $L_i < L \leq L_{i-1}$ .

Where :

$$R(L) = c_i(L_{i-1} - L) + \sum_{j=1}^i c_j(b_j - a_j) \quad (3)$$

- R(L) : lead time crashing cost per cycle
- j,i : index from number component of lead time j,i = 1,2,...,n
- c<sub>i</sub> : crashing cost unit each day of lead time component i
- a<sub>i</sub> : minimal duration lead time i
- b<sub>i</sub> : normal duration component of lead time i

9. Ordering cost constant every order and holding cost constant.
10. Shortage cost equivalent with number of items not fulfillment plus with marginal profit every units.
11. Systemic cost and order cost was ignored in calculated total cost.

### 3. THE MATHEMATICAL MODEL

Criteria Performance from development model in this paper is minimize total inventory cost consist of order cost ( $O_p$ ), holding cost ( $O_s$ ), shortage cost ( $O_k$ ), damaged item product cost ( $O_d$ ), and crashing cost ( $O_c$ ). In consequence the total cost in this inventory system can be written as:

$$O_T = O_p + O_s + O_k + O_d + O_c \quad (4)$$

Every cost component described as follows :

1. Ordering cost ( $O_p$ )

Ordering cost calculated from order quantity (D) during planning horizon divided with lot size (Q) multiplied every order. In consequence order cost in this inventory system can be written as:

$$O_p = A \frac{D}{Q} \quad (5)$$

2. Holding Cost ( $O_s$ )

Holding cost calculated from holding cost (H) multiplied with average lot size  $\left(\frac{Q}{2}\right)$  plus safety stocks (ss). In consequence holding cost in this inventory system can be written as:

$$O_s = H \left( \frac{Q}{2} + k \sigma \sqrt{L_i} \right) \quad (6)$$

3. Shortage cost ( $O_k$ )

Shortage cost calculated from number of shortage per cycle (N) multiplied with shortage cost per units ( $\pi$ ). In consequence shortage cost in this inventory system can be written as:

$$O_k = \pi N \quad (7)$$

Shortage becoming if number of demand during lead time (x) more than reorder point (r), on  $x=r$  until  $x = \infty$ . Finally shortage per cycle can be written (Nur Bahagia, 2006) :

$$\begin{aligned} N &= \int_r^{\infty} (z - r) \cdot f(z) \cdot dz \\ &= S_L [f(z_\alpha) - z_\alpha \psi(z_\alpha)] \end{aligned} \quad (8)$$

In consequence shortage cost in this inventory system can be written as:

$$O_k = \pi \cdot S_L [f(z_\alpha) - z_\alpha \psi(z_\alpha)] \quad (9)$$

4. Damaged Item Product Cost ( $O_d$ )

Damaged item product cost calculated from number damaged items per cycle ( $N_d$ ) multiplied damaged item product ( $c_d$ ) per unit defective on finish product can be happened lost, base on assumption then number damaged items ( $N_d$ ) in every cycle is

$$N_d = \begin{cases} 0 & \text{if } \tau \geq t \\ \theta P(t-\tau) + \int_0^{t-\tau} 2(1-x) \cdot dx & \text{if } \tau < t \end{cases} \quad (10)$$

Base on power series theorem, then  $e^{-\lambda t}$  value can be approached with  $e^{-\lambda t} = 1 - \lambda t + \frac{(\lambda t)^2}{2!}$ .

Then number damaged item product per cycle is :

$$\begin{aligned} N_d &= (\theta P + 2P) \left\{ t + \frac{1}{\lambda} \left( 1 - \lambda t + \frac{(\lambda t)^2}{2!} e^{-\lambda t} - 1 \right) \right\} + P \left\{ t^2 + \frac{2\lambda t}{\lambda^2} + \frac{2(1 - \lambda t + \frac{(\lambda t)^2}{2!} - 1)}{\lambda^2} \right\} \\ &= (\theta P + 2P) \frac{\lambda t}{2} + P - 2t^2 \\ &= \frac{\lambda}{2} (\theta + 2) P t + 2P t^2 \end{aligned} \quad (11)$$

In order to obtained in lot size ( $Q$ ), then  $t$  variable  $t$  change became :

$$t = \frac{Q}{P} \rightarrow P t = Q \quad (12)$$

Then be obtained number damaged item per items is :

$$N_d = \frac{\lambda}{2} (\theta + 2) P t + 2P t^2 \quad (13)$$

Damaged product in one year is number of damaged product per cycle ( $N_d$ ) multiplied with number cycle (frequency) in one year ( $f$ ).

$$\begin{aligned} (N_d)_{year} &= Q \left\{ \frac{\lambda}{2} (\theta + 2) P t + 2P t^2 \right\} \times \frac{D}{Q} \\ &= \left\{ \frac{\lambda P (\theta + 2) + 4Q}{2P} \right\} D \end{aligned} \quad (14)$$

In consequence damaged item product cost in this inventory system can be written as:

$$O_d = c_d \left\{ \frac{\lambda P (\theta + 2) + 4Q}{2P} \right\} D \quad (15)$$

5. Crashing Cost ( $O_c$ )

Crashing cost is cost out came per time unit for shorted lead time product coming, product crashing from normal duration and minimum duration component of lead time process from supplier. Crashing done for accelerate product order arrival from supplier. Arrival time from product have different component of lead time. Where :

$$L_i = L_{\max} - \sum_{j=1}^i (b_j - a_j)$$

$L_i$  =long of lead time each component 1, 2, ...,  $i$  and calculate

$R(L)$  given as  $L_i < L \leq L_{i-1}$

$$\text{Then, } R(L) = c_i (L_{i-1} - L) + \sum_{j=1}^i c_j (b_j - a_j)$$

(16)

Then to calculated crashing cost ( $O_c$ ) is demand devided lot size ( $q_o$ ) , then multiplied with R to L in  $R(L)$  function.

$$O_c = \frac{D}{q_o} R(L) \tag{17}$$

**4. SOLUTION MODEL**

To obtain decision variable Q optimal and r done with use optimization concepts. Optimization used to find first derivative from total cost ( $T_c$ ) with lot size (Q). Where

$$\begin{aligned} N &= \int_r^{\infty} (z - r) \cdot f(z) \cdot dz \\ &= S_L [f(z_\alpha) - z_\alpha \psi(z_\alpha)] \end{aligned} \tag{18}$$

Then to find  $\alpha$  , can be obtained is :

$$\alpha = \frac{H \cdot Q_o}{c_d D} \tag{19}$$

Decision variable in this paper are optimal lot size (Q), reorder point (r) and safety stocks (ss). To find each decision variable can be written :

$$1. \quad Q^* = \sqrt{\frac{2P(A + \pi S_L [f(z_\alpha) - z_\alpha \psi(z_\alpha)] + R(L))}{D\{HP + 4c_d D\}}} \tag{20}$$

$$2. \quad r^* = DL + z_\alpha S_L \tag{21}$$

$$3. \quad ss = z_\alpha S_L \tag{22}$$

**5. NUMERICAL EXAMPLE**

To illustrate the present model, the following examples are considered. The problem to be solved for damaged item product. In table 2 explained parameter used in mathematical model to solve decision variable.

Table 2: Parameter

Parameter	Unit	Quantity
D	Unit/year	10000
S	Unit/week	2000
H	IDR/unit/year	100000

A	IDR/order	1000000
$C_d$	IDR/unit/year	50000
$\pi$	IDR/unit	100000
$\alpha$	5%	1
$Z_\alpha$		0.05
$\theta$	%	1.65
$f_{z\alpha}$		0.1023
$\Psi_{z\alpha}$		0.0206
P		100000

Parameters are already known then included into mathematical model to solve problem, where to find decision variable. Another total inventory cost, decision variable in this inventory model are lot size (Q), reorder point (r) and safety stock (ss).

Table 3: Calculating Inventory Total Cost

i	Li	R(L)	r	ss	Q	OT
0	6	0	2275	1121	2029	223251019
1	4	5.6	1684	915	1840	192890901
2	2	22.4	1032	647	1594	153504749
3	1	57.4	650	458	1420	125830246

From calculating above then can be have decision that lead time needed is one week get minimum inventory total cost. Then having result optimal inventory policy.

## 6. DECISION

Inventory problem discussed in this paper is inventory problem in real world case, especially in high tech industries having variable lead time. The numerical example were shown to evidence the usefulness of the proposed model to find minimum total inventory cost and decision variable. Then inventory in this paper have assumption not use back order or lost sale in calculating inventory total cost. So future reach can be development inventory total cost with calculating shortage cost into model with variable lead time and calculating shortage cost into model with variable lead time for lost sale case.

## ABSTRACT

All the manufacturers are always tries to fulfill fluctuating and uncertain market demand in satisfy the customer needs. PT. XYZ is a music equipment manufacturing, especially piano. Over the last 2 years piano type UP B1 PE has the highest sales.

This research aims to estimate the length of lead time an optimal ordering of raw materials and raw materials requirement planning for next 5 months. Estimated lead time of ordering raw materials made using two methods, namely fuzzy techniques and Monte Carlo simulations. Both methods will then be compared using statistical techniques two side independent test using a significance level of 0.05 to determine the shortest lead time of ordering raw materials. To plan the requirement of raw materials use techniques of material requirements planning (MRP) because this method can be implemented in the company.

The results showed that the lead time of ordering raw materials using fuzzy techniques is smaller than the Monte Carlo simulation. To plan raw material piano UP B1 PE companies must begin planning on 6 November 2010 are for a component Treble Bridge. While the raw materials requirements planning piano UP B1 PE will end on June 23, 2011 as many as 26 types of components

## Keywords

*Lead time, material requirement planning, order, fuzzy, simulation*

## 1. INTRODUCTION

All manufacturers always try to fulfill fluctuating and uncertain market demand accurately according to customer needs. With a good material requirement planning, the company can make the process of production according to customer demands. PT. XYZ an industry in the field of manufacturing of pianos. There are two types of pianos is produced by this company which are Grand type and UP Right type. Based on the historical data, known that the number of piano UP Right types has a higher rate of sales than Grand piano type. We choose B1 PE for the highest sales of piano UP right type.

In material requirement planning estimated delivery times of raw materials from suppliers who has planned is often does not match with the actual time that have set. There are several ways that can be used for estimate the lead time of ordering raw materials, 2 of them using fuzzy techniques and Monte Carlo Simulation. The problems occur at this time in the PT. XYZ is company do not have a good method for their material requirement planning. PT. XYZ do not apply a special method in planning of raw materials, currently company only calculate it manually. Planning done by setting the amount of production during a few period for be used as reference in planning ordering raw materials for the next period.

Based on background, the problem can be formulated as follows:

1. Which most method appropriate for determining the estimate lead time of ordering raw materials piano UP B1 PE using fuzzy technique or Monte Carlo Simulation?
2. How the sequence of raw materials requirements planning appropriate to piano UP B1 PE?

The objectives to be achieved in this research are:

1. Estimating the optimal lead order of arrival raw material piano UP B1 PE on time so that piano production process can went well.
2. Plan right number and the time needs for raw materials for piano UP B1 PE in order to fulfill the production targets that have been set.

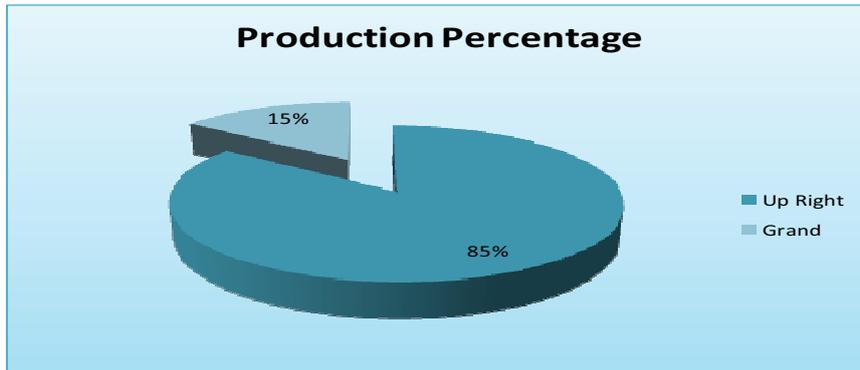

Figure 1 : Production Percentage of PT. XYZ

## 2. LITERATURE REVIEW

Earlier studies were can be used as a source of literature conducted by [1] with title Application of Fuzzy Lead Time to a Material Requirement Planning System. Discussion of this research is the application of fuzzy techniques for estimating the lead time of ordering in material requirements planning. Estimated lead time ordering using fuzzy techniques will be compared with Monte Carlo simulation. Monte Carlo simulations created using a random number between 1 to 10.000 for 20 independent samples. To compare both methods used 2-way ANOVA statistical techniques. The results showed the fuzzy technique has the raw material ordering lead time is shorter compared to the Monte Carlo simulations

## 3. RESEARCH METODOLOGY

Estimating lead time is conducted to determine lead time optimal to be used for planning ordering raw material piano UP B1 PE. Estimating lead time done in 2 ways with fuzzy technique and Monte Carlo simulations. Both methods will be tested with statistical technique to choose the best method in estimating a lead time of ordering raw material B1 piano UP PE.

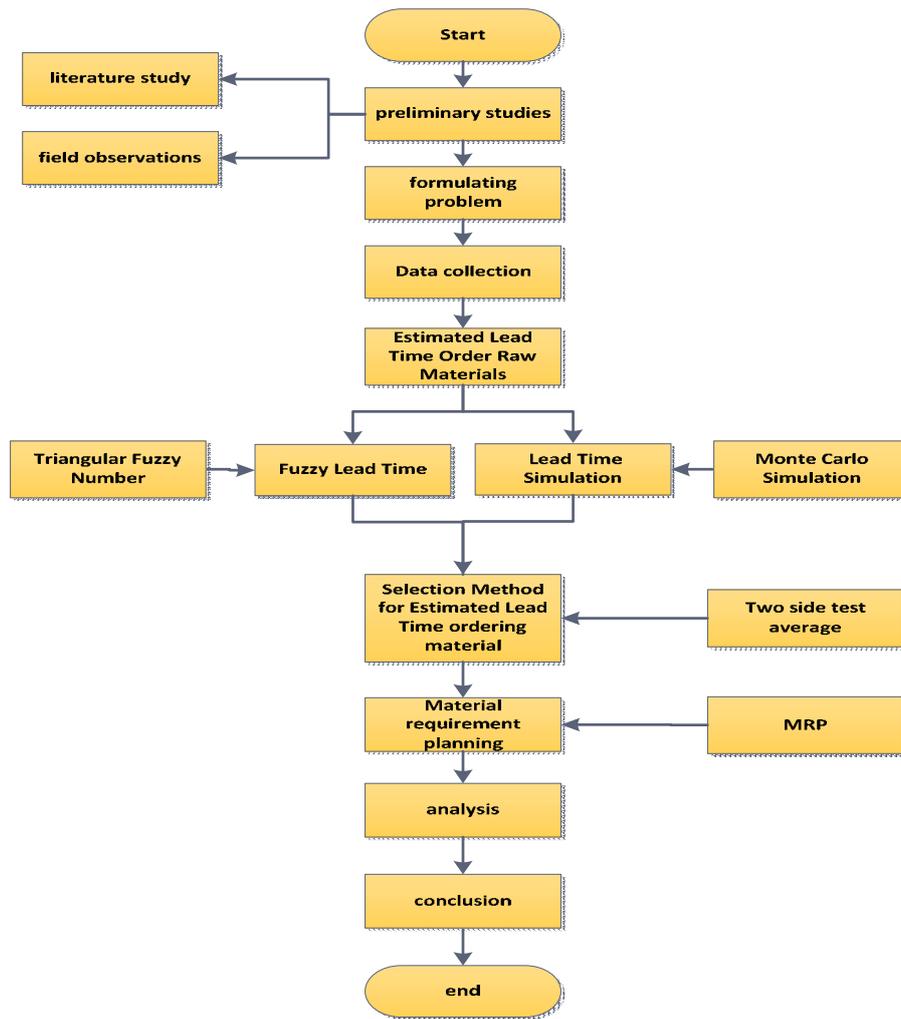

Figure 3 : Research Flowchart

Membership functions used in this research is triangle function (triangular fuzzy number). The steps in estimating a lead time of ordering raw materials consists of two processes that is fuzzyfication and defuzzyfication. [2]

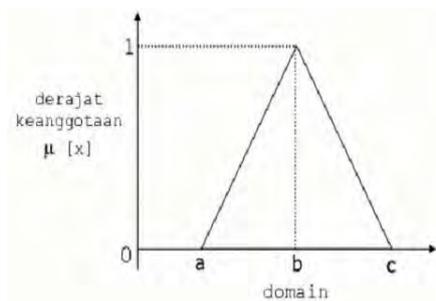

Figure 4 : Triangular function

To choose the best method between fuzzy techniques and Monte Carlo simulations in estimating lead time ordering raw materials used testing two hypotheses concerning two independent averages. From this statistical test is selected the average amount of lead time smallest.

The results of the plot pattern data used to determine the appropriate forecasting methods to forecast demand for the next 5 months. Piano sales forecasting UP B1 PE is calculated based on sales data last 24 periods. To forecast the demand piano UP

B1 PE comparison is done three forecasting methods. Forecasting methods used to forecast sales of pianos UP B1 PE in this research are a double moving average (3 monthly, 4 monthly, and 6 months), double exponential smoothing (using an alpha value of 0,1 to 0,9), and the naive method. To test accuracy of forecasting techniques are used MAPE (mean absolute percentage). The results MAPE smallest among forecasting method will be selected to forecast sales of pianos UP B1 PE.

#### 4. RESULT AND DISCUSSION

Fuzzification process can be seen in table 2. Domain fuzzy set is consists of three values represented by the triangular fuzzy number. Linguistic language used are:

- Fast (F). Fast interpreted orders component pedal rail iron up to fast with fuzzy variables 19, 19, 39.5 in units of days
- Medium (M). Medium interpreted orders component pedal rail iron up to Medium with fuzzy variables 19, 39.5, 49 in units of days
- Slow (S). Slow interpreted orders component pedal rail iron up to slow with fuzzy variables 39.5, 49, 49 in units of days

Table 1: Determination of the variable and the Universe Discussion Ordering Component Pedal Rail Iron

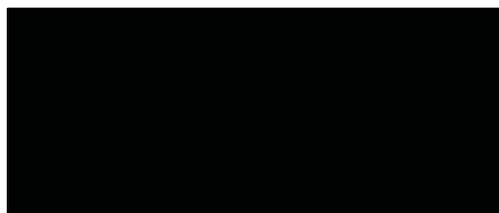

Table 2: Fuzzyfication Lead Time Oder Component Pedal Rail Iron

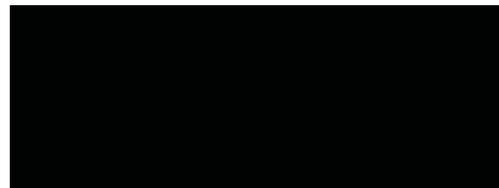

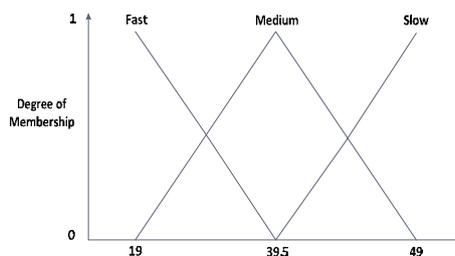

Figure 5: TFN Curve Representation Lead Time Order Components Pedal Rail Iron

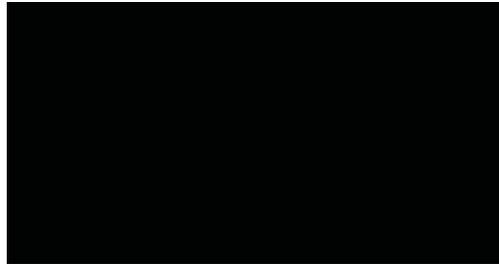

Based on table 3 both experts are equally say fast, so defuzzification lead time order Components Pedal Rail Iron as:

Table 3: Expert opinion, Average Geometry and Crisp Value Components Pedal Iron rail

The basis of the Monte Carlo simulation is the experimental probability distribution using random numbers. Column order is defined as a period of raw material orders. On column LT defined as lead time actual delivery orders period n with the actual number of actual delivery orders (SUM). Cumulative column is cumulative probability ordering. Column interval is the limit number representing the probability of each result. Determination of the interval based on cumulative probability. Here are the results of Monte Carlo simulations for the components Pedal Rail Iron:

Table 4: Probability Distributions and Cumulative Probability Distribution

Tabel 5: Recap Replication Monte Carlo Simulation

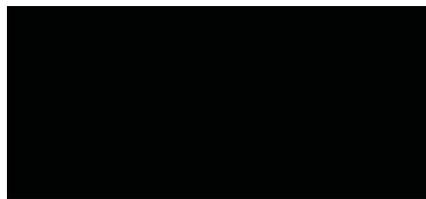

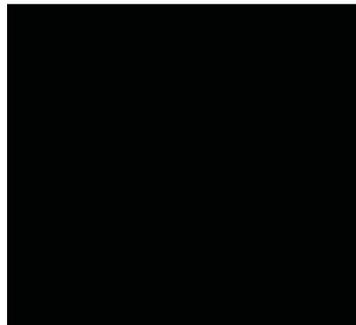

Table 6: Monte Carlo Simulation Component Pedal Rail Iron

For selection estimation method of lead time ordering raw material piano UP B1 PE used statistical techniques two side independent test average. The purpose of this test is to determine the smallest estimate of lead time. The company wants raw materials can come fast. Here is two side independent test average:

Hypothesis:

$$H_0 : \mu_1 = \mu_2$$

$$H_1 : \mu_1 > \mu_2$$

As  $Z > Z_{0,05}$ , then Z is in the region of rejection so the decision  $H_0$  is rejected. Based on these decisions can be interpreted that estimated average lead time ordering raw materials using fuzzy techniques is smaller than using Monte Carlo simulations

Plot of sales data shown in Figure. 6. Based on a plot of data patterns on Figure 6 data in the period September 2009, November 2009 and December 2009 had an abnormal data patterns. A third data is removed then created a new plot of data patterns, shown in Figure 7. Based on table 8 forecasting methods has the smallest MAPE is double moving average 3 (DMA 3), and it will be selected in this research.

Lead time is result of fuzzy techniques for ordering the components Pedal Iron Rail is 24 days. Amount required to make 1 unit of the piano is as much as 2 units. Based on the inventory records that have been described, requirement planning component Pedal Rail iron are as:

Table 9: Recap MRP

#### 4. CONCLUSION

1. Using a statistical technique two side independent test using significant level 0,05 z test statistic value of 5.83 and 1.645 for the z value table. Z value obtained test statistic is greater than the value of the z table, based on hypotheses which have made can be concluded that the optimal method for estimating the lead time of ordering raw materials piano type B1 UP PE is a fuzzy technique.
2. The method used for material requirement planning for pianos UP B1 PE is MRP technique. To plan material requirement planning pianos UP B1 PE companies must begin on 6 November 2010 for component Treble Bridge. Material requirement planning pianos UP B1 PE will be end on 23 June 2011 as many as 26 types of component

### ABSTRACT

This paper primarily investigates the single-manufacturer and single-buyer integration tool under deterministic environment. At the manufacturer, each product is produced with the constant rate, while at the buyer each product has a deterministic and constant demand. It is assumed that the manufacturer has sufficient capacity to meet the buyer's demand. Vendor-Managed Inventory (VMI) is an integration tool where manufacturer is authorized to manage the buyer's inventory stock-keeping units. This approach integrates the inventory cost between the manufacturer and the buyer through information sharing. Using EDI or internet, buyer is able to share the inventory information with manufacturer on a real-time basis. Manufacturer can then use this information to manage the inventory level at the buyer's facility. Using lot-streaming delivery policy the manufacturer delivers the product to the buyer during the production run and as soon as the quantity is equal to the batch size. This study shows that under a certain circumstances, information sharing for integrating inventory policy between manufacturer and buyer with VMI is more beneficial compare to the system without VMI. Therefore, an algorithm is developed to obtain the optimal strategy and numerical examples are presented to demonstrate the results of the integrated inventory model using VMI.

### Keywords:

*Single-manufacturer and single-buyer, information sharing, lot-streaming delivery policy, vendor-managed inventory.*

### 1. INTRODUCTION

The global economic crisis has caused a great burden in company's performance. This is an inevitable reality, for the companies producing complex products such as motor vehicle, heavy equipments, jig and fixtures, and electronics. To overcome the global crisis successfully, a competitive production which integrates between manufacturer and buyer has encourage both parties to optimize the system-wide performance. Moreover, the increasing relationship between manufacturer and buyer has challenged these companies to make synergies through the integration of various decision processes [1]. Minimizing the integrated inventory cost is one of the alternative solutions in increasing profit to both parties involves in the production systems network.

Vendor Managed Inventory (VMI) is an integration tool where manufacturer is authorized to manage the buyer's inventory. Reference [2] studied the benefits of VMI in an integrated inventory system for the short-term and long-term period. Specifically, VMI always provide greater benefits to buyers, whereas profits at the manufacturer may vary. For manufacturers, VMI with a long-term relationship will provide higher returns than the short-term. Meanwhile, study on comparison between the traditional approach and the VMI's approach in the integrated inventory system has been carried out by [3]. Conclusion of these two approaches is shown that for the dynamic demand is significantly more benefits provided by the integrated inventory system using VMI. The cost saving with the system using VMI is depended on the problem parameters. The ratio of the order cost of the supplier to the buyer as well as the ratio of the carrying cost of the supplier to the buyer will affect the value of saving cost [4]. According to [5] VMI enables to replenish decision making by the manufacturer. In this case the manufacturer makes delivery to the buyer based on buyer's inventory level. Hence the buyer inventory level observed continuously by the manufacturer. Therefore the buyer doesn't need to place an order. Reference [6] has proposed two delivery policies from the manufacturer to the buyer, i.e. 1) when deliveries are made after the production run, and 2) when deliveries are executed during the production run, as soon as the quantity is equal to the batch size, namely lot-streaming delivery policy.

This paper is divided into five sections. Section 2 addresses the assumptions and notations. Mathematical model of joint total cost with VMI is given in section 3. In section 4, a procedure is developed to determine the position of the continuation of the relationship between manufacturer and buyer using VMI. A numerical example is provided in section 5. Finally, some conclusions are given in section 6.

## 2. ASSUMPTIONS AND NOTATIONS

The model studied involves a single manufacturer that produces a single product at a production site and delivered it to a single buyer. Both the manufacturer and the buyer is a company engaged in the automotive industry. Demand from buyer is known and constant. One product buyer needs one unit of product manufacturer. According to the negotiation process, the manufacturer and the buyer has agreed to collaborate in the long-term contract as teamwork. The other assumptions are as follows; 1) no quantity discount is applied, 2) no backordered is allowed, 3) manufacturer and buyer are two companies that are not interdependent, and 4) manufacturer's production rate is constant and greater than the demand's rate. The following notations are used:

Parameter:

$D$	: demand rate for the buyer
$P$	: production rate for the manufacturer
$S$	: setup cost (\$/setup)
$A_p$	: cost of issuing an order (Rp./order)
$A_r$	: cost of receiving an order (Rp./order)
$A$	: buyer's total ordering cost (Rp./order), for $A = A_p + A_r$
$r$	: fraction of holding cost (%/period)
$C_b$	: unit purchase price at the manufacturer's (Rp./unit)
$C_w$	: unit holding cost in inventory at buyer's (Rp./unit/period)
$h_b$	: carrying cost of one unit in inventory at buyer's site (Rp./unit/period), for $h_b = rC_b + rC_w$
$C_v$	: unit holding cost in inventory at manufacturer's (Rp./unit/period)
$h_v$	: carrying cost of one unit in inventory at manufacturer's site (Rp./unit/period), for $h_v = rC_v$
$F_v$	: transportation cost (Rp./trip)

Decision variables:

$z_1^*$	: optimal ordering lot size without VMI (unit)
$z_2^*$	: optimal ordering lot size with VMI (unit)
$Q_v$	: production lot size at manufacturer (unit)
$n$	: number of deliveries per cycle

Objective function:

$TC_{b1}$	: buyer's total cost without VMI (Rp.)
$TC_{b2}$	: buyer's total cost with VMI (Rp.)
$TC_{v1}$	: manufacturer's total cost without VMI (Rp.)
$TC_{v2}$	: manufacturer's total cost with VMI (Rp.)

## 3. MATHEMATICAL MODELING

The relationship between manufacturer and buyer begins with the ordering of products at economic lot size,  $z_1$ , from the buyer to the manufacturer. Manufacturer makes deliveries on demand buyer. At the moment buyer received the product, the manufacturer gave the bill to the buyer for payment, and the product becomes the property of buyer. Finally, the products sold by the buyer to the end-user. For buyer, the total inventory cost per period is the sum of ordering cost  $((D/z_1)A)$  plus holding

cost  $((z_1/2)h_b)$ , where  $A = A_p + A_r$  and  $h_b = rC_b + rC_w$ . The buyer's total inventory cost equation can be written as follows:

$$TC_{b1}(z_1) = (D/z_1)(A_p + A_r) + (z_1/2)(rC_b + rC_w) \quad (1)$$

Equating the first derivative of (1) with regard to  $z_1$  to zero and solving the equation, the buyer's economic lot size is given by

$$z_1^* = \sqrt{(2(A_p + A_r)D)/(rC_b + rC_w)} \quad \text{or} \quad z_1^* = \sqrt{2AD/h_b} \quad (2)$$

Substituting (2) into (1), the optimal buyer's total inventory cost is

$$TC_{b1}(z_1^*) = \sqrt{2DAh_b} \quad (3)$$

This paper assumes that the manufacturer have known the quantity and the number of ordering from buyer, because of the information sharing. Thus it can be assumed that the manufacturer will begin production when the inventory level of buyer at the level of  $z_1$ . During the production period,  $T_p = Q_v/P$ , manufacturer produces at the rate of P. Therefore, the total inventory system increases at the rate of  $P - D$ . Manufacturer can still make the deliveries even if the production period has not been completed. Shipping is done if the lot size deliveries have been met, known as lot-streaming delivery policy. Although, the period of production has been completed, manufacturer still make the delivery to buyer until there are no more items in inventory of manufacturer. The manufacturer does not produce any product in the period of  $((Q_v/D) - (Q_v/P))$ . Inventory cycle time for the manufacturer is  $T = Q_v/D$ . The total accumulated inventory in manufacturer is  $(Q_v/2n)((2-n)D/P + n - 1)$ . The average inventory level for manufacturer is  $(Q_v/2n)((2-n)D/P + n - 1) + z_1/2$ , while the average inventory level for buyer is  $z_1/2$ . Finally, the average inventory level for system-wide is  $(Q_v/2n)((2-n)D/P + n - 1) + z_1$  [5]. The manufacturer's total cost is composed of setup cost, holding cost, shipment release cost and transportation cost. Therefore, the equation is given by

$$TC_{v1} = \frac{D}{Q_v}S + \frac{Q_v}{2n} \left( (2-n)\frac{D}{P} + n - 1 \right) h_v + \frac{z_1}{2} h_v + \frac{D}{z_1} F_v \quad (4)$$

Equation (4) is consisted of controllable and uncontrollable variables. The controllable variables are setup cost and holding cost, whereas the uncontrollable variable is determined by buyer, as a function of  $(z_1)$ . If equation (3) is substituted into equation (4), and  $Y = (D/Q_v)S + (Q_v/2n)((2-n)(D/P) + n - 1)h_v$ ,  $\gamma = F_v/A$ , and  $\phi = h_v/h_b$ , then equation (4) becomes

$$TC_{v1} = Y + (\gamma + \phi) \sqrt{\frac{DAh_b}{2}} \quad (5)$$

In this case manufacturer tend to change the uncontrolled variables become the control variables through collaboration with buyer by proposing vendor managed inventory (VMI) approach. According to VMI the buyer's ordering cost ( $A_p$ ) becomes the manufacturer's cost. Since the ordering cost is done by the manufacturer, the ordering cost becomes more efficient, with an efficient factor  $(1 - \alpha)$  for  $0 < \alpha < 1$  and it gives  $\alpha A_p$  as the manufacturer's cost. The manufacturer's total cost with VMI is given by

$$TC_{v2} = \frac{D}{Q_v}S + \frac{Q_v}{2n} \left( (2-n)\frac{D}{P} + n - 1 \right) h_v + \frac{D}{z_2} \alpha A_p + \frac{z_2}{2} h_v + \frac{D}{z_2} F_v \quad (6)$$

The first partial derivatives of equation (6) to  $z_2$ , yielding

$$z_2^* = \sqrt{(2D(F_v + \alpha A_p))/h_v} \quad (7)$$

Letting  $\lambda_1 = A_p/A$  and  $\lambda_2 = A_r/A$ , with  $\lambda_1 + \lambda_2 = 1$ , the lot size equation (7) can be written as follows

$$z_2^* = \sqrt{(\gamma + \alpha\lambda_1/\phi)}\sqrt{2AD/h_b} \quad (8)$$

By substituting equation (8) into equation (6), it will simplify the manufacturer's total cost by

$$TC_{v2} = Y + \sqrt{\phi(\gamma + \alpha\lambda_1)}TC_{b1} \quad \text{or} \quad TC_{v2} = Y + \sqrt{\phi(\gamma + \alpha\lambda_1)}\sqrt{2DAh_b} \quad (9)$$

Therefore, the manufacturer will implement VMI if  $TC_{v2} < TC_{v1}$  with saving cost  $\Delta TC_{v1-2} > 0$  for  $\Delta TC_{v1-2} = TC_{v1} - TC_{v2}$ .

**Proposition 1:**  $TC_{v2} < TC_{v1}$ , if  $(\gamma + \phi) > 2\sqrt{\phi(\gamma + \alpha\lambda_1)}$

**Proof:**  $TC_{v1} = Y + (\gamma + \phi)\sqrt{\frac{DAh_b}{2}}$  or  $TC_{v1} = Y + \sqrt{2DAh_b} \frac{(\gamma + \phi)}{2}$ , and

$$TC_{v2} = Y + \sqrt{2DAh_b} \sqrt{\phi(\gamma + \alpha\lambda_1)}. \quad TC_{v1} - TC_{v2} > 0 \text{ for } \sqrt{2DAh_b} > 0;$$

subsequently  $\sqrt{2DAh_b} \frac{(\gamma + \phi)}{2} > \sqrt{2DAh_b} \sqrt{\phi(\gamma + \alpha\lambda_1)} \rightarrow (\gamma + \phi) > 2\sqrt{\phi(\gamma + \alpha\lambda_1)}$ .

For buyer, the cost of issuing an order ( $A_p$ ) is removed to manufacturer's cost. Therefore, the buyer's total cost with VMI is given by

$$TC_{b2} = \sqrt{\frac{DAh_b}{2}} \left( \frac{(1 - \lambda_1)\phi + (\gamma + \alpha\lambda_1)}{\sqrt{(\gamma + \alpha\lambda_1)\phi}} \right) \quad (10)$$

Similarly, buyer will accept the proposal from manufacturer for implementing VMI, if  $TC_{b2} < TC_{b1}$  with saving cost  $\Delta TC_{b1-2} > 0$  for  $\Delta TC_{b1-2} = TC_{b1} - TC_{b2}$ .

**Proposition 2:**  $TC_{b2} < TC_{b1}$ , if  $(1 - \lambda_1)\phi + (\gamma + \alpha\lambda_1) < 2\sqrt{(\gamma + \alpha\lambda_1)\phi}$

**Proof:**  $\Delta TC_{b1-2} = TC_{b1} - TC_{b2} > 0$

$$\sqrt{2DAh_b} - \sqrt{\frac{DAh_b}{2}} \left( \frac{(1 - \lambda_1)\phi + (\gamma + \alpha\lambda_1)}{\sqrt{(\gamma + \alpha\lambda_1)\phi}} \right) > 0 \quad \text{or} \quad 2 - \left( \frac{(1 - \lambda_1)\phi + (\gamma + \alpha\lambda_1)}{\sqrt{(\gamma + \alpha\lambda_1)\phi}} \right) > 0$$

subsequently  $(1 - \lambda_1)\phi + (\gamma + \alpha\lambda_1) < 2\sqrt{(\gamma + \alpha\lambda_1)\phi}$ .

Therefore, the saving cost for system wide is given by the joint total cost between manufacturer's cost and buyer's cost, for  $TC_{v2} + TC_{b2} < TC_{v1} + TC_{b1}$  and  $\Delta TC_{s1-2} = (TC_{v1} + TC_{b1}) - (TC_{v2} + TC_{b2}) > 0$ .

**Proposition 3:**  $TC_{v2} + TC_{b2} < TC_{v1} + TC_{b1}$ , if

$$(\gamma + \alpha\lambda_1)(2\phi + 1) + (1 - \lambda_1)\phi < (\gamma + \phi + 2)\sqrt{(\gamma + \alpha\lambda_1)\phi}$$

**Proof:**  $\Delta TC_{s1-2} = (TC_{v1} + TC_{b1}) - (TC_{v2} + TC_{b2}) > 0$

$$TC_{v1} = Y + (\gamma + \phi)\sqrt{\frac{DAh_b}{2}} \quad \text{and} \quad TC_{v2} = Y + 2\sqrt{\frac{DAh_b}{2}}\sqrt{\phi(\gamma + \alpha\lambda_1)}$$

$$TC_{b1} = 2\sqrt{\frac{DAh_b}{2}} \text{ and } TC_{b2} = \sqrt{\frac{DAh_b}{2}} \left( \frac{(1-\lambda_1)\phi + (\gamma + \alpha\lambda_1)}{\sqrt{(\gamma + \alpha\lambda_1)\phi}} \right)$$

$$\Delta TC_{s1-2} = \sqrt{\frac{DAh_b}{2}} \left( (\gamma + \phi + 2) - \left( \left( \frac{2(\gamma + \alpha\lambda_1)\phi}{\sqrt{(\gamma + \alpha\lambda_1)\phi}} \right) + \left( \frac{(1-\lambda_1)\phi + (\gamma + \alpha\lambda_1)}{\sqrt{(\gamma + \alpha\lambda_1)\phi}} \right) \right) \right)$$

$$2(\gamma + \alpha\lambda_1)\phi + (1-\lambda_1)\phi + (\gamma + \alpha\lambda_1) < (\gamma + \phi + 2)\sqrt{(\gamma + \alpha\lambda_1)\phi}$$

$$(\gamma + \alpha\lambda_1)(2\phi + 1) + (1-\lambda_1)\phi < (\gamma + \phi + 2)\sqrt{(\gamma + \alpha\lambda_1)\phi}.$$

#### 4. SOLUTION PROCEDURE

The following procedure is developed to determine the position of the continuation of the relationship between manufacturer and buyer using VMI. Algorithm 1:

- Step 1 Calculate the value of  $\gamma = F_v/A$ ,  $\lambda_1 = A_p/A$ , and  $\phi = h_v/h_b$ .
- Step 2 Substituting the value of  $\gamma$ ,  $\lambda_1$ , and  $\phi$  into Proposition 3.
- Step 3 Examining Proposition 3, whether it meets the criteria?  
If YES, then go to step 4, otherwise go to step 9.
- Step 4 Substituting the value of  $\gamma$ ,  $\lambda_1$ , and  $\phi$  into Proposition 1
- Step 5 Examining Proposition 1, whether it meets the criteria?  
If YES, then go to step 6, otherwise go to step 5a.
- Step 5a Is the manufacturer intends to evaluate the manufacturer's total inventory cost?  
If YES, then go to step 5b, otherwise go to step 9.
- Step 5b Do improvements to the constraints that affect the manufacturer's total inventory cost, then go to step 4.
- Step 6 Substituting the value of  $\gamma$ ,  $\lambda_1$ , and  $\phi$  into Proposition 2.
- Step 7 Examining Proposition 2, whether it meets the criteria?  
If YES, then go to step 8, otherwise go to step 7a.
- Step 7a Is the manufacturer intends to evaluate the buyer's total inventory cost?  
If YES, then go to step 7b, otherwise go to step 9.
- Step 7b Do improvements to the constraints that affect the buyer's total inventory cost, then go to step 6.
- Step 8 Partnership between manufacturer and buyer using VMI is advised to continue.
- Step 9 Partnership between manufacturer and buyer using VMI is advised not to continue.

After learning that the partnership can be continue, the manufacturer determines the optimal delivery lot size, numbers of delivery, manufacturer's total inventory cost, buyer's total inventory cost, and overall system's total inventory cost with the following algorithm. Algorithm 2:

- Step 1 Calculate  $\gamma$ ,  $\phi$ , and  $\lambda_1$ .
- Step 2 Substituting  $\gamma$ ,  $\lambda_1$ , and  $\phi$  into equation (8), to get the optimal ordering lot-size with VMI ( $z_2^*$ ).
- Step 3 Set  $n = 1$ .
- Step 4 Substituting  $n$  and  $z_2^*$  into equation (9), to obtain the manufacturer's total cost ( $TC_{v2}$ ).
- Step 5 Is  $n = 1$ ? If YES, then go to step 5a, otherwise go to step 6.
- Step 5a Set  $n = n + 1$ , then repeat step 4 and step 5, to get the new value of  $TC_{v2}$ .
- Step 6 Is  $TC_{v2}(n) \leq TC_{v2}(n-1)$ ? If YES then go to step 5a, otherwise go to step 7.
- Step 7 Set  $TC_{v2}(n) = TC_{v2}(n-1)$ .
- Step 8 Substituting  $\gamma$ ,  $\lambda_1$ , and  $\phi$  into equation (10), to get the buyer's total cost ( $TC_{b2}$ ).
- Step 9 Calculate  $TC_{v2}(n) + TC_{b2}(n)$  as the total inventory cost for the overall system.

#### 5. NUMERICAL EXAMPLE

In order to illustrate the algorithms described earlier, it considers an inventory system with data as follows: for manufacturer:  $P = 15,000$  (unit/period),  $C_v = 20,000$  (Rp/unit),  $h_v = 2,000$  (Rp/unit/period),  $S = 360,000$  (Rp/setup),  $F_v = 30,000$  (Rp/trip), and  $\alpha = 0.2$ ; for buyer:  $D = 10,000$  (unit/period),  $C_b = 25,000$  (Rp/unit),  $h_b = 3,500$  (Rp/unit/period),  $A = 100,000$

(Rp/order),  $A_p = 10,000$  (Rp/order),  $D_v = 10,500$  (unit/period),  $C_w = 10,000$  (Rp/unit), and  $r = 0.1$ . In this example, the values are fixed for  $\phi = h_v/h_b = 0.571$ ,  $\lambda_1 = A_p/A = 0.1$ , and  $\gamma = F_v/A = 0.3$ . Referring to Eq. (2) and (3), the buyer's economic lot size is  $z_1^* = 756$  units and the buyer's total inventory cost is  $TC_{b1}(z_1^*) = 2,646,000$ . The minimum manufacturer's total inventory cost is obtained at four times delivery with  $TC_{v1}^*(z_1^*, n^* = 4) = 3,603,000$ , and for the system is  $TC_{s1} = TC_{v1}^*(z_1^*, n^* = 4) + TC_{b1}(z_1^*) = 6,249,000$ . It is showned that both parties has different optimal value for the total inventory cost. Therefore, manufacturer would like to offer a contract with buyer using vendor managed inventory (VMI). Before signing the contract, both parties agree to investigate whether the relationship beneficial. For algorithm 1, substituting  $\gamma, \phi$ , and  $\lambda_1$  into Proposition 3, 2, and 1 respectively. The calculation results show that all the criteria are met, hence the relationship between manufacturer and buyer can proceed to VMI. Further by VMI, the manufacturer determines the lot size and the number of deliveries that minimize the total cost of inventory. Using algorithm 2, substituting the value of  $\gamma, \phi$ , and  $\lambda_1$  are 0.3, 0.571, and 0.1 respectively into Eq. (8), to get  $z_2 \approx 566$  unit. Next, set  $n = 1$ , substituting  $z_2$  and  $n$  into Eq. (9), to get  $TC_{v2}(z_2 = 566, n = 1) = 7,869,000$ . Repeat step 4 to 6, until the value of  $TC_{v2}(n)$  is greater than  $TC_{v2}(n - 1)$ .

Finally, the result shows that  $TC_{v2}(z_2 = 566, n = 6) = 3,512,000$ ,  $TC_{b2}(z_2 = 566) = 2,581,000$ , and  $TC_{v2}(z_2 = 566, n = 6) + TC_{b2}(z_2 = 566) = 6,093,000$ . The saving cost for the manufacturer, buyer, and the overall system are shown as follows:

*Table 1: Saving cost for manufacturer, buyer, and overall system.*

	Without VMI	With VMI	Saving cost
Manufacturer	$TC_{v1} = 3,603,000$	$TC_{v2} = 3,512,000$	91,000
Buyer	$TC_{b1} = 2,646,000$	$TC_{b2} = 2,581,000$	65,000
System	$TC_{s1} = 6,249,000$	$TC_{s2} = 6,093,000$	156,000

Table 1 shows that the result for manufacturer and buyer under VMI will gain 2.5% saving cost. Nevertheless, the relationship between both parties has been influenced by the value of  $\gamma, \phi$ , and  $\lambda_1$ . The manufacturer will gain the benefit of the relationship, in the conditions; 1) if  $\gamma < 0.39$  and  $\gamma > 0.78$  (it obtains by using interpolation), 2) if  $\phi > 0.4793$ , for  $\gamma = 0.3$ . It means that the manufacturer's saving cost will increase significantly if the different between manufacturer's and buyer's holding cost becomes larger, and 3) if  $\lambda_1 < 0.2$ , for  $\gamma = 0.3$ .

## 6. CONCLUSION

This study develops the model of [5] by including transportation cost. At the beginning of the relationship between manufacturer and buyer, the lot size and numbers of delivery are determined by the buyer. Thus the manufacturer cannot influence the ordering lot size. Consequently, the manufacturer's total cost is not optimal, since the lot size determination is not based on manufacturing inventory policy. By offering VMI, manufacturer wants to minimize the total inventory cost of all parties, including manufacturer, buyer and the overall system. Numerical results show, by using VMI the relationship between manufacturer and buyer will provide cost savings for both parties, if it meets all the criteria required in propositions 1, 2, and 3.

### ABSTRACT

Uniqueness and uncertainty in a project is not easy to manage. Ability to manage the uncertainty is needed to minimize the risk. To manage the risk, the company have the project risk management to solve them. But today, the project risk's concept developed into more comprehensive concept, which called project complexity.

This study was more focused on determining the variables of project complexity. Variables obtained from the data taken in construction company and literature study. These variables are used to make the research instruments. Instruments conducted a qualitative pilot study, test reliability and test validity to evaluate the effectiveness of the instrument. To collect the data, the questioner was developed and distributed to 69 project managers in the construction industry. The processing data using exploratory factor analysis's methods to construct the dimension. Subsequently, the result provided was compared by the previous empirical study.

Based on the research process, it can be inferred that there are many improvements in developing the instrument. Validity and reliability produce 12 variables of complexity. While exploratory factor analysis showed that there are four dimensions of uncertainty in goals, uncertainty in methods, size complexity and interdependence. This is consistent with theoretical studies conducted by William.

*Project complexity, variabels, expert judgment, exploratory factor analysis.*

## 1. INTRODUCTION

The project is an important value of any construction company. Managing the project is a must. One of ability to manage the project is manage the risk of the project. The ability to handle and analyze project risks is usually done by the Project Risk Management. Mismanage the risk can lead to anticipate non-profitable projects, even the loss project.

The development and application of project management research shows that the concept of risk profiles have started to develop more widely. The concept of risk developed into a part of a more comprehensive concept, called the concept of project complexity. The concept of risk is the perspective of the value of uncertainty. When that happens the higher the uncertainty, the higher the risk of the project that must be faced, and vice versa. The uncertainty is one of project complexity dimension [1].

Complexity is an important part that can be used in managing a project. Complexity can reflect the characteristics and conditions that may occur in a project. In this case, the research on the complexity of the project has not been done by previous researchers. Testing the empirical models project complexity has been done.

Table 1: Project Complexity Theory

No	Researcher	Size	Uncertainty	Interaction	Diversity
1	Simon (1982) [2]	V		V	
2	Morris and Hough (1978) [3]		V		
3	Jones (1993) [4]		V	V	V
4	Turner and Cochran (1993) [5]		V		
5	Siestman (1994) [6]	V	V	V	
6	Baccarini (1996) [7]	V	V		
7	William (2002) [1]	V	v	V	

Based on Table 1. Project Complexity Theory, William theory is more up to date theory and comprehensive theory because William try to resume the past theory from the past researcher.

The dimension of complexity by William (Willams, 2002):

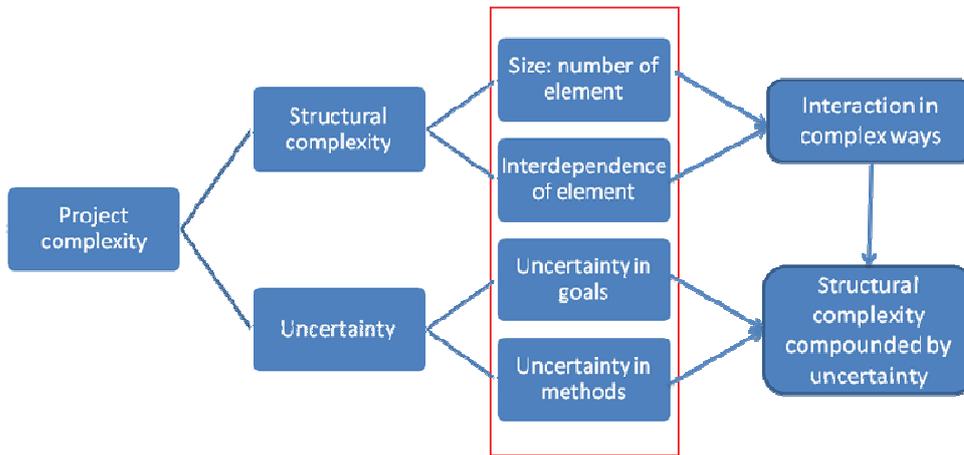

Figure 1: dimension of complexity by william

## 2. METHOD

This research is a part of studies to understand and to develop project complexity as a knowledge in project management. This research try to define the variabls of project complexity for more understanding project management study. In the first step, understanding in past study is an important stage. This research not only depends on past study but also try to generate the number of variabls using interview to national EPC company. Therefore, to represent the variabls of project complexity, this research used project manager in the construction company as respondents. In addition, this research was conducted by empirical approach known as cross-sectional survey with using primary data provided by questionnaire and survey.

The development of instrumental survey were assessed qualitatively, namely face validity and content validity by conducting pilot study. Face validity and content validity are obtained by using the pilot study to six practitioners about their respond on instrument proposed. After that, the instrument was ready to distributed.

Table 2 explains about the response rate, in which there were three methods for distributing questionnaire, namely email (52 questionnaires), survey mail (9 questionnaires) and direct survey (8 questionners). By using three methods are obtained the response rate as much as 50.7%. Hence, the sample size achieved is 35 respondents.

Table 2: Response Rate

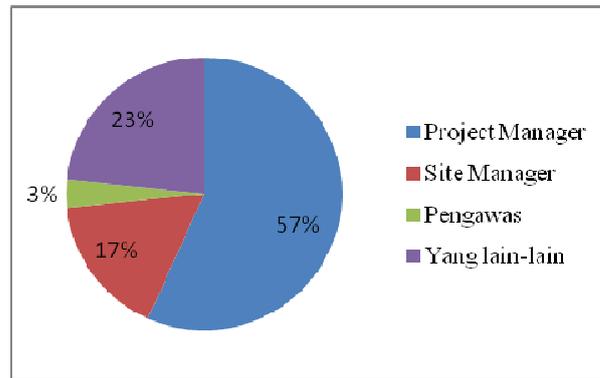

Questionnaire Distributed	Amount	Response Rate
Email	52	50,7%
Survey mail	9	
Direct Survey	8	
TOTAL	69	

## 3. RESULT AND DISCUSSION

Having distributed the quistionner and survey, the questioner was returned into researcher with response rate, for 50.7% (35 respondents) showed on Table 2. However by data cleansing, 5 of 35 data cannot be used because of the lack of experience of respondents. CAPM stated that the project practitioners can be guaranteed as the experience practitioners when they have experience more than three years.

### 3.1 Respondent

Rspndent's proffile can be described by all pie chart

Figures 1. Project respondent

Based on figures 1. Project respondent, most respondents are project managers. As we know that project anagers is a relevance respondent because their knowledge about managing the project.

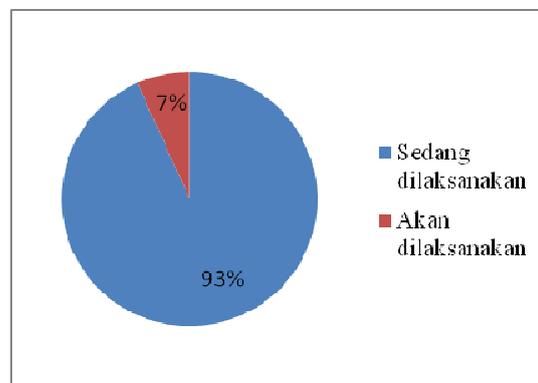

Figure 2. Project statue

Based on figures 2. Project Statue, most project are on going projects. This survey not accomodate past project because we argue that any possibility of over-confidence from project manager perception.

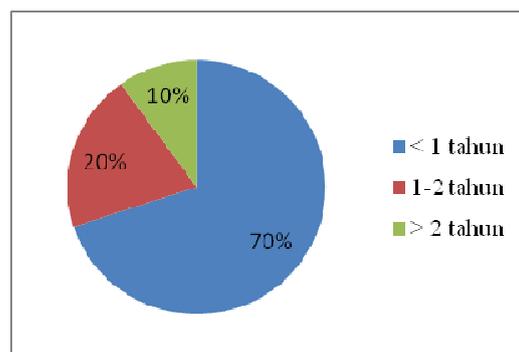

Figure 3. Project Duration

Based on figures 3. Project Duration, most project are going on less than a year projects.

Several stages were carried out to conduct the research. After descriptive analysis from the survey, the research were carried out to normality test, reliability test and validity test. 35 variables are tested, then the research get 12 right variables.

Table 3. Reliability testing

The result of this research can use to try define the contingency budget using project complexity. The dimension of project complexity, uncertainty in goals, can describe as the project risk which basically use to define contingency budget. Based on William, project risk is a component of uncertainty in goals where project risk usually use to predict contingency budget [1].

#### 4. CONCLUSION

There are 12 variables out of 35 variables that pass the test of validity and reliability related to the complexity of the project. Overall variable is derived from a combination of theoretical and the results of interviews with practitioners. Based on the results identified four dimensions of complexity. The study shows the suitability of the number of dimensions derived from empirical tests with William Complexity Theory.

# Multipliers And Structural Path Analysis For Logistics Sectors In Social Accounting Matrix Framework Of Indonesia

Christine Natalia

*Industrial Engineering Department, Engineering Faculty,  
Atma Jaya Catholic University, Jakarta, Indonesia.  
Email : chrisnatalia@atmajaya.ac.id*

## ABSTRACT

The role of logistics sectors which considered more important in supporting the development of Indonesia economics and prosperity has become a starting point of this research. The research objective is to analyze the impact of changing income in logistics sectors on others sector, labor and household income. The analysis is using Social Accounting Matrix Model of Indonesia 2005 with disaggregation in logistics sectors. Based on multipliers analysis, the result show that income changing as an effect of economic stimulus or injection in logistic sectors has biggest impact on manufacturing industry sector. The result of more intensive research showing that income changing in logistic sectors can boost Indonesia's GDP. This increment achieved as a result of income rising in production factor, which is salary earning of production worker, transportation operation, manual and unskilled workforce. The impact to household mostly gain by low class household, both in rural and urban. This means income changing in logistics sectors will increase the income of most Indonesian low class society, which also means it could decrease poverty rate in Indonesia at the end. Path structural analysis showing that the biggest economic impact is flew directly from logistic sector to others sector. The most effective economic stimulus is the sectors that play a role as leading sector, which is Railway Transport Sector, Road Transport Sector, and Services Allied To Transport Sector.

## 1. INTRODUCTION

In the world economic order, logistics or logistics management has an important role in supporting economic development and prosperity of a country. The World Bank has a special view of the logistics sector, which is to reduce costs and improve the quality of logistics and transport system that will improve access to international markets, increase trade, and through this, it will increase revenue and furthermore it means to reduce poverty significantly.

World Bank periodically conduct a survey on the performance of the logistics sector on many countries in the world, known as the Logistics Performance Index (LPI) in 2007, while Indonesia is ranked 43 (out of 150 countries surveyed), under Singapore, Malaysia and Thailand. Other research and survey called the Global Competitiveness Index (GCI) of the World Economic Forum in 2007-2008 put Indonesia on the order to 54 of the 131 countries surveyed, under Thailand (28), Malaysia (21), and Singapore (7). Both international survey showed that the logistics sector seen increasingly important role in supporting the development of the competitiveness of trade and industry of the country. Indonesia's national logistics system is now known to be "inefficient and ineffective" (Minister of Economic Coordinator Team, 2008). Some problems of distribution of commodities / products often become strategic issues at the national level, which showed weak support for a national logistics sector. The problems about the distribution of fertilizer, fuel, rice, sugar, and Election logistics are a few examples of logistics. Therefore, Ministry of Economy Coordination elaborate a blueprint of structuring and developing Indonesia's logistics sector so that the logistics sector could grow and become one of the greatest infrastructure for building national competitiveness.

The role of the logistics sector are considered increasingly important role in supporting economic development and prosperity of a country, this is the starting point of this research. Government effort shows by this Blueprint needs to proceed with precaution policies, such as through study or analysis using a specific methodology to anticipate the impact of the policy. The model commonly used in analyzing the impact of policy on the economy and social sector simultaneously is a model Social Accounting Matrix (SAM). Use of SAM models based on several aspects of the following (Sinaga and Alim, 2007): (1) SAM models can explain the link between the activities of production, distribution, consumption of goods and services, savings and investment, and foreign trade, (2) SAM can provide a framework that unites and serves the entire regional economic data, and (3) national economy can be calculated by SAM multiplier that is useful to measure the impact of the injection in the logistics sector on other sectors income, labour factor income and household income, which describes the structure of the economy. There are two main methods within a SAM framework, a Multiplier Decomposition and Structural Path Analysis (Pyatt and Round, 1995; Shantong, et al, 2004). The basic idea of the methods is to grouped the SAM accounts into into several sets in two major groups, namely endogenous and exogenous account and then to see what related effects happen as a result of the

external injection on certain endogenous account. Multiplier Decomposition shows the magnitude of global effect and reveals the quantity distribution of the global effect within and among endogenous accounts. Based on this values, Structural Path Analysis further illustrates the operation path and mechanism of external injection, i.e., along what path and to what extent does an external injection act on other accounts in an economy. Such analysis results will provide greater reference for policy makers and decision makers.

There is no research conducted on the impact of the policy in the logistics sector to the national economy as a whole. Most research related logistical problems focus on building models to minimize inventory costs, transportation models that minimize the total cost of transport to support the efficiency of logistics. Most research in the field of economics that uses SAM models focus on upstream industrial sectors, such as agriculture and agribusiness, as well as the downstream industry or manufacturing industry. Logistics hold supporting role as enablers in the flow of the supply chain, which is not involved directly to the trade and related industries, but providing supporting services, which is effectively and efficiently logistics services. Supporting role as participants make the logistics sector as if it does not have direct and significant on earnings, but through other sectors which hold main role as producer in the supply chain. This study fills a different space with previous research, where this research was to analyze the impact of government policies in the logistics sector to the national economy and other socioeconomic indicators by using Multiplier Decomposition and Structural Path Analysis method in a comprehensive manner of the SAM-logistics model of Indonesia in 2005.

## 2. LITERATURE REVIEWS

There are at least three major economic activity (Gilarso, 2004), namely: production, distribution, and consumption. Economic activity is conducted by the various parties, or the subject of economic actors. The beginning of the economic problems is the existence of human needs that can be met through the consumption of goods and services. Demand for commodities is desirable to be met through the production process. The process of production of goods and services can be done because of the participation factors of production are mostly owned by the household. So with the demand for goods and services production process occurs, which in turn creates income for owners of factors of production. From this it can be expected to occur in the distribution of income groups of households as owners of factors of production. The value-added (income) generated by the factors of production due to their participation in the production process (as corrected by depreciation, transfer payments, taxes, and subsidies), related to the household income distribution. This economic activity is comprehensively summarized in the Social Accounting Matrix (SAM) model.

SAM model is a traditional double accounting economic matrix in the form of a partition matrix that records all economic transactions between agents in the economy, especially between sectors in production blocks, sectors within institutional blocks (including households), and sectors within production factors (Pyatt and Round, 1995; Sadoulet and de Janvry, 1995; Hartono and Resosudarmo, 1998). It is a solid database system, since it summarises all transaction activities in an economy within a given time period, thus giving a general picture of the socio-economic structure in an economy and illustrating the income distribution situation. The multiplier models in the SAM may indicate changes in income that occur in particular when there is an endogenous variable injection or exogenous economic stimulus on the balance sheet (Defourney and Thorbecke, 1984). Social Accounting can be classified into two types (Shantong, et al, 2004), namely micro and macro SAM. The definition of a macro SAM framework is a macro picture of the economic and social aspects, in which the balance-sheet that is grouped into several sets in two major groups, namely endogenous and exogenous balance. General framework of the macro SAM is like the table 1.

Micro SAM is the development of a macro SAM with a more detailed classification in accordance with the subject who want to study and the availability of data. This study is a micro SAM with a more detailed classification in the logistics sector, according to the focus of this study. Multiplier decomposition analysis in SAM framework started with define of average expenditure propensities matrix, or long-term trend of expenditure, expressed as a proportion, that is similar to the matrix of direct input coefficients of IO model. (Prihawantoro and Resosudarmo, 1999; Shantong, et al, 2004). To get the numerical value of each element in the matrix, just divide the corresponding element of SAM by the total of the column which contains the element. Using  $A_n$  to denote the matrix of average expenditure propensities and then block  $A_n$  according to the pattern of 3x3 endogenous accounts matrix in the simplified SAM, we get

$$A_n = \begin{bmatrix} 0 & 0 & A_{13} \\ A_{21} & A_{22} & 0 \\ 0 & A_{32} & A_{33} \end{bmatrix}$$

Table 1. Framework of macro-SAM

Expenditure Income		Endogenous accounts			Exogenous accounts	Total
		1. Activities	2. Factors	3. Institutions		
Endogenous accounts	1. Activities	$T_{11}$		$T_{13}$	$X_1$	$Y_1$
	2. Factors	$T_{21}$			$X_2$	$Y_2$
	3. Institutions		$T_{32}$	$T_{33}$	$X_3$	$Y_3$
Exogenous accounts		$L_1$	$L_2$	$L_3$	$LX$	$Y_4$
Total		$Y_1$	$Y_2$	$Y_3$	$Y_4$	

Source : Shantong et al, 2004

In SAM framework, the total of column and the corresponding row must be equal, therefore the total income of endogenous accounts can be written as following:

$$Y_n = A_n \cdot Y_n + X \quad (1)$$

Transform the equation (1) and we can get the following equation which captures the relationship between the endogenous incomes  $Y_n$  and the exogenous injections  $X$ .

$$\begin{aligned} I \cdot Y_n &= A_n \cdot Y_n + X \\ I \cdot Y_n - A_n \cdot Y_n &= X \\ (I - A_n) \cdot Y_n &= X \\ (I - A_n)^{-1} \cdot (I - A_n) \cdot Y_n &= (I - A_n)^{-1} \cdot X \\ Y_n &= (I - A_n)^{-1} \cdot X \end{aligned} \quad (2)$$

If  $M_a = (I - A_n)^{-1}$ , then

$$Y_n = M_a \cdot X \quad (3)$$

The  $M_a$  is known as a multiplier matrix account, which shows the global impacts of changes in a particular economic sector on other sectors by a backward linkages approach as well, and  $(I - A)^{-1}$  is like as Leontief inverse matrix in the IO model (Susilowati, 2007). This multiplier matrix account in SAM reflects the global effects of the exogenous injection  $X_i$  on endogenous account  $Y_j$ . In order to examine the nature of linkage in the economy that leads to these outcomes, it is possible to decompose the SAM multipliers further into three multiplicative components (Pyatt and Round, 1995; Shantong, et al, 2004) :

$$M_a = I + (M_{a,1} - I) + (M_{a,2} - I) M_{a,1} + (M_{a,3} - I) M_{a,2} M_{a,1} \quad (4)$$

In the equation (4), matrix  $M_{a,3}$  is a block diagonal matrix which captures the circular transferred relationship of the income flows among endogenous accounts, thus it is referred to as *closed-loop* or circular multiplier matrix. Matrix  $M_{a,1}$  is also block diagonal, it reflects the effects of certain group of accounts on itself through direct transfers and is independent of the closed-loop nature of the system. It is referred to as the *transfers'* multiplier matrix. Matrix  $M_{a,2}$  is not diagonal and its diagonal blocks are all identity matrices. It captures all effects between partitions of the accounts. Therefore the matrix is called as the cross-effects matrix or *open-loop* multiplier matrix. Figure 1 visually exhibits the three effects of multiplier decomposition. Transfers' multiplier effects are reflected within the production activities accounts and the institutions accounts. Open-loop multiplier effects are reflected between any two different groups of endogenous accounts. Close-loop multiplier effects can start from any account and finally go back to the origin after a series of interactions.

Multiplier analysis only provide us with some quantitative reference and the mechanism of interactions remains a "black box", since the decision makers cannot find out that, along what paths do the influences among accounts transmit and which paths are better than the others in transmitting influences (Shantong et al, 2004). Based on multiplier decomposition, structural path analysis further reveals the transmission mechanism of the interactions among accounts, thus opens the "black box". The following will briefly describe the theory of structural path analysis by the aid of topology language. Take every endogenous account in SAM as pole and the link between any two poles is represented by arc  $(i, j)$ , then we can define the element  $a_{ji}$  in the average expenditure propensity matrix  $A_n$  as the intensity of arc  $(i, j)$  which reflects the magnitude of influence transmitted from pole  $i$  to pole  $j$ . A sequence of consecutive arcs  $(i, k), (k, l), \dots, (m, j)$  form a path and the number of arcs composing it is referred to as length of path. A path which does not pass more than one time through the same pole is called an elementary

path. A path whose pole of origin coincides with its pole of destination is referred to as circuit. In Figure 2,  $i \rightarrow x \rightarrow y \rightarrow j$  is an elementary path and  $x \rightarrow y \rightarrow z \rightarrow x$  is a circuit.

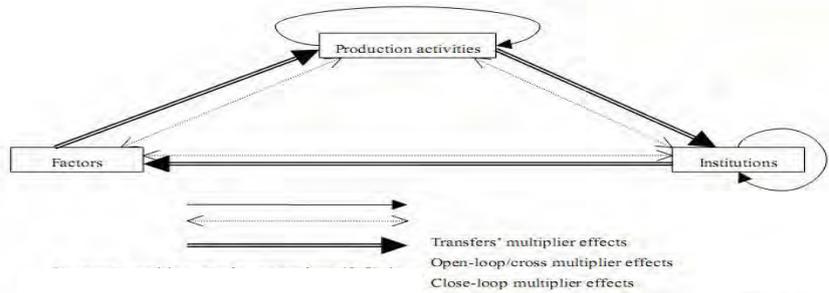

Figure 1. Three Different Multiplier Decomposition Effect in SAM framework

Source : Shantong et al, 2004

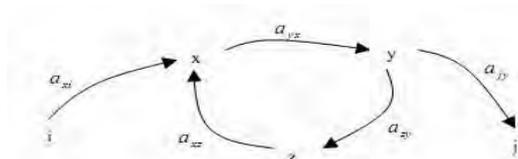

Figure 2. Circuit and elementary path

Source : Shantong et al, 2004

Suppose account  $i$  is disturbed by external injection and finally acts on account  $j$  by way of path  $s$ , then we can use  $(i \rightarrow j)_s$  to denote the influence of  $i$  on  $j$ . There are three kinds of influences between accounts: direct influence, total influence and global influence.

### 3. METHODOLOGY

In accordance with the background issues that have been described previously, the research generally aims to analyze the impact of the policy in the logistics sector using the model of Social Accounting Matrix (SAM) model of Indonesia. SAM model is used because these models can explain the integration relationship between economic and social aspects. However, the logistics sector has not been a specific sector within the framework of Indonesian' SAM. Therefore at the early stages, it must be modify SAM basic model of Indonesia to develop the sectors, that is included in the logistics sector, and the result is referred to as a SAM-Logistics model of Indonesia. This model became the first aim of this study. Subsequently, it was determined the logistics sector which acts as a leading sector using the backward and forward linkages index. Then determined the value of the multiplier of the sector and analyzed the effects of injection on this logistic sector to household incomes. Influence or impact is measured from the value of the multiplier on other sectors, the value of the multiplier factor of production as well as domestic institutions. Multiplier value indicates the amount of change in income that occurs when the balance of exogenous injections done. All of these changes can be obtained simultaneously using a multiplier (multiplier) balance in the SAM, where it is one of the reasons the use of SAM models. For multiplier analysis purposes, first do some preparatory steps which are grouping the balance-sheet according to macro SAM framework to look at the interactions that occur between the balance sheet through the block matrix operations. Preparatory steps include endogenous and exogenous aggregation of balance sheet.

SAM multiplier balance equation can be written in the matrix as in the equation (2) and equation (3) where  $M_a$  is the multiplier matrix account and  $(I - A_n)^{-1}$  is called the Leontief inverse matrix ( Susilowati, 2007). The model explains that the revenue of endogenous accounts (i.e accounts of production factors, the accounts of production sector and the institutions accounts ) expressed in the notation  $Y_n$ , will be changed by  $M_a$  units due to changes in exogenous accounts, expressed in notation  $X$  by one unit. The  $M_a$  amount is determined by the magnitude of multiplier coefficient matrix  $(I - A_n)^{-1}$ . The first step is to determine the matrix  $A_n$ . The matrix  $A_n$  is a matrix that shows the magnitude of the average expenditure propensity.  $A_n$  matrix is obtained by dividing each cell in the matrix of  $T$  with the number of columns.

Furthermore, the matrix multiplier is determined by the inverse matrix operation from the result of identity matrix reduced with the  $A_n$  matrix.  $M_a$  multiplier values indicate a global impact or impacts received a balance after the whole system. Multiplier backward linkages show show the spreader power, meaning that an increase in final demand for a particular sector, then the sector will drive an increase in output of all sectors with a multiple of the value of the multiplier. Meanwhile, forward linkages shows the degree of sensitivity of a given sector to final demand of all other sectors. The greater coefficient of backward linkage mean the longer of the rear linkage. Conversely, the smaller the multiplier coefficients imply its shorter association.

Sectors that have a degree of sensitivity index value or forward linkages effect ratio  $\beta_i > 1$  indicates that the sector has a role as an adjusting sector, a sector that is fast to react in the form of changes in the value of output of the sector as a result of any change in income from other sectors.

#### 4. RESULT AND DISCUSSION

Logistics sector consists of a wide range of sectors that serve to support logistics activities in accordance with the definition of Ballou (1992). In the framework of SAM, the sectors included in the logistic activities are part of the Production Activity account. As the sector is the focus of this study, it is necessary to develop a conceptual model within the framework of SAM with logistic sectors separate from other production activities in blocks of Production Activities. The separation was intended to determine the interaction between logistics sectors with the overall economic activity. Once the conceptual model of the logistics sector in the SAM framework has been developed, the next step is to develop the logistics sectors following the transaction values accordingly. Sectors within the framework of SAM Indonesia 2005 which amounted to 24 sectors are aggregations of 175 sectors in the Input Output Tables Indonesia 2005. This study defines the logistics sector based solely on the flow of material, then the sectors included in the logistics sector in the SAM framework sector: infrastructure (roads, bridges, ports), transportation (land, sea, air), and logistical support services. Infrastructure sector (roads, bridges, ports) is the sector with the code 146 in the Input-Output Tables and is a part of the construction sector in SAM framework, so we need to bring out this sector separately. The following table outlines what sectors should be developed to bring out logistics sectors.

Table 2. Logistics Sector disaggregation in Social Accounting Matrix (SAM) Framework

Sector Name in SAM (2005)	Sector Code in Input-Output Table	Sector Name in Input-Output Table
Construction	144	Residential and Non-Residential Buildings
	145	Agricultural infrastructure
	146	Roads, bridges and ports infrastructure
	147	Building and electricity, gas and water supply installations
	148	Other buildings
Land Transportation	152	Railway Transportation
	153	Road Transportation
Water and Air Transportation, Communication	154	Sea Transportation
	155	River and Lake Transportation
	156	Air Transportation
	158	Communication Services
Transportation Support Services, Warehousing	157	Transportation Support Services, Warehousing

There are seven logistics sector which are the sectors that are marked in the table above, and that made totally up to 32 sectors, both within the Production Sector account and Domestic and Import Commodity account. Hence the size of the SAM with the development of the logistics sector is 131 x 131. Additional data are used to fill the cells of other account transactions, which are data from (i) the National Socio-Economic Survey (SUSENAS) year 2007, (ii) the National Labor Force Survey (SAKERNAS) in 2007, (iii) Indonesia' Economic Indicators 2007, and (iv) Special Survey on Household Investment and Savings (SKTIR) in 2007. Once all of the relevant transaction cells filled, then balancing performed using cross-entropy method. Data resulting from the development of the logistics sector is processed directly by the BPS (Central Bureau Statistics of Indonesia) as a secondary data exclusively for the purposes of this study, because the primary data in SUSENAS, SAKERNAS and SKTIR not allowed to be used outside the BPS.

After the SAM-Logistics model of Indonesia was constructed, multiplier analysis used for further analysis of the linkages among sectors so that it can be determined which logistics sector play a role as a leading sector based on backwards and forwards linkage index. Index of dispersion or backward linkage effect and forward linkages effect can be seen in the table below:

Table 3. Backward Linkages and Forward Linkages for Logistics Sectors

Code	Sector Name	Backward Linkages		Forward Linkages	
		Value	Index	Value	Index
44	Roads, bridges and ports infrastructure	5.93	0.98	2.66	0.44
50	Railway Transportation	6.93	1.15	2.15	0.36

51	Road Transportation	6.85	1.13	5.17	0.86
52	Sea Transportation	5.95	0.98	2.77	0.46
53	River and Lake Transportation	5.36	0.89	2.39	0.40
54	Air Transportation	5.27	0.87	3.01	0.50
56	Transportation Support Services, Warehousing	6.32	1.05	3.37	0.56

Based on table 3 above, we can see that Railway Transportation Sector is the sector with the highest position as the leading sector, followed by Road Transportation Sector, Transportation Support Services Sector, and Warehousing, because they have Index of dispersion  $\alpha_j > 1$ . Also we can see that all logistic sector have forward linkages indeks  $\beta_i < 1$ , that means all logistics sector uneffective as following sector, means react slower for every changing in other sector income. Figure 3 and 4 show global effect of the injection that is done in Railway Transportation Sector and Road Transportation Sector to other sectors.

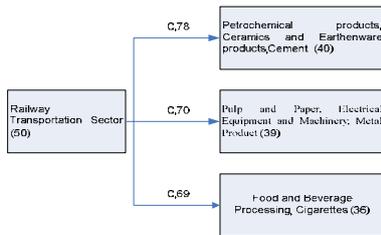

Figure 3: Global effect of Railway Transportation Sector

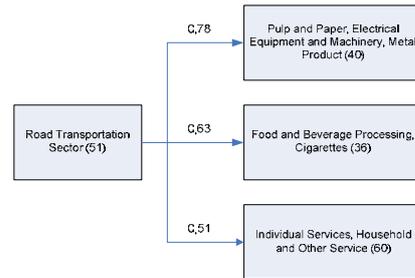

Figure 4: Global effect of Road Transportation Sector

The following tables describe the global impact of the injection that is done in the logistics sector to production factor and to institutional income:

Table 4  $M_a$  Value of logistics sector that give global impact on Production Factor

$M_a$  multiplier values can be decomposed into several components. Pyatt and Round (1995) decompose the SAM multipliers further into three multiplicative components, ie transfer multiplier, open loop multiplier and closed loop multiplier. Transfer multipliers show the impact occurred in a balance sheet in which the initial economic stimulus provided. For example, if you want to know the pressure on the land transport sector due to the injection of other sectors in the block production activity, then the multiplier transfer ( $M_{a1}$ ), the magnitude of the pressure can be determined. Logistics sector that is able to become a leading sector is the Railway Transportation Sector, followed by the Road Transportation Sector and Transportation Support Services Sector, and Warehousing. Based on multiplier decomposition, structural path analysis further reveals the transmission mechanism of the interactions among accounts. The table below is specifically showing the structural path analysis of the injection on Railway Transportation Sector that transfer directly their effect of the injection to Petrochemical products, Ceramics and Earthenware sector by 52,81%, and rest of the effect are transmitted to other sectors, production factor and institution income.

Table 5:  $M_a$  Value of logistics sector that give global impact Institution Factor

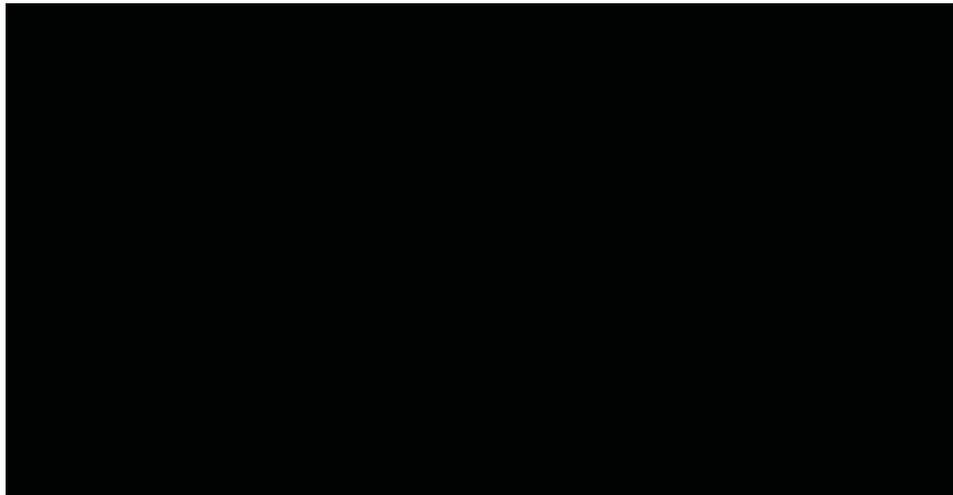

Table 6. Structural Path Analysis for Railway Transportation Sector to other's

No	Point of origin	Point of Destination	Global Effect Ma	Elementary Path	Direct Effect An	Path Multiplier Mp	Total Effect	Proportion (%)
	(1)	(2)	(3)	(4)	(5)	X (6)	= (7)	(8) = (7) / (3)
1	Railway Transportation (50)	Petrochemical products, Ceramics and Earthenware products,Cement (40)	0.7815	(50) --> (40)	0.0911	4.5324	0.4127	52.81%
2	Railway Transportation (50)	Pulp and Paper, Electrical Equipment and Machinery, Metal Product (39)	0.6952	(50) --> (39)	0.0491	5.5745	0.2740	39.41%
3	Railway Transportation (50)	Food and Beverage Processing, Cigarettes (36)	0.6891	(50) --> (36)	0.0056	5.3123	0.0299	4.34%
4	Railway Transportation (50)	Food Crops (29)	0.3317	(50) --> (29)	0.0000	4.7517	0.0000	0.00%
5	Railway Transportation (50)	Electricity, Gas and Clean Water (41)	0.2728	(50) --> (41)	0.0467	4.9985	0.2336	85.61%

## 5. CONCLUSION

Based on the analysis that has been described above, it can be concluded some of the following:

1. Logistics sectors within the framework of The 2005 Indonesian Logistics Social Accounting Matrix constructed in this research consists of seven sectors, namely: Roads, Bridges and Ports Infrastructure Sector (Code: 44); Railways Transportation Sector (50); Road Transportation (51); Sea Transportation Sector (52); Rivers and Lakes Transportation Sector (53), Air Transportation Sector (54), and Transportation Support Services Sector, and warehousing (50).
2. Logistics sector that is able to become a leading sector based on the analysis of backward linkages with  $\alpha_j > 1$  is the Railway Transportation Sector, followed by the Road Transportation Sector and Transportation Support Services Sector, and Warehousing. These sectors are able to attract other sectors to grow when performed injection on these sectors.
3. In general, injection on logistics sectors will give globally impact on specific sectors, namely Paper Industry, Printing, Transportation Goods and Metals Industry (39), Chemicals Industrial, Fertilizers, Clay, Cement (40), and Food, Beverages and Tobacco (36). These sectors are the manufacturing sector in 9 sectors classification of Input Output table. These results are consistent with the results of Firman's research (2007), which means that during five years (2000-2005), logistics sectors remains as the largest contributor to the manufacturing sector.
4. Certain labour factor income are affected by a change in logistics sectors, particularly on Formal Production, Transport Equipment Operators, Manual worker in Urban Area (6) ; Formal Clerical, Sales, Service Labour in Urban Area (10); and Informal Agricultural Labour in Rural Area. Labor factor accounted 51.30% of the Gross Domestic Product (GDP) of Indonesia in 2005 (CBS, 2007), and most of the value comes from the labour factor mentioned above . Thus, the injection of the logistics sector can boost the value of Indonesia's gross domestic product.
5. Injection on logistics sectors will give globally impact on specific household income, which are: Small Business Entrepreneur , Clerical , Sales, Transportation Worker , Individual Service Worker, Manual Worker in Urban Area (25) ; Medium to Large Business Entrepreneur , Non Agricultural Entrepreneur , Manager, Military, Professional, Technician, Teacher, Sales Executive in Urban Area (27) ; Small Business Entrepreneur , Clerical , Sales,

- Transportation Worker , Individual Service Worker, Manual Worker in Rural Area (22). In other words, the global impact of the injection in the logistics sector received by lower class households, both in rural and urban area.
6. Average expenditure propensity analysis of Railways Transportation Sector shows that the greatest expenditure of this sector is for operational cost, such as for fuel that derived from the oil refinery sector (USD 747.408 billion) and coal fuel derived from other items from nonmetal materials sectors (USD 20.943 billion). Expenditures for operation and maintenance of cleanliness and train stations from soaps and cleaning materials sector (USD 11.420 billion) in third place.
  7. Injections on Railways Transportation Sector will provide the greatest global impact on the sector itself to the value of the coefficient multiplier of 2.030. This value means that if the injection occurred in Railways Transportation Sector at IDR 1 then this sector income will be increased by IDR 2.030, which increased revenue by IDR 1 as a direct impact and IDR 1.030 as an indirect impact.
  8. Injection in Railways Transportation Sector will drive revenues increased mostly in the manufacturing, agriculture and Electricity, Gas and Clean Water sector.
  9. Injection in Railways Transportation Sector also has a smooth influence on labor in both rural and urban area, especially on Formal Production, Transport Equipment Operators, Manual worker. Labor factor accounted 51.30% of the Gross Domestic Product (GDP) of Indonesia in 2005 (CBS, 2007), and most of the value comes from Formal Clerical, Sales, Service Labour factors (36 , 44%) and Formal Production, Transport Equipment Operators, Manual worker. Labor factor (32.17%). Thus, the injection of Railways Transportation Sector has a great impact on Indonesia's gross domestic product.
  10. Global impact of injection on the Railways Transportation Sector received by lower class households, both in rural and urban.
  11. The effects of injection on the Railways Transportation Sector for the Petrochemical products, Ceramics and Earthenware Sector of 52.81% is transmitted directly between sectors.

# Improving Product Quality Of Dining Table Through Painting Process By Using Taguchi Method

Eko Muh Widodo, Oesman Raliby, Candra Widiarso

Industrial Engineering Departement Faculty of Engineering, Muhammadiyah University of Magelang  
Email: emwidodo@yahoo.co.id

## ABSTRACT

In the process of painting a product, it commonly occur defect results including corrugated painting, perforated, less smooth, speckled and uneven surface of painting. This can occur due to the setting parameters in the process of painting is not appropriate. This research is done to reduce the high rate of defects in the process of painting products of table by setting parameters using the Taguchi method. Processing data using the Taguchi method are distinguished by two ways: (1) to see the impact of uncontrollable factors on the percentage of defective products and (2) to see the controllable factors to the variability of the number of defective products. Controllable factors in this study are: composition of paint, painting distance, pressure and temperature. The survey results revealed that a significant factor level against average and variability of percentage number of defective products are composition of the paint level 2 (0.75: 1), the distance painting level 2 (20-25 cm), pressure level 1 (50 psi fluid tip round 1.88 mm), temperature level 2 (60 ° C), sanding sealer level 2 (15-20 cm) and a clear top coat level 1 (20-25 cm).

## Keywords

*Product Defects, Level Factor, Taguchi*

## 1. BACKGROUND

The increasing demands of consumers and the development of science, technology and information lead to changes in consumer tastes toward a product. Thus, consumer demand for the product will be more variety to fulfill the market segmentation that affects the tightness of the competitiveness of the company. One way to ensure that the product is able to compete and survive in the market is to control the quality of products. Furniture Company is a business that requires good quality control in term of aspects of components or finished products produced. One important variable in the furniture company is the quality of painting process. One attempt to improve the quality of the product needs to be a good design parameter that defective products can be reduced. In this case the concept of quality control that is used is the Taguchi method.

Taguchi Concepts is a method to analyze a variety of variables and parameters in bulk and interactions among different variables to achieve a high quality which time and cost is relatively low. The application of the method is expected to solve the problems of the company that is able to find the right parameters in reducing defects so that the products produced are in accordance with the specification set.

## 2. PROBLEMS

Based on the background of these problems, the research is done to improve the quality of painting furniture product so that it is to reduce the level of defects by (1) determining a significant factor level against the contribution of defect rate (2) determining the sensitive parameters to lower defective products and (3) comparing the level of defects between the policies of the company with the proposal based on setting parameter.

## 3. METHOD

The quality of the product is a combination of characteristics products and services both in terms of engineering, manufacturing, marketing and maintenance so as to meet customer needs. To produce products that have a strong performance, Taguchi introduced the design method in three stages (Isa S. Toha, et ell, 1996) (1) designing system that is an attempt to bring the concepts, ideas and methods to improve the quality of products (2) designing parameters, that is selecting the best design of controllable factors and minimizing the environmental impact (3) designing tolerance, that is the stage of range to find a balance between making a loss (manufacturer) and buyer (consumer) products.

The Taguchi method is an effective method to reduce variation in products and processes through optimization process of designing the robust product using orthogonal array in the design of experimental procedures. Taguchi method also uses financial considerations through quadratic loss function to determine tolerance.

## 4. THE RESULT OF RESEARCH

In this study, there are two factors that can be identified as controlled factors and interference factors. Controllable factors are factors which its value can be set or factor which its value is to be regulated or controlled, while the interference factor is a factor which its value can not be regulated or controlled. In control experiments for each factor are two levels as follows:

Table : Controlled Factors

Factors Control	Composition 1	Composition 2
Paint Composition	0,5 : 1	0,75 : 1
Distance Painting	15-20 cm	20-25 cm
Wind Pressure	50 Psi Fluid tip Round 1,8 mm	60 Psi Fluid tip Round 2 mm
Temperature	± 50 minute with a temperature of 50 <sup>0</sup> C	± 50 minute with a temperature of 60 <sup>0</sup> C
Sanding Sealer	20-25 cm	15-20 cm
Top Coat Clear	20-25 cm	15-20 cm

Source : PT Kayu Lima Utama Temanggung

As for the uncontrollable factor is as follows:

Table 2: Factors Not Controlled

Factor Not Controlled	Level	
	1	2
Working time	Morning	Noon
Physical and biological workers	Dedication	Extras
Environment	Comfort	Crowded

Source : PT Kayu Lima Utama Temanggung

From the experimental results, controllable variables considered to be influence to the process of painting is the composition of paint used to compare the viscosity of paint (A), the distance of the painting process (B), the wind pressure when painting process (C), the temperature used during the drying paint (D), sanding sealer when painting process (E) and a clear top coat when painting process (F). The test results are as follows:

Table 3: The results of calculation of the average number of squares

Source of variation	Df	Sum of Squares (SS)	Mean of Squares (MS)
A	1	20	20
B	1	16.78	16.78
C	1	16.78	16.78
D	1	37.03	37.03
E	1	56.18	56.18

SS <sub>t</sub>	29	344	11.86

Source: Processed Data

Incorporating factor starting from the number of the least squares of insignificant factor combined with the number of errors. The incorporation of an insignificant factor to these errors will result anova table structure as follows:

Table 4: First Pooling Effect Factor ANOVA

Factor	Df	SS	MM	SS'	P %	F. Count	F(0.05;150)
A	1	20	20	14.44	5.81	3.59	2.70
B	1	16.78	16.78	11.22	4.87	3.01	2.70
C	1	16.78	16.78	11.22	4.87	3.01	2.70
D	1	37.03	37.03	31.47	10.76	6.66	2.70
E	1	56.18	56.18	50.62	16.45	10.10	2.70
F	1	18.37	18.37	12.81	5.34	3.30	2.70
AB	1	17.95	17.95	12.39	5.21	3.22	2.70
BC	1	15.32	15.32	9.76	4.58	2.75	2.70
CD	1	16.78	16.78	11.22	4.87	3.01	2.70
DE	1	20	20	14.44	5.81	3.59	2.70
EF	1	18.37	18.37	12.81	5.34	3.30	2.70
E	18	100.17	5.56				
SS <sub>t</sub>	29	344	11.86				

Source: Processed Data

Based on the average of each factor and the calculated level can be explained most optimum level for defective product as follows:

Table 5. Average Response Effect Each Factor

Factor	Level 1	Level 2	Diference	Rank
A	3.22	2.72	0.5	5
B	3.05	2.88	0.17	1
C	2.88	3.05	0.17	1
D	3.22	2.88	0.34	3
E	3.22	3.05	0.17	1
F	2.83	3.11	0.28	2
AB	2.27	3.16	0.89	6
BC	2.83	3.00	0.17	1
CD	2.88	3.05	0.17	1
DE	3.22	2.72	0.45	4
EF	3.11	2.83	0.28	2

Source: Processed Data

After doing confirmation experiments to prove that the results are in accordance with previous experimental results. The experiments were conducted for 4 times, the first experiment uses set proposal as follows:

Table 6: Proposed Composition

Level control	Factors
Paint composition	A2
Painting distance	B2
Wind pressure	C1
Temperature	D2
Sanding sealer	E2
Top coat clear	F1

Source: Processed Data

The results of experiments using proposal composition as follows:

Table 7: Proposed Composition Experiment Results

Control factor	Code	N Experiment	Defective paint	
			Unit	% Unit
Paint Composition	A2	19	2	10.52%
Painting distance	B2	19	2	10.52 %
Wind pressure	C1	19	1	5.26 %
temperature	D2	19	1	5.26%
Sanding Sealer	E2	19	2	10.52%
Top coat clear	F1	19	2	10.52%
Total			10	56.60%
Average			1.67	8,76%
Sd			0.5163	

Source: Processed Data

The experiment using factor level of company policy is as follows:

Table 8. Composition of Company Policy

Control factor	Level
Paint Composition	A1
Painting distance	B1
Wind pressure	C2
Temperature	D1
Sanding sealer	E1
Top coat clear	F2

Source: Processed Data

The experimental results using the composition of the company's policy as follows:

Table 9. Experiment results of Company Policy

Control factor	Code	N Experiment	Defective Product	
			Unit	% Unit
Paint Composition	A1	19	4	21.05%
Painting Distance	B1	19	4	21.05%
Wind Pressure	C2	19	3	15.78%
Temperature	D1	19	5	26.31%
Sanding sealer	E1	19	3	15.78%
Top coat clear	F2	19	3	15.78%
Total			22	115.75%
Average			3.67	19.29%
Sd			0.8164	

Source: Processed Data

Based on the validation test is known that early experimental results that do not differ from the results of experimental confirmation. Loss costs as shown in the graph loss function for defective product, the proposed parameter with an average value of 1.67 and Ly 122,979.85 shown on the chart shown below:

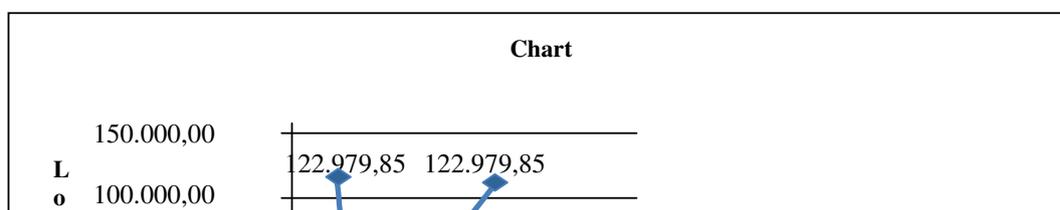

Figure 1: Loss Function of Composition Proposal Chart

While the loss function charts for defective products of company policy parameters with the average value of 3:00 and Ly 416,264, - is shown in the figure below:

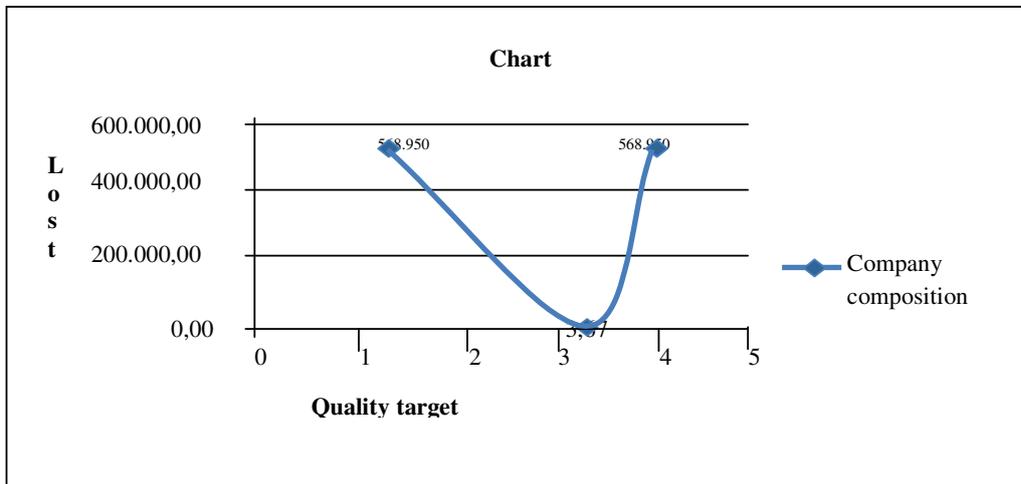

Figure 2: Lost function of company policies chart

## 5. CONCLUSION

Based on the results of research and discussion, the following conclusions can be drawn:

- 1) Level factor that has significant contribution to the percentage of a defective product, are factor level of paint composition at B2 level, factor level of painting distance at B2 level, factor level of air pressure at C1 level, air temperature at D2 level, sanding Sealer at E2 level and clear coat top at F1 level.
- 2) Sensitive parameters that affect the quality of the painting are the composition of paint, painting distance, air pressure, temperature, sanding sealer and top coat clear.
- 3) Setting the parameters proposed by the research can reduce defects percentage from 19.29% to 8.76%.

### ABSTRACT

Traditional market, in this time, start to lose their customer because they fail to compete with the modern market in several aspects. Common problem faced by traditional market is no arrangement for the traders that causes the traditional market is always impressed disorganized as traders are free to sell the product at anyplace. This unorganized also causes consumers are difficult to buy their needs effectively and efficiently. This paper presents two step to redesign traditional market where the first step classify traders based on the type of their product sold and the second step place a group of traders based on proximity characteristics between traders. There are two data mining techniques used in this approach, clustering for the first step and association rules for the second step. A case study in one traditional market is used to describe this approach.

### Keywords

*Traditional Market, Clustering, Association Rules*

### 1. INTRODUCTION

The traditional market basically is the place where the sale and purchase between grassroots communities met. The existence of this traditional market in addition is not only to connect rural and urban economies but also a source of quest and fulfillment of daily needs for some people [4]. The bargaining activities as prices formation process becomes its own characteristics that make traditional markets on the one hand not only economic value but also social value.

One thing that kept bothering existence of traditional markets is the existence of the modern market as supermarkets, retail, self service, franchise and so on. Although basically each type of market has its own mass base but the modern market that built close to the traditional market tends to disserve because it saturates consumers who have a common goal to purchased the same products [3]. The responsive enthusiasm of the community is also lead modern retail businesses continue to increase their business by increasing the number of outlets in various parts of the region

The traditional market is a place for buyers sellers met that are located close to a residential community with a certain environment and certain cultural conditions as well. According [5] traditional market conditions commonly observed are as follows:

1. Simple building shape, room to sell is not extensive, have sufficient lighting and no air conditioners.
2. Hygiene market is usually less secure, many scattered garbage that cause odor. If it rains, the market looks muddy and dirty.
3. Limited parking facilities.

Major problems being faced by the traditional market is increasingly left by visitors are turning to the modern market. This is likely due to the impression of a dirty, chaotic, and uncomfortable, smell has always been associated with the market environment. Lack of knowledge and skills of the HR business market is also a factor. This problem can actually be solved by restructuring the facility to restore the image of the market that is clean, safe, comfortable, and regular [7]. Reference [6] stated some basic differences between the traditional with the modern market (the Table 1).

Table 1: Differences Characteristics between Traditional Market and Modern Market

No	Aspect	Traditional Market	Modern Market
1	Historic	Long evolution	New phenomenon
2	Physical	Mostly are deficient	Good and lux
3	Ownership	Community, Local Government	Generally private companies
4	Capital	Poor capital, subvention, local community	Strong capital by private companies
5	Consumers	Generally, the lower middle class	Generally, middle class and above
6	Service Method	Be served, bargaining	Service him/her self, fixed price
7	Land Status	State-owned land	Land owned by a private company
8	Financing	Oftenly getting subvention	No subvention
9	Construction	Generally, the physical development by local governments / village / community	Generally, provided by private companies
10	Sellers who entered	Variouly, mass, informal sector to middle and strong seller	Owners of capital are also merchants (single) or several medium and large formal sellers
11	Opportunity to join the market	Mass	Limited (sellers that have strong financing)
12	Network	Regional market	Cooperation chain system

The traditional market has a typical transaction. The process of buying and selling occurs interactively. Price is not a definite, but it is the result of an agreement through negotiation between sellers and buyers [1] That cultural values has become the marketability of a traditional market. But the shortage of structuring facilities still needs to be fixed because basically consumers are not only looking at price alone but also choose a more convenient and representative place.

The rapid growth and development of modern markets become serious competitors to traditional markets. Each year, 2 percent decline of traditional market is recorded. The problem faced by the traditional market includes policy and management market. [3] stated that the issues are related to the physical market, operational management and government policy. Physical problems include building markets, infrastructure and spatial market. Operational management is associated with the management of the market and traders. Government policies is related to restructuring and retail markets, fostering market management, finance, supply-demand, commodity prices and policy consistency

One feature of the market itself in general is the number of traders that are not accommodated by the capacity of the market stalls so many traders are scattered outside the market, the market is not maintained cleanliness and location settings irregular traders. It makes the consumer difficulty in shopping. Sometimes buyers have toured the market for similar goods just because a remote merchant location. In general, the image generated from the unorganized market design is the impression of dirty, messy and inefficient. This should be a matter for local government studies as traditional market managers how to increase the chances of developing markets essentially have to revamp the traditional market design based on meeting the needs of consumers so that consumers feel comfort to visit and shop at traditional markets.

References [5] have arranged a research plan to redesign the layout of a traditional market where using data mining techniques approach. This study will attempt to realize this vision for redesigning traditional markets using data mining techniques such as cluster analysis (Clustering Analysis) and (MBA Market-Based Analysis). Cluster analysis is used to determine the distribution maps so that consumers and merchants profiling and placement used in the design can be run more effectively. MBA is used to design the layout strategy based on traditional market shoppers spending close relationship groove at a time. This technique became known for his ability to analyze the contents of a shopping cart in a supermarket as a basis for setting the rack setting (display) products. In this study, the analysis technique will be tested applied to traditional buyers in the market to produce a new design that is expected to reinforce the existence and competitiveness of traditional markets in the face of the growth of the modern market. For ease of analysis, the case study will be conducted in one of the traditional markets in Sleman as an illustration of the constructed model approach.

### 1.1 Research Objective

The purpose of this study is to redesign the traditional market that focuses on the relationship with the seller and buyer using data mining techniques..

## 2. DISCUSSION

The first step in redesigning the layout of traditional markets is to knowing the clusters of traders in the market based on the products sold. These types of traders in traditional markets based on the products sold.

Table 2: Market trader types

No	Types of traders	No	Types of traders
1	Onion, garlic, pepper, salt	24	Rice
2	Spinach, carrots, kale, celery, green beans, etc.	25	Grated Coconut Services
3	Soap, T-shirts, shirts, trousers, skirts, etc.	26	Squeeze Oil
4	Klepon, martabak, agar-agar, risoles, sponge, etc.	27	slippers
5	rice, vegetables, fried fish, fried chicken, etc	28	underpants
6	T-shirts, shirts, trousers, skirts, etc.	29	Shoes
7	food and drink wrappers from plastic	30	Tailor
8	Soap, cigarettes, detergents, flour, beverage packaging, etc.	31	Broom
9	Meat, shredded, bones, meatballs	32	Toy
10	Walok	33	Banana
11	Coconut, Salak, Onion	34	T-shirts, shirts, trousers, skirts, etc.
12	Seasonings Padang cuisine	35	home and kitchen furnishings
13	jewelry	36	Cabinets
14	Fish	37	Pillow
15	Chicken	38	Wood home furnishing
16	Watermelon, mango, bark, etc.	39	Cooking materials
17	Accessories	40	girl bag
18	Snack, Bakpia, chocolate, chips, etc.	41	Bucket, bucket, basin etc.
19	Accessories, bag	42	Casual Bag
20	Glassware	43	Flower
21	Soap, toothpaste, toothbrushes, etc.	44	Spices
22	Yarns, Accessories, Scissors	45	Satai
23	vegetables, fried tofu, fried tempeh, catfish, fried chicken		

K-Means clustering method is used to classify the types of merchants above. There are three instrument variables are used as the basis for grouping, namely:

1. The nature of the goods (dry or wet goods)
2. Type of goods (food, clothing, or shelter goods)
3. Categories of Goods (raw or finished goods)

The calculations using SPSS16 shows that there are 5 clusters existing traders in traditional markets such as shown in Figure 1 and Figure 2.

	Cluster				
	1	2	3	4	5
Kind_of_product	1	1	1	1	0
Type_of_product	1	2	3	1	1
Category_of_product	1	0	0	0	1

Figure 1: Final Cluster Centers

Cluster 1	9.000
2	10.000
3	15.000

	4	7.000
	5	4.000
Valid		45.000
Missing		.000

Figure 2: Number of Seller in each Cluster

The five clusters formed and the members of seller included in are performed in Table 3 .

After getting the grouping of market stalls, the study followed by observing the tendency of consumer shopping behavior. It is based on the frequency of purchases and the relationship of the five groups that have been defined previously. Researchers asked each respondent in one time period what are the shopping items they buy. Then the researchers put the data in accordance with the market stalls that have been clustered. If there is no buyer who only make purchases only on one group of market stalls, then the buyer will not be included in the market basket analysis.

Table 3: K means clustering result

Name of Cluster	Member of Sellers			
<b>Kitchen's needs</b>	1	Onion, garlic, pepper, salt	6	Grated Coconut Services
	2	Spinach, carrots, kale, celery, green beans, etc.	7	Cooking materials
	3	Coconut, Salak, Onion	8	Spices
	4	Seasonings Padang cuisine	9	shredded coconut
	5	Rice		
<b>Mini Ritel</b>	1	Soap,T-shirts, shirts, trousers, skirts, etc.	9	Toy
	2	food and drink wrappers from plastic	10	home and kitchen furnishings
	3	Soap, cigarettes, detergents, flour, beverage packaging, etc.	11	Cabinets
	4	Glassware	12	Pillow
	5	Soap, toothpaste, toothbrushes, etc.	13	Wood home furnishing
	6	Yarns, Accessories, Scissors	14	Bucket, bailer, basin etc.
	7	Tailor	15	Flower
	8	Broom		
<b>Fast Food</b>	1	Klepon, martabak, agar-agar, risoles, sponge, etc.	5	Watermelon, mango, bark, etc.
	2	rice, vegetables, fried fish, fried chicken, etc	6	Snack, Bakpia, chocolate, chips, etc.
	3	Walok	7	Banana
	4	vegetables, tofu, fried tempeh, catfish, fried chicken		
<b>Side Dish</b>	1	Meat, shredded, bones, meatballs	3	Chicken
	2	Fish	4	Satai
<b>Fashion</b>	1	T-shirts, shirtshouse dress	6	underpants
	2	jewelry	7	Shoes
	3	Accessories	8	T-shirts, shirts, trousers, skirts, etc.
	4	Accessories, bag	9	girl bag
	5	slippers	10	Casual Bag

This is due to the current study focused on the relation of market stalls that require spending information over an existing market stalls. After the data is collected the next step is to perform calculations using the Market Basket Analysis consists of the support, confidence and lift ratio with the following results (Table 4):

Table 4: The Result of Market Basket Analysis (Ten of The Largest Mark)

Conf. (%)	Antecedent (a)	Consequent (c)	Support(a U c)	Support (%)	Lift Ratio	Total Mark (Conf*S support)
-----------	----------------	----------------	----------------	-------------	------------	-----------------------------

Conf. (%)	Antecedent (a)	Consequent (c)	Support(a U c)	Support (%)	Lift Ratio	Total Mark (Conf*S support)
76,92	Kitchen's Need=>	Fast Food	140	0,466667	1,044205	35,896
63,35	Fast Food=>	Kitchen's Need	140	0,466667	1,044205	29,56333
69,88	Mini Ritel=>	Fast Food	116	0,386667	0,948591	27,02027
79,21	Side Dish=>	Fast Food	80	0,266667	1,075221	21,12267
78,22	Side Dish=>	Kitchen's Need	79	0,263333	1,289305	20,59793
52,49	Fast Food=>	Mini Ritel	116	0,386667	0,948591	20,29613
56,63	Mini Ritel=>	Kitchen's Need	94	0,313333	0,933404	17,74407
74,47	Kitchen's Need, Mini Ritel=>	Fast Food	70	0,233333	1,010879	17,37633
79,75	Kitchen's Need, Side Dish=>	Fast Food	63	0,21	1,082536	16,7475
78,75	Side Dish, Fast Food=>	Kitchen's Need	63	0,21	1,298077	16,5375

By knowing the relationship between the five groups of stalls in the traditional market, the new stall layout plan prepared in order to increase profits and the level of visits to the market by providing services in accordance with the trend of buyer behavior where it has been represented by the results of the analysis of Market Basket Analysis . As in this case study, it is assumed that the two market stalls that had the highest relationship, will be brought closer in the layout of the new market stalls. It is based on the idea that it will facilitate buyers to shop. In addition, it can also be assumed to improve profit due to the buyer as if reminded not to forget to buy the goods that had been being associated in the minds of buyers. The final result of planning the layout is performed in Figure 3.

Size layout described above is based on a percentage of the number of traders in the market Sleman. Layout is also a representation of the form of the land market. Market stall trader from the fashion should be placed the back because the value of the top ten association rule calculation, it does not have a relationship with another market stall so it is assumed he was in a fairly indirect encountered by most buyers. It may also be based on the likelihood that the most visited market to meet the needs of the community kitchen.

## 7. CONCLUSION

Based on the discussion above, it could be taken a conclusion that:

1. Based on three grouping variables, namely, nature of the goods, type of goods, and category of Goods, saler members are classified in five groups. They are kitchen's needs, Fast Food, Mini Ritel, Side Dish, and Fashion.
2. Market relayout has been performed based on market basket analysis. Proposed layout is expected to be able to satisfy buyers by easier finding products and shorter distance.

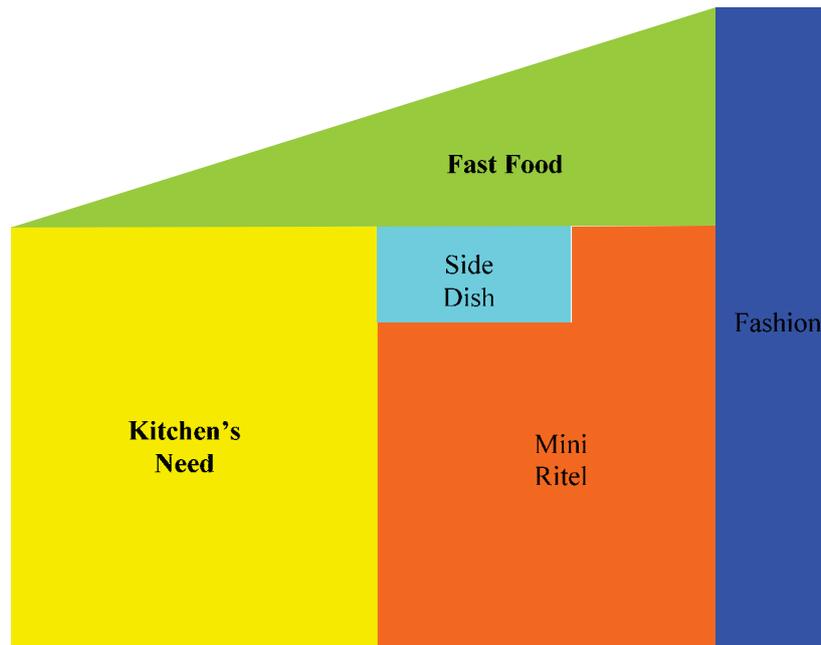

Figure 3 Proposed Market Stalls Based on Analysis

## ACKNOWLEDGMENT

This research was supported, in part, by Directorate of Research and Community Service Universitas Islam Indonesia.

### **ABSTRACT**

The Steepest Ascent (SA) method had been proven for its ability in moving experiment factor levels to optimal area in Response Surface Methodology (RSM). This method leads the design of experiment to track direction of factor levels movement, so that the global optimum would be reached. However, sometimes response variable being optimized by using RSM can't fulfill the classic statistical assumption following the surface regression model. Taguchi's orthogonal array as alternatives for RSM gives more loosely statistical assumption in performing the analysis. This method doesn't yet support for moving the factor level to optimum direction. Following the procedures of RSM in finding the optimal level combination by SA method, the Taguchi experiment also can lead to the global optimum response.

Integrating SA method in Taguchi experiment then was applied to a simulated response surface. The performance of this procedure then was evaluated according to its direction to reach the optimum. The simulation data was generated for two factors, representing the real case. The proposed procedure was then applied. The result from simulation study shows that the integrated SA method for Taguchi experiment successfully find the factor level combination that yields optimum response even not as close as possible as the RSM done.

### ABSTRACT

*Food and beverage industry is the largest industrial sub-sector in Indonesia. This research reports the assessment of quality management practices at Indonesian food and beverages companies. Assessment criteria were developed based on Malcolm Baldrige National Quality Award (MBNQA) 2011-2012 criteria. The survey was conducted to 27 food and beverage companies from small, medium to large industries. The results show the implementation of quality management practices at Indonesian food and beverages companies are at intermediate level. The results of factors measurement (scale from 1 to 9) consist of leadership (6.250), strategic planning (6.568), customer focus (3.880), measurement, analysis, and knowledge management (4.863), workforce focus (5.306), operations focus (5.200), and result (5.929). The results also indicate the influence of business scale and certification to quality management implementation in the companies. Six from seven existing factors show significant differences when grouped by business scale as well as certification. The factors that have significant differences are leadership, customer focus, measurement, analysis, and knowledge management, workforce focus, operations focus, and results.*

*Quality Management, MBNQA, Food and Beverages Industry, Indonesia*

### 1. INTRODUCTION

Food and beverage industry is the largest industrial sub-sector in Indonesia. Association of Indonesian Food and Beverage Companies (GAPMMI) [1] stated that, until the year 2009, there were 1.159.983 companies in this sub-sector, where 6.316 are large and medium industries, 66.178 small industries and the rest, 1.087.489 are home industries. The export from Indonesian food and beverages industry also increased during 2005 to 2009 with an average growth to 16% per year. During the period from January to May 2011, there is an increase in exports by 17.02% over the same period of the previous year. This growth in export market indicates the acceptable of Indonesian products in global market.

Since 2010, there has been an agreement in trading between ASEAN countries and China called China ASEAN Free Trade Area (CAFTA). One of the challenges facing the company, according to the Indonesian Directorate General of International Trade Cooperation Department of Commerce [2] is the way companies improve the efficiency and effectiveness of production. In addition, the company's ability in the mastery of information and communication technology is also kind of challenges. The government also faces the challenge of creating a good environmental business climate as well as regulations that are transparent, efficient and friendly to business world. Quality management is an answer to those challenges. American Society for Quality (ASQ) defines Total Quality Management (TQM) as a management approach to achieve long-term success by giving customer satisfaction through continuous improvement in quality, in terms of products, services, human resources, processes, and also the environment.

Over the last two decades, many researches have been done in quality management. Saraph, Benson, and Schroeder [3] initiated a study to identify critical success factors of quality management implementation. The study produced eight factors, namely management leadership, regulation of quality, training, product or service design, relationship with suppliers, process management, data and reports on quality, and employee relations. Tamimi and Gershon [4] developed an instrument to measure the implementation of quality management based on Deming's 14 points. Powell [5] developed 12 factors based on

the criteria of Deming, Juran, Crosby, and Malcolm Baldrige National Quality Award (MBNQA) 1992. The specific research in quality management implementation based on the criteria of MBNQA was conducted by Lau, Zhao, and Xiao [6]. They compared the application of quality management in companies focused on inspection, quality control (QC), and total quality management (TQM) in China. The result showed companies that focus on TQM have superior performance than companies that focus on inspection or QC. Prybutok, Zhang, and Peak [7] conducted a study to test the application criteria of MBNQA 2002 in the sectors of government organizations. The research concluded that MBNQA criteria model 2002 can be used to review and measure organizational performance.

Some researchers also tried to identify factors that may affect the application of quality management. Wali [8] examined factors such as firm size, ownership, cooperation, export, quality experience, leadership style, formal communication, informal communication, and competition. The research showed that only some factors such as ownership, quality experience, and leadership styles that affect the application of quality management. Yusof [9] conducted a study concerning the application of quality management in manufacturing small and medium-scale (small and medium enterprise) in Malaysia. Yusof also compare the critical success factors of quality management implementation between small and medium enterprises and large enterprises. The results show there are significant differences on several factors such as management leadership, resource management, measurement and feedback, and continuous improvement. Research on factors affecting the implementation of quality management was also done by Hendricks and Singhal [10] and Tesfayohannes [11]. Their results showed the influence of firm size on the application of quality management. However, this can not be proved by Saraph, Benson, and Schroeder [3] and Powell [5].

Some researchers also looked at the relationship or influence of ISO on quality management implementation. Gotzamani and Tsiotras [12] conducted empirical studies to look at ISO 9000 contribution to the company towards total quality management. They conducted a survey to measure the implementation of quality management in companies that already have ISO 9000 certification in Greece. The results indicated a good contribution of ISO 9000 for quality management implementation. It is supported by an increase in performance measurements on several factors, although not all of these factors indicate a significant difference before and after certification

The purpose of this research is to measure the implementation of quality management practices in Indonesian food and beverages companies based on MBNQA 2011-2012 guideline assessment. It will also identify the influence of business scale and certification to the results of the assessment.

## 2. LITERATURE REVIEW

Starting in 1987, U.S. Government through the National Institute of Standards and Technology (NIST) annually gives awards to companies and organizations in several fields such as manufacturing, service, education, health, small businesses, and nonprofit who successfully demonstrated quality and excellent performance improvements. This award is known as the Malcolm Baldrige National Quality Award (MBNQA). In 2005, Indonesia established Indonesian Quality Award Foundation (IQAF) who has a similar role with NIST. Annually, IQAF held Indonesian Quality Award which was adopted from the MBNQA.

Figure 1: Baldrige Criteria for Performance Excellence Framework  
 Source: NIST [13]

MBNQA criteria which also known as the **Baldrige Criteria for Performance Excellence** are embodied in seven categories such as shown in figure 1. The **leadership** category examines how senior management leads the organization and

how the organization leads within the community. The way organization fulfills its legal, ethical, and societal responsibilities are also measured in this category. The **strategic planning** category examines how organization develops its strategic objectives and action plan, implement their strategies and actions, and develop performance indicator to measures the progress. The **customer focus** category examines how organization engages its customer for long-term market success. It includes how organization listens to the voice of its customer, builds customer relationship and uses customer information to create improvement and innovation. The **measurement, analysis and knowledge management** category examines how organization collects and uses data to improve its performance. The **workforce focus** category examines organization's ability to assess workforce capability and capacity needs and build a conducive work environment. It also examines how organization empowers and involves its workforce. The **operation focus** category examines how organization designs, manages, and improves its work systems and work processes to deliver customer value and achieve organizational success and sustainability. The **result** category examines organization's performance and improvement in five key areas – product and process outcomes, customer-focused outcomes, workforce-focused outcomes, leadership and governance outcomes, and financial and market outcomes.

### 3. METHODOLOGY

The research method diagram can be seen in figure 2. The research was started with literature review to identify research problem and state the purpose of the research. As was stated before, the purpose of this research is to measure the implementation of quality management practices in Indonesian food and beverages companies based on MBNQA 2011-2012 guideline assessment identify the influence of business scale and certification to the results of the assessment.

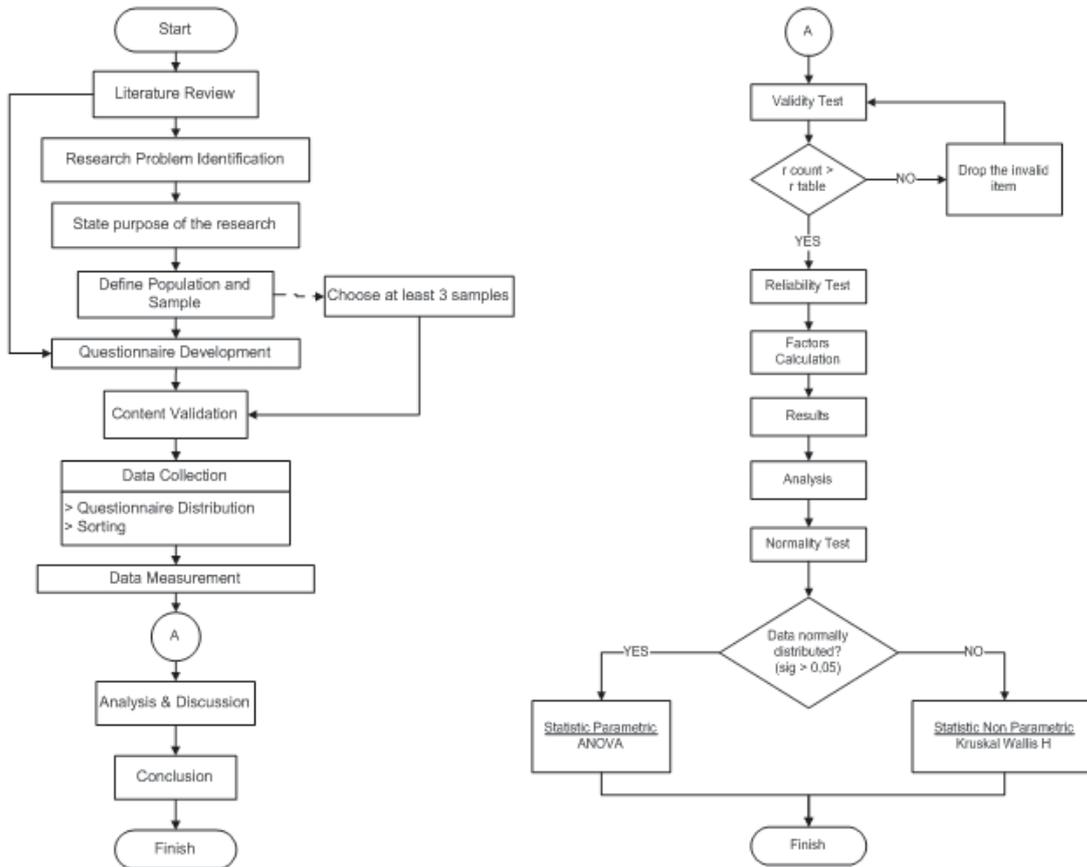

Figure 2: Method Diagram

#### 3.1 Participants

The participants of this research are companies from food and beverages industry in Indonesia. The number of population is 72.494 companies [1]. Based on Krejcie and Morgan [14], the number of minimum samples needed is 382 companies.

Respondents are senior leaders in the companies who are considered to have enough knowledge about the situation in several functional areas of the company.

### 3.2 Measurement

The measurement was based on questionnaires that were answered by the corporate leaders. The content of the questionnaire firstly be validated by minimum three experts who came among the corporate leaders. The questionnaire consists of two major parts. The first part includes profile of respondents and company attributes. The respondent's profile includes job position and the years of work at the company. Meanwhile, the company attributes consist of business area, form of business, number of labors, scope of market, and programs and certifications that have been achieved by company. The second part consists of indicators based on seven factors that were developed based on MBNQA criteria 2011-2012. These factors are leadership (F1), strategic planning (F2), customer focus (F3), measurement, analysis, and knowledge management (F4), workforce focus (F5), operations focus (F6), and results (F7). The response to each indicator was rated on a scale of 1 to 9 with five different type of answer, from very poor to very good. The influence of business scale and certification to quality measurement result later were examined using analysis of variance.

### 3.3 Procedures

The questionnaires were distributed to companies via email. The answered questionnaires then were sorted. Two parts of questionnaires should be answered completely. Hence, the questionnaires were tabulated. The factors then were tested for their validity and reliability. Factors that have been validated and considered to be reliable then be calculated. The results later be analyzed and compared to the previous findings.

## 4. DATA COLLECTION AND MEASUREMENT

The survey was planned to be conducted online by sending a letter and a web-based link address to corporate emails. 382 companies are needed as samples, but only 100 email addresses that successfully obtained. 100 emails were sent and 18 gave response. After a further review, only 12 corporate data can be used. It was then decided to get more data by going directly the respondents. It was done by visiting the exhibition of food and beverage industry and creating an appointment with the corporate leaders. Finally, 15 additional data obtained from direct visits. Thus, the overall data obtained to be processed further for this study is 27, where 14 are small and medium enterprises (SME) and 13 are large enterprise. The percentage number of respondent can be seen in figure 3.

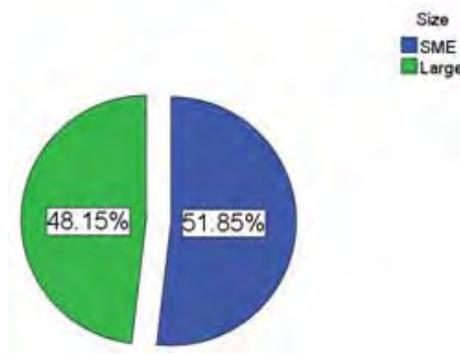

Figure 3: Percentage of Respondent Based on Business Scale

Table 1 shows descriptive results of respondents' profile. Respondents consist of owner, director, manager, and supervisor. Most of them (48,1%) have worked at the company for less than five years. 25,9% have been worked for five to ten years. Only a few (3,8%) who have worked for more than 20 years.

Table 1: Profile of Respondent

		SME (%)	Large (%)	Total (%)
<b>Respondent Position</b>	Owner	29,6	-	29,6
	Director	-	3,8	3,8
	Manager	14,8	25,9	40,7
	Supervisor	7,4	18,5	25,9
<b>Years of work</b>	< 5 years	29,6	18,5	48,1
	5-10 years	7,4	18,5	25,9
	10-15 years	-	-	-
	15-20 years	11,1	11,1	22,2
	> 20 years	3,8	-	3,8

Table 2 shows companies' attributes. Company attributes consist of company age, business form, scope of market and certification. 40,7% companies are less than 5 years. It indicates a growth trend in this industry. The business form consists of five types which were regulated by Indonesian government. Scope of market also consists of types, in local city, inter-city, inter-province, inter-island, and export. It is enabled for a company to have several scope of market. Meanwhile the certification attribute classify companies which have none certification, only national certification, or national and international certification. The result shows 48,2% companies have national and international certification, 37% only have national certification, and only 14,8% who have none of certification. The influence of certification and also business scale to the quality management result will be discussed in the next section.

Table 2: Company Attributes

		SME (%)	Large (%)	Total (%)
<b>Company Age</b>	< 5 years	29,6	11,1	40,7
	5-10 years	7,4	-	7,4
	10-15 years	-	3,8	3,8
	15-20 years	11,1	7,4	18,5
	> 20 years	3,7	25,9	29,6
<b>Business Form</b>	PT (PMA)	-	3,7	3,7
	PT (PMDN)	22,2	44,4	66,7
	CV	3,7	-	3,7
	Proprietorship	18,5	-	18,5
	None	7,4	-	7,4
<b>Scope of market</b>	In Local City	44,4	37,0	81,4
	Inter-City	29,7	37,0	66,7
	Inter-Province	37,0	37,0	74,0
	Inter-Island	37,0	40,8	77,8
	Export	3,7	37,0	40,7
<b>Certification</b>	None	14,8	-	14,8
	National	33,3	3,7	37,0
	National+	3,8	44,4	48,2
	International			

The second part of the questionnaire, the assessment indicators, then were measured by counting the mean of indicators for each factors. Table 3 shows the measurement results. It later be grouped based on their business scale and the certification to identify the influence of business scale and certification to the implementation of quality management in companies. The measurement were done using independent t-test for business scale's group (only two group) and ANOVA for certification's group. Before that, the data should be test for its normality and homogeneity. Based on business scale's group, factor 3 and 7 were found to be not normal. So, they were tested using Mann-Whitney U test, while factor 1, 2, 4, 5, and 6 be tested using independent t-test. Factor 1, 2, 4, 5, and 6 are homogen. Based on certification group, factor 5 and 7 were founded to be not normal. They later were tested using Kruskal-Wallis H test, while factor 1, 2, 3, 4, and 6 be tested using ANOVA. Factor 1, 2, 3, 4, and 6 are homogen.

Table 3: Measurement Results

Factor	Details	Mean
F1	Leadership	6,250
F2	Strategic Planning	6,568
F3	Customer Focus	3,880
F4	Measurement, Analysis, and Knowledge Management	4,863
F5	Workforce Focus	5,306
F6	Operations Focus	5,200
F7	Results	5,929

## 5. ANALYSIS AND DISCUSSION

Data measurement of quality management practices in table 3 shows that the quality management practices in Indonesia are at intermediate or medium level. The lowest score is factor 3, customer focus (3,880). The highest score is factor 2, strategic planning (6,568). Based on the scale used, from 1 to 9, the highest factor's score is still at intermediate level and need to be increased.

The study of Lau, Zhao, and Xiao [6] in companies in China indicated a better achievement in which the average value for each factor ranged from 7 to 8. Table 4 shows the comparison of the measurements of quality management in food and beverage companies in Indonesia with companies (manufacturing and services) in China.

*Table 4: Comparison of quality management measurement between companies in Indonesia and China*

Factor	Results of Quality Management Assessment	
	Indonesia	China
F1	6,250	8,020
F2	6,568	7,440
F3	3,880	7,947
F4	4,863	7,633
F5	5,306	7,563
F6	5,200	7,177
F7	5,929	7,213

The measurement results of quality management implementation in companies in China show superiority on each existing factors. Lau used MBNQA criteria 2002 as guideline assessment. The respondents came from manufacturing and service sector. While in this study, the criteria were based on MBNQA 2011-2012. The respondents were also limited to companies engaged in manufacturing sub-sectors of food and beverage industry. However, the result of Lau, Zhao, and Xiao is expected to give some idea as a comparison of quality management practices among companies of Indonesia and China.

### 5.1 Identification of business scale influence to quality management practices

Business scale is grouped into two categories, small and medium enterprises (SME) and large. The influence will be seen whether there are significant differences between factors on these two categories. Table 5 shows the summary of independent t-test and Mann Whitney U test on the factors.

Table 5 shows that there are significant differences in factor 1, 3, 4, 5, 6, and 7. There is no significant difference in factor 2, strategic planning. The calculation of the average value also clearly indicates the absence of significant differences in this factor. Some indicators in the assessment of this factor is short-term, medium, and long-term planning, forecasting, back-up plan, SWOT (Strengths-Weaknesses-Opportunities-Threats) analysis, considerations in strategic planning (economic conditions, market conditions, customer desires, and competition), making the work plan in accordance with the capacity and capability, and establishing indicators to measure the progress achieved during the implementation strategy of the company. The application of these assessment indicators on SME and large scale enterprises in Indonesia did not differ significantly. SME companies demonstrate the ability of strategic planning that is good enough and does not differ much when compared with large companies. Based on the existing seven factors, one factor did not differ significantly. Thus, it can be stated that the business scale has an influence in the implementation of quality management in the company. These results are supported by the findings of Hendricks and Singhal [10], as well as Tesfayohannes [11]. However, there are also some studies showing there is no effect between the scale of the business with the implementation of quality management, contributed by Saraph, Benson, and Schroeder [3], Powell [5], and Wali [8].

*Table 5: Measurement of Quality Management Practices based on Business Scale*

Factor	Par/nPar	Business Scale		Sig
		SME	Large	
F1	Par	5,735	6,804	Yes
F2	Par	6,213	6,950	No
F3	nPar	2,438	5,433	Yes
F4	Par	3,600	6,223	Yes
F5	Par	4,552	6,119	Yes
F6	Par	4,342	6,124	Yes
F7	nPar	5,402	6,497	Yes

## 5.2 Identification of certification influence to quality management practices

Certifications are grouped into three categories, namely companies that have none of certification, companies that only have national certification, and companies that already have national and international certification. National certifications consist of certification from Indonesian food and drugs regulatory agency, named BPOM and Indonesian National Standard, called SNI. International certifications can be International Standard organization (ISO), Hazard Analytical and Critical Control Points (HACCP), Good Manufacturing Practices (GMP), and other international standards. Table 6 shows summary of ANOVA and Kruskal Wallis H test which are used to identify the influence of certification to quality management practices.

Table 6 shows that there are significant differences in factor 1, 3, 4, 5, 6, and 7 as same as the results showed at table 5. Table 6 also showed companies with national and international certification have the highest score among the other two categories. The scores of companies that only have national certification are found to be lower on some factors than companies that have no certification. The post hoc test also showed that there is no significant difference between factors on companies that have no certification with companies that only have national certification.

Table 6: Measurement of Quality Management Practices based on Companies' Certification

Faktor	Par/ nPar	Certification			Sig
		None	National	National and International	
F1	Par	6,145	5,258	7,045	Yes
F2	Par	6,783	5,925	6,996	No
F3	Par	2,125	2,662	5,356	Yes
F4	Par	3,530	3,903	6,012	Yes
F5	nPar	4,841	4,309	6,217	Yes
F6	Par	4,580	4,004	6,311	Yes
F7	nPar	5,747	5,209	6,539	Yes

The national certification from BPOM can be differed into three labels, SP, MD, and ML. SP is given to small businesses with limited capital and supervision provided by the District Health Office / municipality. MD given to companies with greater capital and are expected to follow the food safety requirements set by the government. While the ML labels are given for processed food products and beverages that are imported products. The existence of various classifications of certification from BPOM results in the lack of standardization if we only look at the label of national certification or certification authorities from BPOM. So, it has to be clearer which type of national certification that the companies have.

The superiority shown by companies with national and international certification in any assessment of factors indicates that the quality management practices at these companies are better than the two other categories. One type of international certification that generally owned by company is ISO. ISO is a certification given to companies that have managed to meet a given set of requirements, depending on the type of ISO certification of registration undertaken by the company. ISO is required by companies to be more competitive in the global market. Gotzamani and Tsiotras [12] also indicated a significant difference in the performance of companies that already have ISO certification with those who have not yet.

## 6. CONCLUSION

This study aims to measure the quality management implementation among food and beverages companies in Indonesia. The survey was conducted of 27 companies engaged in food and beverage industry subsector. The study lasted four months, from August 2011 to November 2011. The following are results that can be inferred from the data analysis and discussion that has been done.

1. The measurement of quality management implementation is based on seven factors with the common assessment scale 1 (very poor) to 9 (very good). The results of measurements of these factors consist of leadership (6.250), strategic planning (6.568), customer focus (3.880), measurement, analysis, and knowledge management (4.863), workforce focus (5.306), operations focus (5.200), and result (5.929).
2. The application of quality management in food and beverage industry in Indonesia is at intermediate level. It is shown by an average factor value of 5.428.
3. Factor with the highest score is strategic planning (6,568). Factor with the lowest score that needs special attention from the company is customer focus (3.880).
4. Results identify the influence of business scale to quality management implementation. There are significant differences on the leadership factor (sig. 0.028), customer focus (sig. 0.000), measurement, analysis, and management information (sig. 0.000), workforce focus (sig. 0.002), operations focus (sig. 0.004), and the results (sig. 0.009).

5. Results also identify the influence of the company's certification to quality management implementation. There are significant differences in leadership (sig. 0.001), customer focus (sig. 0.000), measurement, analysis, and management information (sig. 0.000), workforce focus (sig. 0.005), operations focus (sig. 0.001), and the results (sig. 0.015).

## ABSTRACT

Electronic Toll Collection (ETC) has been implemented in Indonesia as a response of congestion caused by toll payment system inefficiency. The implementation of ETC and the utilization in Jabodetabek is still very low because there are wide variations in user characteristics and other factors influencing toll users' preferences in choosing toll payment alternatives. The main contribution of this research is to analyze user characteristic and determine factors affecting the selection of toll payment system using nested logit method. Nested logit predicts probability of each alternatives and coefficient of independent variables that affecting dependent variables. The result of this study shows that transaction time, initial investment, age, gender, frequency of using toll, and the use of e-toll card are significantly affect consumers' choice. The most preferred alternative is e-toll card (37,2%), e-toll pass (34,3%), and cash payment g(28,5%).

## Keywords

*Nested Logit, Electronic Toll Collection, Discrete Choice Analysis, E-toll Card, E-toll Pass*

## 1. INTRODUCTION

Toll road was built as an alternative to reduce the congestion that often occurs in metropolitan cities like Jakarta. However, congestion often occurs in the toll road itself, which is often the case of a very long queue at the toll gate. This is due to the toll payment system that is not efficient; especially by using the manual payment system that only accept cash. Manual payment system takes time because every car should stop between 4-6 minutes to make payment on the toll booths. One way to cope with long queues at the toll gates is to use an Electronic Toll Collection system (ETC).

In an effort to increasing its services, PT. Jasa Marga as the operator of toll roads, has started to implement the use of ETC in the form of e-toll-card in 2009. However, the ETC facility is only available in some toll roads only. Later, in 2012, PT. Jasa Marga introduces another alternative payment through ETC that is by using e-toll-pass. E-toll-pass can only be used at toll booths that have Automatic Toll Gate (GTO) system. E-toll-pass is an electronic toll payment system using communication devices installed on the vehicle (onboard-unit / OBU) which is automatically detected by the devices installed on the toll booth / GTO, so the vehicles passing through the toll booth does not need to stop for transaction. Just like the e-toll-card, e-toll-pass can only be used on some toll roads only.

Apart from the benefits in reducing congestion at the toll gates, the adoption of ETC usage in Indonesia is still low, where in the last three years the level of ETC used is only 20% of the total transactions. The low level of use of e-toll card could be because people are afraid of the risks in adopting new technology that they do not know well [1; 2; 3]. Along with efforts to increase the use of ETC, it is necessary to investigate factors that may affect users in choosing ETC to pay for the toll, so it can help PT. Jasa Marga in formulating marketing strategies of ETC. This study aimed to determine factors that affect the user in selecting toll payment system using Nested Logit method.

## 2. METHODOLOGY

Nested logit is one of the Discrete Choice methods that can be used to model problems in the selection of discrete alternatives. Nested Logit basically using logistic regression method to model discrete choices in the form of a hierarchical structure (nested), which describes the relationship between discrete alternatives as the dependent variable ( $Y_i$ ) and factors that influence the choice of discrete alternatives as the independent variables ( $X_{ij}$ ). The goal is to predict the probability of each alternative (the dependent variable) and to estimate the regression coefficients of each independent variable that may affect the dependent variable. Logistic regression is a type of regression that is appropriate for use when the dependent variable is categorical and has value between 0-1, while the independent variable is a variable that has a metric scale.

General notation of the Logit function can be described below [4]:

$$P(z) = \frac{1}{1 + e^{-z}} \quad (1)$$

Where  $P(z)$  is the probability of the dependent variable, and  $Z$  is the utility function of the independent variables. Utility function is a function that comes from all the independent variables used in the model. General notation of a utility function ( $z$ ) is described below:

$$Z = \beta_0 + \beta_1x_1 + \beta_2x_2 + \dots + \beta_ix_i \quad (2)$$

where  $\beta_0$  is a constant parameter, and  $\beta_1, \beta_2, \beta_i$  is the regression coefficient of the variable  $x_1, x_2, x_i$ . Logistic regression models can be classified based on the structure and number of dependent variables in the model. The simplest type of logistic regression is a binomial logit, where the dependent variable is only two. While in the multinomial logistic regression, the number of dependent variable number can be more than two. This study uses a Nested Logit as the number of dependent variable more than two, and the model has the form of a hierarchy.

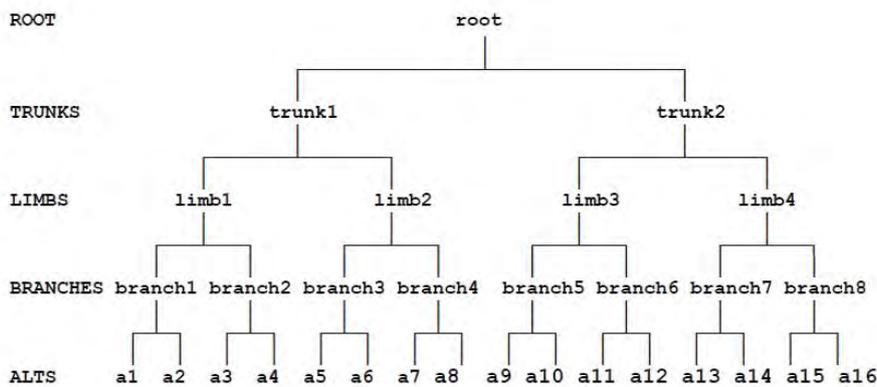

Figure 1: Hierarchical structure of nested logit model

This study uses primary data collected through questionnaires. To simplify the number of trials (the number of questions in the questionnaire), a "fractional factorial design" was used [5]. Hierarchical structure of the model used in this study can be seen in Figure 2 below.

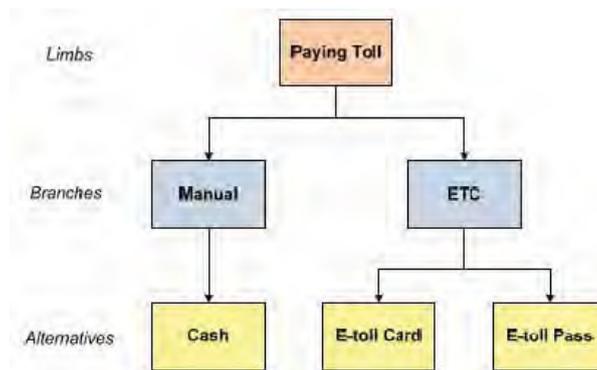

Figure 2: Hierarchical structure of the model in the selection of the toll payment system

Independent variables used in this study are: age, gender, education, marital status, occupation, income, frequency of using toll in a week, toll road which most often used, whether to use the e-toll card, transaction time and length of queue at the toll gate, total saving using ETC, bank provider of the e-toll card, initial investment to be able to use the e-toll card.

Dependent variable is considered to have a strong relationship with the customer behavior that can be formulated in the following utility function [6].

$$U = f(V_1, V_2, V_3, \dots, V_n) \quad (3)$$

where  $U$  is the total value of customer satisfaction, and  $f(V_1, \dots, V_n)$  is the functional relationship of the independent variables that affect the value of total customer satisfaction.

To get the values of the constant and coefficients of the regression function, this study uses the Maximum Likelihood Estimation method (MLE), that is, by maximizing its likelihood function [7]. Mathematically the likelihood function can be expressed as follows:

$$f(x_i) = p(x_i)^{y_i} [1 - p(x_i)]^{1-y_i} \quad (4)$$

Since each observation is assumed to be independent, then the likelihood function is the product of the individual likelihood function, namely:

$$L(\beta) = \prod_{i=1}^n f(x_i) \quad (5)$$

To maximize the likelihood function, it is necessary to find the maximum value of the function by using a differential technique, i.e. by changing the likelihood function into logarithmic form, as follows:

$$\ln L(\beta) = \ln \left( \prod_{i=1}^n f(x_i) \right) = \sum_{i=1}^n \ln f(x_i) \quad (6)$$

Once the utility function is obtained, then the expected number of consumers who choose an alternative toll can be estimated using the Nested Logit method. The probability of each alternative  $j$ , on branch  $b$ , limb  $l$ , and trunk  $r$  ( $j | b, l, r$ ) can be formulated as follows:

$$P(j|b,l,r) = \frac{\exp(\beta' \alpha_j | b,l,r)}{\sum \exp(\beta' \alpha | l,r)} \quad (7)$$

The probability of selecting a particular branch on limb  $l$  and trunk  $r$  can be written as follows:

$$P(b|l,r) = \frac{\exp(\alpha' \gamma | l,r) + \beta | l,r | b | l,r}{\sum \exp(\alpha' \gamma | l,r)} \quad (8)$$

While the probability of choosing limb  $l$ , on trunk  $r$  can be formulated as follows:

$$P(l|r) = \frac{\exp(\beta' \alpha | l,r) + \beta | l,r | l | r}{\sum \exp(\beta' \alpha | l,r)} \quad (9)$$

The probability of selecting trunk  $r$  is formulated as follows:

$$P(r) = \frac{\exp(\beta' \alpha | r) + \beta | r | r}{\sum \exp(\beta' \alpha | r) + \beta | r | r} \quad (10)$$

Hence, the probability of an individual in choosing an alternative can be formulated as follows:

$$P(j,b,l,r) = P(j|b,l,r) \times P(b|l,r) \times P(l|r) \times P(r) \quad (11)$$

### 3. RESULTS AND DISCUSSION

Data were collected from 210 samples, each consisting of 1890 observations (210 x 9 observations). Results of Nested Logit estimation can be seen in Figure 3. From the estimation results, it can be seen that costumers tend to prefer Electronic Toll Collection (ETC) with a probability of 71.53%, where the use of e-toll card is 37.25%, while the e-toll-pass 34.28%. This means that the majority of toll road users still prefer to use e-toll card instead of the e-toll-pass. But the probability is not very significantly different. When viewed from the respondents with a low frequency of using toll (1-2 times a week), it can be seen that the probability of the e-toll-pass is still quite large.

To determine the effect of the independent variables, it is necessary to compare the Wald test with its p-value of each variable. In Wald test, the null hypothesis is  $\beta_i = 0$  (no significant effect), while the alternative hypothesis is  $\beta_i \neq 0$  (there is a significant effect). If the independent variable significantly affect the selection of alternatives (the dependent variable), then the effect can be seen in the utility function (i.e., whether the regression coefficient is positive or negative). If positive, it will add to the utility, otherwise will reduce the utility.

Table 1 shows the result of the Wald test with its p-value. The t critical value for Wald test with  $\alpha = 0.05$  and  $df = 20$ , is 1.96. From Table 1 it can be seen that factors that significantly affect the individual in choosing the toll payment system are: age, gender, frequency of using toll in a week, whether to use the e-toll-card, transaction time and length of queue at the toll gate, and initial investment to be able to use ETC.

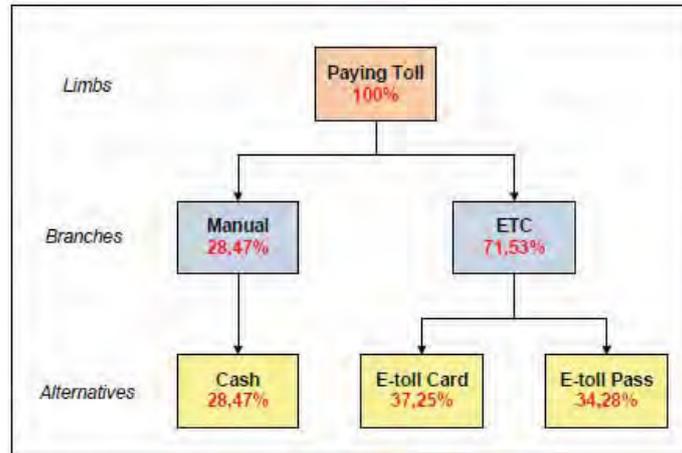

Figure 3: Probability of choosing the Toll Payment System

Table 1: Significance test

Variable		Wald Test		P-value test		Conclusions
		b/St. error	t-critical	P-value	$\alpha$	
Cash	Transaction Time	-2.35486	$\pm 1,96$	0.01853	0,05	reject Ho
E-Card	Transaction Time	-2.16179	$\pm 1,96$	0.030634	0,05	reject Ho
	Saving	0.972375	$\pm 1,96$	0.330864	0,05	accept Ho
	Bank Provider	-1.49746	$\pm 1,96$	0.134274	0,05	accept Ho
	Initial Investment	-2.13543	$\pm 1,96$	0.032726	0,05	reject Ho
E-Pass	Saving	1.91244	$\pm 1,96$	0.05582	0,05	accept Ho
	Bank Provider	-1.7894	$\pm 1,96$	0.073551	0,05	accept Ho
	Initial Investment	2.49134	$\pm 1,96$	0.012726	0,05	reject Ho
Age		-2.11456	$\pm 1,96$	0.034468	0,05	reject Ho
Gender		-2.15549	$\pm 1,96$	0.031124	0,05	reject Ho
Education		-0.97676	$\pm 1,96$	0.328686	0,05	accept Ho
Marital Status		-0.65342	$\pm 1,96$	0.513487	0,05	accept Ho
Occupation		1.94095	$\pm 1,96$	0.052264	0,05	accept Ho
Income		1.83422	$\pm 1,96$	0.066621	0,05	accept Ho
Frequency of using toll		2.17386	$\pm 1,96$	0.029716	0,05	reject Ho
Toll road which most often used		-1.67552	$\pm 1,96$	0.093832	0,05	accept Ho
Whether to use ETC		2.17196	$\pm 1,96$	0.029859	0,05	reject Ho

Based on the gender variable, it can be seen that the proportion of men who choose ETC system is larger than of women. Men who chose ETC is 78%, where women who choose ETC (e-toll card or e-toll pass) is 63.9% and 36.1% of them choose to pay in cash. This shows that men tend to prefer the ETC, while women tend to prefer the manual payment system (in cash). This may be due to the mindset of men who are able to accept and try new technology than women [8].

Table 2 shows the constant and coefficients of the utility functions of each alternative. While the probability of an individual in choosing the toll payment system (i.e. paying by cash, using the e-toll card, or using the e-toll pass) can be seen in formula 12, 13, and 14.

Table 2: Utility Function of each alternative

Choice Alternatives	Alternatives	Utility Function
Alternatives	Cash	- 0,1737 transaction duration - 0,0096 age - 0,0693 gender - 0,0091 education level - 0,0218 marital status + 0,0295 occupation + 0,0007 income + 0,0286 toll frequency - 0,0104 toll segment + 0,1801 use card

(14)

#### 4. CONCLUSIONS

Adoption of Electronic Toll Collection (ETC) by toll road users in the Greater Jakarta (Jabodetabek) area is still low. Using Nested Logit method, this study aims to look at the effect of user characteristics in selecting toll payment system, which consists of 3 discrete choices, i.e. payment by cash, using the e-toll card, and using e-toll-pass.

The results of this study show that the characteristics of toll users are significantly influence the selection of toll payment system. Based on the Wald test, it was found that: age, gender, frequency of using toll in a week, whether to use ETC, transaction time and length of queue at the toll gate, initial investment to be able to use ETC were statistically affect the individual in choosing the toll payment system. The results of this study also showed that the toll payment system most widely used by respondents is the e-toll card (37.2%), followed by e-toll-pass (34.3%), and payment in cash (28.5%), where the proportion of men who use the ETC is more than that of women. Probability of toll users to use the ETC is 71.55%, which shows that the ETC is very potential to be developed in the Greater Jakarta (Jabodetabek) area.

## ABSTRACT

*The study assessed the quality of public Housing in Nigeria, using accommodation capacities, structural qualities and material types indicators with a view to highlight the performance of State Housing Corporations in the provision of quality housing units for sustainable development. The major objectives are to identify the accommodation capacities, structural qualities and material types used in Housing Corporations' developments and analyse the relationship between houses developed by State Ministries of Housing and State Housing Corporations. Literature on relevant topics such as housing policy and housing development efforts in Nigeria were reviewed. Systematic random sampling technique was adopted to sample three states in Nigeria. The study reveals that the quality of houses developed by the State Housing Corporations is less than that of the State Ministries of Housing. Therefore Corporations should improve the materials used in their developments especially by venturing into local materials in their individual states to guarantee sustainable development.*

## Keywords

*Housing quality, public housing, housing development, housing corporations, ministries of housing*

## 1. INTRODUCTION

Housing is one of the most basic necessities of life, and the most important durable and long-time basic need of human life [16]. The relative importance of housing has through the years been generally recognised in the international development agenda. Virtually most of the studies, policies, programmes and strategies for international development agenda ranging from those of the International Year of Shelter for the Homeless (IYSH) between 1987 and 1988, to the Istanbul Declaration, the Habitat Agenda (1996), the Global Strategy for Shelter by the year 2000 (GS – 2000) and the declaration on cities and other human settlements in the New Millennium (2001) had all acknowledged and affirmed the critical importance of housing [3].

Reference [4] quoted a UN estimates (cited in Durand – Lasserre), which indicated that Africa has the world's highest urban growth, with an annual average of 4%. 37% of the total population of Africa live in an urban area and by 2030 the urban population is expected to account for more than 50% of the total population. Over the next two decades, it was estimated that nearly 90% of the population growth in Africa will take place in urban areas [2]. In 2008, the Nigerian housing deficit (to meet such growth) was estimated to be 14 million units, requiring about ₦35 trillion (\$270 billion) to fund. In fact, the World Bank estimated that Nigeria requires the production of about 720,000 housing units annually for 20 years in order to solve the housing needs of the country [25]. The agencies involved in housing delivery in Nigeria comprise of the Federal Mortgage Bank of Nigeria, Private Real Estate Developers, the Primary Mortgage Institutions, Commercial/merchant banks, insurance companies, pension administrators and State Housing Corporations.

## 2. BACKGROUND TO STUDY

Housing Corporations, as state owned corporate bodies operate under the general direction and supervision of Boards of Directors that are appointed by the state governments. The authority to appoint the Boards is almost exclusively vested with the state governors. This means that the Housing Corporations have separate legal personalities and can therefore enter into legally binding agreements and contracts with third parties, and they can sue and be sued in a court of law. The states own and control them by virtue of holding their share capital and appointment of their Board members and key officers [9]. While many agree that these corporations still have a role to play in the housing delivery system, there is a lack of consensus on how to go about making them more effective players in the production of quality units for the housing market. Some have suggested privatisation in one form or the other [10, 11, 9], while others have foresighted that more competition from private developers will force the Corporations to live up to expectation by producing most cost effective, cheapest and high quality houses in their respective states [18]. As there was no empirical evidence to justify their performance on housing quality especially for comparison with other public Housing Institutions, this study bridged the gap by providing in-depth comparative empirical study using performance indicators like accommodation capacity of the houses, structural quality and material types used.

Therefore, this study provided the yardstick that can be used to measure the sustainability or otherwise of the present policies of the State Housing Corporation. The contemporary issue is how far have these Housing Corporations gone in providing quality housing to the citizens? This refers to the quality of the houses as against that of other public housing institutions like State Ministries of Housing. When these issues were localised to the North Eastern region of Nigeria, then this research becomes relevant, soul searching and provide far reaching solution to Housing Corporation problems and the housing dilemma in general, especially with the growing urban needs for housing. The study sets to answer the questions; what is the accommodation capacity of the houses? How is the structural quality of the houses? What types of materials were used in public housing developments in the study area?

The aim of the study is to compare the performance of State Housing Corporations with State Ministries of Housing through housing quality with a view to highlight the performance of State Housing Corporations in the provision of quality housing units for sustainable development. To achieve the aim, the following objectives were forwarded;

- i) To identify the accommodation capacity of the houses developed by State Housing Corporations and State Ministries of Housing in North Eastern Nigeria.
- ii) To analyse the structural quality of the properties developed by State Housing Corporations and State Ministries of Housing in the study area.
- iii) To find out the type of materials used in the developments by State Housing Corporations and State Ministries of Housing in the study area.
- iv) To assess the differences in accommodation capacities, structural qualities and material types of the houses developed by State Housing Corporations and State Ministries of Housing in the study area.

### 3. LITERATURE REVIEW

As far back as 1996, [18] have observed that a little more than 50 years before, fewer than 7% of Nigerians lived in urban centre (that is, settlements with populations of 20, 000 or more). This proportion rose to 10% in 1952 and 19.2% in 1963. It was estimated that it was more than 45% in 1996. In fact, Nigerian cities are among the fastest growing in the world. Nigeria now has more than 7 cities with populations at 1 million; 18 cities, at more than 500,000; 36, at more than 200,000; and 78, at more than 100,000. As well, there were 5,050 towns with more than 20,000 people [18]. Furthermore, in 2002 [21] estimated that there are more than 85 cities in Nigeria with at least 200,000 people. Governments at Federal, State and local levels are therefore concerned with ensuring adequate provision of acceptable minimum standard houses to all households in demand [22] by implementing policies that address the problems of housing development, such as encouraging local materials development[20]. Building materials are believed to constitute 55% to 65% of the total cost of construction input. For instance, the table 1 from [14,15] below shows that iron sheets is the most commonly used roofing material in north eastern Nigeria while local materials such as mud bricks and wood bamboo were the least. These materials are the most available in Nigeria and if used effectively can make quality houses.

*Table 1: Percentage distributions of households in north eastern Nigeria by type of roofing materials*

State	Mud/Mud Bricks	Thatch/ Grass	Wood Bamboo	Iron Sheets	Cement Concrete	Roofing Tiles	Others	Total
Adamawa	10.8	34.5	0.6	53.2	0.7	0	0.2	100
Bauchi	9.9	47.2	1.4	33.3	0	0	8.1	100
Borno	7.8	19.5	1.6	56.2	1.5	0.2	13.1	100
Gombe	17.7	31.7	0.2	45.7	0	1.6	3.1	100
Taraba	14.4	29.4	0.6	43.0	0	0.6	12.0	100
Yobe	31.0	17.2	0.9	45.9	0.1	0	4.9	100

Another critical problem in quality housing production in Nigeria is sustainability of existing housing programmes. [8] asserted that the concept of sustainable development first emerged in the context of ecological and environmental concerns relating to the impact of human activity especially in developed industrial countries on the natural world. Sustainability is about meeting the needs of both the present and the future through clear thinking and sound planning. There is serious concern in Nigeria on sustainability of housing policies, finance, programmes and even housing institutions. It is a tradition in Nigeria and some African countries that whenever there is a change of government, most of the housing policies, finance system, programmes, and even institutions will be reshuffled, not because they are not performing but to suit the junta's interest, while Policy is a yardstick and cannot be thrown away with whenever and wherever the meaningful result is desired. This position might have been the reason for the introduction of the numerous housing-related policies witnessed in Nigeria. This includes the establishment of the Federal Mortgage Bank of Nigeria (1977); enactment of the Land Use Act (1978); founding of primary mortgage institutions (1989); floating of the Federal Housing Authority (1990); launching of a National Housing Policy (1991); introduction of the National Housing Fund (1992); initiation of the 'Housing for all by the year 2000' campaign; endorsement of and prosecution of the Vision 2010 crusade; formation of the various National Development and Rolling Plans; coming on board of an autonomous Ministry of Housing and Urban Development (2003); ratification of the NEPAD Initiative

and the Millennium Development Goals (MDGs); articulation of the National Policy on Housing and Urban Development (2004); extensive re-structuring of the banking sector (2006) and a host of such other efforts [1,19]. [24] complained that “with all beautiful programmes put forward to solve the housing problems in Nigeria, the problems of execution at the managerial level have been the stumbling block of these programmes”. The numerosity in housing policies in Nigeria may be blamed for the inconsistencies and overlap in their provisions. This factor further brings confusion to the investing public as they end up not knowing which policy or legislation takes precedence over the other to guide their housing developments.

The importance of Housing Corporations in housing development in Nigeria and worldwide cannot be overemphasized in view of the critical need for housing. [6] pointed that one of the major efforts by the government aimed at increasing housing delivery is the establishment of Federal Housing Authority and the counterpart State Housing Corporations. [5] observed that internationally, housing investments constitute 2 – 8% of Gross National Product (GNP), 20 -50% of household expenditure that indicates a significant correlation between the housing sector and the level of a country’s level of economic growth and development. Housing corporations have over the years assumed a strategic role in the housing delivery process. This can be attributed to the ever-widening housing delivery gap and the need to bridge the gaps. Although the appellation varies in different countries, the functions of the Housing Corporations are usually the same and are essentially geared towards housing delivery. In Nigeria, there are State Housing Corporations of which their names are inclined to the respective state and there is Federal Housing Authority (FHA), in Kenya, they called it National Housing Corporation (NHC), in Tunisia, Societe Nationale Immobiliere de Tunisie (SNIT), Botswana, The Botswana Housing Corporation (BHC), in Namibia, National Housing Enterprise (NHE), Tanzania, National Housing Corporation (NHC), and in Senegal, Office des Habitations a LogerModere (OHLM) to mention but a few [5].

#### 4. RESEARCH METHODOLOGY

The study was carried out through the interview and administration of questionnaire containing various questions on the components of the houses; such as number of bedrooms, living rooms, toilets, kitchens, availability of a garage, fence and materials used in ceiling, roof and floor. The data required for the purpose of this study were grouped and presented in the analysis according to the objectives and scope of the study [13] as demonstrated in table 2 below;

Table 2: Data requirement

Accommodation Capacity	Structural Qualities	Material Qualities
Number of Bedroom	Kitchen Quality	Windows/Doors Materials
Number of Kitchen/Store	Toilets Quality	Ceiling Materials
Number of Toilets/Baths	Doors/Windows Quality	Roofing Materials
Number of Living Rooms	Ceiling Quality	Wall Materials
Open Space	Floor Quality	Floor Materials
Fence	Roofing Quality	
Garage		

A total number of 500 questionnaires were administered and 311 were collected. The parameters used in measuring the quality variables of the houses on the questionnaire were presented in table 3 and table 4 below. Individual options were scaled based on their importance to the general public. Hence, an institution with higher points at each group and or after summation of the groups is determined to have better quality than the other.

Table 3: Measurement scale on accommodation

Questions	Scale			
	4	3	2	1
No. of rooms	Otherwise	5-6	3-4	1-2
No. of kitchen/store		Above 2	1-2	None
No. of toilets/baths		Above 2	1-2	None
No. of living room(s)		Above 2	1-2	None
Open space			Available	Not available
Fence			Available	Not available
Extra space			Available	Not available
Garage			Available	Not available

Table 3 above presents the parameters used in measuring accommodation spaces in the properties, with four (4) options given.

Table 4: Measurement scale on structural quality

Questions	Scale		
	3	2	1
Kitchen	Good	Fair	Bad
Toilets	Good	Fair	Bad
Doors/Windows	Good	Fair	Bad
Ceiling	Good	Fair	Bad

Floor	Good	Fair	Bad
Roofing	Good	Fair	Bad

There are three options given on structural quality of the house components in table 4 above. This was because the material and the accommodations were measured separately.

Table 5: Measurement scale on material type

QUESTIONS	SCALE				
	5	4	3	2	1
Window/door	Glass	Glazed Aluminium	Metal	Wood	Otherwise
Ceiling	Suspended	Asbestos sheet	Wooden	Plain Board	Otherwise
Roofing			Long span aluminium	Asbestos	Corrugated Iron sheet
Wall			Bricks	Sandcrete blocks	Mud
Floor	Tiles	Ceramics	Cement secrete	PVC	Otherwise

There are five (5) options given on materials as shown in table 5 above.

## 5. DATA PRESENTATION AND ANALYSIS

The data collected to answer the Research Questions were statistically presented in mean tables and descriptively analysed. The term Housing Corporations and Ministries of Housing were abbreviated 'Corps' and 'Mins' respectively. Analysis of the data collected for hypotheses was carried out with t-test statistical tool and descriptively analysed.

### 5.1 Accommodation Capacity of Houses

Table 6: The mean for accommodation capacity of houses developed by corporations and ministries

	Bedroom No.		Kitchen/Store No.		Toilets/Baths No.		Living Rooms No.		Open Space		Fence		Extra Space		Garage	
	Corps	Mins	Corps	Mins	Corps	Mins	Corps	Mins	Corps	Mins	Corps	Mins	Corps	Mins	Corps	Mins
Mean	1.44	1.70	2.04	2.05	2.04	2.37	2.05	2.19	1.90	1.77	1.54	1.50	1.71	1.78	1.19	1.49
Std. Error of Mean	0.045	0.044	0.016	0.024	0.017	0.039	0.023	0.037	0.025	0.032	0.042	0.038	0.039	0.032	0.045	0.046
Mode	1	2	1	2	1	2	1	2	2	2	2	1	2	2	1	1
Std. Deviation	0.527	0.575	0.186	0.312	0.204	0.508	0.277	0.485	0.301	0.425	0.500	0.501	0.457	0.413	0.531	0.598
Variance	0.277	0.331	0.035	0.097	0.042	0.258	0.077	0.235	0.091	0.180	0.250	0.251	0.209	0.171	0.282	0.357

The accommodation capacity of most houses developed by State Housing Corporations in North Eastern State are 1 – 2 bedrooms with 1 – 2 number of kitchens, toilets and living rooms. There are open spaces, fences and extra spaces for future development in the houses. There are more houses without garages than those that have it. However, when compared with the houses developed by State Ministries of Housing, It can be seen that the major areas of diversion are in the number of bedrooms, the houses developed by State Ministries of Housing are mostly 3-4 bedrooms capacity in contrast to 1-2 bedrooms with more kitchens/stores, toilets/baths, living rooms and availability of fencing.

Table 7: The t – test of significance on mean responds from corporations and ministries on accommodation capacity

		Test for Equality of Variances		t-test for Equality of Means				
		F	Sig.	t	df	Sig. (2-tailed)	Mean Difference	Std. Error Difference
NO. OF ROOMS	Equal variances assumed	0.415	0.520	-4.010	309	0.000	-0.253	0.063
	Equal variances not assumed			-4.045	305.097	0.000	-0.253	0.063
NO. OF KITCHENS	Equal variances assumed	7.843	0.005	-0.565	309	0.573	-0.017	0.030
	Equal variances not assumed			-0.592	284.401	0.554	-0.017	0.029
NO. OF TOILETS	Equal variances assumed	407.478	0.000	-7.102	308	0.000	-0.325	0.046
	Equal variances not assumed			-7.654	232.937	0.000	-0.325	0.042
NO. OF LIVING ROOMS	Equal variances assumed	58.668	0.000	-2.971	309	0.003	-0.137	0.046
	Equal variances not assumed			-3.127	278.262	0.002	-0.137	0.044
OPEN SPACE	Equal variances assumed	45.217	0.000	3.141	309	0.002	0.134	0.043
	Equal variances not assumed			3.246	303.114	0.001	0.134	0.041
FENCE	Equal variances assumed	1.052	0.306	0.743	308	0.458	0.042	0.057
	Equal variances not assumed			0.743	295.483	0.458	0.042	0.057
SPACE FOR DEVELOPMENT	Equal variances assumed	9.370	0.002	-1.549	309	0.122	-0.076	0.049
	Equal variances not assumed			-1.534	283.512	0.126	-0.076	0.050
GARAGE	Equal variances assumed	30.336	0.000	-4.624	309	0.000	-0.300	0.065
	Equal variances not assumed			-4.679	306.921	0.000	-0.300	0.064

Table 7 above shows that there is a significant difference in Number of Rooms, Toilets and Garage at 0.001 levels, while Number of Living Rooms and Availability of Open space are significant at 0.05 level. There is no significant difference in Number of Kitchen, Fence and Space for Future Development. In addition, t is significant within the institutions at 0.001 in Number of Toilets, Living Rooms, Open space and Availability of Garage. It is also significant in Space for Future Development. In contrast, t is not significant within the institutions in Number of Rooms and Fence.

## 5.2 Structural Qualities of Houses Produced by State Housing Corporations

Table 8: Structural qualities of houses developed by state ministries of housing

	Kitchen Quality		Toilets Quality		Doors/Windows Quality		Ceiling Quality		Floor Quality		Roofing Quality	
	Corps	Mins	Corps	Mins	Corps	Mins	Corps	Mins	Corps	Mins	Corps	Mins
Mean	2.50	2.65	2.41	2.58	2.50	2.47	2.42	2.35	2.44	2.62	2.47	2.71
Std. Error of Mean	0.044	0.043	0.045	0.043	0.043	0.044	0.047	0.044	0.047	0.041	0.045	0.039
Mode	3	3	2	3	3	2	3	2	3	3	3	3
Std. Deviation	0.578	0.509	0.583	0.509	0.558	0.515	0.613	0.521	0.615	0.487	0.588	0.458
Variance	0.334	0.259	0.339	0.259	0.311	0.266	0.376	0.271	0.379	0.238	0.346	0.209

Table 8 above presents that the kitchen, doors and windows, ceiling, floor and roofing components in Housing Corporation developments were of good quality with 3points each, and toilets were of fair quality with 2points. In contrast, the kitchen, toilet facilities, floor and roofing materials were also of good quality in Ministries developments, while that of doors and ceilings were of fair quality.

Table 9: The t – test significance of mean responds from state housing corporation and state ministries of housing on structural quality

		Test for Equality of Variances		t-test for Equality of Means				
		F	Sig.	t	df	Sig. (2-tailed)	Mean Difference	Std. Error Difference
KITCHEN QUALITY	Equal variances assumed	10.811	0.001	2.404	308	0.017	0.150	0.063
	Equal variances not assumed			2.435	306.000	0.015	0.150	0.062
TOILET QUALITY	Equal variances assumed	5.642	0.018	2.673	306	0.008	0.169	0.063

		Test for Equality of Variances		t-test for Equality of Means				
		F	Sig.	t	df	Sig. (2-tailed)	Mean Difference	Std. Error Difference
DOOR QUALITY	Equal variances not assumed			2.708	304.836	0.007	0.169	0.062
	Equal variances assumed	2.193	0.140	-0.360	306	0.719	-0.022	0.062
CEILING QUALITY	Equal variances not assumed			-0.363	301.830	0.717	-0.022	0.061
	Equal variances assumed	10.542	0.001	-1.139	306	0.255	-0.075	0.066
FLOOR QUALITY	Equal variances not assumed			-1.157	305.675	0.248	-0.075	0.065
	Equal variances assumed	17.935	0.000	2.814	306	0.005	0.181	0.064
ROOF QUALITY	Equal variances not assumed			2.877	305.594	0.004	0.181	0.063
	Equal variances assumed	33.732	0.000	3.892	306	0.000	0.238	0.061
	Equal variances not assumed			3.986	305.118	0.000	0.238	0.060

Table 9 reveals that there is a significant difference between the institutions in Kitchen Quality, Quality of Toilet, Floor Quality and Roof Quality. There is also a significant difference within the institutions in the Ceiling, Floor and Roofing Qualities, while there is no significance in Quality of doors both between and within the institutions.

### 5.3 The material quality of houses produced by State Housing Corporations

Table 10: Material qualities of houses developed by state Housing Corporation

	Windows/Doors Materials		Ceiling Materials		Roofing Materials		Wall Materials		Floor Materials	
	Corps	Mins	Corps	Mins	Corps	Mins	Corps	Mins	Corps	Mins
Mean	4.11	3.68	2.91	3.77	2.39	2.79	2.07	2.09	3.38	3.89
Std. Error of Mean	0.065	0.080	0.111	0.073	0.077	0.043	0.036	0.031	0.071	0.081
Mode	4	4	2	4	3	3	2	2	3	3
Std. Deviation	0.769	1.043	1.308	0.952	0.911	0.566	0.427	0.404	0.844	1.065
Variance	0.591	1.088	1.711	0.907	0.830	0.320	0.182	0.163	0.712	1.135

The response in table 10 shows that glass doors/windows, plain board ceiling, long span aluminium, sandcrete block wall and cement in floors were widely used. The only difference with properties developed by State Housing ministries is in ceiling materials where the suspended ceiling materials were used instead of plain boards. The table 11 below presents the statistical relationship between material qualities of housing units developed.

Table 11: The t – test of significant on mean responds from corporations and ministries on material type

		Test for Equality of Variances		t-test for Equality of Means				
		F	Sig.	t	df	Sig. (2-tailed)	Mean Difference	Std. Error Difference
DOOR TYPE	Equal variances assumed	22.962	0.000	4.058	309	0.000	0.430	0.106
	Equal variances not assumed			4.180	305.798	0.000	0.430	0.103
CEILING TYPE	Equal variances assumed	43.656	0.000	-6.737	309	0.000	-0.865	0.128
	Equal variances not assumed			-6.533	247.654	0.000	-0.865	0.132
ROOFING TYPE	Equal variances assumed	102.973	0.000	-4.694	309	0.000	-0.397	0.084
	Equal variances not assumed			-4.490	222.489	0.000	-0.397	0.088
WALL TYPE	Equal variances assumed	1.614	0.205	-0.345	309	0.730	-0.016	0.047
	Equal variances not assumed			-0.343	290.031	0.732	-0.016	0.047
FLOOR TYPE	Equal variances assumed	55.354	0.000	-4.607	309	0.000	-0.510	0.111
	Equal variances not assumed			-4.714	308.680	0.000	-0.510	0.108

It is clear from the table 11 that there is a significant difference in between the institutions in types of Door, Ceiling, Roofing and Floor materials used. It can be seen that only in Wall Type there is no significant difference. However, the table also reveals that there is a significant difference within the institutions in Types of Doors, Ceiling, Roofing and Floor Types used and there is also no significant difference in the Wall as between them mentioned above.

## 6. DISCUSSION OF FINDINGS

The reveals that State Housing Corporations were mostly involved in the production of 1-2 bedrooms, State Ministries of Housing was mostly involved in the production of 3-4 bedroom houses, the types of material and quality in State Housing Corporation houses were inferior to that of the State Ministries of Housing. The study identified two major quality deficient areas which are quality of toilets (table 8) and type of ceiling (table 10). These are the only areas, apart from the number of rooms, that the State Housing Corporation units were ranked lower than State Ministries of Housing and at the same time showing a significant level of difference between the institutions. The State Housing Corporations also have an edge over State

Ministries of Housing in provision of a fence (table 6), doors/windows and ceiling quality (table 8) but there is no significant difference between them. Therefore, the quality of houses developed by the State Housing Corporations is lower than that of State Ministry of Housing.

The findings of this study confirmed the criticism levelled against State Housing Corporations by [5]. He argued among other things that quality of houses developed by Housing Corporations is generally low which affect programmes and delivery capabilities. The findings of this study were further confirmed by personal interviews with staff of both institutions and physical observation of the houses. Hence, as good housing quality is important to the economic development of the households and quality of life [17] and also reduces cost of maintenance, hence encourages saving and effective economic planning. Housing Corporations should improve on the utilisation of standard building material types in their respective states. This can be achieved through research on locally available building material resources. Housing Corporations should as a matter of importance devise a means of utilising their microfinance banks and security development institutions in funding such researches toward improving quality housing developments. Reference [12] opined that “the answer to the question whether Housing Corporations should be privatised or commercialised can best be given by individual (states) considering their circumstances as revealed by this study. This study agreed that while some states are really trying, some need improvement as far as quality of houses is concern. Hence, they are not the required solution for efficient housing delivery in the region.

## 7. CONCLUSION

The continued government participation in housing delivery has generated a wide range of argument and concerns amongst analysts and researchers. Housing Corporations are very vital institutions for implementation of public housing programmes but they are poorly managed. The efforts of the State Housing Corporations in North Eastern Nigeria need applause here, as in most of the 18 number of the indicators used, their performance are relatively good. This shows that with little effort, Housing Corporations can be symbols of efficiency which can lead other public housing development institutions toward the provision of quality houses for sustainable public housing development.

### ABSTRACT

In recent years, a topic of body-centric wireless communications (BCWCs) has received an increasing amount of attention due to their potential applications in several areas, such as personal healthcare, identification system, entertainment and medical applications. Above all, many researchers have considered personal healthcare as the biggest potential application with all kinds of wearable wireless devices which can be used in on-body and off-body communications. For on-body communications, the communication range is limited on the human body. Both wearable transmitter and receiver are mounted on the surface of the human body, and biophysical signals obtained from body sensors can be transmitted along the human body. Off-body communications usually mean the communication between a device on the surface of the human body and a near external device. At least one antenna is located on the human body and biophysical signals can be transmitted from the antenna on the human body to the external device. For on-body communications, relatively low frequency bands (tens of MHz) are of great interest to a number of researchers, while for the off-body communications, 2.45 GHz ISM (industrial, scientific and medical) band is a good candidate, because higher data rate can be carried out and license is not needed. In this review paper, we introduce a simple dual-mode wearable antenna for BCWCs. In on-body mode, the received voltage at 10 MHz and in off-body mode, the reflection coefficient and radiation patterns at 2.45 GHz will be investigated. We consider a practical situation where the proposed antenna can be used for a medical care system. Some wearable and implantable sensors are mounted on or implanted into the human body. The proposed dual-mode antenna is mounted on the human arm. Medical information such as body temperature, blood pressure and heartbeat is transmitted from the sensors at 10 MHz to the receiver which is of dual-mode function for on-body communication. After receiving the information, the collected medical data can be transmitted from the antenna to an external device at 2.45 GHz. For a further study, we will develop more practical and useful wearable antennas for BCWCs.

### ABSTRACT

Since invention of *transistor* in 1948, dopant atoms have played key roles in semiconductor technology, and we have utilized averaged effect of a statistically large number of dopant atoms on electronic properties. However, with continuous miniaturization of transistors in silicon integrated circuits, the number of dopant atoms is dramatically reduced, reaching even below ten in the nanometer-sized channel. Thus, we are facing at huge fluctuation in  $I$ - $V$  characteristics of transistors due to *individuality of dopant atoms*. Nowadays, many researchers in Si technology are working to suppress the dopant-induced fluctuation.

However, our direction is different, and we are challenging to create a new type of devices, that is, *atom transistors*. The atom transistors are promising in terms of the highest density of transistors and the lowest consumption energy in integrated circuits. We believe that the single-dopant-atom technology opens up future of nanoelectronics.

**Abstract**—We have developed electron beam excitation assisted optical microscope, and demonstrated its resolution higher than 50 nm for live cell observation. In the microscope, a light source in a few nanometers size is excited by focused electron beam in a luminescent film. The microscope makes it possible to observe dynamic behavior of living biological specimens in various surroundings, such as air or liquids. Scan speed of the nanometric light source is faster than that in conventional near-field scanning optical microscopes. The microscope enables to observe optical constants such as absorption, refractive index, polarization, and their dynamic behavior on a nanometric scale. We also have developed a direct electron-beam excitation assisted optical microscope with a resolution of a few tens of nanometers and it can be applied for observation of dynamic movements of nanoparticles in liquid. In the microscope, fluorescent materials are directly excited with a focused electron beam. The direct excitation with an electron beam yields high spatial resolution since the electron beam can be focused to a few tens of nanometers in the specimens. We demonstrated an observation result of living CHO cells. The microscope opens new microscopy applications in nano-technology and nano-science.

**Keywords**—Optical microscopy, electron scanning microscopy, near-field optical microscopy, nano-imaging, bio-imaging, cathodoluminescence

## I. INTRODUCTION

Nanoimaging of specimens in liquid conditions are highly required in various applications such as analysis of colloidal solutions, observation of microcrystal growth and self-assembly process, etc. Especially, imaging of biological specimens with high resolution is crucial for a deeper understanding of cell functions. Fluorescence microscopy has been widely used to analyze the dynamic behavior of cellular components in living cells, because stained molecules of interest in the specimens can be imaged with high contrast [1, 2]. In addition, the use of light for cell imaging enables relatively non-invasive observations under physiological conditions. However, many structures in cells are small to be resolved with a standard optical microscope as a consequence of the finite resolution due to the diffraction limit of light.

Recently, several concepts for super-resolution techniques have been developed and proposed for observations of nanostructures in cells [3–6]. Fluorescence microscopy is required to become an even more useful tool for biological analysis with nanometer-scale resolution.

Near-field optical scanning microscopes [7-9] (NSOMs) are possible to overcome the resolution limitation, because they confine illumination area on the specimen by small aperture of metal-coated fiber probe [10-13], or apertureless tip probe [14,15], optically-trapped gold particle [16], solid immersion lens [17], non-optically probing technique [18]. Images are acquired by scanning the small aperture near specimen surface while keeping a constant distance from the specimen surface. A common method of keeping probe-specimen distance is detection of shear forces between the end of the near-field probe and the specimen surface [19,20].

In the NSOMs low throughput [11] of the small aperture limits the scanning speed, because accumulation of signal is required in order to obtain a higher signal-to-noise ratio. Throughput of the fiber probe is given by  $< (d/\lambda)^4$  where  $d$  is the diameter of the aperture and  $\lambda$  is wavelength. Signal-to-noise ratio decreases in proportion to the fourth power of the diameter of the aperture, and worsens rapidly with increasing the resolution. Therefore, the scanning speed of the fiber probe is restricted by difficulty of keeping the probe-specimen distance and low signal-to-noise ratio. The low frame rate of the NSOMs limits the applications to observe dynamic process of living biological specimens or other fast phenomena.

Here, we present electron beam excitation assisted optical (EXA) microscope in which electron beam focused on a luminescent thin film excites nanometric light source near the specimen. The light emission is well known as cathodoluminescence [21,22]. It is possible to excite a light source of a nanometric size, because electron beam can be focused to a few nanometers. EXA microscope combines scanning electron microscopy that has nanometric resolution and optical microscopy that is advantageous to dynamic observation of living biological specimens.

## II. 2. DEVELOPMENTS OF EXA OPTICAL MICROSCOPY

Figure 1(a) shows schematic diagram of the proposed EXA microscope. An electron beam is focused on a luminescent film. A specimen is put on the luminescent film directly. The inset in Fig. 1(a) shows magnified image of the luminescent film and the specimen. Nanometric light source is excited in the luminescent film by the focused electron beam. The light source illuminates the specimen, and the scattered or transmitted radiation is detected with a photomultiplier tube (PMT). The light source is scanned by scanning of the focused

electron beam in order to construct on image. Figure 1(b) shows the structure of sample holder used in EXA microscope. A square aperture of  $100 \times 100 \mu\text{m}^2$  size was fabricated on silicon substrate and sealed by SiN film with a thickness of 50 nm.

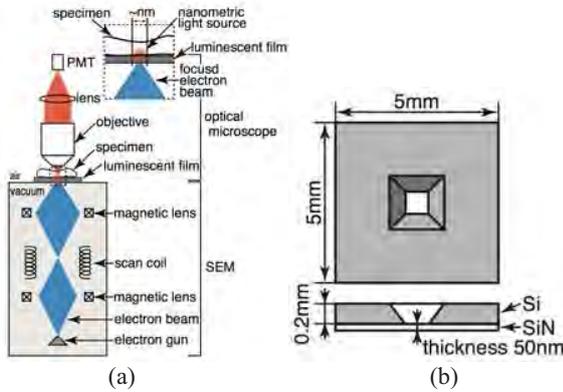

Fig. 1. (a) Schematic diagram of EXA microscope. The scanning electron microscope (SEM) is used for excitation and scanning of nanometric light source and the optical microscope is used to detect the light. (b) Layout of silicon nitride membrane.

In EXA microscope, focusing of the electron beam confines the size of optical spot instead of small apertures used in conventional NSOMs. A few tens nanometer size optical spot is produced easily, by electron beam focused in a few nanometers area. The microscope has a potential to observe dynamic activities of living biological specimens with video frame or faster frame rate, because electron beam can be scanned with modulation of magnetic or electric field without any mechanical moving parts. Higher signal-to-noise ratio is possible, by using highly efficient luminescent film for electron beam irradiation.

Another unique advantage of EXA microscope is the possibility to observe specimens in various environments, such as air, gases, liquids, as well as vacuum. The luminescent film separates air or liquids surrounding specimens from vacuum where electron beam is focused. Since electron beam energy is converted to light at the luminescent film, and scattered and transmitted radiation from the specimen is detected as signal, vacuum is not required on the specimen side. If the luminescent film does not have enough strength for the separation, one may support the film with transparent thin film.

To verify feasibility of the high resolution EXA microscope, we used silicon nitride (SiN) film of 50 nm thickness as a luminescent material [23] and all optical components were inserted in vacuum chamber of scanning electron microscope (SEM) (JEOL, JSM-6390). SiN film emits blue to ultra-violet (UV) light by irradiation of electron beam. We confirmed in a preliminary experiment that SiN film of 50 nm thickness had enough strength to separate 1 atm air pressure from vacuum.

In the experiment, electrons were accelerated with 10 kV voltage and focused to a 8 nm diameter spot on the SiN film to excite nanometric light source. Scattered or transmitted light

from the specimen was collected by a lens with numerical aperture 0.65 and detected with a photomultiplier tube (PMT) (Hamamatsu Photonics, R7400-U20). Images were reconstructed from the signal detected with raster scanning of electron beam using a computer. We used polystyrene latex spheres dispersed on the SiN film directly as specimens for resolution verification. The latex spheres were dispersed in monolayer, which was confirmed with an atomic force microscope (Seiko, SPI-3800).

Figure 2(a) shows observation results of latex spheres of 50 nm diameter with EXA microscope. Figure 2(b) shows intensity distribution on the solid line indicated in Fig. 2(a). It is recognized that EXA microscope can resolve aligned spheres of 50 nm diameter clearly. We believe that the developed EXA microscope has a potential to achieve a few tens nanometer resolution because electron beam can be focused in a few nanometers.

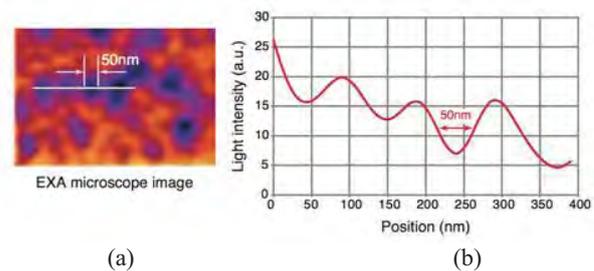

Fig. 2. (a) Observation image of 50nm diameter latex spheres with EXA microscope. (b) Intensity distribution on the solid line indicated in (A). The latex spheres were dispersed in a monolayer on SiN surface.

### III. 3. D-EXA MICROSCOPY FOR DIRECT EXCITATION

We also have developed a direct electron-beam excitation assisted optical microscope (D-EXA microscope) combining a scanning electron microscope (SEM) with a fluorescence microscope [24,25]. The D-EXA microscope is another type of the super-resolution fluorescence microscopes, which has the advantages of spatial resolution of a few tens of nanometers, and the ability to image dynamic behavior of nanoparticles in liquid conditions. In the microscope, fluorescent particles, which is can be used for labeling of biological specimens, are placed on the film used as the electron transparent window, and irradiated with a focused electron beam to directly excite luminescence. A high spatial resolution is achieved by direct electron beam excitation through the film, since the electron beam can be focused in a smaller region than that of light even if some of the electrons are scattered in the film. Specimens can be observed in their native state in a liquid environment, because the film is used to separate the environment of the specimen from the vacuum in the microscope. The excited luminescence with the electron beam is the so-called cathodoluminescence [26-29]. In this work, we observed the dynamic behavior of fluorescent nanoparticles in solution, and demonstrated the application to live cell imaging in culture

solution using a prototype D-EXA microscope in order to demonstrate the potential for live cell imaging.

Figure 3 shows the principle of direct excitation with a focused electron beam in the D-EXA microscope. Specimens are directly placed on a thin film, and irradiated with an electron beam through the thin film. The focused electron beam directly excites luminescence. The electron beam can be focused to an area of approximately 2 nm in diameter in vacuum [29], and the focus spot was broadened in a few tens nanometers region by electron scattering in the film and specimens. The scattering was estimated with Monte-Carlo simulation [30]. High spatial resolution can thus be realized by exciting with this focused electron beam.

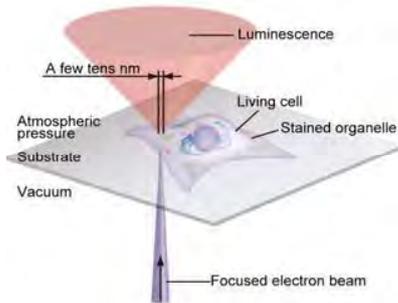

Fig. 3. Principle of the D-EXA microscope.

Since the thin film separates the vacuum from the environment such as air or liquid where the specimens are placed, the specimens do not need to be in vacuum and it is possible to observe the dynamic behavior under various conditions. The D-EXA microscope allows for the analysis of cell functions in the nanometer-scale under physiological conditions.

We selected 100 nm zinc oxide (ZnO) nanoparticles (SIGMA-ALDRICH, PN. 544906) as fluorescent materials that can be excited with an electron beam. The microscope also required an electron-transparent film to separate the vacuum section from atmospheric pressure to observe specimens in a liquid. A silicon nitride ( $\text{Si}_3\text{N}_4$ ) film was employed as the thin film. The thickness of the film was 50 nm with a size of  $50 \mu\text{m} \times 50 \mu\text{m}$ .

We observed the movements of ZnO nanoparticles in ultrapure water to demonstrate the potential to observe the dynamic behavior of nanoparticles in a liquid. ZnO nanoparticles move by convective flow in the droplet. The observation was started just after the droplet containing ZnO nanoparticles was dropped on the thin film. The dynamic behavior of the moving nanoparticles was observed and tracked by time lapse imaging.

The observation result is shown in Figs. 4(a)-4(e) show five frames from the video. The video was acquired at 3 fps with the size of  $256 \times 256$  pixels. Figures 4(f)-4(j) show magnified images of the respective areas indicated by the squares in Figs. 4(a)-4(e). In Figs. 4(b) and 4(c), the ZnO nanoparticles indicated by the dashed circle disappeared in the subsequent image. Since the electron beam was focused on the surface of

the thin film, nanoparticles move away from the surface of the film and the nanoparticles disappeared from the observed image. On the contrary, when the ZnO nanoparticles moved close to the surface of the film, the nanoparticles were observed in the luminescence image as shown within the solid circles in Fig. 4(c). Figures 4(f)-4(j) show ZnO nanoparticles moving along the surface of the film. As shown in Figs. 4(f)-4(j), the ZnO nanoparticle, indicated by an arrow in the figures, moved in a planar direction with changing luminescence intensity. Figure 4(k) shows a track of the moving ZnO nanoparticle. The ZnO nanoparticle moved a total of  $1 \mu\text{m}$  over 96 s. We also observed other nanoparticles randomly moving with the change in the luminescence intensity. The change in the luminescence intensity showed that the nanoparticles move up and down within the focal plane of the electron beam.

These results demonstrated that fluorescent materials and their movements in a liquid can be observed with direct electron beam excitation in the D-EXA microscope.

We observed living MARCO-expressing CHO cells, using the D-EXA microscope to confirm the potential for live cell imaging. In order to observe cells in our method, cells were directly cultured on the  $\text{Si}_3\text{N}_4$  film. After incubation, the culture dish was set to the specimen holder of the D-EXA microscope and observed.

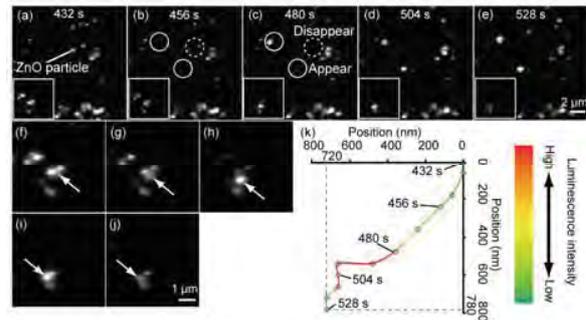

Fig. 4. Observation results of the movements of 100 nm ZnO nanoparticles in a water solution. (a)-(e) Time lapse images of the movements of ZnO nanoparticles. (f)-(j) Magnified images of the areas indicated by the squares in Figs. 4(a)-4(e). The ZnO nanoparticle indicated by the arrow moved along the surface of the film. (k) An analysis of the movement of the ZnO nanoparticle.

Figure 5(a) shows a luminescence image of the cells acquired with the D-EXA microscope, and Fig. 5(b) shows a phase contrast microscope image. Cells were observed in culture solution without any treatments, such as fixation and drying. The shape of each cell was clearly recognized and some bright spots were observed in cells. We believe that the bright spots indicated with arrows were auto-fluorescence of intracellular granules and light-grey regions were auto-fluorescence of cell membranes. It is clearly demonstrated that the D-EXA microscope is useful tool for observation of living biological cells in physiological conditions.

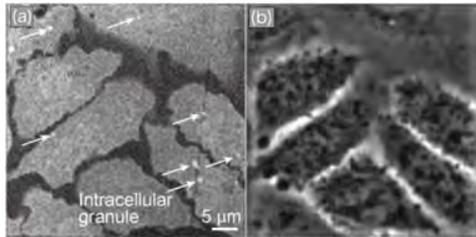

Fig. 5. Observation results of living cells using the D-EXA microscope. (a) A luminescence image of living MARCO-expressing CHO cells in culture solution without any treatments. The intracellular granules indicated with arrows are observed as white spots and the cell membranes are observed as light-gray contrast against the dark-gray background. (b) A phase contrast microscope image of the living cells. It represents the same area as Fig. 5(a).

#### IV. 4. CONCLUSION

We proposed a new type high-resolution optical microscope and demonstrated its resolution higher than 50 nm. The concept of EXA microscope is an integration of a high-resolution SEM and an optical microscopy suitable for observation of living biological specimens and spectroscopic analysis of materials. Due to the conversion of the electron beam to light source, specimens can be placed in air or liquids, as well as vacuum. Since electron beam can be scanned at a fast speed, it is possible to observe dynamic behavior of specimens with fast frame rate. We expect that the EXA microscope can resolve the scanning speed limitation of conventional NSOMs due to low signal-to-noise ratio at higher resolution, and difficulty of maintaining the probe-specimen distance.

It is possible to apply EXA microscope in a variety of research fields by using functionalized thin film as the light emission layer. Fluorescent imaging can be obtained with UV emission materials, and spectroscopic properties of specimens can be analyzed by using a luminescent layer emitting in a broad wavelength region. Dot-array structure [31,32], nanohole array [33] and nano-cylinder array structure [34] in luminescent films may be effective to reduce electron scattering in luminescent films.

We have also developed the D-EXA microscope as a technique with high spatial resolution beyond the diffraction limit of light. A spatial resolution greater than 100 nm was achieved for the D-EXA microscope and the dynamic behavior of moving nanoparticles in water was observed by time-lapse imaging. We also demonstrated luminescence image of living cells in culture solution without any treatments. The D-EXA microscope can be applied for the analysis of cell functions in live cells stained with fluorescent materials such as ZnO.

In future work, we need to evaluate the damage to the specimen by electron beam irradiation as well as optimization of the acceleration voltage of the electron beam, the film thickness and the material in order to minimize any damage to the sample and improve the spatial resolution. We believe that EXA and D-EXA microscopes open new microscopy

applications because it realizes a new tool in nano-technology and nano-science.

**Abstract**— The purpose of this paper is to investigate an application of a piezoresistive microcantilever for gas sensor using a dynamic mode operation. The working principle of the microcantilever sensor is based on the measurement of microcantilever deflection or resonance frequency change due to the objects attached on the microcantilever surface. The measurement was performed by using Wheatstone bridge circuit, which is constructed by two piezoresistors in the microcantilever and two external resistors, in order to measure the resonance frequency shift of the microcantilever vibration. The result shows that the voltage of oscillation peak-to-peak from the output of Wheatstone bridge circuit, which represents the microcantilever vibrations, decreases with the time due to the gas detection. This occurs due to the resonance frequency shift caused by the addition of gas molecules mass on the microcantilever surface. This result indicates that the developed system can be used as gas sensor.

## I. INTRODUCTION

In a last decade, a development of a microelectromechanical system (MEMS) technology has promoted an innovative microcantilever-based sensors. Such sensors have big potential to replace many conventional sensor systems because of a relatively low cost of production, high sensitive, rapid response, and a reduced size of the active area (typically  $10^{-6}$  cm<sup>2</sup>) [1-3]. Moreover, the microcantilever sensors have been investigated in the fields of environment, medicine, chemistry, physics, and biology. Basic principle of the microcantilever sensor is a detection of the microcantilever bending, so called as deflection, due to the attachment of the objects (bacteria, virus, glucose, molecule gas, etc.) on the microcantilever surface.

Gas sensor is one of important issue in the industry. For many industries, monitoring and controlling gas are needed for efficient and safety of the production process. A rapid and accurate measurement of the gas have become a challenge for a long time. Recently, MEMS technology-based microcantilever sensor is very popular to miniaturize various kinds of sensors, including the gas sensor. However, to our knowledge, few experiment studies have been devoted on the detection of the gas [4-6]. Especially, Liquefied Petroleum Gas (LPG) detection has not been reported. So far, our group

have studied the detection of humidity using piezoresistive microcantilever and the design of the microcantilever for chemical object detection [7,8]. In this work, we investigate the possibility of piezoresistive microcantilever as the gas sensor using the dynamic mode measurements. Here, a Wheatstone bridge circuit is constructed in order to detect a change of piezoresistor in the microcantilever due to the gas molecules attached on the microcantilever surface.

## II. DYNAMIC MODE MEASUREMENT

The microcantilever sensor has two operation modes, i.e., static mode and dynamic mode. The static mode operation directly measures the deflection of the microcantilever. For the dynamic mode operation, the deflection of the microcantilever is not directly measured. The dynamic mode one measures the resonance frequency shift of the microcantilever vibration due to the object detection. In the experimental setup, the microcantilever is usually placed on the piezoelectric. When the microcantilever is vibrated by giving a signal generator to the piezoelectric, the resonance frequency of the microcantilever can be calculated by equation (1) [9].

$$f = \frac{1}{2\pi} \sqrt{\frac{k}{M}} \quad (1)$$

where  $k$  is the spring constant and  $M$  is the effective mass of the microcantilever.

Next, the addition of mass on the microcantilever surface will cause a decrease in the resonance frequency. Therefore, mass changes  $\Delta m$  can be obtained from the resonance frequency shift caused by molecular adsorption according to the equation (2) [9].

$$\Delta m = -2 \frac{m}{f} \Delta f \quad (2)$$

From the equation above, a mass sensitivity  $S$  of the microcantilever-based sensors is as follow,

$$S = \frac{\Delta m}{\Delta f} = -2 \frac{m}{f} \quad (3)$$

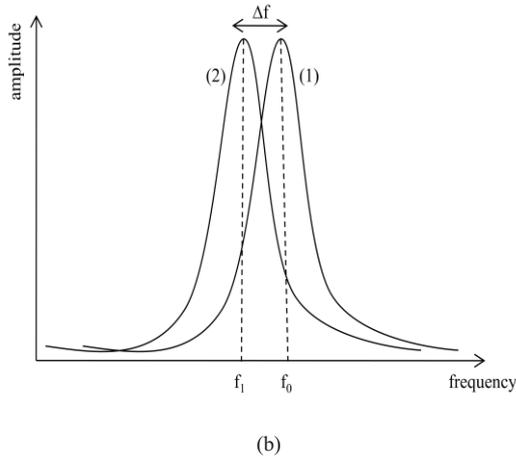

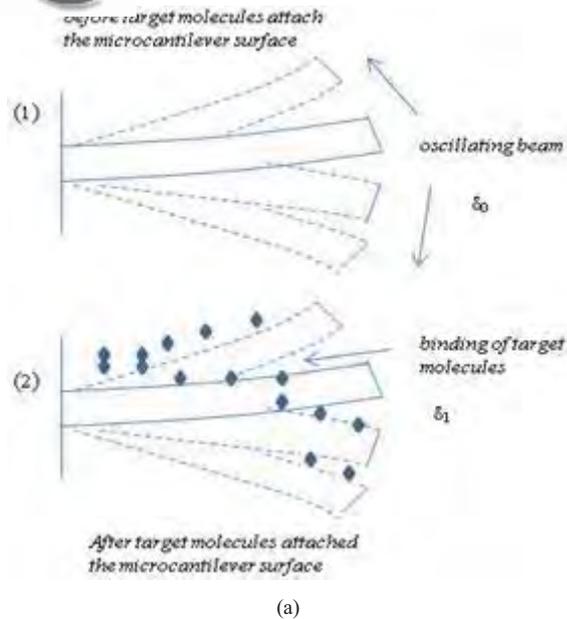

Figure 1. (a) Microcantilever vibration before and after molecules detection, (b) Resonance frequency shift due to the molecules detection

Figure 1(a) shows illustrations of the microcantilever vibration before (1) and after (2) the target molecules attach on the microcantilever surface. Before the molecules attach on the microcantilever surface (1), the microcantilever has the deflection of  $\delta_0$  and vibrates with a certain frequency of  $f_0$  [10]. The microcantilever then captures the target molecules (2), resulting in the change in both resonance frequency due to the additional mass ( $\Delta m$ ) of the microcantilever, as shown in Fig. 1(b). The resonance frequency shifts to lower value, after the target molecules are captured on the microcantilever surface.

### III. EXPERIMENTAL SETUP

In the experimental setup, the microcantilever sensor system consists of function generator, Wheatstone bridge, Op-Amp and oscilloscope, as shown in the Fig. 2 [7]. The Wheatstone bridge circuit was constructed by two

piezoresistors in the microcantilever and two external resistors. The piezoresistive microcantilever used here is commercially manufactured by Seiko Instrument Inc., Japan. Even the microcantilever was designed to be an atomic force microscope application, we suggest that the sensor system with same microcantilever structure in Fig. 2 can be used for chemical sensor, including gas detection. A long microcantilever has a length of  $110 \mu\text{m}$ , a width of  $50 \mu\text{m}$ , area  $9.80 \times 10^{-5} \text{cm}^2$  (both sides), weight  $46 \text{ng}$ , spring constant  $40 \text{N/m}$  and piezoresistor  $R_1$  of about  $630 \Omega$  [11]. The scanning electron microscope (SEM) image of this microcantilever can be seen in Fig. 3. It is noted that the short microcantilever with piezoresistor  $R_2$  of about  $630 \Omega$  is a reference cantilever, which was designed to be unchangeable during the measurement. Such reference cantilever is crucial in order to reduce background noise, such as thermal drift and gas turbulence [12].

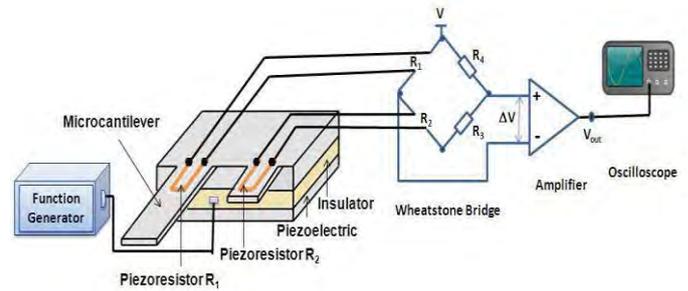

Figure 2. Block diagram of the whole sensor system

The output of Wheatstone bridge ( $\Delta V$ ) in Fig. 2 could be written as  $\Delta V = (R_1 R_3 - R_2 R_4) V / (R_1 + R_2)(R_3 + R_4)$ . Such  $\Delta V$  will be modified if the value of piezoresistor  $R_1$  changes due to the gas detection. The  $\Delta V$  is then amplified by amplifier instrument, resulting in  $V_{out}$ , which is monitored by oscilloscope. It is noted that the gas molecules attached on the microcantilever surface causes the microcantilever deflection, so that the stress on the base of the microcantilever increases. This results in the change in the piezoresistor, which is located in the base of microcantilever.

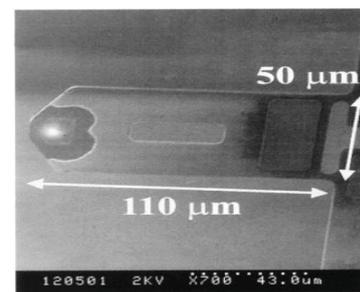

Figure 3. SEM image of the piezoresistive cantilever

In the measurement based on the dynamic mode operation, the activation of the piezoelectric will vibrate the microcantilever with a certain frequency. In our work, the sensor system is firstly placed inside the box, and the

resonance frequency of the microcantilever vibration was measured. Next, Liquefied Petroleum Gas (LPG) is introduced in box, and then the resonance frequency shift was measured by the oscilloscope.

#### IV. RESULTS AND DISCUSSION

In present experiment, we recorded the  $\Delta V$  oscillation peak-to-peak ( $V_{pp}$ ) which represents the microcantilever vibration change due to the gas flow into the box. The  $\Delta V$  oscillation is then analyzed by a Fast Fourier Transform (FFT). Figure 4(a) shows the FFT graph before LPG gas is introduced into the box. It is found that the resonance frequency of the microcantilever vibration is about 318 kHz.

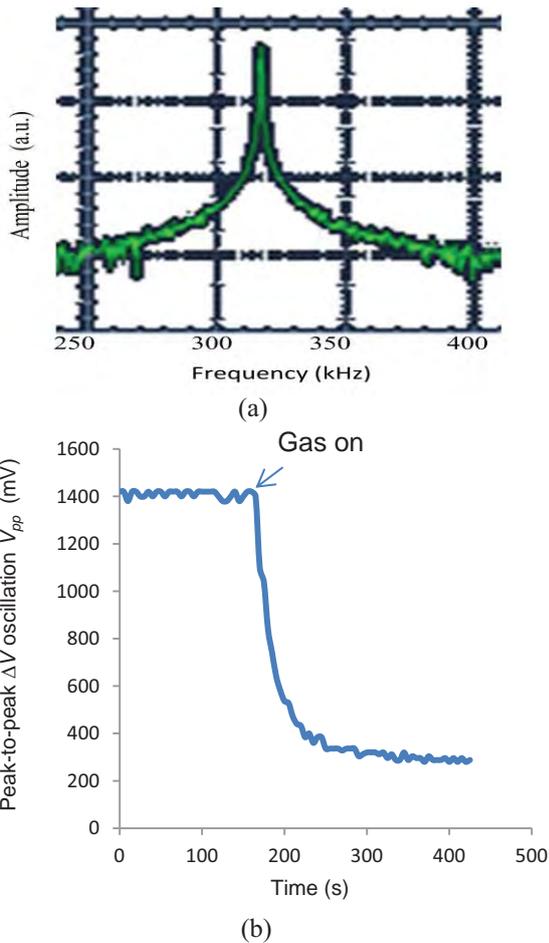

Figure 4. (a) FFT analysis of the initial resonance frequency and (b) change of peak-to-peak  $\Delta V$  oscillation due to gas detection

Next, the gas is introduced and then the change of  $\Delta V$  oscillation peak-to-peak ( $V_{pp}$ ) is recorded, as shown in Fig. 4(b). It can be seen that, before the gas is introduced, the  $V_{pp}$  is almost constant of about 1400 mV. When gas enters the box at the time of 155 s, the  $V_{pp}$  abruptly decreases. After the time of 200 s, the  $V_{pp}$  slowly decreases, and then there is no significant change in  $V_{pp}$ . We suggest that the decrease in the  $V_{pp}$  due to the gas flow corresponds to the resonance frequency shift, as our illustration in Fig. 5. In present experiment, since we

measured the  $\Delta V$  oscillation in the fixed frequency of 318 kHz, the detected  $V_{pp}$  is not always at the peak of the resonance frequency. The value of  $V_{pp}$ , which is indicated by A-F points (see Fig. 5(a)), changes may be due to the resonance frequency shift to the left (see Fig. 5(b)). When the resonance frequency shifts to the lower value, the detected  $V_{pp}$  reduces. After the time of 200 s, the attached gas molecules are saturated so that there is no  $V_{pp}$  change. We suggest that, since the value  $V_{pp}$  in Fig. 4(b) reached a constant after about 250 s, the resonance frequency shift is about 57.14 kHz, such shift represents the mass change  $\Delta m$  of about 16.5 ng due to the gas molecule on the microcantilever surface.

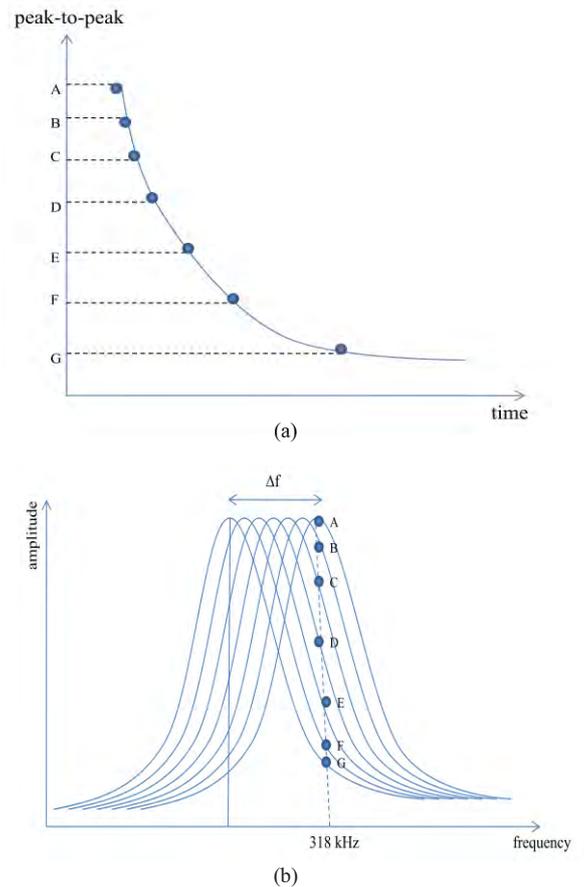

Figure 5. Illustration of relationship between the decrease in the  $V_{pp}$  and the resonance frequency shift

#### V. CONCLUSION

We have investigated the possibility of the piezoresistive microcantilever as the LPG gas sensor using the dynamic mode measurements. The Wheatstone bridge circuit was built in order to detect the resonance frequency shift due to the detection of the gas. The gas detection is indicated by the decrease in the microcantilever vibration amplitude, which represents the resonance frequency shift. Even the linearity of gas-cantilever response relation and the coating of the microcantilever surface need to be clarified, we believe that

such results open up the possibility of the gas detection using piezoresistive microcantilever-based sensor.

**Abstract**—Silicon-on-insulator (SOI) provides distinctive characteristics to photodetectors based on optical confinement and carrier confinement, resulting in enhanced light absorption and sensitive detection of photo-generated carriers, respectively. Specifically, the waveguiding modes in the SOI photodiode can be induced by the diffracted light from the surface plasmon antenna on top to give an enhanced light sensitivity, and wavelength and polarization selectivities. The carrier confinement in the SOI body enables one-by-one detection of the photo-generated carriers in SOI MOSFET, leading to the single-photon detection. In this report, such new features of photodetectors attained by SOI will be introduced.

**Keywords**—silicon-on-insulator (SOI); photodetector; surface plasmon (SP) antenna; single-photon detection

## I. INTRODUCTION

Silicon-on-insulator (SOI) is a unique material comprising of a single-crystal silicon layer, buried silicon dioxide (BOX) underneath, and a supporting silicon substrate. It is widely used as a material for high-performance large-scale integrated circuits (LSIs) due to the low parasitic capacitance and complete electrical isolation between devices [1],[2]. In addition, extremely thin SOI MOSFET is regarded as a viable device structure for LSI scaling down to 20 nm node and beyond because of the superior short-channel characteristics, etc.[3] Considering these, it is worthwhile to develop SOI-compatible photodetectors to give new function to LSIs.

In addition, SOI also provides distinctive characteristics to photodetectors based on optical confinement and carrier confinement, which lead to enhanced light absorption and sensitive detection of photogenerated carriers, respectively. In this report, such new features of photodetectors attained by SOI will be discussed.

## II. OPTICAL CONFINEMENT

Thickness of the silicon layer used in high-performance SOI LSIs is thin (usually less than 200 nm), and the light absorption efficiency is low. In order to solve this problem, surface plasmon (SP) antenna was applied to lateral pn-junction photodiode. Surface plasmon is a charge density wave propagating on the surface of noble metal (e.g. Au, Ag), which can be resonantly excited by the incident light if a periodic grating structure is made of the metal. Because of the intense near field generated by the surface plasmon, light can be

efficiently absorbed by the Si photodiode placed nearby. Based on such an idea, SOI photodiode with SP antenna in Fig. 1(a) was designed [4], in which thickness of the gate oxide separating the antenna and the Si was minimized (~5 nm) insofar as the leakage current through the oxide is prevented.

According to the finite-difference time domain (FDTD) simulation, the proposed photodiode exhibited high light absorption efficiency at the wavelength determined by the period of the SP antenna grating, and one order of magnitude higher quantum efficiency (QE) than that of the case without SP antenna was expected. For example, efficiency of 37% was expected for 550 nm wavelength light with 100 nm thick Si

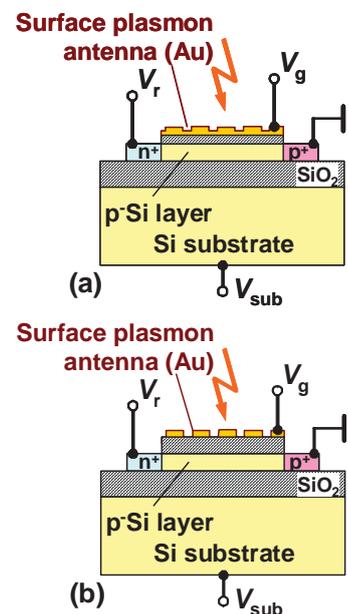

Fig. 1. Schematic cross-section of the lateral pn-junction SOI photodiode with surface plasmon (SP) antenna [4],[5]. (a) Continuous-grating antenna with thin (~5 nm) gate oxide, and (b) separate-grating antenna with thick (~100 nm) gate oxide [6],[8].

and 200 nm period Au antenna grating [4].

However, expected enhancement was not experimentally achieved due to the optical loss in the Ti adhesion layer inserted between Au antenna and the gate insulator SiO<sub>2</sub> [5].

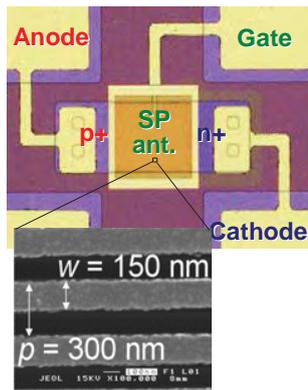

Fig. 2. Fabricated SOI photodiode with surface plasmon (SP) antenna corresponding to the structure in Fig. 1(b).

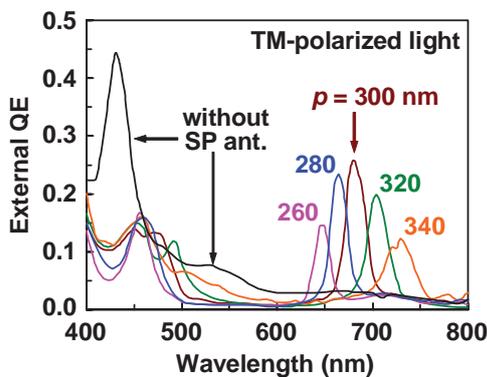

Fig. 3. Spectroscopic external quantum efficiency (QE) of the fabricated photodiode. SOI thickness is 95 nm.

This problem was later solved by adopting the separate-grating antenna with thick (~100 nm) gate oxide shown in Fig. 1(b) [6],[8].

Fig. 2 shows the optical and electron micrographs of the fabricated photodiode according to Fig. 1(b) [6]. The lateral pn-junction photodiode has a metal-oxide-semiconductor (MOS) structure, and the SP antenna also works as a gate electrode. By applying appropriate voltages to the gate and substrate, nearly entire  $p^-$  area can be made depleted, and the QE is maximized.

Fig. 3 shows the spectroscopic sensitivity of the fabricated photodiode for various grating periods. The QE peaks at a specific wavelength determined by grating period of the SP antenna. For instance, QE of 25% (enhancement by a factor of 8.2) can be obtained at 680 nm wavelength with a 300 nm period grating.

Fig. 4 shows the polarization angle dependence of the external QE. TM polarization is the condition in which the grating direction is parallel to the magnetic field of the incident light, and the surface plasmon can be excited most efficiently by the grating coupling. As is expected, QE becomes maximum at TM polarization, and the extinction ratio to the minimum at TE polarization is as high as 46.

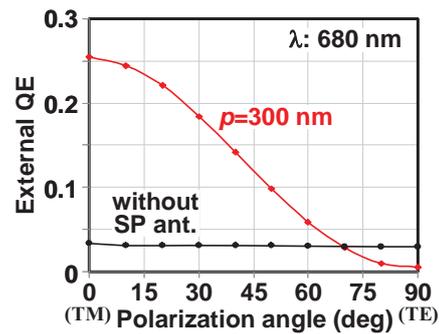

Fig. 4. Polarization angle dependence of external quantum efficiency (QE).

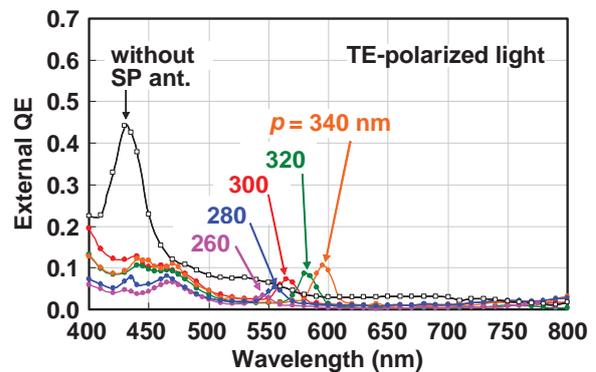

Fig. 5. Spectroscopic quantum efficiency (QE) for TE-polarized light.

SP antenna has functions of wavelength and polarization filters, and more importantly, diodes with different characteristics can be integrated easily in one chip since the filter characteristics can be tailored only by the layout design without changing the materials. This feature brings a new opportunity to spectroscopic and polarization imaging.

In terms of efficient use of the near field, the device structure with thick gate oxide in Fig. 1(b) is not necessarily appropriate. Moreover, due to the separate-grating structure, propagation of the surface plasmon across the grating is less likely. In order to understand the mechanism behind the separate-grating structure, the spectroscopic QE for TE-polarized light, which is not favorable to excite surface plasmon, is measured. As shown in Fig. 5, new QE peaks are found at wavelengths different from those for TM-polarized light.

This phenomenon can be explained based on the dispersion relationship (i.e. propagation wavelength  $\lambda_g$  in the waveguide vs. free-space wavelength) for the Si slab waveguide of SOI layer sandwiched with infinitely thick  $\text{SiO}_2$ . The theoretical dispersion (solid lines in Fig. 6) [7] coincides well with the experimental relationship between the grating period and the peak wavelength (symbols in Fig. 6) [8], indicating that the QE is enhanced by the coupling of the diffracted light from the antenna grating with the waveguide modes in the Si slab. This

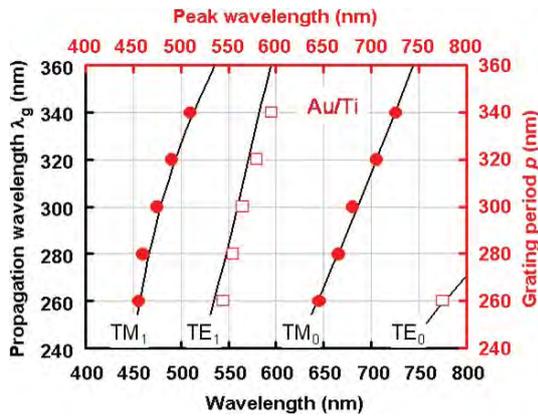

Fig. 6. Dispersion relationship for the Si slab waveguide of SOI layer sandwiched with infinitely thick SiO<sub>2</sub> (black solid lines, left/bottom scales), and relationship between peak wavelength and grating period for the photodiode (red symbols, right/top scales).

is unique to SOI structure, where the light can be confined in the Si with high refractive index surrounded by the SiO<sub>2</sub> with low refractive index.

### III. CARRIER CONFINEMENT

In the SOI MOSFET, generation of minority carriers in the Si body leads to the change in the threshold voltage (floating body effect), since the carriers cannot be drained easily. Due to the down scaling of the device, threshold voltage change caused by a single carrier becomes large enough to be observed, realizing a new type of single-photon detector that counts photo-generated carriers one by one without multiplication.

Fig. 7 shows the verified device structures with an n-type channel. The double-layer-gate device in Fig. 7(a) confines the photo-generated holes in the potential well created by the applied voltages to upper and lower gates [9],[10]. In this case, electron current in the bottom channel is modulated by the stored hole below the lower gate. The single-layer-gate device in Fig. 7(b) confines holes in the potential well formed by the npn junction [11]. Similarly, the stored holes are detected by the electron current in the bottom channel.

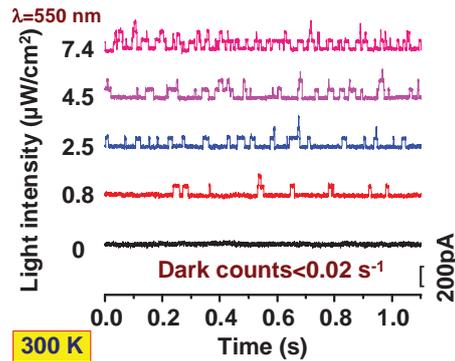

Fig. 8. Drain current waveforms for different light intensities for double-layer-gate SOI MOSFET with  $I_{soi} = 50$  nm,  $L = 65$  nm and  $W = 105$  nm.

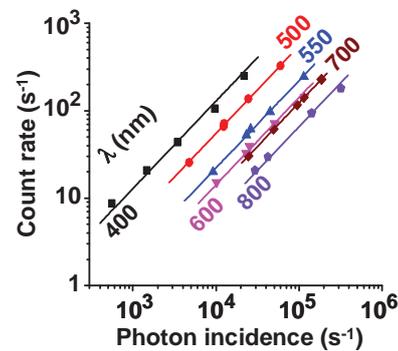

Fig. 9. Pulse count rate with respect to the photon incident rate. The later is the nominal value obtained by multiplying areal light intensity and the area of p<sup>-</sup> region.

The double-layer-gate device has merits of higher sensitivity to the stored holes due to the smaller potential well, and larger photosensitive area corresponding to the p<sup>-</sup> offset region, but has a drawback of the complex structure. The single-layer-gate device has a simple structure similar to that for ordinary LSI. Hereafter, we will focus on the former device [10].

Fig. 8 shows the drain current waveforms for different levels of light intensity. Current levels are discrete, and correspond to the number of stored holes of 0, 1, 2, 3 ... from the lowest level. The rise of the current is caused by the hole generation by photo-excitation, and the fall is caused by the hole recombination. As the light intensity increases, the pulse frequency increases, and at the same time, probability of the higher current levels increases. Dark counts at zero illumination intensity is less than 0.02 s<sup>-1</sup>, which is about four orders of magnitude lower than that of avalanche photodiode. Low operation voltage around 1 V is another superior point.

Fig. 9 shows the relationship between the pulse count of drain current and the photon incident rate for various wavelengths. Count rate increases proportionally to the photon incident rate, supporting the single-photon detection, and the proportionality constant is the QE for each wavelength. The

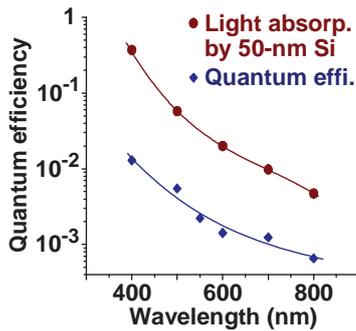

Fig. 10. Wavelength dependence of the quantum efficiency.

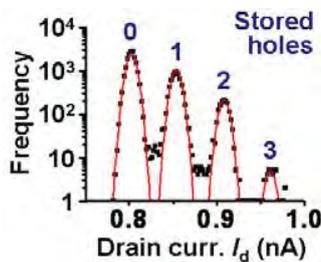

Fig. 11. An example of the drain current histogram corresponding to the waveform for  $4.5 \mu\text{W}/\text{cm}^2$  in Fig. 8. Solid lines are Gaussian fitting curves.

wavelength dependence of the QE is shown in Fig. 10, together with the light absorption by the Si layer with the same thickness (50 nm) as that of MOSFET, calculated using absorption coefficient. The QE and light absorption curves are parallel to each other indicating that the spectroscopic characteristics of the QE is governed mainly by the Si absorption coefficient. One order of magnitude smaller QE than the light absorption is caused by the opaque metallic upper gate, and could be improved by replacing the gate with transparent one.

Thanks to the extremely small dark counts, minimum detectable optical power (NEP) is as low as  $7.7 \times 10^{-18} \text{ W}/\sqrt{\text{Hz}}$ , although the QE is low (1.3% at 400 nm). However, due to the small light receiving area, the detectivity  $D^*$  is calculated to be  $4.3 \times 10^{12} \text{ cm}^2/\sqrt{\text{Hz}}/\text{W}$ , which is comparable to that of pin photodiode.

It is possible to extract the lifetime of a few holes by analyzing the drain current waveforms. Specifically, histogram of the drain current is made as shown in the example of Fig. 11. Here, the peaks from the left correspond to the number of stored holes of 0, 1, 2 and 3, and the probability of state for each number of holes can be calculated from the peak height.

Fig. 12 shows the relationship between the probability of state and the count rate (i.e. hole generation rate), and solid lines are theoretical curves obtained from the steady-state rate equations. By optimizing the hole lifetimes  $\tau_1$ ,  $\tau_2$  and  $\tau_3$  for

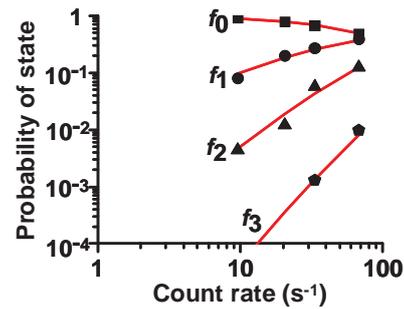

Fig. 12. Relationship between probability of state and count rate (hole generation rate) for different numbers of stored holes. Solid lines are theoretical curves based on the rate equation.

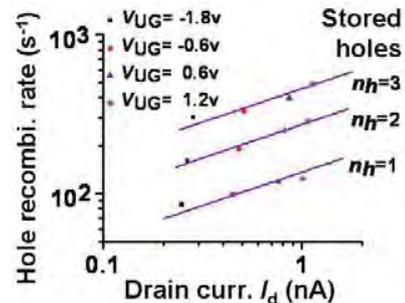

Fig. 13. Hole recombination rate (inverse of hole lifetime) with respect to the drain current for different numbers of stored holes.

hole numbers 1, 2 and 3 to minimize error, 11, 5 and 2 ms are obtained, respectively.

Fig. 13 shows the hole recombination rate (inverse of hole lifetime) vs. drain current controlled by the upper gate voltage  $V_{UG}$ . The recombination rate is nearly proportional to the number of stored hole  $n_h$ , and electron current to the power 0.41. This result contradicts the previous report [9] of the direct proportionality to the current, suggesting the indirect recombination of holes via traps.

#### IV. CONCLUSION

In this report, an SOI photodiode with SP antenna and SOI MOSFET single-photon detector are introduced. In the former, optical confinement effect specific to SOI contributes to the enhancement of QE, and in the later, carrier confinement effect (floating body effect) enables the detection of single holes generated by the incident light. The unique characteristics utilized in these photodetectors, along with the evolution of SOI-based LSIs, will open up new opportunities of optoelectronic integrated circuits.

**Abstract**— We study nanosize-effect in lateral nanoscale *p-n* and *p-i-n* junction devices under light illumination. Current versus voltage (*I-V*) and current versus time (*I-time*) characteristics were investigated at low and at room temperature. At low temperature, only *p-n* junction devices show a photon sensitivity in *I-V* characteristics due to co-existence of donor-acceptor pair. At room temperature, both devices show photovoltaic nature, i.e., increase of reverse current is observed under light illumination. In addition, devices with narrow channel-width tend to produce larger photocurrent which is ascribed to the nanosize effect.

**Keywords**— Nanoscale *p-n* and *p-i-n* junctions; individual dopants; nanosize effect

## I. Introduction

Silicon based *p-i-n* and *p-n* devices have been commonly used for a variety of photonic and electronic applications along with semiconductor history [1]. Taking advantages of present fabrication technology, recently, novel properties of nanoscale *p-i-n* and *p-n* junctions have been studied and their advantages have been demonstrated [2–7]. Co-axial *p-i-n* and *p-n* nanowires are reported to be highly efficient in solar cell applications [2,3]. Two-dimensional (2D) *p-n* junctions are known to have a higher breakdown voltage and a lower capacitance than conventional *p-n* junctions [6]. Also, 2D *p-n* junctions have enhanced photoluminescence and electroluminescence efficiency, because of quantum-mechanical confinement effect of carriers [7]. Thus, nanoscale *p-i-n* and *p-n* diodes are of increasing importance for novel photodevices.

It is important to be noted that as devices are scaled down into nanometer scale, the number of dopant atoms is limited and countable. In this nanoscale regime, individual dopant atom potential may influence the device operation. In fact, nanoscale MOSFETs with doped-channels have been intensively studied [8–15]. In those single-dopant devices, individual potentials of dopant atoms are intentionally utilized as miniaturized quantum dots. The role of individual dopant atoms in nanoscale lateral *p-n* junctions at low temperature has also been reported [16]. Since room temperature operation is the main goal for more practical application, it is important to study room temperature behavior of nanoscale lateral *p-n* and

*p-i-n* junctions and their characteristics under light illumination. The effects of nanosize also need to be clarified.

In this work, we first present a review of low temperature characteristics of nanoscale lateral *p-n* and *p-i-n* junction devices. Next, we study room temperature characteristics and the effect of channel width. The devices are characterized in dark and under light illumination. As a result, at low temperature, only *p-n* junction devices show a photon sensitivity in *I-V* characteristics which is ascribed to the charging and discharging of donor-acceptor pair by photogenerated carrier. At room temperature, we found that both *p-n* and *p-i-n* devices show photovoltaic nature, i.e., current is enhanced in the reverse bias condition under light illumination. It is even more important that, narrow channel-width devices show higher photo response and it is ascribed to the nanosize effects.

## II. Methodology

We fabricated and studied two types of nanoscale diode, *p-n* and *p-i-n*. Schematic device structure, bias configuration and schematic top view for both devices are shown in Fig. 1. The nanodiode was patterned on silicon-on-insulator (SOI) structure using electron beam lithography. The width, length, and thickness are estimated to be 15, 1000, and 5 nm, respectively. Boron and phosphorus atoms were selectively diffused to create lateral *p-n* junction and *p-i-n* devices. In *p-n* junction devices, a co-doped region was doped with phosphorus and boron simultaneously. Boron concentration is higher than phosphorus concentration. For both devices, final phosphorous and boron concentration derived from secondary ion mass spectrometry (SIMS) are estimated to be  $N_D \approx 1 \times 10^{18} \text{ cm}^{-3}$  and  $N_A \approx 1.5 \times 10^{18} \text{ cm}^{-3}$  respectively. In the *p-i-n* devices, an area in the middle part of the nanowire was kept un-doped. The nanowire is covered with a 10-nm-thick  $\text{SiO}_2$  layer. The *p*-Si substrate ( $N_A \approx 1.5 \times 10^{15} \text{ cm}^{-3}$ ) is used as a backgate. The thickness of the buried oxide layer is 150 nm.

Devices were measured in a vacuum chamber of an electrical measurement system. *p*-type region was connected to the voltage source, while *n*-type region and substrate were kept grounded. Light is illuminated onto the device from a halogen, light emitting diode (LED), or a monochromatic light source in the visible wavelength range. Light source is connected with optical fibers through a quartz window. The

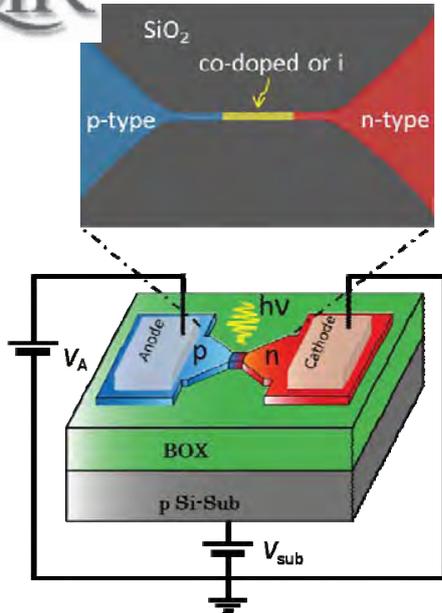

Fig. 1. Schematic device structure, bias configuration and schematic top view of *p-n* and *p-i-n* junction area.

illumination area in the device has a diameter of about 3.2 mm. By dividing the measured optical power at the sample surface over the illumination area and the photon energy, the incident photon flux is estimated.

For analysis, we performed low temperature (~20 K) and room temperature measurement (~296 K). In both conditions, the devices were measured in dark and under light illumination.

### III. Experintal Results and Discussion

#### A. Low temperature measurement

We measured anode current versus voltage ( $I-V_A$ ) characteristics at  $T \sim 20$  K. Anode voltage was swept from negative to positive while substrate voltage ( $V_{sub}$ ) was kept constant at 0 V. The main results of low temperature characteristics had been reported in our previous work [16] and will be briefly summarized in this paper. Typical  $I-V_A$  characteristics in semi logarithmic scale for *p-i-n* and *p-n* devices at low temperature are shown in Fig. 2 (a) and (b) respectively. Both devices show current enhancement under light illumination indicating that both devices are photosensitive. Although both devices show similar photosensitive behavior, it is apparent that only *p-n* junctions device show noise feature under light illumination. For further analysis, we focused on *p-n* junction devices and performed current versus time (*I-time*) measurement for fixed  $V_A$  and  $V_{sub}$  in the noisy region. In dark, current is constant, while under light illumination, current switch between two or more levels and is observed as random telegraph signal (RTS). By increasing photons intensity ( $\Phi$ ), we found that the number RTS increases, indicating that the RTS is triggered by

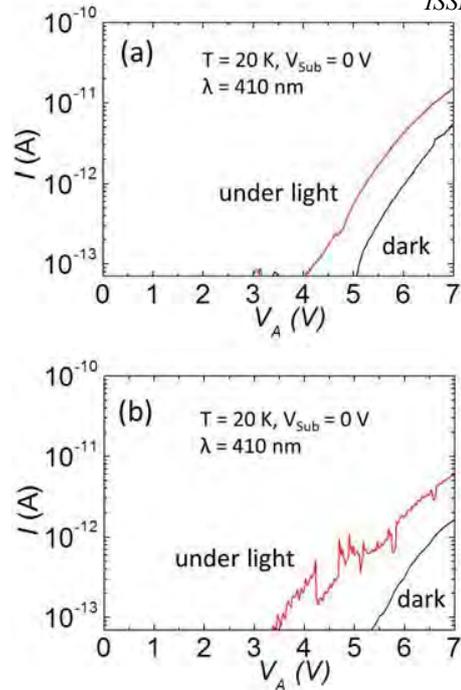

Fig. 2. Low temperature  $I-V_A$  characteristics of (a) *p-i-n* devices and (b) *p-n* junction devices. Only *p-n* junction devices show noise feature under light illumination [16].

photons. *I-time* characteristics in dark and under light illumination of several photon fluxes are shown in Fig. 3. As reported detail in our previous work, the noise feature is ascribed to the charging and discharging of photoexcited carrier by donor-acceptor pair in the depletion region. It is known that, at low temperature, most dopants are freeze-out [17]. The ionized donors and acceptors create a potential landscape with hills and valleys allowing electrons and holes to flow as diffusion current. The diffusion current in this device is used as a sensor to sense potential fluctuation in the channel. In dark, current is constant with time indicating no potential fluctuation. Under light illumination, photogenerated carriers can be trapped by ionized dopants causing a sudden potential change. This is sensed as anode current fluctuation (RTS) in the *I-time* characteristics. Since individual dopants basically can only accommodate a single photogenerated carrier, we suggest that, at low temperature, the nanoscale *p-n* junction devices can be utilized as single photon detectors.

#### B. Room temperature measurement

As low temperature characteristics have been clarified, it is important to analyze room temperature behavior for more practical application. For that purpose, we increased the temperature up to 296 K.  $I-V_A$  characteristics were measured in dark and under light illumination. Typical  $I-V_A$  characteristics in dark and under halogen light illumination for several photon fluxes ( $\Phi$ ) for *p-i-n* devices (a) and *p-n* devices (b) are shown in Fig. 4. Current, in absolute value, is plotted in a semi logarithmic scale; horizontal axis is applied voltage from negative (reverse) to positive (forward).

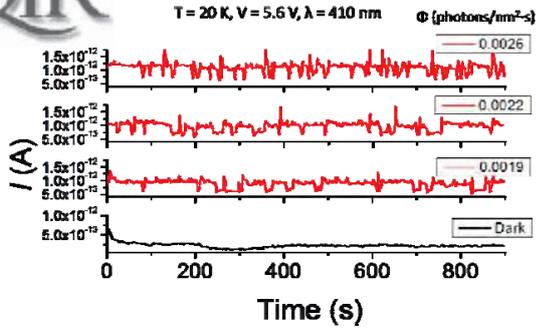

Fig. 3. *I*-time characteristics in dark and under light illumination. Under light illumination, current switch between two or more levels. By increasing incident photon flux ( $\Phi$ ), from bottom to up, number of RTS increases, suggesting that current jumps are triggered by photons [16].

In dark, both *p-i-n* and *p-n* devices show rectifying nature which is typical characteristics of conventional diodes, i.e., current flow in forward bias and is blocked in reverse bias condition. Although both devices have different structure, *p-i-n* and *p-n* devices show identical *I-V<sub>A</sub>* characteristics. Lower current in the *p-n* junction devices in the forward bias condition comes from the fact that *p-n* junction devices tend to have narrower channel size due to multiple etching processes during device fabrication. Under light illumination, both devices show photovoltaic effect, i.e., reverse current increases in negative direction by increasing photon flux ( $\Phi$ ), as shown in Fig. 4.

Although both devices show the same photovoltaic effect, apparently some differences can be observed. At larger forward bias condition, *p-n* junction devices show strong dependence on  $\Phi$ . On the other hand, *p-i-n* junction devices show almost photon-independence. These results indicate that *p-n* junction devices are more sensitive to  $\Phi$ . The origin behind this behavior most likely comes from the fact that final dimension of the *p-n* junction devices are narrower compared to *p-i-n* junction devices. This is caused by additional consumption of silicon by the double doping process in the co-doped region in *p-n* junction devices, as previously stated. The origin of the photocurrent enhancement under forward bias in *p-n* junction devices can be described as follows.

Due to narrow channel width in the *p-n* junction devices, resistance of the channel becomes high and the channel becomes insulator-like. Under bias condition, potential along the channel is tilted allowing electrons and holes to flow. Under light illumination, additional electrons and holes are generated in the channel. A small number of electrons and holes which are generated in the depletion region are immediately drifted in the opposite direction from the main diffusion current. As a result, the diffusion current is slightly reduced. On the other hand, large number of photo-carriers generated in the channel beyond the depletion region is

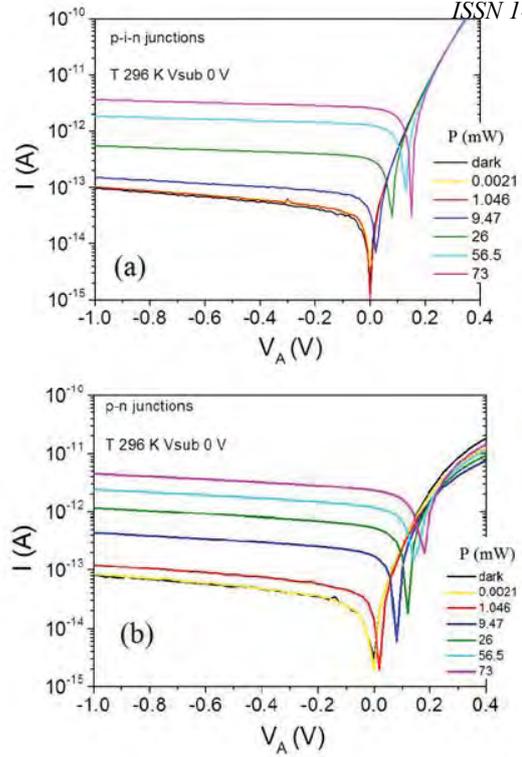

Fig. 4. Typical room temperature *I-V<sub>A</sub>* characteristics of (a) *p-i-n* and (b) *p-n* junctions in dark and under light illumination. Both devices show photovoltaic effect under halogen light illumination, i.e., reverse current increases by increasing photon flux.

flowing in the same direction with the main diffusion current due to potential difference. This photo current increases the diffusion current.

Next, we study the effect of channel-width on device characteristics. Since both *p-i-n* and *p-n* devices show identical behavior, we focus only on the *p-n* junction devices. Fig. 5 shows typical *I-V<sub>A</sub>* characteristics in dark (a) and under light illumination (b) for devices with channel length of 1000 nm and channel width varied from 275 to 1000 nm. From Fig. 5 (a), it is apparent that, in dark, current level increases by increasing channel width. These results are consistent with theoretical prediction. It is well known that dark current in *p-n* junction devices is proportional to the device area (*A*). Increasing the device width will eventually increase the dark current as well. Observation of reverse bias current under light illumination, however, is surprising. As shown in Fig. 5 (b), for *V<sub>A</sub>* below 0 V, devices with narrow channel-width tend to have larger current enhancement under the same  $\Phi$ . The trend of current enhancement for several devices with different channel width is plotted in Fig. 6.

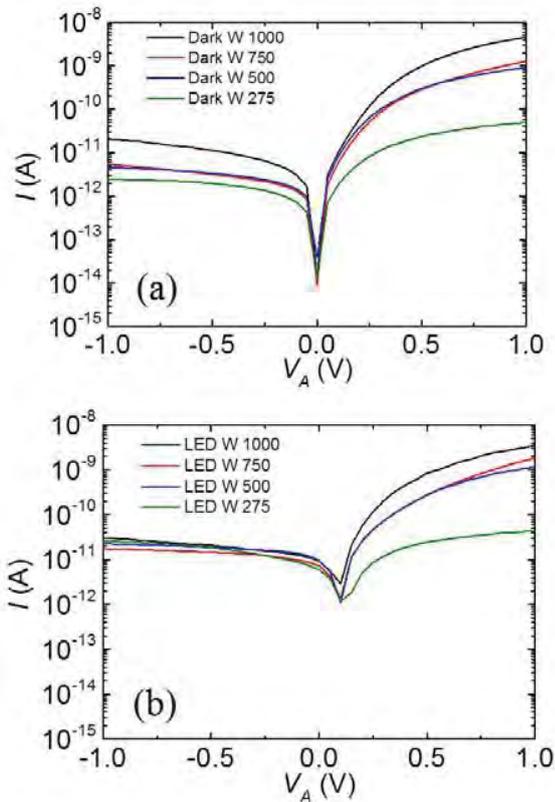

Fig. 5.  $I$ - $V_A$  characteristics of  $p$ - $n$  junction devices in (a) dark and (b) under LED illumination for several devices with different channel width. Under LED illumination, narrow channel-width devices show higher photosensitivity.

As shown in Fig. 6, the current enhancement, i.e., the different current measured in dark and under light illumination, due to photovoltaic effect is larger for devices with narrow channel width. These results suggest that narrow devices are more effective in generating current under the same photon flux. Although the reason behind this trend has not been fully clarified, it is most likely that narrow devices, due to nanosize effect, have wider space-charge region as theoretically predicted by Petrosyan [18].

In conclusion, we experimentally studied nanosize effect in nanoscale lateral  $p$ - $n$  and  $p$ - $i$ - $n$  junction devices at low and at room temperature. At low temperature, due to nanosize effect, individual donor-acceptor atom in  $p$ - $n$  junction devices plays an important role for photon detection. At room temperature, narrow channel-width devices have larger current enhancement under light illumination. Thus, nanoscale  $p$ - $n$  junction devices are promising for future photonic application.

### Acknowledgment

We thank S. Miki for his support during experiment and R. Nowak for helpful discussions.

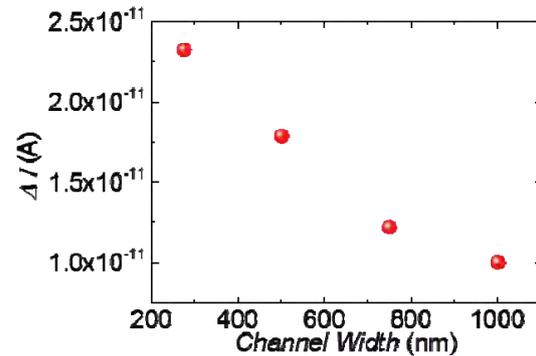

Fig. 6. Current enhancement ( $\Delta I$ ) due to light illumination for several devices with different channel-width. Narrow devices have larger  $\Delta I$  indicating that they are generating current from photons efficiently.

**Abstract**—This paper presents experiments and results on lung tuberculosis (TB) identification by using computer. This research's attempt is to reduce patient waiting time in obtaining X-ray diagnosis result on lung TB disease due to the mismatch the ratio of radiologist to the number of patients, especially in remote areas in Indonesia. To imitate radiologist which make visual examination on textural feature of thoracic X-ray images to make diagnosis, we exploit textural features calculated by computer to be used as descriptor in classifying images as TB or non-TB. We used statistical feature of image histograms by calculate five features: mean, standar deviation (std), skewness, kurtosis, and entropy. Features calculated where then reduced to two and one principal feature using Principal Componen Analysis (PCA) method. Finally, we used minimum distance classifier as classifier method based on two and one principal feature as descriptor. This experiment results shown that it is possible to classify TB and non-TB images based on statistical features on image histogram.

**Keywords**— X-ray image; Tuberculosis; statistical feature; PCA; minimum distance classifier

## I. INTRODUCTION

Rapid computer applications in medical areas provide many advantages in healthcare applications. Some applications include: telemedicine, medical image analysis, and databases on medical information such as medical record or medical image. Medical image analysis is related to the specific purposes of medical image that is one of diagnostic tools. X-Ray image is one kind of medical images used as diagnostic tools. Our previous research on making identification on disease based on X-Ray image was a research on Osteoporosis Image of proximal femur X-Ray Image [1], [2].

A thoracic X-Ray image commonly is used by physician as diagnostic tool to find some diseases related to human lung, such as lung TB. Tuberculosis is a disease caused by an infection of *Mycobacterium tuberculosis* [3]. It is a systemic disease that can strike any part of human organs with lung as the primary infection. In 2009, World Health Organization reported that Indonesia was the world's fifth largest TB patients population.

To make an X-Ray image, the patient will need several days before receiving the result. X-Ray image need to be examined, diagnosed, and notated by radiologist before given

to the patient. In Indonesia, the number of radiologist expert doesn't match the number of patient [4]. This condition makes the waiting time for patient to receive X-Ray images result relatively longer than those in advanced countries, especially for patient from remote areas in Indonesia.

Our research is to develop an application based on pattern recognition to identify lung TB using computer. Identification using computer in this research is conduct using thoracic X-ray image of the patient. The images classification of TB image and non-TB image will be based on their image textural feature. This application is expected to give benefit to TB lung patients to reduce the waiting time in obtaining the result.

## II. UDERLYING THEORY

### A. Statistical Image Feature

If  $u$  is a random variable that represent of image grey level, probability of one level occurance from grey level is defined as [5]:

$$p_u(x) \cong \frac{\text{the number of pixel with grey level } x}{\text{the number of pixel in an image}} \quad (1)$$

Statistical features can be derived from the equation above as:

$$\text{Moment: } m_i = E[u^i] = \sum_{x=0}^{L-1} x^i p_u(x), \quad i = 1, 2, \dots \quad (2)$$

$$\text{Center moment: } \mu_i = E\{[u - E(u)]^i\} = \sum_{x=0}^{L-1} (x - m_1)^i p_u(x) \quad (3)$$

$$\text{Entropy: } H = E[-\log_2 p_u] = -\sum_{x=0}^{L-1} p_u(x) \log_2 p_u \text{ bits} \quad (4)$$

From those formula, the most common histogram feature are: mean =  $m_1$ , varians =  $\mu_2$ , std =  $\sqrt{\mu_2}$ , skewness =  $\mu_3$ , kurtosis =  $\mu_4 - 3$ , and entropy.

### B. PCA for Feature Vector Dimension Reduction

Feature vector dimensions reduction by PCA method is to specify as many varians as possible using as few variables as possible [6]. In PCA, the original data are transformed into new

lower dimension coordinate systems. These new coordinate systems can remove redundancies. However, we have to consider between efficiency achievement must and sufficient information result in this features extraction. Fig.1 shown flowchart on PCA algorithms for dimension reduction used in this research.

### C. Minimum Distance Classifier

The Minimum distance classifier is one of the decision-theoretic approaches to recognition that based on the use of decision (or discriminates) function [7]. Let  $\mathbf{x} = (x_1, x_2, \dots, x_n)^T$  represent the n-dimensional descriptor vector for  $W$  descriptor

classes:  $\omega_1, \omega_2, \dots, \omega_w$ . Suppose that we define the prototype of each descriptor class to be the mean vector of the descriptor of that class:

$$\mathbf{m}_j = \frac{1}{N_j} \sum_{\mathbf{x} \in \omega_j} \mathbf{x}_j \quad j = 1, 2, \dots, W \quad (5)$$

where  $N_j$  is the number of pattern vectors from class  $\omega_j$

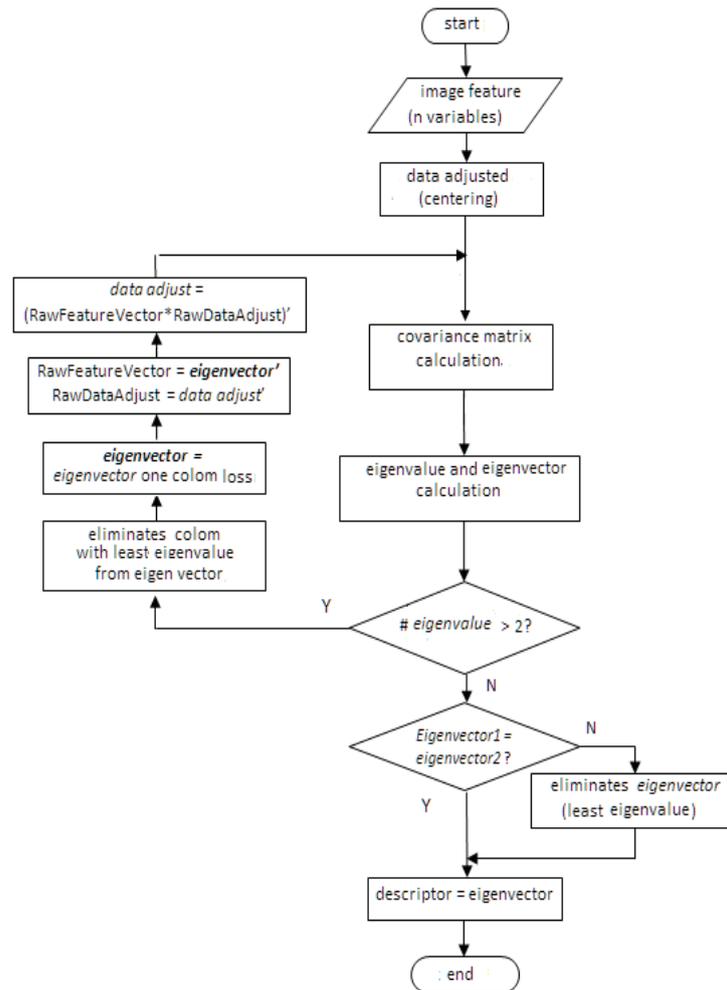

Fig.1. Flowchart of PCA feature dimension reduction from n to 1.

The distance between descriptor vector  $\mathbf{x}$  and the mean vector can be computed using the Euclidean distance:

$$D_j(\mathbf{x}) = \|\mathbf{x} - \mathbf{m}_j\| \quad j = 1, 2, \dots, W \quad (6)$$

Then descriptor  $\mathbf{x}$  is assigned to be the member of class  $\omega_i$  if  $D_j(\mathbf{x})$  is the smallest distance. Selecting the smallest distance means evaluating the function:

$$d_j(\mathbf{x}) = \mathbf{x}^T \mathbf{m}_j - \frac{1}{2} \mathbf{m}_j^T \mathbf{m}_j \quad j = 1, 2, \dots, W \quad (7)$$

and assigning  $\mathbf{x}$  to class  $\omega_i$  if  $d_j(\mathbf{x})$  yields the largest numerical value.

The decision boundary between classes  $\omega_i$  and  $\omega_j$  for minimum distance classifier is:

$$d_{ij}(\mathbf{x}) = d_{ij}(\mathbf{x}) - d_{ij}(\mathbf{x}) = 0 \quad (8)$$

Using this decision boundary function, substitution of any descriptor from class  $\omega_i$  would yield  $d_{ij}(\mathbf{x}) > 0$  and substitution of any descriptor from class  $\omega_j$  would yield  $d_{ij}(\mathbf{x}) < 0$ .

### III. MATERIALS AND METHODS

The data used in this research are the copy of digital X-ray thoracic images from Dr. Sardjito Hospital Yogyakarta. We used 50 thoracic X-Ray images to design this application; i.e. 25 images of healthy persons and 25 images of patients with Lung TB. All images were previously identified by radiologist. The design was broken down into two major steps: to find the image descriptor and to build an application for lung TB identification. Finding descriptor was performed on pre-

processing image and feature extraction processes. The pre-process image was useful to reduce non-uniformity data. Feature image extraction process was consisted of: features image calculation, features image dimension reduction, and features image selection as image descriptor. The application for lung TB identification based on image descriptor selected was built using minimum distance classifier method. Tests on identification accuracy of this application was done for 70 test images; i.e. 30 images of healthy persons without disease, 10 images of bronchitis-infected persons, and 30 images of Lung TB patients.

#### A. Pre-processing

The raw data acquired from Radiology Unit of Sardjito Hospital are not-uniform data. The non-uniformity the images covered in qualities, sizes, and body position X-Ray images. Fig. 2 shows data images and their histograms. Pre-processes was performed before image feature extraction to reduce the non-uniformities. Steps on this process are shown in Fig. 3. Image pre-process was consisted of image quality enhancement and object isolation. Image quality enhancement is conduct by using spatial filtering and histogram equalization of image. Spatial filtering is for noise reduction and pixel intensity transformation using histogram equalization is used to enhance image quality and make intensity level of all data in uniformity. Object isolation was aimed to select the region of interest (ROI) of the image. The ROI was an image area which its feature will be measured. ROI image taken to deal with non-uniformity in data size and human body pose of raw data image.

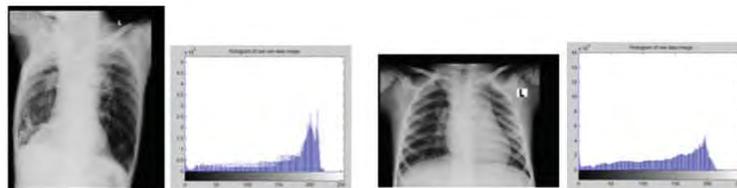

Fig. 2. Raw data images and their histogram.

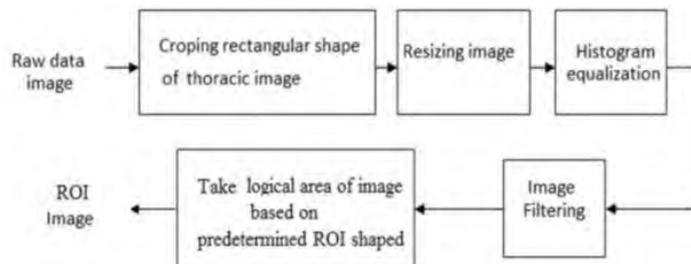

Fig. 3. Block diagram of raw data images pre-processes

Proper ROI image had an important role on calculating the best image feature for image classification. Getting ROI image in this experiment was broken down into three steps: cropping rectangular shape of thoracic images, resizing images and take

logical area of ROI images based on pre-determined shape. Fig. 4 shown raw data image (a) and image after cropping process (b). This process eliminated image and image area without pulmonary part from X-Ray thoracic image at once.

Pre-determined shape of ROI in this experiment was used four different shapes as shown in Fig. 5.

### B. Features Images Extraction

Radiologist searched specific features to diagnose Lung TB by examining X-ray image visually [3]. To imitate this work, this experiment calculated textural features based on statistical feature of image histogram. Five statistical image features are calculated from 50 image sample, that are mean, standard deviation (std), skewness, kurtosis, and entropy. From feature image calculation we have 5 dimension feature vectors. Feature dimension reduction and selection is conduct to reduce features vectors from 5 to 2 and 1. We used PCA method in this process to make sure that selected feature is the most principal feature of image. These two dimensions of principal features and one dimension principal feature will be used as image descriptors.

We also chose the best ROI from four pre-defined ROIs to be used in image identification. Image data plotted based on descriptor for all ROI template used in image pre-processing step. Selection was then made by comparing Euclidean distance and Mahalanobis distances between TB class and normal class for each ROI. The ROI showed the longest distances between classes was chosen as the best ROI and was be used as ROI in the next process.

### C. Images Identification

We used minimum distance classifier method in image identification application. We made two applications: image identification based on one image descriptor and based on two image descriptors, and compared them. Decision function in minimum distance classifier was made based on feature vector resulted from feature image extraction. Test on image identification as TB diseased image and normal image application was performed by making image identification of 70 sample thoracic X-ray image. In this research, application performance evaluated by its accuracy, fault acceptance rate (FAR), and fault rejection rate (FRR) [8].

$$\text{Accuracy} = \frac{\# \text{ True identification}}{\# \text{ Sampel}} \quad (9)$$

$$\text{FAR} = \frac{\# \text{ Fault Accepted Elements}}{\# \text{ Sampel}} \quad (10)$$

$$\text{FRR} = \frac{\# \text{ Fault Rejected Elements}}{\# \text{ Sampel}} \quad (11)$$

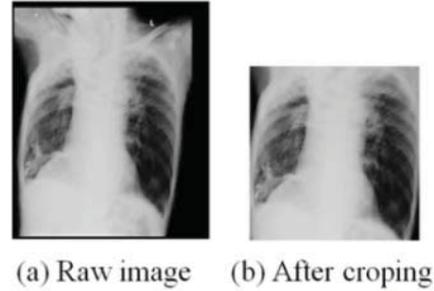

Fig. 4. Image data before and after cropping.

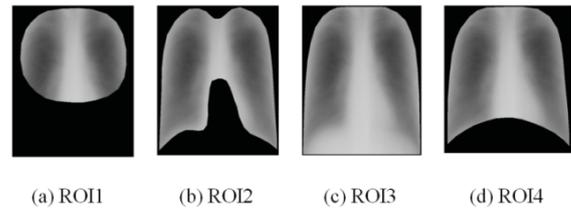

Fig. 5. Pre-determined shapes of ROI image.

## IV. RESULTS AND DISCUSSIONS

### A. Feature Extraction on Raw Images

Experiment in raw image feature extraction performed by extracting feature from raw data image without pre-process step. Five statistical features of image histogram were calculated in feature extraction; i.e. mean, standar deviation (std), skewness, kurtosis, and entropy. This calculation yielded 50 X 5 feature matrix. Based on this matrix, PCA was aimed to reduce five dimension feature vectors down to two, and then down to one feature. These component features would become the descriptor of image. Fig. 6 shows plots of raw image data based on two descriptors from PCA feature dimension reduction. Fig. 7 shows raw images data plots based on one descriptor (plots on image feature line).

Experiment in image feature extraction from raw data image showed extracted features could not be used as specific feature to classify image as TB or non-TB image. Those figure showed that many image data were overlapped between two classes. This was caused by the non-uniformity of raw data images.

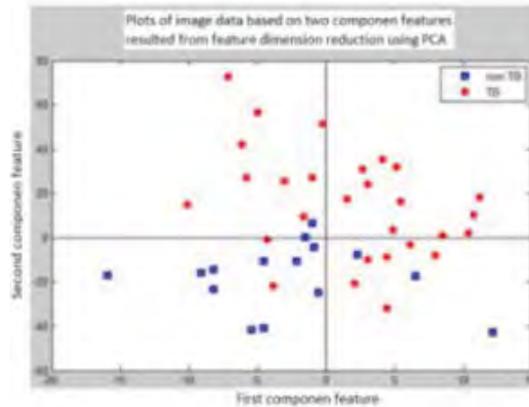

Fig. 6. Plots of raw images data based on two descriptors.

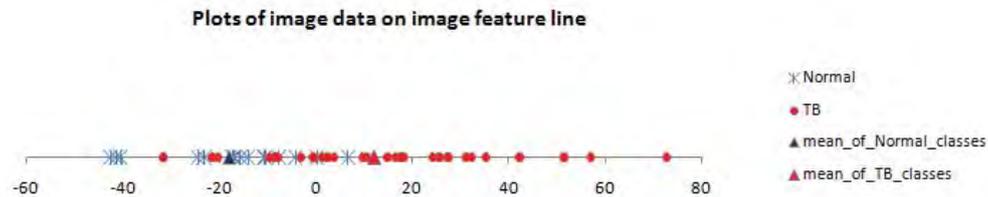

Fig. 7. Plots of raw images data on image feature line.

### B. Features extraction on pre-processed images

In this experiment, raw data image was pre-processed before feature extraction. Pre-processed was aimed to reduce the non-uniformities. As mentioned above, we used four pre-determined ROI images in pre-processing. Fig. 8 shows a clustering achieved from pre-processed image plots based on two descriptors for each ROI shape. Fig. 9 shows pre-processed image plots based on one descriptor, for each ROI image.

Fig. 9 and Fig. 10 shows that ROI2 and ROI4 gave better performance in clustering data image then other ROIs. Table 1 shown Euclidean distances and Mahalanobis distances calculated from image plots based on two image descriptor of each ROI and Table 2 for image plots based on one descriptor. Those table shows that ROI2 template gave the longest distance. From this calculation results we took ROI2 as ROI templates in further process.

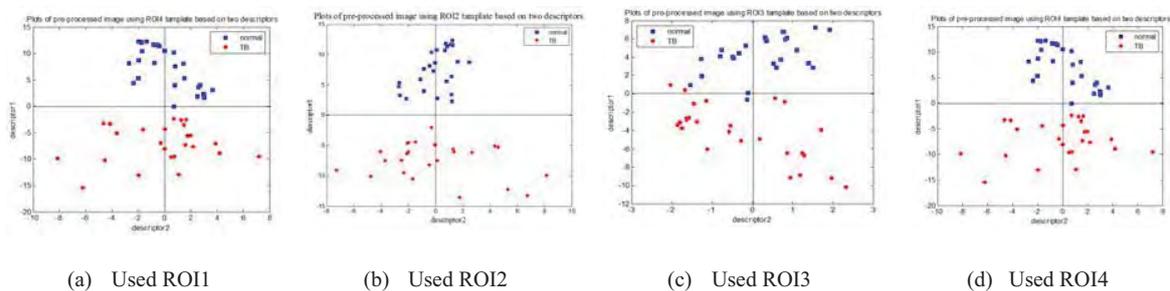

Fig. 8. Plots of pre-processed data image based on two descriptors from PCA feature dimension reduction for each ROI.

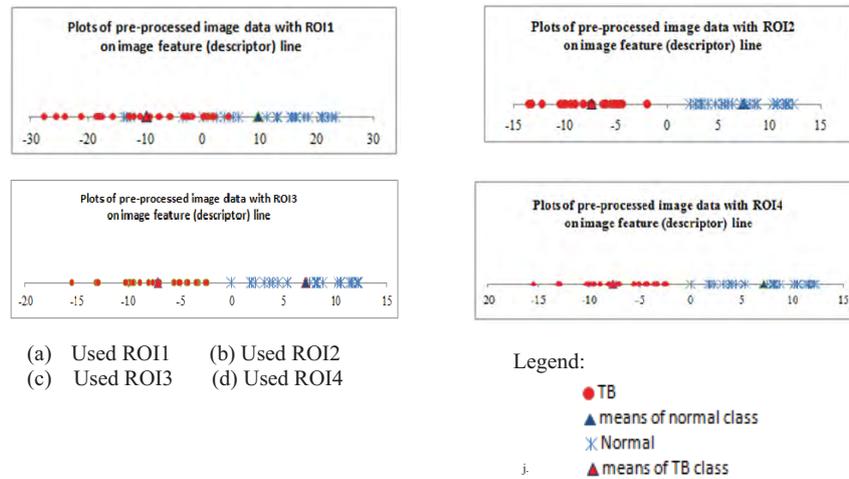

Fig. 9. Plots of pre-processed images data above one component feature for each pre-determined ROI

TABLE 1. EUCLIDEAN DISTANCE AND MAHALANOBIS DISTANCES BETWEEN TWO DIMENSIONAL DESCRIPTORS OF TB CLASS AND NORMAL CLASS FOR EACH ROI TEMPLATE

Distances	ROI1	ROI2	ROI3	ROI4
Euclidean between mean descriptor two classes	19.6091	<b>14.8860</b>	8.4277	14.3275
Mahalanobis distance between descriptor mean of TB class and all descriptors of normal class	3.6106	<b>25.6790</b>	18.6382	24.8969
Mahalanobis distance between descriptor mean of normal class and all descriptors of TB class	4.1437	<b>27.0854</b>	16.9891	16.2793

TABLE 2. EUCLIDEAN DISTANCE AND MAHALANOBIS DISTANCES BETWEEN ONE DESCRIPTOR OF TB CLASS AND NORMAL CLASS FOR EACH ROI TEMPLATE

Distances	ROI1	ROI2	ROI3	ROI4
Euclidean between mean descriptor two classes	19.6029	<b>14.8859</b>	8.4148	14.3219
Mahalanobis distance between descriptor mean of TB class and all descriptors of normal class	3.0227	<b>20.0858</b>	15.9174	13.4158
Mahalanobis distance between descriptor mean of normal class and all descriptors of TB class	4.0796	<b>25.5369</b>	7.4206	16.0064

### C. Image Identification

Image classification in this experiment is conducted using ROI2 for object isolation in pre-processing image. We use minimum distance classifier method in classifying image data based on two image descriptors and one image descriptor. We define boundary decision in minimum distance classifier using two components and one component feature of 50 sources of data image. Fig. 10 shows decision boundary line for minimum distance classifier based on two image descriptors and Fig. 11

shows decision boundary point for minimum distance classifier based on one image descriptor. Decision boundary line for minimum distance classifier based on two descriptors image is defined by equation:

$$descriptor2 = (0.0081) \cdot descriptor1 + 2.5287 \cdot 10^{-4} \quad (12)$$

Decision boundary point for minimum distance classifier based on one descriptor is defined by as:

$$descriptor = 4 \cdot 10^{-6} \quad (13)$$

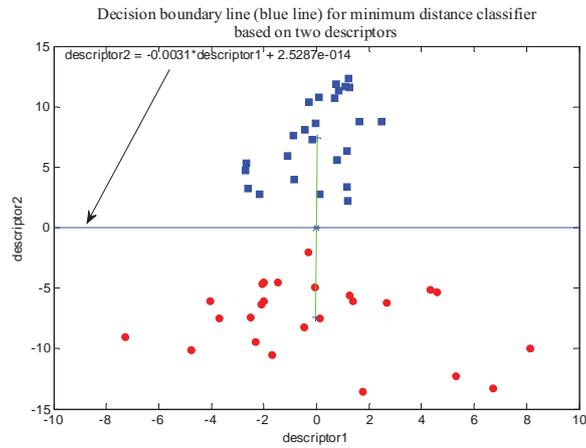

Fig. 10. Decision boundary line (blue line) for minimum distance classifier based on two descriptors.

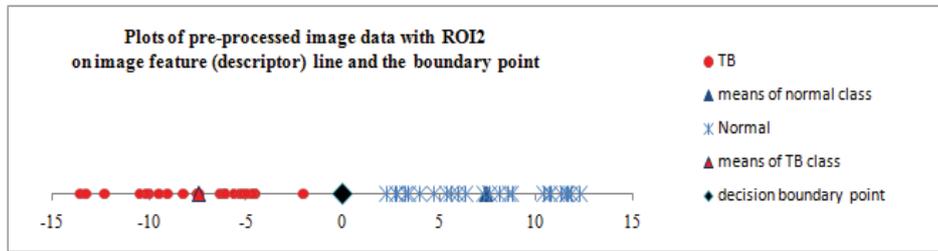

Fig. 11. Decision boundary point (black point) for minimum distance classifier based on one descriptor.

TABLE 3. IMAGE IDENTIFICATION RESULTS

Images sample test	Identification result	
	Positive TB	Negatif TB
30 images of healthy persons	0	30
30 images of Lung TB patients	28	2
10 images of Bronchities patients	1	9

We used test images; i.e. 30 images of healthy persons without disease, 10 images of bronchitis-infected persons, and 30 images of Lung TB patients. All images data had been examined and been diagnosed by radiologist. Tests result shown in table 3. Classification performance wereshown from its accuracy, fault acceptance rate (FAR), and fault

rejection rate (FRR). Experiment on image identification using two and one principal component image feature shows same results. The systems classification performance test results are: accuracy: 95.7%, FAR: 3.33%, FRR = 6.67%.

## V. CONCLUSION

1. Pre-processed images before feature extraction with filtering, histogram equalization, and image segmentation could be used to reduce non-uniformity on raw data image to improve image clustering.
2. Feature dimension reduction using PCA assure that selected feature is the most principal feature on image.
3. The best ROI shape on image segmentation was ROI2 which is shows lung area with as few as possible of non-lung area.
4. The results on identification of 70 image tests using two and one descriptors were: accuracy: 95,7%, FAR: 3.33%, FRR = 6.67%. These results indicate the possibility on identifying lung TB automatically based on image textural features.

## ACKNOWLEDGMENT

The first author would like to thank to: Prof. Dr.dr. Maesadji T., Sp.RAD(K)ONK and the Dr.Sardjito hospital, Yogyakarta for supporting in digital X-ray image data accuision. I would also like to thank to my former Promotor, Prof. Dr. Ir. Thomas Sri Widodo, for supervising my PhD research; and Electrical Engineering and Technology Information Department, University of Gadjah Mada, for permitting to carry my PhD work in UGM.

**Abstract**— Operation speed of the single-photon detector based on the silicon-on-insulator (SOI) metal-oxide-semiconductor field-effect transistor (MOSFET) is affected by the noise and minority carrier lifetime, both of which are found to be dependent on the substrate bias. The noise spectrum are obtained at various substrate voltages in dark condition while keeping the average drain current constant. The noise becomes minimum at around the transition point between front- and back-channel operations, and in the back-channel region near the transition point. On both negative and positive sides of the substrate voltage, the noise shows peculiar Lorentzian spectra. Minority carrier lifetime is evaluated by the analysis of drain current histogram at different substrate voltages. It is found that the peaks in the histogram corresponding to the larger number of stored holes become higher as the substrate bias becomes more positive. This can be attributed to the prolonged lifetime presumably caused by the higher electric field inside the body of SOI MOSFET. It can be concluded that, once the inversion channel is induced for detection of the photo-generated minority carriers, the small absolute substrate bias is favorable for short lifetime and low noise, leading to high-speed operation.

**Keywords**— Substrate bias effect, Low-frequency noise, SOI MOSFET, single-photon detector, minority carrier lifetime  
**Introduction**

## I. INTRODUCTION

It has been reported that a short- and narrow-channel silicon-on-insulator (SOI) metal-oxide-semiconductor field-effect transistor (MOSFET) can operate as a single-photon detector, featuring dark counts several orders of magnitude smaller than that of conventional avalanche photodiode (APD), and low operation voltage less than a few volts [1], [2]. Although this SOI MOSFET had a special double-gate structure with a short lower gate (LG) and a long upper gate (UG) covering the p-doped offset area between LG and n<sup>+</sup>-doped source/drain, it was later found that the ordinary SOI MOSFET with LG-source/drain overlap can operate as a single-photon detector with the same feature [3]. In order to improve the performance of this detector low-frequency noise in the output and lifetime of the photo-generated holes stored in the body of the MOSFET must be analyzed, which are closely related to the dark count rate and the operation speed of the single-photon detection. In this paper, we will describe the behavior of the drain current noise and the hole lifetime under different

substrate biases in search of optimum operation condition of the SOI MOSFET single-photon detector.

## II. EXPERIMENTS

This time, we focus on the ordinary n-channel SOI MOSFET without offset region as shown in Fig. 1. It has n<sup>+</sup> poly-Si-gate and p<sup>+</sup> channel region with dopant concentration less than 10<sup>15</sup> cm<sup>-3</sup>. The SOI is of a wafer-bonding type supplied by Soitec [4]. Thicknesses of buried oxide, SOI and gate oxide are 145, 50 and 5 nm, respectively. The gate length is fixed at 300 nm, and the channel width is varied among 90, 95 and 110 nm. In the noise measurement and the hole lifetime analysis, we changed  $V_{sub}$ , while keeping the drain current at the constant level of 1 nA by adjusting the front gate voltage  $V_g$ . The drain current noise was measured in dark condition at 300 K, and the hole lifetime was evaluated by the analysis of drain current histograms for different levels of light intensity also at 300 K.

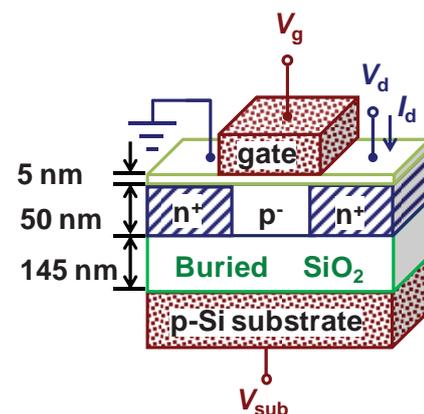

Fig. 1 Schematic diagram of the SOI MOSFET. Thicknesses of buried oxide, SOI and gate oxide are 145, 50 and 5 nm, respectively.

## III. RESULT AND DISCUSSION

### A. Analysis of drain current noise

Figure 2 shows an example of  $I_d$ - $V_g$  characteristics with  $V_{sub}$  as a parameter ranging from -10 to 10 V. Drain voltage  $V_d$  is kept at 50 mV. From these data, front-gate threshold voltage  $V_{th}$  corresponding to the  $I_d$  of 1 nA is extracted for setting the operation condition and further analysis. Figure 3 shows noise power for the bandwidth of 5 Hz, and the threshold voltage  $V_{th}$  plotted against the substrate voltage for various channel widths. In the  $V_{th}$ - $V_{sub}$  characteristics, the deflection point 1 corresponds to the transition point between front- and back-channel operations, and the deflection point 2 to the transition between inversion and accumulation conditions at the buried oxide/substrate interface [5]. The noise levels show horseshoe shape, and become low at around the deflection point 1 and in the back-channel region between deflection points 1 and 2.

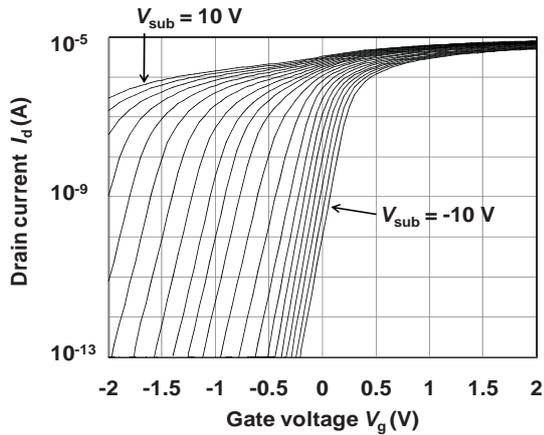

Fig. 2  $I_d$ - $V_g$  characteristics with  $V_{sub}$  as a parameter. Drain voltage  $V_d$  is kept at 50 mV. Device sizes are  $L=300$  nm and  $W=110$  nm.

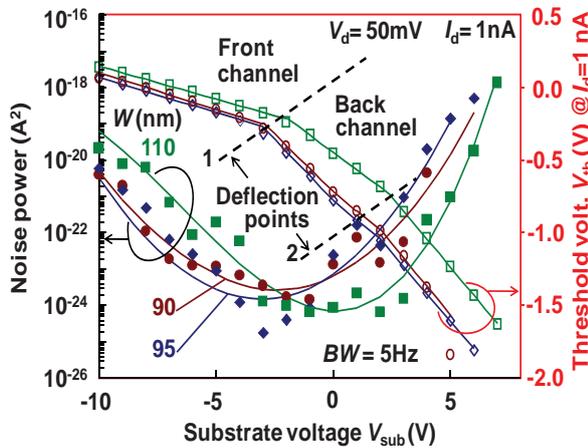

Fig. 3 Noise power and front-gate threshold voltage  $V_{th}$  at 1 nA as a function  $V_{sub}$ . The gate length is fixed at 300 nm, channel width is varied among 90, 95 and 110 nm.

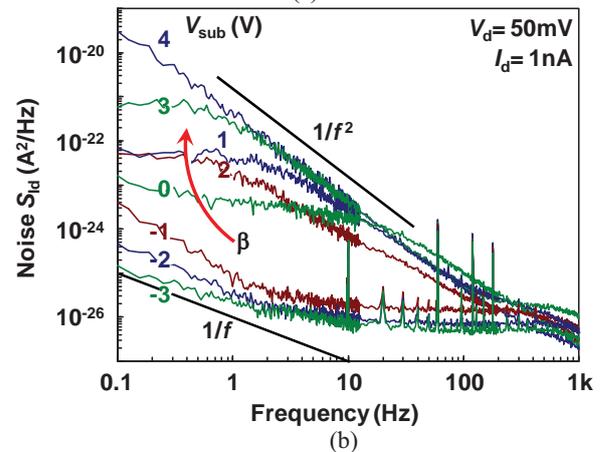

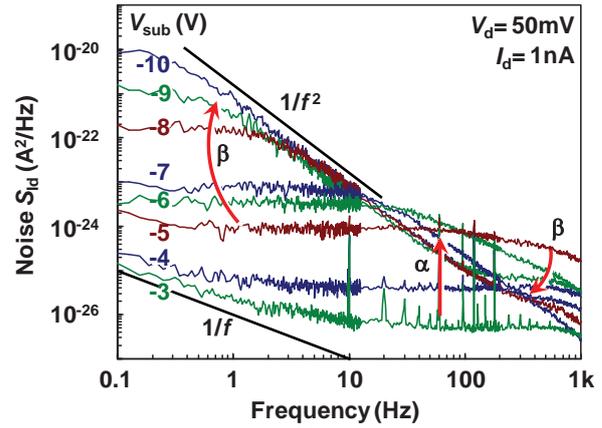

Fig. 4 Drain current noise spectra for (a) front-channel ( $-10 \leq V_{sub} \leq -3$  V), and (b) back-channel ( $-3 \leq V_{sub} \leq 4$  V) operations. Device sizes are  $L=300$  nm and  $W=95$  nm.

Figure 4(a) shows the drain current noise spectra for front-channel operation in  $-10 \leq V_{sub} \leq -3$  V. It can be seen that, as the  $V_{sub}$  decreased, the Lorentzian noise at high frequency increases only in the plateau level at first ( $\alpha$ ), and after that, the noise spectra asymptotically approaches a single  $1/f^2$  line ( $\beta$ ), indicating that the plateau level increases and the cut-off frequency decreases simultaneously. The similar noise behavior was found by D. S. Ang, et al. in the nearly fully depleted SIMOX SOI n-MOSFET operating at a low drain voltage, and they attributed this to the generation and recombination (GR) of carriers via bulk electron traps [6]. It is interesting to see the resemblance regardless of the difference in SOI material. Figure 4(b) shows the noise spectra for back-channel operation in  $-3 \leq V_{sub} \leq 4$  V. The similar behavior of the evolution of the GR noise can be observed ( $\beta$ ), but the initial increase only in the plateau level ( $\alpha$ ) cannot be seen.

### B. Analysis of hole lifetime

Figure 5 shows typical drain current waveforms for different levels of light intensity at the wavelength of 550 nm. Baseline

current is adjusted to 1 nA by  $V_g$ , and each waveform is shifted for clarity.  $V_d$  and  $V_{sub}$  are 0.05 and 1.49 V, respectively. In this figure, we can clearly see that the photo-generated holes modulate the drain current to discrete levels corresponding to the number of stored holes below the gate, while the operating condition is set to  $V_g < 0$  and  $V_{sub} > 0$ , so that the electrons flow in the back-channel.

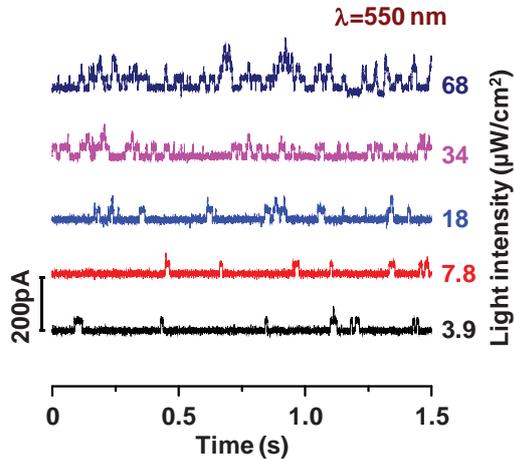

Fig. 5 Typical drain current waveforms at 300 K for different levels of light intensity at the wavelength of 550 nm. Baseline current is adjusted to 1 nA by  $V_g$ , and each waveform is shifted for clarity.  $V_d$  and  $V_{sub}$  are 0.05 and 1.49 V, respectively. Device sizes are  $L=300$  nm and  $W=110$  nm.

Figure 6 shows the histograms of drain current for (a)  $V_{sub}=1.27$  V, (b)  $V_{sub}=1.49$  V, (c)  $V_{sub}=1.72$  V, and (d)  $V_{sub}=1.93$  V with different  $V_g$  to keep the baseline drain current at the same level of 1 nA. The closed symbols are obtained data and solid lines are fitting curves with Gaussian distribution. The peaks from left to right correspond to the number of stored holes of 0, 1, 2 and 3. It can be seen that the peaks in the histogram corresponding to the larger number of stored holes become higher as the  $V_{sub}$  increases. This may be caused by the longer hole lifetime, higher light absorption efficiency or higher collection efficiency of the photo-generated holes. In order to understand the bias dependence of the light absorption and hole collection, hole generation rate is plotted against the light intensity in Fig. 7. There is proportionality between hole generation rate and incident light intensity regardless of  $V_{sub}$ , indicating that light absorption or hole collection efficiencies is not much changed by the bias condition. This also means that the hole lifetime can be controlled without affecting the nominal QE, which amounts to 5% in this case assuming the photosensitive area of  $300 \times 110$  nm<sup>2</sup>.

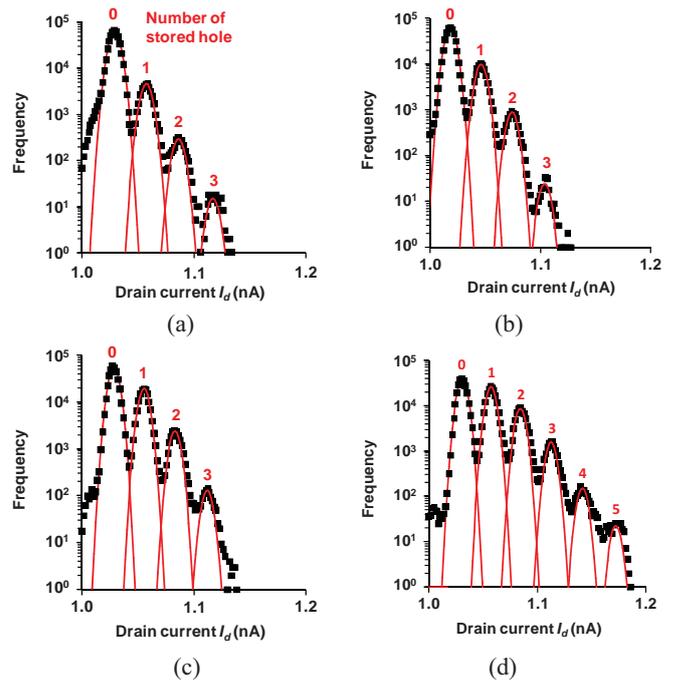

Fig. 6 Histograms of drain current for (a)  $V_{sub}=1.27$  V, (b)  $V_{sub}=1.49$  V, (c)  $V_{sub}=1.72$  V, and (d)  $V_{sub}=1.93$  V with different  $V_g$  to keep the baseline drain current at the same level of 1 nA under the continuous light illumination of  $34 \mu\text{W}/\text{cm}^2$ . The first, second, third, and fourth peaks correspond to the number stored holes of 0, 1, 2 and 3, respectively. Data acquisition time period and time step are 2.45 s and  $49 \mu\text{s}$ , respectively, and 50000 ( $=2.45\text{s}/49\mu\text{s}$ ) data points (current values) are classified into bins with a width of 2 pA. Device sizes are  $L=300$  nm and  $W=110$  nm.

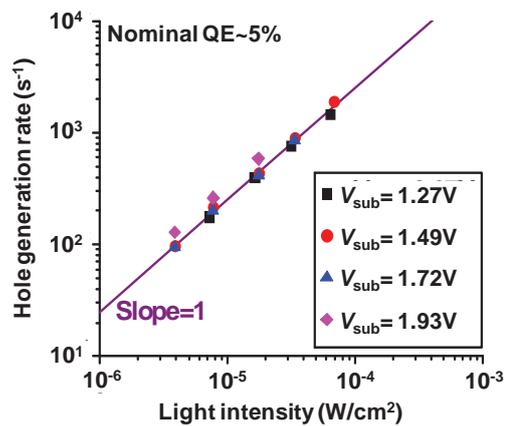

Fig. 7 Hole generation rate as a function of incident light intensity for each bias condition. Slope of the fitting line is one.

The hole lifetimes are obtained as fitting parameters to describe the evolution of drain current histogram based on the rate equation under steady state conditions,  $f_i / \tau_i = f_{i-1} R$  and  $\sum f_i = 1$ , where  $\tau_i$  and  $f_i$  are hole lifetime and probability of state corresponding to hole number  $i$ , and  $R$  is hole generation rate [2]. The hole lifetimes at different  $V_{\text{sub}}$  are depicted in Fig. 8. It can be seen the hole lifetime increases significantly as  $V_{\text{sub}}$  increases. It is estimated that higher  $V_{\text{sub}}$  (higher transverse electric field) separates the stored hole and electron more effectively, and reduces the probability of recombination, leading to the longer lifetime.

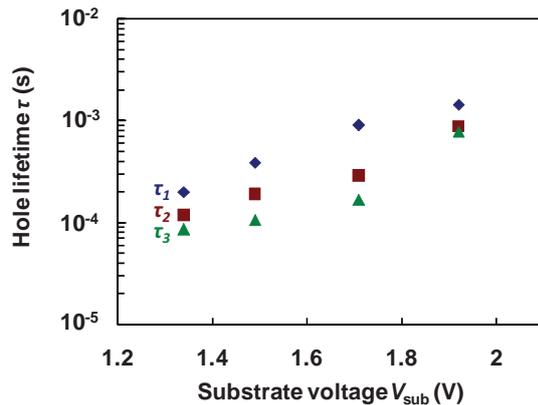

Fig. 8 Hole lifetime as a function of  $V_{\text{sub}}$ .  $\tau_1$ ,  $\tau_2$  and  $\tau_3$  are the lifetimes when the number of the stored holes are one, two and three, respectively.

#### IV. CONCLUSION

Low-frequency current noise in SOI MOSFET was analyzed for single-photon detection under different substrate biases in dark condition while keeping the average drain current constant. It was found that the noise in the SOI MOSFET became low at the transition point between the front- and back-channel operations, and in the back-channel region near the transition point. On both sides, the noise spectra asymptotically approached a single  $1/f^2$  line, indicating that the active trap density and carrier lifetime increased simultaneously. In order to understand the substrate bias dependence of hole lifetime, the drain current histograms of the SOI MOSFET single-photon detectors were analyzed under different substrate voltages and different light intensity. It was found that the peaks in the histogram corresponding to the larger number of stored holes became higher as the substrate bias decreased. This was attributed to the prolonged hole lifetimes caused by the higher electric field inside the body of SOI MOSFET. It can be concluded that, once the inversion channel is induced for detection of the photo-generated minority carriers, the small absolute substrate bias is favorable for short lifetime and low noise, leading to high-speed operation.

#### ACKNOWLEDGMENT

The author are indebted to Keisaku Yamada of University of Tsukuba, Toyohiro Chikyo of National Institute of Materials and Science, Tetsuo Endoh of Tohoku University, Hideo Yoshino and Shigeru Fujisawa of Semiconductor Leading Edge Technologies, Inc. for their cooperation in the device fabrication.

**Abstract**—Quorum sensing is a mechanism used by most of pathogenic bacteria to coordinate their gene expression. Through this kind of mechanism the bacteria could detect the density of their local population until at a certain level they will act together to emerge virulence which cause disease in their host organism. Thus, the inhibition ability to quorum sensing mechanism is commonly used as an indicator to evaluate the potentiality of extracts from plants as antibacterial in drugs development. The quorum sensing activity could be detected using luminescence method. When the colony of bacteria reach the quorum and express certain activity, the luminescence will be produced. Microplate is a kind of experiment media which is used to conduct such experiment. The luminescence as the experiment result were captured as a digital image. The luminescence then examined to determine the plant performance to inhibit the bacteria virulence activity. Regarding most of the researcher's experience, it is believed that manual evaluation of those luminescence images is hard to interpret due to subjectivity factor and also inefficiency in time, especially when working with a large number of experiments. Therefore, in this research we developed a computer application to run quantification of the luminescence automatically. The automation process begin with gridding algorithm followed by object recognition and segmentation algorithm based on neural network learning. In order to improve the accuracy, image enhancement module were also attached to the system. In the output section, the quantification report presented using some statistical parameter to simplify interpretation and facilitate the researcher to run additional data analysis. With this application, the potentiality of extracts from plants as antibacterial agent could be inferred quickly, easily and accurately.

**Keywords**—digital image processing; artificial neural network; automation; luminescence; quorum sensing

## 1. Introduction

Quorum sensing is bacterial mechanisms which is regulating some specific proteins expressions by calculating population density in their environment. Genes which are regulated by quorum sensing mechanism will only express (activated) at the time the bacteria population reached certain level of density. Some examples of genes whose expression

was regulated by this mechanism are genes that regulate the formation of flagella and biofilm, and genes associated with virulence properties [1]. The fact that the virulence factor is also regulated by quorum sensing mechanism raises new hope to discover many techniques and/or agents to inhibit virulence of pathogenic bacteria. In this research, extracts from some Indonesian Medicinal plants was evaluated for their performance to inhibit quorum sensing mechanism of *Pseudomonas aeruginosa* (one of the pathogenic bacteria which have resistance to many antibiotics). The evaluation was done by measuring the level of luminescence which is produced by the colony of *Pseudomonas aeruginosa* when they reach the quorum and express certain activity. This experiment was conducted in a microplate which is a flat plate with multiple holes/wells used as small test tubes. Both of the bacteria colony and the extracts from plants was loaded into the holes. The level of luminescence then captured and transformed into digital image [2]. Next task is comparison of the result. Brighter luminescence indicates weak inhibition to the *Pseudomonas aeruginosa* quorum sensing mechanism. Most of the researcher use manual comparison to evaluate these luminescence images. Unfortunately, this method is not the best way to get good inference of the result. Manual comparison has many weaknesses due to subjectivity of the evaluator and also inefficiency in time when run multiple experiments. Hence, we propose the application of automatic digital image processing to quantify the luminescence images in the form of software named Microplate Luminescence Automated Digital Analyzer (MILDA). Therefore, the researcher could run various statistical data processing to get accurate and fast conclusion.

The first generation of MILDA was developed using hough transform algorithm for the segmentation (separation of the luminescence and the background area) procedure. But, due to the problem of imprecise circular form of the luminescence area, this method is found to be ineffective [3]. In this research, the artificial neural network algorithm was applied to improve the segmentation result.

## II. Materials and methods

Input of the software are luminescence images using microplate as experiment media. Fig. 1 is the examples of the input images. The bright round shapes are the luminescence produces by the experiment in the round shape wells. Each well was loaded with the *Pseudomonas aeruginosa colony* and extract from particular medicinal plant. The medicinal plants used in this experiment are fennel, lawang, selasih, temu ireng, temu putih, temu giring and temu lawak. When the quorum sensing mechanism was totally inhibits by the extracts, the well will not produce any luminescence and will appears as black round shape. The micro plate could contain various numbers of wells, such as 36, 96, 384 and 1536.

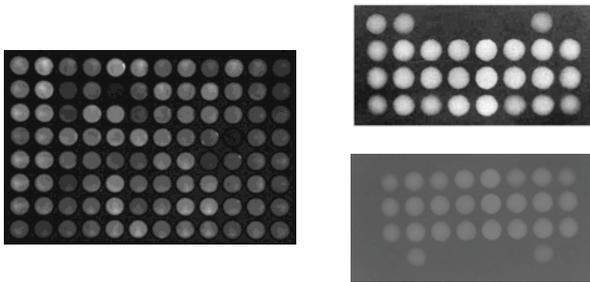

Fig. 1. Examples of the input images

The first step of the MILDA's system is preprocessing the input image to enhance its quality, the second step is run gridding procedure. In this procedure the system will automatically make a pattern of regularly spaced horizontal and vertical lines forming squares on the input image with modified fixed spot position algorithm.. At the end of the procedure, each square will only contain one round shape. Next, segmentation procedure was applied to each square. The aim of this procedure is to classify each pixel in the square as object (the luminescence) or background. Classification was done using neural network algorithm. Finally, the last step is quantification of the object pixels. In order to simplify the quantification result, MILDA was equipped with the statistical report feature. Fig. 2 depict the flowchart of the system. Details algorithm of each step will be explained in the next sections.

## III. system design

### A. Preprocessing

In order to improve the accuracy of the luminescence value as the systems output, preprocessing the input image is one of the important step. Input image could have various quality due to its clarity, color intensity, color contrast or symmetricalness. Preprocessing will reduce the complexity of the algorithm in the next procedures. Some of the image

enhancement algorithms was applied in preprocessing step which are noise reduction, image rotation and normalization. Noise reduction was conducted using median or wiener filtering algorithm. Median filtering reduced salt and pepper noise and wiener filtering reduced Gaussian noise [4].

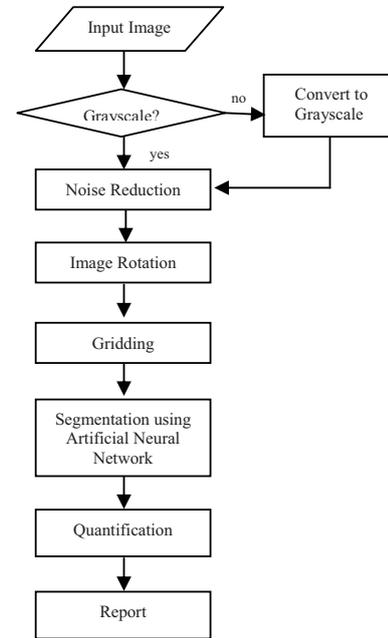

Fig. 2. Flowchart of the system

Fig. 3 depict the example of noise reduction result on the input image. Image rotation was applied due to symmetricalness problem of the input image. Asymmetric image will cause problems in the gridding procedure. Therefore radon transformation [5] algorithm used to transform asymmetric image into a symmetric one. Fig. 4 depict the example of image rotation to fix asymmetric image.

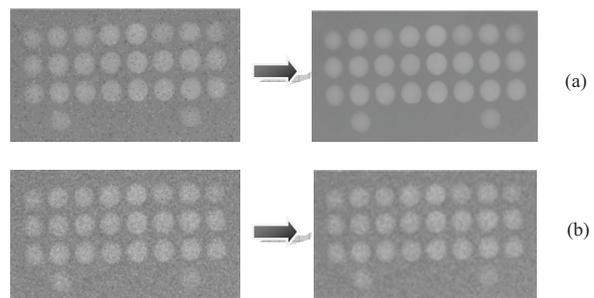

Fig. 3. Example of noise reduction, (a) Salt and Pepper, (b) Gaussian

Finally, the normalization algorithm was applied to adjust the color intensity range, such adjustment will increase the color

contrast as shown in Fig. 5. Normalization was done using (1),  $O$  is intensity value before normalization and  $N$  is intensity value after normalization.

$$N_{x,y} = \frac{N_{max} - N_{min}}{O_{max} - O_{min}} \times (O_{x,y} - O_{min}) + N_{min} \quad \forall x,y \in 1,N \quad \dots(1)$$

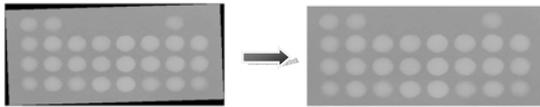

Fig. 4. Example of image rotation

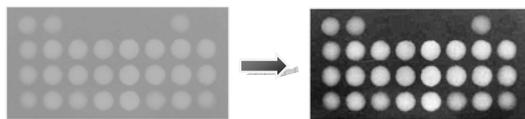

Fig. 5. Example of image normalization

### B. Gridding Procedure

This procedure contain techniques to find the location of the objects (the round shape luminescence) automatically. In general, the basic concept is iteratively creates vertical and horizontal lines on the input image such that in the final step each object will be placed exactly on the center of a square. The algorithm used for this process is fixed spot position [6] with some modification. Formerly the input image should be transform into grayscale type and followed by application of particular intensity threshold value to identify each pixel as object or background. Vertical and horizontal line will divide two objects in equal distance regarding the edge pixels of both objects. Fig. 6 is the example of the gridding procedure result. Now, each square carried out one object.

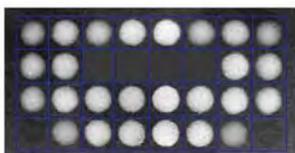

Fig. 6. Result of the gridding procedure

### C. Segmentation Procedure

After gridding procedure, the system will save position of each square with the object inside. Thus, the extraction of the objects is ready to be proceeded. The first step to extract the object is finding all the object's pixels. To find those pixels, the system should have the ability to well recognize the characteristic of the color intensity of the object pixels as well as the background pixels. In order to increase this ability, neural network (NN) method was applied here. Intensity

histogram was chosen as the input of the NN architecture. Therefore, 256 nodes are used in the input layer. For the hidden layer it is found that one layer with 6 node give the best output prediction. One output node represents the color intensity threshold value that will classify each pixel as object or background. Fig. 7 depict the best NN architecture implemented in the system. At the end of the process, the system will store the position of each object pixel and the corresponding intensity value in its database.

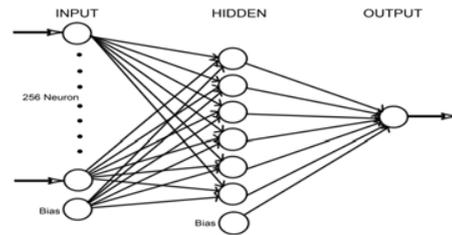

Fig. 7. Neural network architecture for segmentation process

### D. Quantification

This is the step to summarize all object pixels intensity values (from the segmentation procedure) in the database and represent them in more sophisticated format. Quantification of each object luminescence should appear as single value. For this purpose, the system provide option button such that user could choose the method of summarization which is mean, median, maximal or minimal value. Fig. 8 shows example of the quantification process result using mean value.

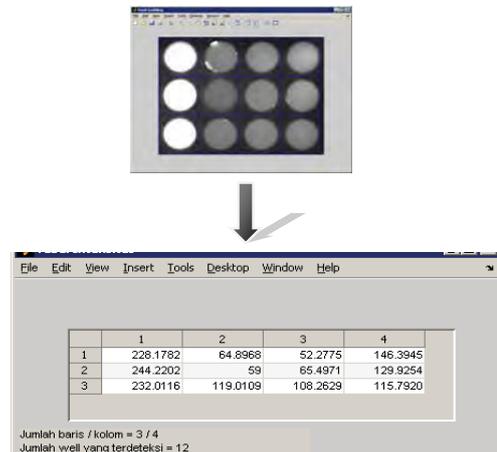

Fig. 8. Example of the quantification process result

E. Report

Report feature was attached to the system to facilitate user for advance data processing. The report will be in .xls format which is contains the position and luminescence intensity of each object pixels. By this feature the researcher could easily prepare raw data to run various kinds of statistical data processing such as testing hypothesis, ANOVA, regression and cluster analysis.

#### IV. result and discussion

In general the performance of the system is good. The quantification performance of the intensity value is depends the input image. From all input images sample with various level of quality, the system could give reasonable quantification result for 87.5% among them. The system only fail on very low quality of input image. For this kind of input image, the systems already fail in gridding process thus no intensity value reported on the output interface. The accuracy of the system was proven too by changing the concentration of the plant extract. In theory, the increasing concentration of quorum sensing inhibitors will result on decreasing luminescence intensity [7]. The quantification result shows exactly the same tendency in almost all of the samples as shown in Table 1. In the matter of time, the run time depend on the number of the microplate wells. MILDA could run all the process less than 15 second. This result is better than previous system using circular hough transform for its segmentation process [3].

TABLE I. THE ABILITY OF PLANTS EXTRACT IN VARIOUS CONCENTRATION TO INHIBIT THE LUMINESCENCE

Plant	Concentration (mg/ml)	Luminescence Inhibition (%)
Fennel	23.8	59.2
	19.0	65.4
	14.3	53.9
Lawang	23.8	34.1
	19.0	19.2
	14.3	-3.2
Selasih	23.8	59.8
	19.2	47.9
	14.3	44
Temu Ireng	38.1	44.1
	19.0	39.7
	9.5	7.7
Temu Giring	38.1	16.3
	19.0	3.9
	9.5	7.9
Temu Putih	38.1	-0.3
	19.0	4.9
	9.5	28.8
Temulawak	38.1	16.5
	19.0	23.5
	9.5	6.3

#### V. conclusion

Although this system could perform good quantification result, it is known that the quality of input image still bring major difficulties. Therefore, for the future works we propose to design a customized media to capture the luminescence directly from the microplate. This media then integrated to the MILDA software such that the quantification could run in real time.

**Abstract**—Although the introduction of nanostructures into thermoelectric materials is one of key technology for enhancement in thermoelectric conversion efficiency, a technique for characterizing the nanometer-scale materials is required. With the aim of evaluating Seebeck coefficient of nanostructured thermoelectric materials, we propose a new technique by Kelvin-probe force microscopy (KFM) which gives us local surface potential corresponding to the Fermi energy difference of a sample relative to the cantilever. Hence, thermoelectromotive force and temperature difference are obtained from the surface potentials and temperatures at the high- and low-temperature regions on the sample, which leads to evaluation of Seebeck coefficient. First of all, the Seebeck coefficients of bulk Si wafers and Si-on-insulator (SOI) layers were measured. At present, the Seebeck coefficient is evaluated to be  $-2.8\text{mV/K}$  for a SOI layer, which is larger than the value obtained by a conventional method.

**Keywords**—thermoelectric material; nanostructure; Seebeck coefficient; Kelvin-probe force microscopy

## I. Introduction

The introduction of nanometer-scale structures into thermoelectric materials has been expected to lead to breakthroughs for enhancing the thermoelectric figure-of-merit [1-4]. A number of researchers are engaged in characterizing nanometer-scale thermoelectric materials [5-8]. However, it is very difficult to measure the thermoelectric characteristics of these nanostructured materials because of the very small dimensions. For evaluating the Seebeck coefficient, external disturbances such as lead-wire contact essential to the conventional thermoelectromotive force (TEMF) measurement affect accurate evaluation. Recently, probe microscopy techniques have attracted significant attention for the thermoelectric characterization of nanometer-scale materials [9-11]. In these techniques, a probe is contacted with the sample surface and the thermoelectric characterization is performed on the basis of the vertical temperature difference (i.e. normal to the sample surface). Therefore, contact of the metallic probe with the sample surface cannot be avoided, and specially-customized equipment is needed.

With the aim of measuring the Seebeck coefficient on a nanometer scale, we propose a new technique using Kelvin-probe force microscopy (KFM), which allows non-contact

measurement. Another advantage of the proposed technique is that, by adjusting the sample holder, commercial KFM equipment can be used. In the present paper, it is demonstrated that the construction and improvement of the measurement technique through Seebeck-coefficient evaluation for Si and Si-on-insulator (SOI) wafers [12-14].

## II. Measurement Principle

The KFM is a powerful tool for measuring the electric potential of nanometer-scale structures. Using this technique, it is possible to obtain the surface potential corresponding to the work-function difference between the cantilever and the sample, that is, the Fermi energy of the sample relative to that of the cantilever metal. Figure 1 shows the band diagram of the cantilever (Au-coated Si) and the n-type Si sample under a temperature difference across the sample parallel to the surface. When the temperature difference is applied to the sample, the Fermi energy of the Si will be spatially distributed. Generally, the Fermi energy in the high-temperature region  $E_{FH}$  is lower than that in the low-temperature region  $E_{FL}$  in the n-type Si, as shown in Fig. 1.

The Seebeck coefficient  $S$  is expressed as follows:

$$S = -\Delta V/\Delta T = -1/q \cdot (E_{FH} - E_{FL}) / (T_H - T_L) = (\phi_H - \phi_L) / (T_H - T_L), \quad (1)$$

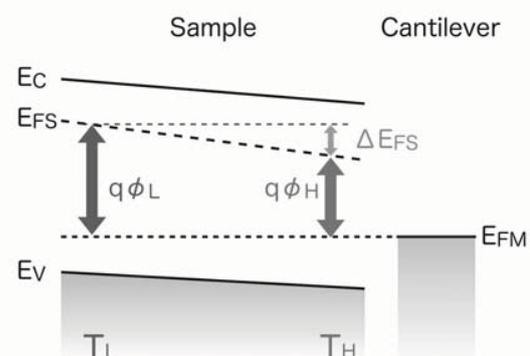

Fig. 1. Fermi energy positions of n-type semiconductor under a temperature difference.

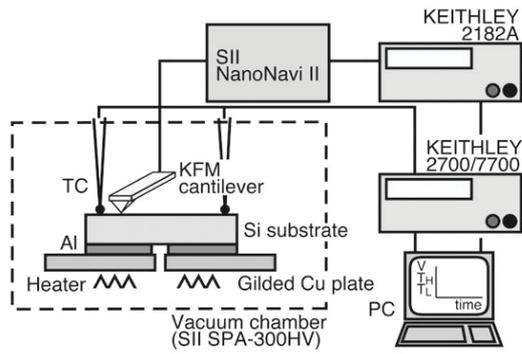

Fig. 2. Schematic diagram of KFM apparatus for measuring Seebeck coefficient.

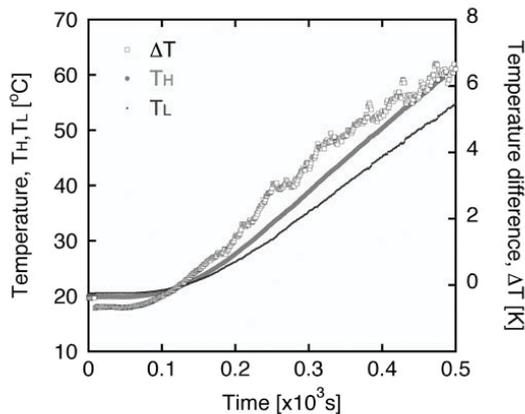

Fig. 3. Time evolution of temperature and temperature difference.

where  $q$  is the elemental charge.  $\Delta V$  is the TEMF defined as  $\phi_H - \phi_L$ , where  $\phi_H$  and  $\phi_L$  are respectively the surface potentials in the high- and low-temperature region measured from the cantilever Fermi energy, as shown in Fig. 1.  $\Delta T$  is the temperature difference  $T_H - T_L$ , where  $T_H$  and  $T_L$  are the temperature in the high- and low-temperature regions, respectively. Consequently, the Seebeck coefficient can be evaluated from the measurement of the surface potential for each region under a given temperature difference across the sample parallel to the surface.

### III. Improvements in Equipment and Sample Structure

Figure 2 depicts a schematic diagram of the experimental setup, where we introduced the new KFM control unit (Seiko Instruments Inc., NanoNavi II) and the measurement devices. The surface potential of the sample was monitored using a nanovoltmeter (KEITHLEY, 2182A), and the temperatures of

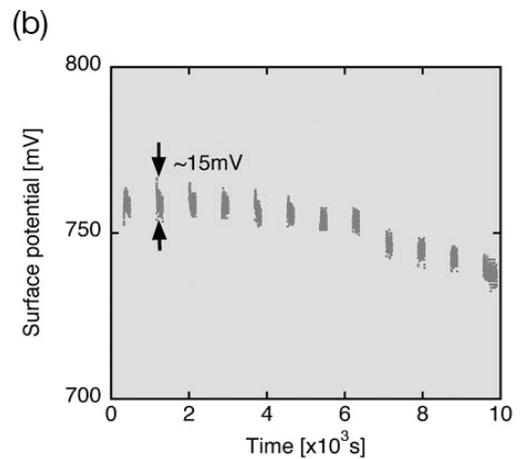

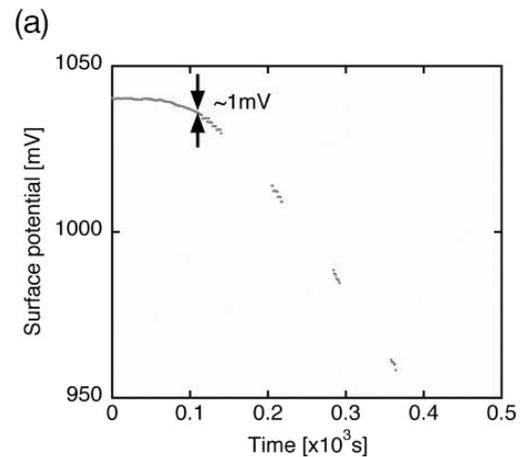

Fig. 4. Time evolution of surface potential obtained by (a) the improved system and (b) the previous system.

the sample were measured using a digital multimeter (KEITHLEY, 2700). A sample was bridged over two gilded Cu plates separated by a gap of 3 mm. Joule heaters were applied to each Cu plate. The temperature difference was applied to the sample by individually flowing a current to the heaters. Two K-type thermocouples were directly attached to both ends of the sample surface in order to measure the temperature. At the high- and low-temperature regions of the sample surface, the time evolutions of temperature and surface potential were measured simultaneously. Measurements were performed in a vacuum chamber (Seiko Instruments Inc., SPA-300HV) at a pressure of  $4 \times 10^{-5}$  Pa.

In the present study, we measured an n-type Si wafer with an impurity concentration of  $1 \times 10^{13} \text{ cm}^{-3}$ . In our previous paper, the analysis for evaluating the Seebeck coefficient from the KFM data was complicated because of the influence of the Schottky contact at the n-type Si/Ag paste interface [12]. In order to avoid such a troublesome analysis, an ohmic contact

was formed at the bottom of the Si sample, which leads to the direct determination of surface potential from the KFM data.

The time evolution of the temperature in the high- and low-temperature regions and the obtained temperature difference  $\Delta T$  are shown in Fig. 3. The temperature difference

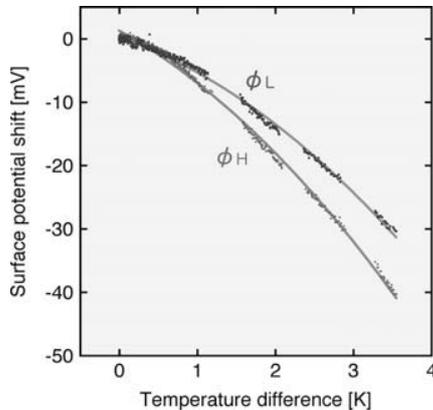

Fig. 5. Relationship between surface potential shift and temperature difference in the high- and low-temperature regions.

was found to increase with increasing sample temperature. In this case, the temperature difference was more than 6 K, which is sufficient to produce a large TEMF. Figure 4(a) is the time evolution of the surface potential obtained simultaneously with the temperatures in Fig. 3. There are spaces between the measured surface-potential values because the measurement could not sufficiently follow the time evolution of the surface potential due to an overflow in the vertical piezoelectric-control (z-gain) during the temperature evolution. This phenomenon originates from the thermal expansion of the sample. Therefore, we kept the cantilever away from the sample and brought it near the sample surface again only when the z-gain overflowed.

The surface potential was found to decrease with increasing time (or  $\Delta T$ ). In Fig. 4(a), the measured values are scattered within 1 mV, which is greatly reduced compared to the scatter of the previous values, which was within 15 mV, as shown in Fig. 4(b). Moreover, Fig. 4 indicates that the time spent for the measurement is shortened by 5% owing to the improvement in the measurement accuracy.

#### IV. Characterization of SOI Seebeck Coefficient

When Si nanostructures such as a Si nanowire are fabricated, the SOI wafer will be preferably used for the fabrication. Hence, we evaluated the Seebeck coefficient of an 85-nm-thick SOI layer with a P concentration of  $1 \times 10^{17} \text{ cm}^{-3}$  by our new technique. The measurement was performed by the same procedure as mentioned above, except for an electric earth. In the KFM measurement, the sample must be electrically earthed with the sample holder (gilded Cu plates in

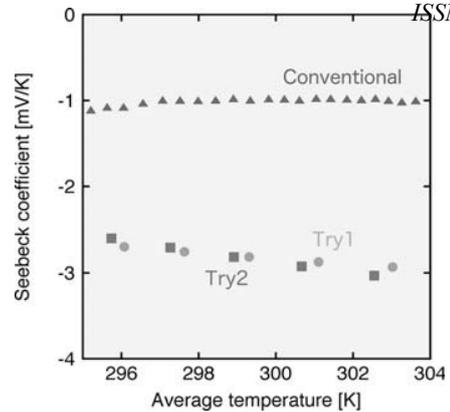

Fig. 6. Seebeck coefficient as a function of average temperature. The measurement by KFM system was performed two times (Try 1 and 2). Seebeck coefficient obtained by a conventional method is also shown.

our system). However, the SOI layer is insulated from the sample holder by the buried oxide. In the present study, therefore, we deposited an Al electrode on the SOI surface and connected a lead-wire between the electrode and the Cu plate. The wire was positioned away from the cantilever-scanned region and therefore the thermal disturbance was unlikely to influence the measurement.

Figure 5 is the relationship between surface potential shift and temperature difference obtained from the time evolutions of surface potentials and temperatures. The TEMF is given by  $(\phi_H - \phi_L)$  at the same temperature difference. It is found from Fig. 5 that the experimental TEMF is well expressed by a quadratic function of  $\Delta T$ . According to (1), the Seebeck coefficient is evaluated from the fitted lines, which is plotted in Fig. 6 as a function of average temperature. The circle and square data are the value evaluated using KFM, and the diamond data are obtained by a conventional method [15]. The Seebeck coefficient is obtained to be -2.8 mV/K for the KFM technique, which is about 2.5 times as large as the values for the conventional method. Unfortunately, the reason of the disagreement is not clear yet. Thus, we are now making sure of the certainty and the validity of evaluated Seebeck coefficient.

#### V. Conclusion

We proposed and improved a new technique for evaluating the Seebeck coefficient on a nanometer scale using KFM. The Seebeck coefficient of a thin SOI layer by this technique was evaluated to be -2.8 mV/K. However, there was disagreement between the Seebeck coefficients obtained by the KFM technique and the conventional method. Therefore, the certainty and the validity of the KFM evaluation is now under investigation.

**Abstract**—Recently,  $p$ - $n$  junction characteristics in nanometer scale have been investigated in relation with photonics and electronics applications. In this paper, we report the experimental observation of negative differential conductance (NDC), the basic indication of tunneling, in nanoscale  $p$ - $n$  junctions under forward bias condition. The NDC has been observed only at low temperatures, suggesting that tunneling is mediated by some states in the band gap, most likely by individual dopants with deeper energy levels compared to bulk. Furthermore, we also observed random telegraph signal (RTS) at low temperatures, which is ascribed to sudden changes of charge states of an individual dopant. These results illustrate the nature of individual dopants in nanoscale  $p$ - $n$  junctions and their impact on device characteristics.

**Keywords**—NDC; tunneling; nanoscale  $p$ - $n$  junction; individual dopant.

## I. Introduction

Reduction in Si MOSFET dimensions brings several difficulties in conventional device operation [1]. By decreasing device size, operating voltage will be lowered, but it is difficult to appropriately maintain a good on/off current ratio. In order to overcome this problem, it is proposed that the transport mechanism must be drastically changed from the conventional thermionic-emission transport and that tunnel field-effect transistors (TFETs) are promising candidates for improving the operation conditions.

Tunneling is a quantum mechanical effect, where electrons (holes) have a finite probability of transmission through an energy barrier and this effect becomes most pronounced in nanometer-scale structures. In  $p$ - $n$  junctions, tunneling mechanism can be observed both under reverse and forward bias. Tunneling mechanism under reverse-bias mode, so-called Zener tunneling, is inter-band tunneling, as indicated by a rapid increase of current. It is basically the main tunneling mechanism in TFETs [2-4].

Under forward bias for heavily doped (degenerated)  $p$ - $n$  junctions, there is another inter band tunneling mechanism, which is the basis of Esaki tunneling diodes [5]. The tunneling in forward-bias mode can be seen as negative differential conductance (NDC), i.e, a negative slope in current-voltage ( $I$ - $V$ ) curve. So far, tunneling in nanometer-scale  $p$ - $n$  junctions has been reported in vertical nanowires in forward-bias mode [6,7] and in lateral gated  $p$ - $n$  junctions in reverse-bias mode [8]. In this work, we study nanoscale lateral  $p$ - $n$  junctions in forward-bias mode and report the experimental observation of NDC at low temperatures. RTS has also been observed at low temperatures, indicating the effect of a single charge trap. We

ascribe these phenomena to the influence of individual dopants on the electrical characteristics.

## II. DEVICE STRUCTURE AND MEASUREMENT SETUP

We fabricated nanoscale silicon-on-insulator (SOI)  $p$ - $n$  junctions. Figure 1 shows schematically the device structure and  $I$ - $V$  measurement setup. Nanowires were patterned on the SOI layer by an electron beam (EB) lithography technique. Then, a selective doping technique was used to create the  $n$ -type (phosphorus-doped) and  $p$ -type (boron-doped) regions. The channel thickness is about 10 nm, while the device length and width are 1000 nm and 150 nm, respectively. Aluminum contact pads were formed as electrodes.

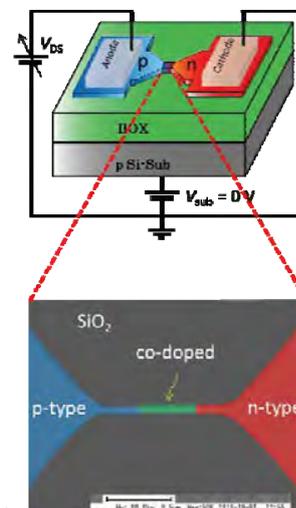

Fig. 1. (a) Device structure and bias configuration for electrical characterization. (b) Co-doped devices, based on SEM images. Co-doped region is located within the thin and narrow nanowire.

The  $n$ -type region was doped with phosphorus (P) to the concentration  $N_D \approx 1.0 \times 10^{18} \text{ cm}^{-3}$ , while the  $p$ -type region was doped with boron (B) to the concentration  $N_A \approx 1.5 \times 10^{18} \text{ cm}^{-3}$ . A co-doped region, doped with both P and B, is designed in the center of the nanowire. The  $p$ -Si substrate was weakly  $p$ -type, doped with boron ( $N_A \approx 1.5 \times 10^{15} \text{ cm}^{-3}$ ).

The thickness of the buried oxide layer between the nanowire and the substrate is 150 nm. The nanowire is covered with a 10-nm-thick SiO<sub>2</sub> layer, grown by thermal oxidation. Devices were measured in a vacuum chamber of an electrical measurement system. The *p*-type region is positively biased for these measurements, i.e., the *p-n* junction is forward-biased, while the *n*-type region and substrate are grounded.

### III. EXPERIMENTAL RESULTS AND DISCUSSIONS

We measured current versus applied bias (*I-V*) characteristics in the dark condition. The measurement results are shown in Fig. 2. *I-V* characteristics at room temperature (*T* = 300 K), as shown in Fig. 2(a), are similar to the conventional diode behavior, although parasitic resistance due to the narrow wire dimension causes suppression of current and shift the current onset.

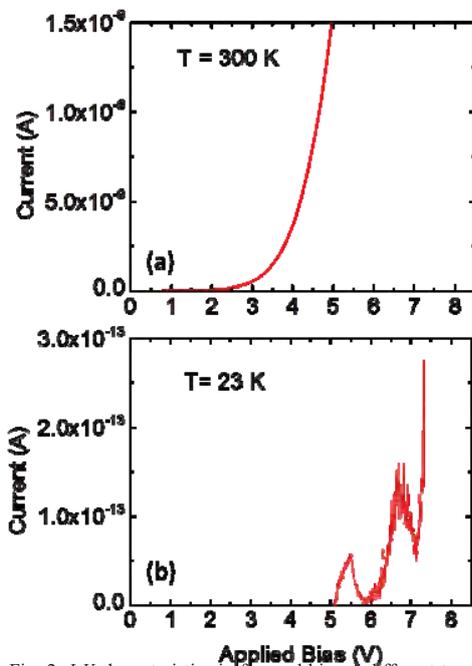

Fig. 2. *I-V* characteristics in forward bias at different temperatures: (a) *T* = 300 K and (b) *T* = 23 K. For *T* = 23 K, NDC can be observed.

At low temperatures, as shown in Fig. 2(b), the voltage for the current onset is further shifted compared to the room temperature behavior. This is caused by the dopant freeze-out effect [9], which leads to an effectively smaller dopant concentration. However, it is even more important to note that, at *T* = 23 K, *I-V* characteristics exhibit NDC. This behavior, except for the observation of a second peak, is similar to Esaki-diode characteristics, suggesting that the observed features are most likely due to resonant tunneling phenomena

in the *p-n* junction. However, since doping concentration of our devices is lower than the doping levels known for Esaki diodes, NDC may occur by a different mechanism. Based on the fact that NDC has been observed just at low temperature, it is likely that tunneling is mediated by some states in the band gap, most likely by individual dopants.

In other devices, a different type of behavior could be also observed. We measured *I-V* characteristic at room temperature and several temperatures below 100 K in the dark condition. Figure 3(a) shows the *I-V* characteristics at *T* = 300 K and at low temperature (*T* = 10 K). We observed current fluctuations in *I-V* characteristics at temperatures below 30 K. These current fluctuations can be ascribed to charge trapping and de-trapping by a single trap site. At different temperatures, time dependence of the current was measured as a function of applied bias. The data at 10 K are shown in Fig. 3(b). Random telegraph signals (RTS) with two levels were clearly observed, suggesting that the trap is most likely a single dopant, which can have only two possible states. The RTS frequency is increased by increasing the forward bias, indicating that the RTS (trapping and de-trapping) is sensitive to the change of electric field near the *p-n* junction. Therefore, a single dopant located in the depletion region may be responsible for the RTS.

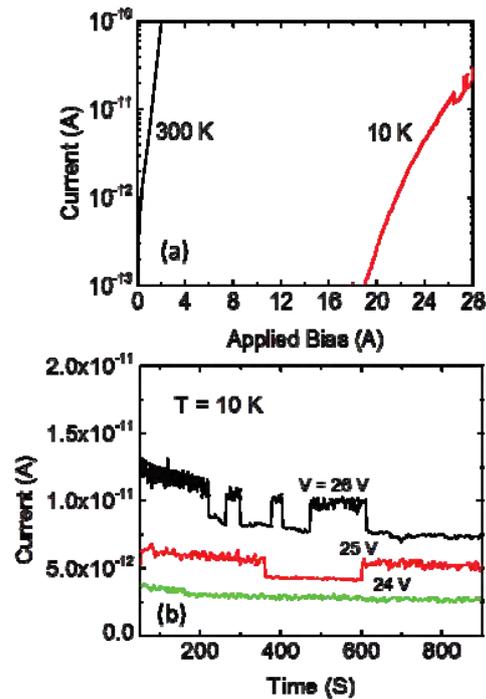

Fig. 3. (a) *I-V* characteristics in forward bias at temperature 300 K and 10 K. For *T* = 23 K, current fluctuations has been observed. (b) Examples of *I-time* characteristics at *T* = 10 K for different applied biases. Two-level RTS can be seen above a certain forward bias.

As mentioned above, we observed NDC and RTS in *I-V* characteristics in the low-temperature measurements. These behaviors may show the nature of individual dopant under forward bias in nanoscale *p-n* junctions. We can analyze the

origin of both behaviors from the energy diagram of the devices, as schematically shown in Fig. 4. In thermal equilibrium, the Fermi levels in the  $p$ -type and  $n$ -type are aligned. When positive bias is applied to the  $p$ -type region, as in the forward-bias case, the Fermi level of the  $p$ -type will be shifted downwards and current starts to flow. Starting from this situation, we can analyze two different cases. The first case is the existence of a pair of deep dopants in the depletion layer, as shown in Fig. 4(a). An electron moving from the  $n$ -type to the  $p$ -type region, as part of the diffusion current, may be trapped by an ionized deep donor in the depletion layer. A similar behavior may also occur for a hole, which may be trapped by a deep acceptor. In a certain forward bias, the ground states of the deep donor and the deep acceptor are aligned and, therefore, the electron can resonantly recombine with the hole. By further increasing the forward bias, the resonant recombination condition turns off, resulting in the reduction of the forward current, i.e., NDC. The second peak, which has been observed at different applied bias, may indicate the existence of a second pair of deep dopants. This second pair of dopant, with different energy level, provide different noise feature, as shown in Fig. 2(b). The background current increasing with applied forward bias is an ordinary diffusion current in the  $p$ - $n$  diode.

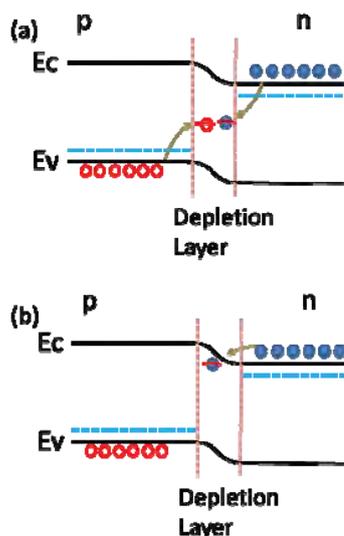

Fig. 4. Band diagrams of  $p$ - $n$  junction under forward bias. Two different cases are illustrated: (a) when a pair of opposite-type deep dopants mediates transport and (b) when one type of dopant, located in depletion layer, works as a charge trap.

A second case, shown in Fig. 4(b), is when a single dopant in the depletion layer works as a charge trap. In this situation, a pair of a donor and an acceptor is not relevant, but only a single dopant nearby the edge of the depletion layer works as a charge trap. The trapped carrier can escape from the dopant due to thermal activation [9]. These trapping and de-trapping events of a carrier cause potential fluctuations, i.e., RTS.

Further investigation is required to fully clarify the origin of this phenomenon.

As illustrated above, the observations of NDC features and discrete-level RTS can be associated with the effects of discrete dopants on the nanoscale  $p$ - $n$  junction's electrical characteristics. These results provide further evidence about the enhanced importance of the discrete dopants in the transport mechanisms in nanoscale devices, as we reported previously [10-13]. These findings also suggest that there is a rich variety of phenomena emerging when the basic structure of the  $p$ - $n$  junction is scaled down into nanometer-order dimensions. This is promising for future applications that combine the well-established conventional  $p$ - $n$  junction theory and technology with novel physics phenomena specific to the nanoscale.

## IV. CONCLUSIONS

We report negative differential conductance and random telegraph signals observed in nanoscale  $p$ - $n$  junctions under forward bias condition. These features are most likely caused by the effects of individual dopants, suggesting the important role that the discreteness of dopant distribution plays in nanoscale. The present results may contribute to the development of dopant-based tunneling FETs on the basis of the nanostructured  $p$ - $n$  junctions.

**Abstract**— We have developed a multi-gated field emitter (FE) such as a quadruple-gated FE with a three-stacked electrode lens and a quintuple-gated FE with a four-stacked electrode lens. Both the FEs can focus the electron beam. However, the quintuple-gated FE has a stronger electron convergence than the quadruple-gated FE, and a beam crossover is clearly observed for the quintuple-gated FE.

**Keywords**— beam crossover; electron beam; focusing; micro-column; multi-gated field emitter

## I. Introduction

A field emitter array (FEA) with a focusing electrode is an attractive device for applications, such as a scanning electron microscope and electron beam lithography and so on. As the FEAs with a focusing electrode, double-gated FEAs have been proposed. However, the double-gated FEA has a problem that the emission current decreases under the strong focusing conditions. This is due to the lowered field enhancement at the emitter tip caused by the low potential of a vicinal focusing electrode. [1] To solve such the problem, we have reported the other approach that uses the focusing electrode located below the extraction gate electrode in a volcano structure. [2, 3] However, we observed that some electrons cannot penetrate the potential barrier formed by the focusing electrode potential under strong focusing conditions. These electrons go back to the extraction gate electrode. To overcome these problems simultaneously (field enhancement and potential barrier), an electrostatic lens using a multistacked-electrode should be integrated at the emitter tip, and at least three additional electrodes are necessary. The first electrode (near the emitter tip) is used to maintain the potential at the emitter tip; therefore, a voltage higher than the extraction gate voltage is applied. The second electrode is used to focus the electron beam; therefore, a voltage lower than the extraction gate voltage is applied. The third electrode is used to inhibit the generation of a potential barrier on the electron trajectory; therefore, a voltage higher than the second electrode voltage is applied. In this paper, we have developed a multi-gated field emitter (FE) with a four-stacked gate electrode, and a FE with a five-stacked gate electrode, that is, quadruple-gated FE with a three-stacked electrode lens and quintuple-gated FE with a four-stacked electrode lens.

## 1. Fabrication of The Multi-gated Field Emitters

The fabrication process for the multi-gated FEs is schematically shown in Fig. 1. (a) An emitter cone is formed from single crystalline Si by reactive ion etching (RIE) using a SiO<sub>2</sub> dot as an etching mask. The apex radius of the tip is 5-10 nm. (b) A SiO<sub>2</sub> insulating layer is deposited by plasma-enhanced chemical vapor deposition (PE-CVD) using tetraethoxysilane (TEOS) gas followed by Nb deposition. (c) After the deposition of SiO<sub>2</sub> and Nb films, a photoresist is spin coated on the Nb film. The thickness of the photoresist on the top of the mountain structure becomes thinner than that on the flat surface. (d) Therefore, the Nb electrode at the tip is selectively etched by the following RIE step without precise lithography. The electrode height can be controlled by the etching time and is adjusted to be the same as that of the emitter tip. The first Nb electrode acts as an extraction gate electrode. (e) In the quadruple-gated FE, three additional electrodes, which form an electrostatic lens, are stacked by repeating the steps from (b) to (d) three times. In the quintuple-gated FE, four additional electrodes, which form an electrostatic lens, are stacked in the similar way. (f) Finally, the emitter tip is opened by the buffered hydrofluoric acid (BHF).

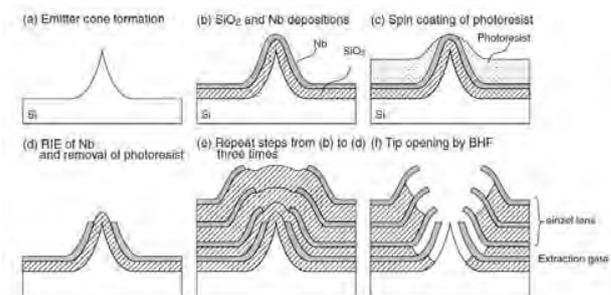

Fig.1 Fabrication process for the quadruple-gated FE with a three-stacked electrode lens.

Figures 2 (a) and (b) show cross sectional SEM images of the quadruple-gated FE and quintuple-gated FE, respectively. In the both FEs, the first Nb electrode acts as an extraction gate electrode. In the quadruple-gated FE, the G<sub>1</sub> and G<sub>2</sub> among the three-stacked electrostatic lens are set at the same voltage. In the quintuple-gated FE, G<sub>1</sub> and G<sub>4</sub> among the four-stacked electrostatic lens are set at the same voltage. G<sub>2</sub> and

$G_3$  ( $G_{2,3}$ ) are connected through a contact hole, and are set at the same voltage. Therefore, both the three-stacked and four-stacked electrostatic lenses form an eizel lens.

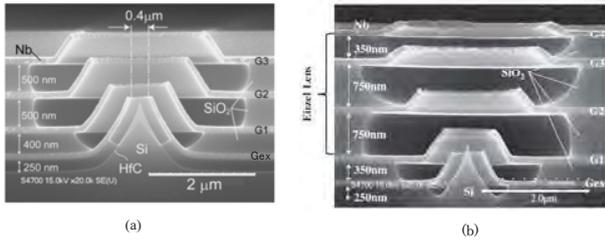

Fig. 2 Cross-sectional SEM images of the quadruple-gated FE (a) and the quintuple-gated FE (b).

Figure 3 shows the top-view micrograph of the quadruple-gated FE. The dotted line in the micrograph shows that the electrode holes from accurate concentric circles with the emitter tip as a center pole. This is due to the full self-aligned process. The alignment of electrode holes is very important for the electrostatic lens to avoid an aberration.

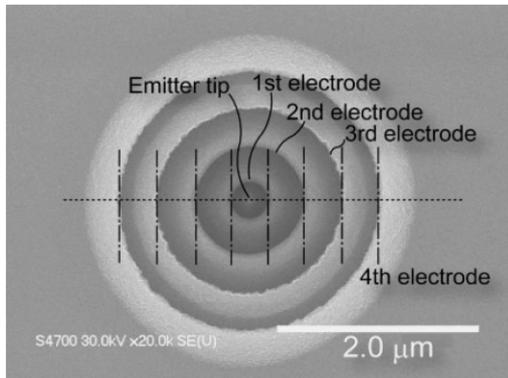

Fig. 3 Top-view SEM image of the quadruple-gated FE.

## II. Electron Emission Characteristics

The electron emission from both the quadruple-gated FE and quintuple-gated FE were measured in a high-vacuum chamber at a pressure of  $1 \times 10^{-7}$  Pa. Figures 4 (a) and (b) show extraction-gate-voltage ( $G_{ex}$ ) versus anode-current characteristics of the quadruple-gated FE and quintuple-gated FE, respectively. An anode phosphor screen biased at 1 kV was located 1 mm above the FE substrate. For the simple anode-current characteristics, the all potentials of the electrostatic lens were set equal to that of the extraction gate electrode, as schematically shown in the insert of Figs. 4 (a) and (b). In the quadruple-gated FE, emission started at 20 V and reached 3 μA at an extraction voltage of 60 V, while in the quintuple-gated FE, emission started at 30 V and reached 100 nA at an extraction voltage of 60 V. In the quintuple-gated FE, more electrons entered the gate electrodes in nonfocusing condition, because the lens size is larger than that of the quadruple-gated FE.

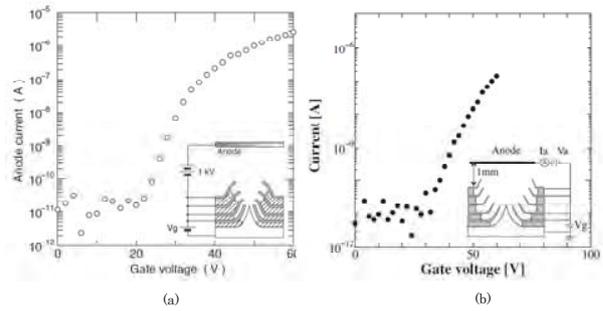

Fig. 4 Emission characteristics of the quadruple-gated FE (a) and the quintuple-gated FE (b).

Figure 5 shows the beam spots measured from the anode phosphor screen images for the quadruple-gated FE and quintuple-gated FE. In the quadruple-gated FE, the voltages of  $G_{ex}$ ,  $G_1$  and  $G_3$  were fixed at 50, 100, and 100 V, respectively. The voltage of  $G_2$  was changed from 100 V (nonfocusing condition) to -20 V (focusing condition). In the quintuple-gated FE, the voltages of  $G_{ex}$ ,  $G_1$ , and  $G_4$  were fixed at 50, 100, and 100 V, respectively. The voltage of  $G_{2,3}$  was changed from 100 V (nonfocusing condition) to -10 (focusing condition). Figure 5 also shows the phosphor images at  $G_{2,3} = 100, 10,$  and  $-10$  V for the quintuple-gated FE. For the quadruple-gated FE, the beam spot monotonously decreases as the  $G_2$  voltage decreases from 100 to -30 V. On the other hand, for the quintuple-gated FE, the beam spot decreases as the  $G_{2,3}$  voltage decreases from 100 to 10 V, but then the beam spot increases as the  $G_{2,3}$  voltage go from 10 to -10 V. This indicates that a beam crossover (a beam focal point) is formed between the anode and the field emitter. Since the field emitter and anode are 1 mm apart and the crossover is formed immediately in front of the field emitter, the beam spot size shown in Fig. 5 are not exact size, and real beam size of the crossover is expected less than 50 nm. The results in Fig. 5 also show that the lens function for the quintuple-gated FE is stronger than that of the quadruple-gated FE.

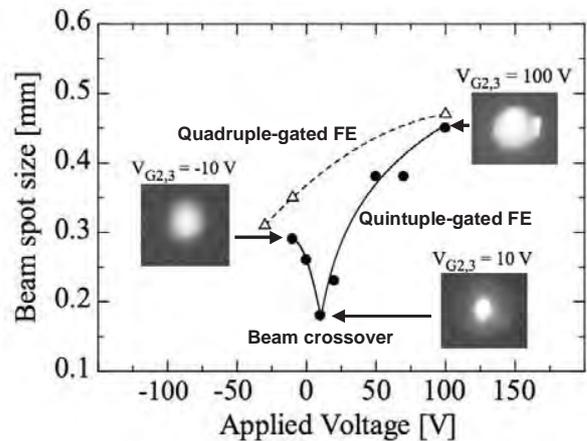

Fig. 5 Beam spots measured from phosphor screen images for the quadruple-gated FE and the quintuple-gated FE. Solid and dashed lines are the least-

square estimations for the quadruple-gated FE and the quintuple-gated FE, respectively.

### III. Conclusions

We have successfully fabricated a multi-gated FE such as quadruple-gated FE with a three-stacked electrode lens and a quintuple-gated FE with a four-stacked electrode lens. The fabrication process uses an etch-back technique. In our method, gate hole opening is a self-aligned process; therefore, the axes of electrode holes are well aligned without precise lithography. Both the quadruple-gated FE and quintuple-gated FE can focus the electron beam. However, lens function for the quintuple-gated FE is stronger than that of the quadruple-gated FE, and a beam crossover is formed for the quintuple-gated FE.

The multi-gated FE is a promising device for a micro-column for a scanning electron microscope and electron beam lithography.

**Abstract**— To achieve ultra-high-speed image sensing faster than 1-giga frames per second, a multi-aperture high-speed imager is proposed. In this paper, the architecture of the imager and a design of digital circuits are presented. Basic operations of the digital circuits are verified by a fast SPICE simulator, NanoSim by Synopsys. Arbitrary shutter pattern of 128 bits and the number of repetition can be reprogrammed. A shutter pattern generation at 100 MHz is successfully verified.

**Keywords**—High-speed camera, CMOS imager, multi-aperture camera

## I. Introduction

High-speed imagers that can capture images at more than hundreds of frames per second (fps) are effective to analyze high-speed phenomena. High-speed continuous capturing has been achieved by high-speed column-parallel analog-to-digital converters (ADCs)[1]. Burst readout with on-chip frame memory enables much higher frame rate, although continuous capturing is not possible; Only the limited number of frames about 100 frames can be captured at once. 1M fps has been achieved by an in-pixel multi-stage charge transfer structure based on the charge-coupled device (CCD) [2], and 20M fps has been realized with a column analog voltage memory structure[3]. The CCD type has a tradeoff between the charge transfer efficiency and the transfer speed. The speed of the column analog memory type is determined by the parasitic resistance of the column readout line and the sample-hold capacitance. In this paper, we propose a burst-readout-type ultra-high-speed imager based on a multi-aperture imaging system whose frame rate is limited only by the saturation speed of electron in silicon, which is about 100 $\mu$ m/ns. Architecture of the imager and design and simulation results of the digital circuits are described.

## II. Multi-aperture Ultra-high-speed Camera

A part of this work was supported by JSPS KAKENHI Grant Number 24686046. This work is also supported by VLSI Design and Education Center(VDEC), The University of Tokyo with the collaboration with Cadence Corporation, Synopsys Corporation, and Mentor Graphics Corporation.

### A. 2.1 Multi-aperture Camera

Multi-aperture camera[4,5] is composed of multiple elemental cameras as shown in Figure 1. Each camera has an imaging lens and an imager, which is called an aperture or a

sub-aperture. Cameras of this kind are used for multi-viewpoint imaging or three-dimensional imaging. However, we are focusing on its potential of ultra-high-speed imaging as suggested in reference [6].

### B. Principle

Figure 2 depicts a procedure of ultra-high-speed imaging with the multi-aperture camera system. In this scheme, a special imager that can implement electronic shutter with an arbitrary temporal binary pattern, and a storage diode is used as a memory. Simplified pixel structure is depicted in Figure 3. The storage diode is a temporary storage to which photocarriers (electrons in this case) can be completely transferred without any noise[7]. The electron transfer is controlled by transfer gates. As shown in Figure 3, the electrons for the shutter OFF state are abandoned to the drain by turning G2 ON. Those for the ON state are transferred to and accumulated in the storage diode. Each aperture captures a complete optical copy of a scene with a specific shutter pattern. Note that the shutter patterns are independent each other. Therefore, temporally resolved images can be reproduced by solving the inverse problem. The temporal resolution is determined by the maximum effective frequency of the shutter pattern.

The virtual maximum frame rate of this scheme is determined only by the electron transfer speed from the photodiode to the storage diode, which is limited by the speed of electron in silicon, typically about 100 $\mu$ m/ns. Another advantage of the proposed method is better signal-to-noise ratio (SNR). Because the signals are temporally multiplexed and accumulated in the storage diode, the number of electrons

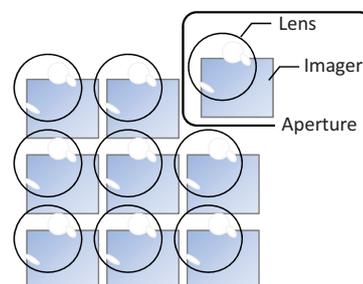

Figure 1: Multi-aperture camera.

per pixel is larger than that for the resultant single frame period. The constraint for smoothness in the reproduction processing will contribute to high-quality image reproduction from noisy measured data. Therefore, it is expected that higher

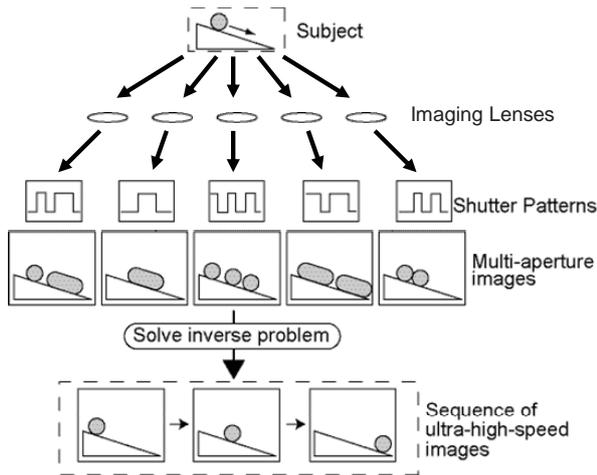

Figure 2: Procedure of image acquisition with the proposed multi-aperture high-speed imager.

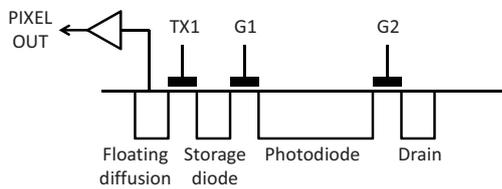

Figure 3: Simplified pixel structure.

SNR of pixel values in our scheme will enable reproduction of a sequence of high resolution ultra-high-speed images.

### C. Sensor Architecture

The sensor architecture of the proposed multi-aperture ultra-high-speed imager is shown in Figure 4. The sub-apertures are integrated on the same chip. To read out images, our imager is equipped with image readout circuits such as vertical and horizontal scanners, column-parallel analog amplifiers (shown as analog double sampling in Figure 4), analog-to-digital converters, digital double sampling, and an output block. A serial peripheral interface is used for setting the imager's parameters, and a reference block supplies reference voltages and currents to analog circuits. The specific parts to our imager are a clock controller, an addressing module, and sub-apertures. In ordinary imagers, photosensing area is a homogeneous array of pixels. On the other hand, sub-aperture is a small imager composed of sub-aperture driver and a pixel array, and the whole sensor is an array of small imagers. The sub-aperture driver generates arbitrary electronic shutter pattern, and controls electron transfer and drain of the pixels in the same sub-aperture.

## III. Digital Circuit Design

### A. Block Diagram

Figure 5 shows more detailed block diagram of digital circuit. Each sub-aperture driver can be reprogrammed from

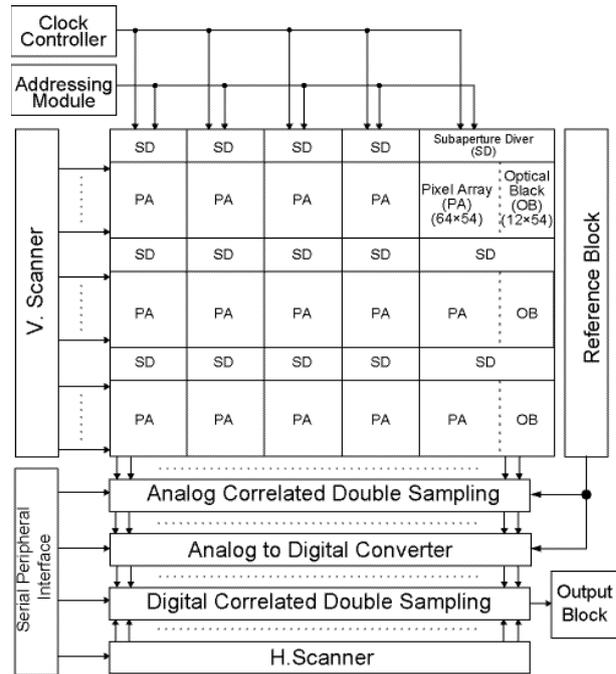

Figure 4: Sensor block diagram.

the outside through serial interface. SDI and SCK mean an input 1-bit datum and a writing clock, respectively. The sub-aperture has two operation modes: shutter pattern setting and pattern generation. In the pattern generation mode, the shutter pattern set in the setting mode is put out 1 to multiple times as programmed. Because the pattern memory is implemented by cyclic shift registers, both of setting and generation are executed by a clock signal. However, the clock signals for setting and generation have to be prepared separately, namely, PAT\_SCK and CLK, respectively. These signals are selected at the clock controller by the signal CK\_SELECT. Then, the clock signal is conveyed to each row of sub-apertures through the clock tree. The sub-aperture to be programmed is selected by the addressing module. The address is specified by ADDR\_IN<7:1>.

### B. Sub-aperture Pattern Generator

The block diagram of sub-aperture is shown in Figure 6. The sub-aperture driver is mainly composed of clock reverse circuit, two kinds of cyclic memories, counter, and a pixel driver. The sub-aperture to be programmed is specified by SUB\_SELECT that is asserted by the addressing module. The clock reverse circuit inverts the clock signal by PAT\_SDI\_CKREV, which is memorized by a 1-bit memory in the sub-aperture, to realize a half clock phase delays. CYC\_MEMORY, which is programmed by CLOCK and PAT\_SDI, stores a 128-bit-long electronic shutter pattern. PAT\_MEMORY programmed by CLOCK and PAT\_SDI\_STF is also 128-bit-long, which shows the head of

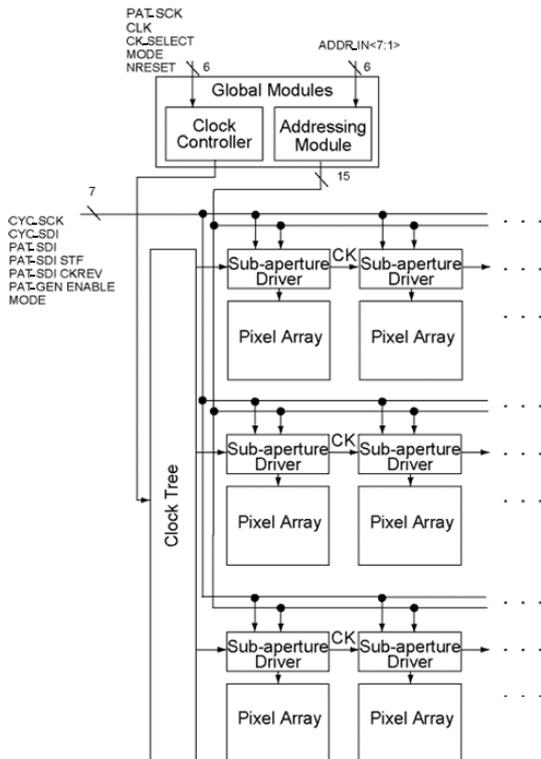

Figure 5: Clock distribution.

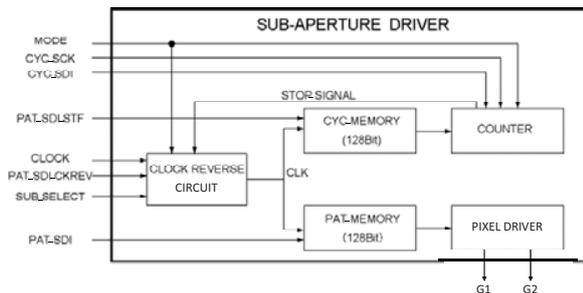

Figure 6: Sub-aperture driver.

the pattern. Namely, only one of the 128 bits is high, and the others are low. The head bit is counted by the counter to generate patterns 1 to multiple times. The number of repetition is set by `CYC_SCK` and `CYC_SDI`. `MODE` determines the operation mode of the sub-aperture: pattern setting mode and pattern generation mode. In the setting mode, `MODE` is set to low. In generating shutter pulses, `MODE` is set to high. Then, pattern generation starts when `PAT_GEN_ENABLE` turns from low to high. When the pattern generation ends, `STOP_SIGNAL` turns from low to high. Finally, whole multi-aperture image is read out.

#### iv. Simulation

The digital part of the ultra-high-speed multi-aperture imager has been designed in the standard 0.11- $\mu\text{m}$  CMOS

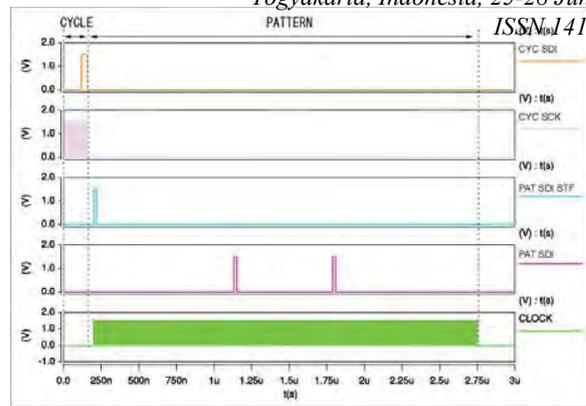

Figure 7: Simulation result of setting phase.

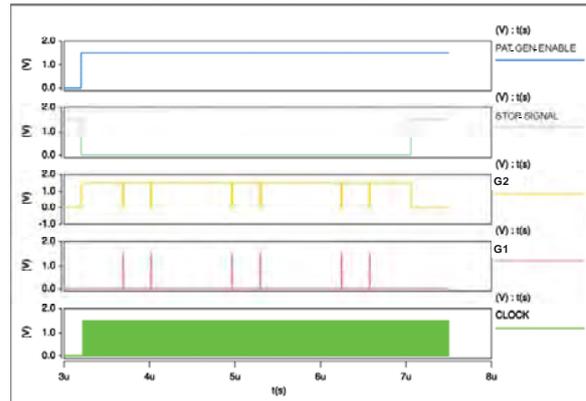

Figure 8: Simulation result of shutter pattern generation.

technology, which is suitable for faster than 1-GHz operation, and its basic operations were verified by a fast SPICE simulator, NanoSim by Synopsys.

Figure 7 shows a simulation result for pattern setting to one aperture. At first, the number of repetition, three in this case, was written. Then, the electronic shutter pattern and the head of the pattern were written. In this example, the pattern includes two pulses.

Figure 8 shows a simulation result for pattern generation. By turning `PAT_GEN_ENABLE` from low to high, it began to generate the pixel driving signals, `G1` and `G2`. The frequency was 100 MHz. After the pattern was put out three times, signal generation was stopped, and `STOP_SIGNAL` turned from low to high to trigger the image readout. From the simulation results, operations of the digital circuit were successfully verified.

#### v. Conclusion

To achieve ultra-high-speed image sensing more than 1-giga frames per second, a multi-aperture high-speed imager is proposed. The architecture of the imager and a design of digital circuits are presented. Basic operations of the digital circuits have been verified by a fast SPICE simulator, NanoSim by Synopsys. Setting a shutter pattern and shutter pattern generation at 100 MHz have been successfully verified.

**Abstract**— We have varied the Seebeck coefficient of n-type ultrathin Si-on-insulator (SOI) layer by tuning the Fermi energy. The Fermi energy was tuned by doping P atoms into the SOI layer and by injecting carriers by applying an external bias to the SOI surface with respect to the p-Si substrate. It was found that the Seebeck coefficient decreases with increasing the impurity concentration, with a peak around  $1 \times 10^{20} \text{ cm}^{-3}$ . From the calculated density-of-states (DOS), it is considered that the peak in Seebeck coefficient is likely to be due to the formation of impurity band near the conduction-band edge, which will demolish the sharp features in low-dimensional DOS. On the other hand, the Seebeck coefficient is found to increase with increasing the external bias which is in agreement with the variation of carrier concentration in the SOI layer under external bias and it is found that the Fermi energy can be controlled without the influences of impurity band.

**Keywords**—Thermoelectric material; thermopile infrared photodetector; Seebeck coefficient; Si on insulator; nanostructure

## I. Introduction

Thermoelectric (TE) devices have attracted much attention owing to their wide application in daily life, not only as a power generator but also as a sensor. However, the low conversion efficiency of such devices currently limits their commercial use. In sensor applications, nanostructured TE materials are important for a highly-sensitive thermopile infrared photodetector, in which the thermocouple (a pair of n- and p-type TE materials) array gives us a thermoelectromotive force (TEMF) corresponding to the temperature difference caused by infrared absorption in the absorber film. The detector sensitivity  $R$  is defined as  $R=nS\eta/G$ , where  $n$  is the number of thermocouples in the thermopile,  $S$  the Seebeck coefficient,  $\eta$  the infrared absorbance, and  $G$  the thermal conductance of the TE material. The enhancement of detector sensitivity is expected by using nanostructure that will increase the number of semiconductor thermocouples and decrease the thermal conductivity due to phonon boundary-scattering [1,2].

Moreover, the Seebeck coefficient is theoretically expected to be enhanced significantly due to quantum confinement

coefficient is proportional to the energy derivative of logarithmic density-of-states (DOS) at the Fermi energy  $E_F$  [3], therefore the  $E_F$  needs to be tuned in the vicinity of the conduction-band edge  $E_C$  in n-type low-dimensional semiconductor materials in order to observe the enhancement. In the present paper, we show the variation of Seebeck coefficient in n-type ultrathin Si layers fabricated on Si-on-insulator (SOI) substrates with tuned  $E_F$  by impurity doping and external bias, with a view to clarifying the suitable control of the  $E_F$ .

## II. Experimental

The sample was fabricated by using SOI wafers consisted of a top Si layer (SOI layer), a buried oxide (BOX) layer and a p-type Si substrate. The BOX layer was 400 nm thick and the p-type Si substrate had an impurity concentration of  $\sim 10^{15} \text{ cm}^{-3}$ . In this paper, the sample for controlling the Fermi energy by impurity doping is referred as “doped SOI sample” and control by external bias is referred as “biased SOI sample,” and detail of fabrication is described elsewhere [4,6,9]. For the doped SOI sample, the SOI wafer was cut to a size of  $10 \times 10 \text{ mm}^2$  and the SOI layer was thinned to a thickness of 6 to 100 nm. P atoms were doped into the SOI layer to form an n-type SOI layer and the impurity concentration ranged from  $1 \times 10^{18}$  to  $2 \times 10^{20} \text{ cm}^{-3}$ . On the other hand, for the biased SOI sample, the SOI layer was thinned to a thickness of 78 nm. It was also doped with P atoms with a concentration of  $\sim 1 \times 10^{18} \text{ cm}^{-3}$ . The SOI layer was patterned to a size of  $7 \times 1 \text{ mm}^2$ . Then, Al electrodes were deposited and patterned to a size of  $0.5 \times 0.5 \text{ mm}^2$  on the surface of the SOI layer, and another Al electrode was deposited over the entire bottom surface of the p-type Si substrate. Finally, the sample was annealed to form ohmic contacts at the Al/Si interface.

The Seebeck coefficient was measured using the same method that was briefly described in our previous studies [4,9]. A temperature difference was given to the sample in a plane parallel to the sample surface. The time evolution of the TEMF was measured simultaneously with the temperature at the high- and low-temperature regions. For the biased SOI sample, during the measurement, a constant external bias was applied to the SOI layer through the patterned Al electrode with respect to the earthed p-Si substrate bottom. The Seebeck coefficient was determined using  $S = -(V_H - V_L)/(T_H - T_L) = -\text{TEMF}/\Delta T$ . Fig. 1 shows the determined Seebeck coefficient as a function of average temperature. From this figure the

This work was financially supported by a Grant-in-Aid for Scientific Research (No. 19560701 and 21360336), a Grant-in-Aid for Challenging Exploratory Research (No. 24651168) and a Grant-in-Aid for JSPS Fellows (No. 23-6002) from the Japan Society for the Promotion of Science. effect of electrons. According to the theory, the Seebeck

Seebeck coefficient is seen to be nearly constant in the measured temperature range. Therefore, the average Seebeck

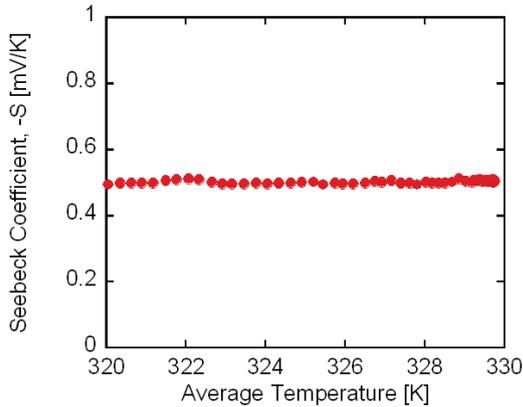

Fig. 1. Seebeck coefficient as a function of average temperature.

coefficient was evaluated from the gradient in the relationship between measured TEMF and temperature difference.

### III. Seebeck Coefficient Of Phosphorus-Doped Soi Layers

The average Seebeck coefficient of doped SOI sample is shown in Fig. 2 as a function of impurity concentration. The numbers adjacent to the filled circles indicate the SOI layer thickness and the solid line represents the theoretical calculation of Seebeck coefficient based on the dispersion relation in simple bulk Si [10]. From Fig. 2 the average Seebeck coefficient decreases with increasing the impurity concentration below  $2 \times 10^{19} \text{ cm}^{-3}$  (indicated by broken line in Fig. 2), as usually observed in n-type semiconductor materials [11,12]. However, experimental results quantitatively differ with the theoretical results. This is likely to be due to the influence of phonon drag and it is known to become weak at high impurity concentration [13]. Therefore, when the impurity concentration is above  $1 \times 10^{19} \text{ cm}^{-3}$ , the experimental values become close to the theoretical values.

On the other hand, the average Seebeck coefficient is found to exhibit unusual behavior by increasing the impurity concentration above  $2 \times 10^{19} \text{ cm}^{-3}$  which is likely to be due to the influences of heavy impurity doping since it is considered that the SOI thickness above 6 nm does not contribute to the enhancement in the Seebeck coefficient [4-8]. Fig. 3 shows the DOS calculated by considering three principle influences of heavy impurity doping; formation of impurity band [14,15], ionization-energy shift of an impurity atom [16,17] and band tailing at the  $E_C$  [16-19], for impurity concentration of  $1 \times 10^{18} \text{ cm}^{-3}$ ,  $1 \times 10^{19} \text{ cm}^{-3}$  and  $1 \times 10^{20} \text{ cm}^{-3}$ , where the original  $E_C$  is set to zero [6-8]. The positions of  $E_F$  evaluated from the charge-neutrality condition are indicated in the figure by arrows. It is found that the DOS of impurity band for  $1 \times 10^{18} \text{ cm}^{-3}$  starts to form around  $-45 \text{ meV}$  and is not connected to the conduction band. In addition, the  $E_F$  is found to be located

in the band gap and far from the conduction band, which shows that the doped SOI sample still has the characteristics

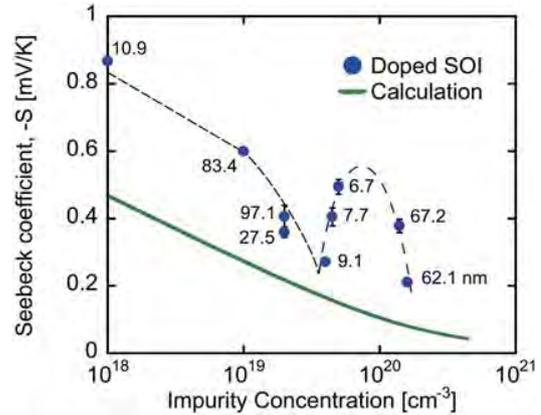

Fig. 2. Seebeck coefficient as a function of impurity concentration. The solid line represents the calculated value and broken line is an eye-guide.

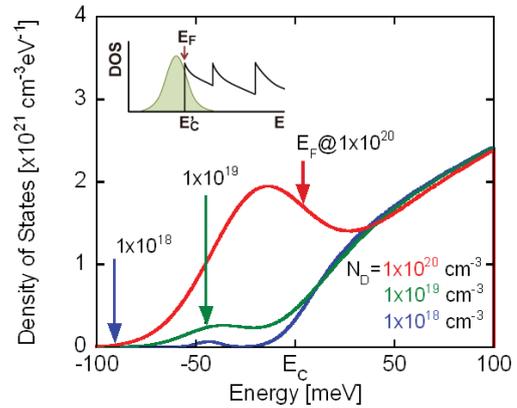

Fig. 3. Calculated DOS for bulk Si with P concentration of  $1 \times 10^{18} \text{ cm}^{-3}$ ,  $1 \times 10^{19} \text{ cm}^{-3}$  and  $1 \times 10^{20} \text{ cm}^{-3}$  where  $E_C$  is set to zero. The inset shows a schematic of DOS distribution in an impurity band and a one-dimensional conduction band. The arrows indicate the Fermi energies.

of a semiconductor. Thus, it is considered that the Seebeck coefficient of lightly-doped SOI sample should behave like the characteristics of normal n-type semiconductor.

However, in the case of DOS for impurity concentration of  $1 \times 10^{19} \text{ cm}^{-3}$  and  $1 \times 10^{20} \text{ cm}^{-3}$ , the impurity band becomes broad and connects with the conduction band. Moreover, the  $E_F$  stays in the continuous band. This band arrangement should exhibit metallic properties, which is likely contributes to the peak in the Seebeck coefficient in heavy doping region [4-8]. As mentioned in "INTRODUCTION," in order to observe the enhancement of Seebeck coefficient by nanostructuring, the  $E_F$  needs to be tuned in the vicinity of  $E_C$ . However, from Fig. 3, it can be seen that even if the  $E_F$  could be tuned by varying the impurity concentration, the impurity band that forms near the  $E_C$  will demolish the sharp features in low-dimensional DOS, as illustrated in the inset of this figure. This suggests that controlling the  $E_F$  by impurity doping is not suitable to obtain the benefits of nanostructured materials.

#### IV. Soi Seebeck Coefficient Controlled By External Bias

In order to tune the  $E_F$  without the influence of an impurity band, the Seebeck coefficient was varied by applying an external bias to the biased SOI sample. Some studies have modulated the Seebeck coefficient of organic materials, Si, and compound semiconductors with a field-effect transistor structure by varying the gate bias [20-23]. On the other hand, we have varied the Seebeck coefficient of biased SOI sample by applying a voltage through an Al electrode deposited on the SOI surface without using a field-effect transistor structure. Fig. 4 shows the average Seebeck coefficient as a function of applied external bias. The average Seebeck coefficients are observed to increase with increasing the external bias. When the SOI sample surface is positively biased, the energy difference  $E_C - E_F$  near the n-SOI/BOX interface increases as schematically depicted in the inset of Fig. 4. In other words, by applying a positive bias the carrier concentration in SOI layer is reduced that makes the Seebeck coefficient to increase, which is in agreement with characteristics of P-doped SOI layer shown in Fig. 2 for impurity concentration below  $2 \times 10^{19} \text{ cm}^{-3}$ .

We used a technology computer-aided design simulator (Synopsys Co. Ltd.) to estimate the carrier distribution in the SOI layer under external bias. The simulated SOI sample had a width of  $195 \mu\text{m}$  (horizontal direction) and a thickness of  $5.462 \mu\text{m}$  (vertical direction). We confirmed that the sample dimension do not affect the carrier distribution. Fig. 5 shows a contour plot of the simulated carrier concentration for biased SOI sample subjected to (a) 0 V and (b) +30 V. This contour plot depicts the cross section of the SOI sample; vertical and horizontal axes respectively represent the depth (thickness) and width of the sample. From Fig. 5, it is found that the electron density in the SOI layer gradually decreases with distance from the surface and that when the SOI surface is positively biased it drops abruptly near the n-SOI/BOX interface. This result is consistent with the band diagram depicted in the inset of Fig. 4. In addition, Fig. 5 shows that the electron density is constant in the horizontal direction. Therefore, the carrier concentration in SOI layers can be varied by external bias, which demonstrates that it may be possible to control the  $E_F$  without the influence of impurity band.

As mentioned above, it is essential to adjust the  $E_F$  in the vicinity of  $E_C$ , the fact that the external bias induces band bending in the SOI may reduce the enhancement of the Seebeck coefficient by smoothing the sharp features in the low-dimensional DOS. However, from the general expression of Seebeck coefficient for the electronic contribution [24], the Seebeck coefficient can be regarded as the integral of its local components, and the sharp features is expected to be preserved at the  $E_C$ . Consequently, nanostructured materials are expected to have enhanced Seebeck coefficient under a given external bias.

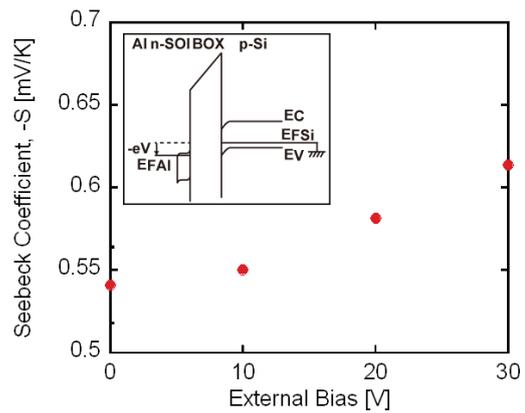

Fig. 4. Seebeck coefficient of biased SOI sample as a function of applied external bias. The inset shows a band diagram of Al/n-SOI/BOX/p-Si under a positive bias with respect to the ohmic contact between p-Si/Al.

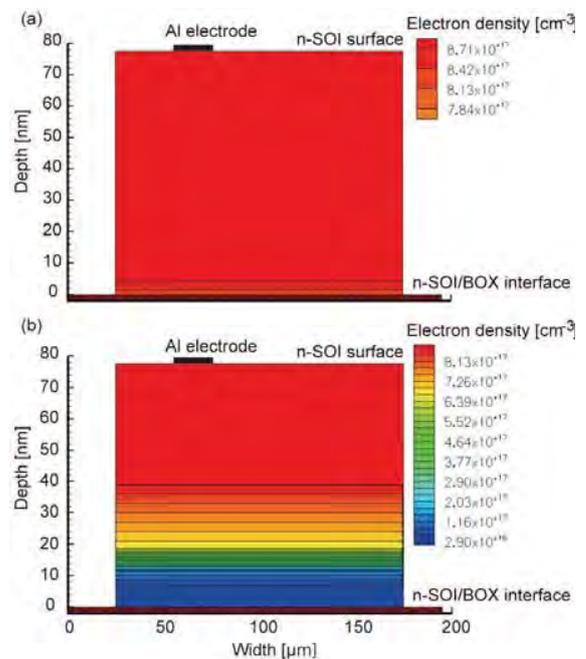

Fig. 5. Contour plot of simulated carrier concentration of n-type biased SOI sample subjected to external bias (a) 0 V and (b) +30V. The vertical and horizontal axes respectively represent the depth and width of the sample.

#### V. Conclusion

We measured the variation of Seebeck coefficient of ultrathin n-type SOI layer by controlling the carrier concentration by doping P atoms into the SOI layer. The Seebeck coefficient is found to decrease with increasing the impurity concentration, with a peak around  $1 \times 10^{20} \text{ cm}^{-3}$ . The enhancement of Seebeck coefficient in heavy doping region is considered to be likely due to influences of formation of impurity band near  $E_C$ . From the calculated DOS including the

influences of impurity doping, it was found that the influences is expected to demolish the sharp features in low-dimensional DOS which resulting a difficulties in achieving the benefit of nanostructure. Therefore, we measured the variation of Seebeck coefficient by applying an external bias for tuning the  $E_F$  without the influence of impurity band. The Seebeck coefficient increases as the external bias becomes increasingly positive, which is qualitatively consistent with the characteristics of P-doped SOI layers by considering the variation of simulated carriers in the SOI layers. This demonstrates that the  $E_F$  can be controlled to enhance the Seebeck coefficient by nanostructures without forming impurity bands by heavy doping.

**Abstract**— The eruption of Merapi Mountain in Yogyakarta in November 2010 spewed a lot of material to the surface of the earth. These conditions could affect the chemical content in ground water, such as iron content. Therefore, in this research will be made an iron content measuring instrument that is used to measure iron content in ground water of Turi, Klangkapan, Kali Kuning and Umbul Pajangan after the eruption of Merapi Mountain.

The measuring iron content in the groundwater in this research is using spectrophotometric method. Because iron is measured at wavelengths between 495-570 nm, so this system will work by using a green laser light source. The results of the data processing will be displayed on the LCD (Liquid Cell Display) in mg/l.

The iron content instrument can measure the iron content 1 – 5 mg/l as well. The iron content instrument still needs improvement because it can not measure iron content below 1 mg/l in accordance with the results should be. The iron content of four springs are increasing with the rate between 19.17 – 305.7%. However, the iron content in the water in the four areas is safe for consumption because it is on the allowed threshold by the Ministry of Health (less than 0.3 mg/l).

**Keywords**—groundwater, Merapi Mountain, eruption, iron content, green laser

## I. Introduction

Ground water is a strategic resource, because it involves the basic necessities lives of many people in various community activities. In November 2010 had occurred eruption of Merapi Mountain in Yogyakarta which spewed a lot of material to the surface of the earth. These conditions could affect the chemical content in ground water, such as iron content. The maximum allowed by the Ministry of Health No.. 416/MENKES/PER/IX/1990 for Fe content in the water not more than 0.3 mg/l [1].

The measuring iron content in the groundwater in this research is using spectrophotometric method. This method is considered a fairly simple method. The analysis is done relatively quickly, and the samples were analyzed in small quantities. Today, the spectrophotometers on the market are very expensive and only certain people that could use a spectrophotometer, so many people are less able to take advantage of these tools. Therefore, we intend to make the iron content in the water measuring instrument more simple,

inexpensive, and easy to use with the spectrophotometric method. Some researcher has been utilizing a spectrophotometer for testing content of iron in the water. One of the existing research conducted by Nia Faricha, in a research entitled "*Pembuatan Alat Ukur Kadar Besi dalam Air dengan Metode Absorpsi Spektrofotometri*". This research used polychromatic light source i.e. a halogen lamp and a light sensor i.e. LDR (Light Dependent Resistor). The results are displayed in units of percent. [2]. Another researcher is Ram Murat Singh et al that developed instrument for measuring iron content in water [3]. The instrument uses RGB-LED (Red Green Blue - Light Dependent Resistor) as light source and LDR receiver. The method of conversion Fe to the red complex solution is done by adding the solution with KSCN.

In this research, an iron content in water measuring instrument will be designed using laser light source. Because the iron is measured at wavelengths between 495-570 nm, so this system will work by using a green laser light. The instrument of iron content that is made will be used to measure iron content in ground water of Turi, Klangkapan, Kali Kuning and Umbul Pajangan to assess changes in the content of iron in groundwater after the eruption of Merapi Mountain. These four areas are located at the edge of Mount Merapi. The results of the data processing will be displayed on the LCD (Liquid Cell Display) in mg/l unit. The iron content measurement tool is equipped with a battery that can be recharged so that it can be brought to a place where there is no power source.

## II. MATERIALS AND METHODS

The stages of this research are as follows:

1. Taking samples of ground water in Turi, Klangkapan, Kali Kuning and Umbul Pajangan
2. Manufacturing iron content instrument

The principle of the measurement of the sample shown in Figure 1. Light with intensity  $I_0$  passes through the sample containing molecules along  $b$ , some light will be absorbed by the molecule. This resulted in the intensity drops to  $I$ . Both the value of the light intensity ( $I_0$  and  $I$ ) were measured by photodetector. Light with intensity  $I_0$ , after passing through the absorber with concentration  $c$ ,

along  $b$ , the intensity will drop to  $I$  follow the relationship

$$\log(I_0 / I) = \epsilon b c \quad (1)$$

where  $\epsilon$  is the molar absorptivity [4],[ 5]

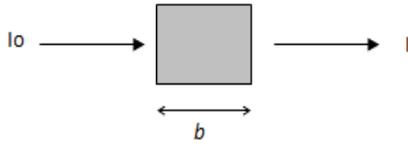

Figure 1 Absorption of light by the sample

Molar absorptivity is a constant that depends on the type of molecule and the wavelength. Equation 1 can be expressed in the form

$$\log(I_0 / I) = A \quad (2)$$

where  $A$ : absorbance, then equation 1 becomes

$$A = \epsilon b c \quad (3)$$

Where  $\epsilon$  and  $b$  is constant and  $A$  is measured, the iron level  $c$  can be obtained. The block diagram of this instrument is shown at Figure 2. The circuit of laser source and photodiode are shown at Figure 3. The flowchart of the measurement process is shown at Figure 4.

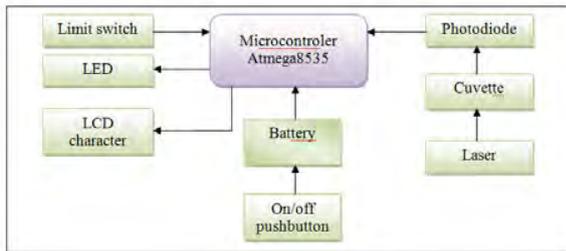

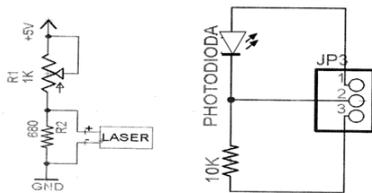

Figure 2. Block diagram

a. Laser source circuit      b. Photodiode circuit  
 Figure 3. The circuit of laser source and photodiode

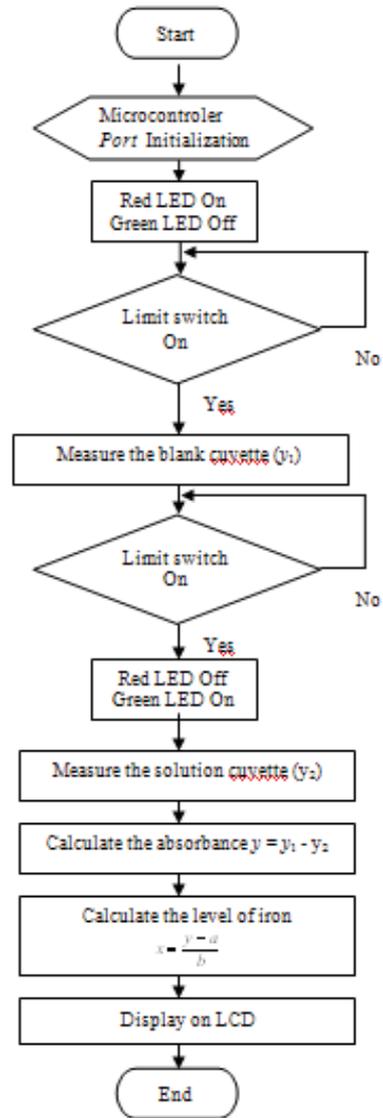

Figure 4. Flowchart of the measurement process

### 3. Preparation of Fe standard curve

- a. 1 ml of standard solution of standard Fe 100 ppm pipetted and put in a 100 ml flask. one drop of 0.2 M Na-acetate, 5 ml solution hidroksilaminklorida 10%, and 5 ml of 0.25% o-phenantrolin added into the flask. Then the solution in the flask is diluted to mark boundaries.
- b. In the same way, the solution to the volume of iron solution 0, 2, 3, and 4 ml were made. The number of drops of a solution of Na-acetate adjusted to the volume pipetted iron, then, 5 ml solution of o-phenantrolin 0.25%, 5 ml solution

hidroksilaminklorida added to the flask and the mixture was diluted to mark boundaries.

4. Measurement of Fe standart series:

- measure the blank cuvette ( $y_1$ ) and iron solution cuvette ( $y_2$ ) for sixth solution above at a wavelength of maximum absorbance
- calculate the absorbance for sixth solution above with formula

$$y = y_1 - y_2 \quad (4)$$

- draw the graph of the absorbance for sixth solution above to obtain a linear equation of Fe standart curve:

$$y = bx + a \quad (5)$$

where  $y$  = absorbance

$x$  = iron content

$b, a$  = constant

5. Calibration of the Fe standart curve measurement between the instrument and standart spectrophotometer

6. Preparation of the sample solution

25 ml water sample is pipetted into a 100 ml measuring flask. One drop of 0.2 M Na-acetate, 5 ml of 10% hidroksilaminklorida solution and 5 ml of 0.25% o-phenantrolin added to the flask and then the solution was diluted to mark boundaries.

7. Measurement of iron content:

- measure the blank cuvette ( $y_1$ ) and iron solution cuvette ( $y_2$ )
- calculate the absorbance ( $y = y_1 - y_2$ )
- calculate the content of iron:  $x = \frac{y - a}{b}$  with  $a$  and  $b$  are obtained from linear equation of Fe standart curve

### III. RESULT AND DISCUSSION

Figure 2 shows the iron content instrument that is made up. This figure shows the outside and inside of the iron content instrument. Table 1 shows the results of the voltage measurement of fifth Fe standart solution according to equation 4, which is further illustrated in Figure 3. The figure shows that the standart solution has 0.989 linearity level. The standart equation is

$$y = 0.003x + 0.002 \quad (6)$$

Table 2 shows the absorbance measurement using standart spectrophotometer, which is further illustrated in Figure 4. The figure shows that the standart solution has 0.994 linearity level. The standart equation is

$$y = 0.1889x - 0.0169 \quad (7)$$

From the two graphs above it is clear that the linearity of the iron content instrument is smaller than the standart spectrophotometer. It means that the iron content instrument still needs improvement.

Table 3 shows the content of Fe in mg/l in groundwater of four region after Merapi Mountain eruption using iron content instrument (in accordance with the equation 6) and standart spectrophotometer (in accordance with the equation 7). Table 4 shows the content of Fe in mg/l at before and after Merapi Mountain eruption that is tested at Balai Besar Teknik Kesehatan Lingkungan dan Pemberantasan Penyakit Menular (BBTKL PPM) Yogyakarta. If Table 3 compared with Table 4, it can be seen that the measured Fe content in groundwater using a standart spectrophotometer is similar to BBTKL PPM measurement result. It means that the method of preparation of the solution is correct. However, the iron content instrument can not measure iron content in accordance with the results should be. This is because the iron content in the water sample is too small. The iron content instruments can not detect iron content that is too small. For further improvement, the sensitivity of iron content instrument will be upgraded so that it can measure the small iron content as well. From table 4, we can know that the iron content after the eruption of Mount Merapi is higher than before the eruption. The greatest change occurred in the springs in the area Kali Kuning, i.e. 305.7%. However, the content of iron in the four springs is still below the threshold required by the Ministry of Health, which is less than 0.3 mg / l, so it is safe for consumption.

Table 1. Absorbance measurement of the iron content instrument.

Solution	Voltage (V)	Absorbance
0 mg/l	4.81	-
1 mg/l	4.805	0.005
2 mg/l	4.801	0.009
3 mg/l	4.797	0.013
4 mg/l	4.795	0.015
5 mg/l	4.791	0.019

Figure 2. Iron content instrument

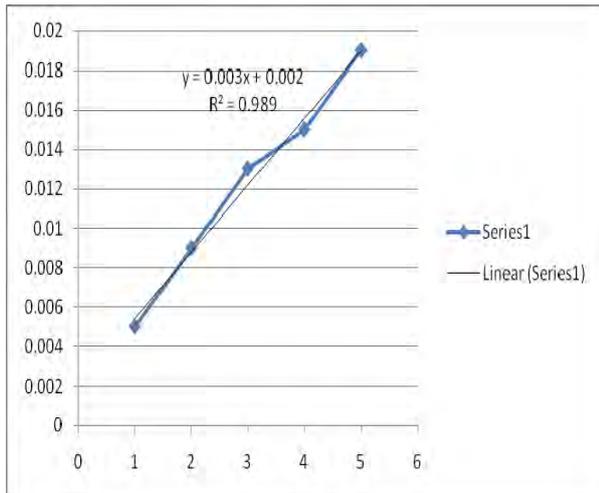

Figure 3. Series solution measurement result of the iron content instrument.

Table 2. Absorbance measurement using standart spectrophotometer

Solution	Absorbance
1 mg/l	0.186
2 mg/l	0.362
3 mg/l	0.535
4 mg/l	0.709
5 mg/l	0.957

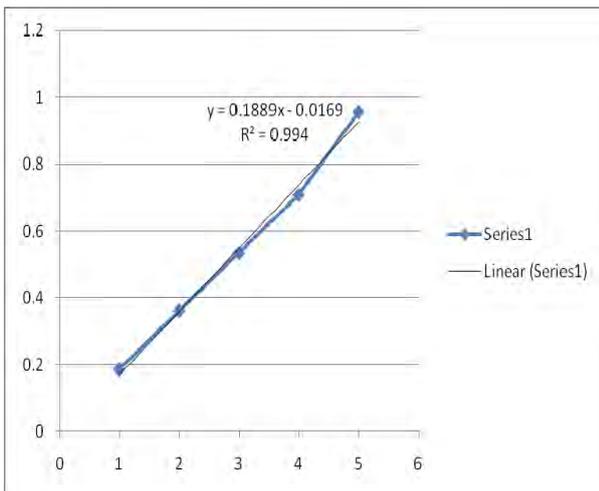

Figure 4. Series solution measurement result of standart spectrophotometer.

Table 3. Fe content of groundwater measurement using the iron content instrument and Standart spectrophotometer

Region	Absorbance Measurement		Fe content (mg/l)	
	Using the iron content instrument	Using Standart spectro-photometer	Using the iron content instrument	Calculating from absorbance using standart spectro-photometer
Klangkapan	0.001	-0.011	-0.333	0.031
Turi	0.001	-0.013	-0.333	0.020
Kali Kuning	0.001	-0.007	-0.333	0.052
Umbul Pajangan	0.001	-0.012	-0.333	0.026

Table 4. Fe content of groundwater measurement (tested at Balai Besar Teknik Kesehatan Lingkungan dan Pemberantasan Penyakit Menular Yogyakarta)

Region	Fe content (mg/l)		Increase (%)
	Before eruption	After eruption	
Klangkapan	0.0193	0.0230	19.17
Turi	0.0193	0.0230	19.17
Kali Kuning	0.0193	0.0783	305.70
Umbul Pajangan	0.0193	0.0230	19.17

#### IV. CONCLUSION

From the explanation above, it can be concluded below:

- The iron content instrument can measure the iron content 1 – 5 mg/l as well
- The iron content instrument still needs improvement because it can not measure iron content below 1 mg/l in accordance with the results should be
- The iron content of four springs are increasing with the rate between 19.17 – 305.7%. However, the iron content in the water in the four areas (Turi, Klangkapan, Kali Kuning and Umbul Pajangan) is safe for consumption because it is on the allowed threshold by the Ministry of Health (less than 0.3 mg/l).

**Abstract**—There have been widely applied many research related to face recognition system. The system is commonly used for video surveillance, human and computer interaction, robot navigation, and etc. Along with the utilization of the system, it leads to the need for a faster system response, such as robot navigation or application for public safety. A number of classification algorithms have been applied to face recognition system, but it still has a problem in terms of computing time. In this system, computing time of the classification or feature extraction is an important thing for further concern.

Classification algorithm that is suitable for very large databases and efficient in time complexity is WaveCluster. WaveCluster based on wavelet transform able to analyze function at different resolution. To enhance system ability as a real-time system, WaveCluster will be present to be parallel process and implemented on GPU using CUDA.

CUDA is a parallel computing architecture that can manage high-performance parallel computing on GPU with large memory bandwidth. The parallelization of WaveCluster algorithm on GPU using CUDA is expected to speed-up the process computing time compared to serial process on CPU. In addition, the system is intended to improve level of accuracy in recognition process of facial images

**Keywords**—face recognition, wavecluster algorithm, parallel computing, GPU, CUDA

## I. Introduction

Face recognition system is one of topics that have been widely studied. This is because of the system is widely used in public safety application, financial security, human computer interaction and robot navigation, etc.

Some researches related to face recognition system have optimized in terms of feature extraction and classification methods. Classification approaches said to be good, if it can classified in a variety of shapes, efficient, sensitive to noise and data input sequence. WaveCluster is classification approaches based on wavelet transform that meet all the criteria mentioned. By using the wavelet transform, a variety of shapes can be identified and classified at different levels of accuracy effectively. In addition, WaveCluster is very efficient in terms of time complexity [1].

However, computational time of wavelet transform in multilevel data decomposition and reconstruction will reduce performance, especially for large size image [2]. Time

complexity of the wavelet transform is  $O(N^2)$ , where  $N$  is image size. The time needed for the computation will be increased with image size [3]. It certainly would not be appropriate when it applies to a system that requires fast computation time and quick response.

Computer Unified Device Architecture (CUDA) is a parallel computing architecture developed by Nvidia. CUDA is software for managing large data parallel computing with high performance on GPU (Graphics Processing Unit) hardware. Each GPU with CUDA-enabled can serve as a data parallel computing devices with large amount of memory on-board [4].

Previous research [5] implements WaveCluster algorithm using GPU with CUDA. There are two sub-algorithms WaveCluster approach implemented with CUDA, the extraction of low-frequency components of signal are obtained by using wavelet transform and connected component labeling. 2D dataset and high-resolution dataset are used for testing. The result concluded that the extraction of low-frequency components using GPU (NVIDIA GTX 465) can speed up the computing process with 107 times faster on the implementation on CPU (Intel Core2Duo 2.4 GHz) and connected component labeling to 6 times faster.

Parallelization of WaveCluster algorithm for face recognition system on GPU with CUDA is expected to accelerate the computing process of image extraction and classification so that it can respond faster and can be utilized for robot navigation or video surveillance in public areas.

## II. WaveCluster Algorithm

Given a set of spatial objects  $o_i$ ,  $1 \leq i \leq N$ , the goal of the algorithm is to detect clusters and assign labels to the objects based on the cluster that they belong to. The main idea in WaveCluster is to transform the original feature space by applying wavelet transform and then find the dense regions in the new space. It yields sets of clusters at different resolutions and scales, which can be chosen based on users needs. The main steps of WaveCluster are shown in Fig. 1 [1].

Algorithm: Input: Multidimensional data objects feature vectors Output: clustered objects 1. Quantize feature space, and then assign
---

- objects to the units.

  2. Apply wavelet transform on the feature space.
  3. Find the connected components (clusters) in the subbands of transformed feature space, at different levels.
  4. Assign label to the units.
  5. Make the lookup table.
  6. Map the objects to the clusters.

Fig. 1. WaveCluster algorithm

### A. Quantization

The first step of WaveCluster algorithm is to quantize the feature space, where each dimension  $i$  in the  $d$ -dimensional feature space will be divided into  $m_i$  intervals. If we assume that  $m_i$  is equal to  $m$  for all the dimensions, there would be  $m^d$  units in the feature space. Then the objects will be assigned to these units based on their feature values. Let  $F_k = (f_1, f_2, \dots, f_d)$  be the feature vector of the object  $o_k$  in the original feature space. Let  $M_j = (v_1, v_2, \dots, v_d)$  denote a unit in the original feature space where  $v_i, 1 \leq v_i \leq m_i, 1 \leq i \leq d$ , is the location of the unit on the axis  $X_i$  of the feature space. Let  $s_i$  be the size of each unit in the axis  $X_i$ . An object  $o_k$  with the feature vector  $F_k = (f_1, f_2, \dots, f_d)$  will be assigned to the unit  $M_j = (v_1, v_2, \dots, v_d)$  if

$$\forall i \quad (v_i - 1) s_i \leq f_i < v_i s_i, \quad 1 \leq i \leq d \quad (1)$$

The number (or size) of these units is an important issue that affects the performance of clustering. Because of multi-resolution property of wavelet transform, it considers different unit size at different scales of transform [1].

### B. Wavelet Transform

In the second step, discrete wavelet transform will be applied on the quantized feature space. Applying wavelet transform on the units  $M_j$  results in a new feature space and hence new units  $T_k$ . Given the set of units  $T_k$ , WaveCluster detects the connected components in the transformed feature space. Each connected component is a set of units  $T_k$  and is considered as a cluster. Corresponding to each resolution  $r$  of wavelet transform, there would be a set of clusters  $C_r$ , where usually at the coarser resolutions, number of clusters is less. The subbands  $LL$  show the clusters at different scales [1].

### C. Label and Make Look Up Table

Each cluster  $c, c \in C_r$ , will have a cluster number  $c_n$ . In the fourth step of algorithm, WaveCluster labels units in the feature space that are included in a cluster, with its cluster number. That is,

$$\forall c \forall T_k, T_k \in c \Rightarrow l_{T_k} = c_n, c \in C_r, \quad (2)$$

where  $l_{T_k}$  is the label of the unit  $T_k$ . The clusters that are found are in the transformed feature space and are based on wavelet coefficients. Thus, they cannot be directly used to define the clusters in the original feature space. WaveCluster makes a lookup table  $LT$  to map the units in the transformed feature space to the units in the original feature space. Each entry in

the table specifies the relationship between one unit in the transformed feature space and the corresponding unit(s) of the original feature space. So the label of each unit in the original feature space can be easily determined. Finally, WaveCluster assigns the label of each unit in the feature space to all the objects whose feature vector is in that unit, and thus the clusters are determined. Formally,

$$\forall c \forall M_j, \forall o_i \in M_j, l_{o_i} = c_n, c \in C_r, 1 \leq i \leq N, \quad (3)$$

where  $l_{o_i}$  is the cluster label of object  $o_i$  [1].

## III. CUDA

Compute Unified Device Architecture (CUDA) is parallel computing architecture included with new parallel programming model and set of formatting instruction to Graphical Processing Unit (GPU). Parallel computing on GPU is used to solve a number of complex computational problems more efficiently than computing on CPU. A compiled CUDA program can be executed on some processor cores. A multithreaded program is partitioned in a number of thread blocks are executed independently of each other, so that GPU with more processor cores will automatically execute the program with much less time than GPU with less processors cores.

CUDA programming model is an extension to the C language. There are three main parts of CUDA programming model, namely kernel, threads, memory. Kernel is a program code to be executed in parallel on GPU. When kernel function is called, then a number of programs to be executed  $N$  times in parallel on  $N$  number CUDA threads. Thread is a mechanism used to execute a program code. Threads in execution are grouped in blocks and grids. Block is a collection of threads executed together, while the grid is a collection of blocks. There are limits on the number of threads in a block. In particular GPU, a block can contain up to 1024 thread. A thread block can be executed independently in parallel or sequentially. A number of threads in a block can coordinate data sharing and synchronization via shared memory execution time for memory access.

CUDA programming model assumes that the thread is executed on a device that serves as a coprocessor for a host running the C program, CPU as a host and GPU as a device. Host and device uses its own memory space in DRAM is referred to as host memory and device memory. So that a program will be set up memory space available for kernel includes device memory allocation and deallocation, and data transfer between host memory and device memory. When a program calling the function kernel, then the kernel will be executed on GPU in parallel, in addition program code will be executed sequentially on CPU.

GPU has been designed with large memory bandwidth than CPU so it can have a high-throughput computing. Available memory bandwidth cannot achieve good performance if all the data are globally accessible memory. Some types of memory on GPU have different behavior and performance which can be influential in improving memory performance. Global memory is memory space that has access

slowest among the other type of GPU memory. Therefore, more data that is accessed from global memory will reduce the computational performance of implementation program result.

#### IV. Proposed Method

This research will proposed an implementation method for parallel computing of WaveCluster algorithm that shows in Fig. 2 and 3. The input is color image and then going through the process to get grayscale intensity of 2D vector. Furthermore, the image recognition needs two main methods, namely feature extraction and classification.

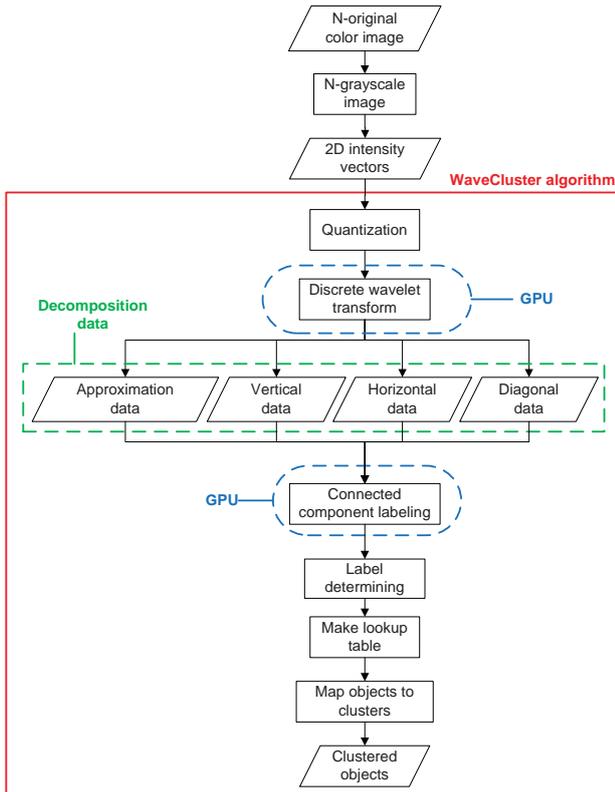

Fig. 2. Parallel computing flow of clustering process with WaveCluster algorithm for face recognition system

WaveCluster algorithm already includes the feature extraction and classification. For feature extraction of face images are used Haar wavelet transform at every level transformation produces four decomposition data, i.e. approximation data, horizontal data, vertical data, and diagonal data. All of decomposition data will be used as input to the classification process with multi-pass connected component labeling algorithm. This is done to analyze the classification results obtained from some combination of decomposition data.

#### v. Future Work

Parallelization for facial image recognition system will be made on WaveCluster algorithm, namely discrete wavelet transform and connected component labeling. Furthermore, the research will be carried out measurements of the computing time of decomposition data on WaveCluster algorithm on GPU and compared with result obtain in previous research [5].

Implementation will be done on the entire process of face recognition system ranging from feature extraction and classification with WaveCluster algorithm and face recognition process with suitability connected component labeling algorithm. Then it will be measured overall computing time implementation is a combination of CPU and GPU computing. From the results of these measurements will be compared with the implementation of the computational process occurs on CPU.

**Abstract**— In this paper we discuss about the initial stages of the study to design a system to detect the volume of fuel in the generator base stations on remote islands precisely at the Bidadari islands on Kepulauan Seribu. As this study designed a simulator that implements change fuel level and transmits the parameter changes to the BTS technician supervisor. In making this simulator, sensors are used to detect changes in elevation are a couple of LED and LDR. Meanwhile, the expected response is a call technicians to fill the fuel tank, in order to call the technician to use mobile phones, and the content of calls is a short message services (SMS) that has been in the program. For sending SMS, we was used FASTER M1306B MODEM. From the test results the design of the simulator system, we can say the system works, and send short messages in a timely manner to the technicians, and we have been proposed this to INDOSAT company.

**Keywords:** Fuel scheduling, simulator, wireless communication.

## I. INTRODUCTION

The company or plant requires a backup power supply for voltage supply equipment using Power Generator Set (GENSET). Performance GENSET one factor influenced by the use of fuel oil (BBM) which should always be monitored or monitored so that no vacuum fuel. Short Message Service (SMS) is a facility to send and receive a short text message via wireless devices, i.e. mobile communication device. One of the advantages of SMS is cost. Besides SMS is a store and forward method so that the benefits are when the mobile phone recipient can't be reached, meaning inactive or outside the service area, recipients can still receive the SMS when the mobile phone is already active. SMS provides a mechanism to send short messages to and from a place using wireless media using a Short Messaging Service Center (SMSC), which acts as a system for maintaining and re-transmit short messages. Wireless networks provide a mechanism to find the destination station and send short messages between the SMSC to the wireless station. SMS users rarely (never) get a busy signal, when the voice network is busy, unless it is an SMS Center is being very busy. By considering the issues

fueling generators and excess SMS to deliver short messages with mobile phone media, we are interested in studying how the short message can be up to in 'real time' for the condition when the tank is empty. For that we are interested in doing research on the issue, and create a form of solution.

## II. BASIC THEORY

### A. Microcontroller AVR ATmega8535

Microcontroller is a semiconductor technology in which there is a combination of millions of transistors and packaged in a single chip IC. In the memory of the microcontroller has two program memory (ROM) is used to store programs and versatile memory (RAM) is used to store temporary data include registers that are used according to the program have been made. AVR Microcontroller (Atmel and Vegard's RISC processor) has a 8 bit RISC architecture, all instructions are packed in 16-bit code (16-bits word) and most of the instructions executed in one clock cycle.

In architecture and the instructions used, can be said to be almost the same. Therefore, one used Atmel AVR products, namely ATmega8535. In addition to readily available and cheaper, ATmega8535 microcontroller also has complete facilities. For the type of AVR there are 3 types of ATtiny, classic AVR, ATmega. They differ only in facilities and I/O are available as well as other facilities such as ADC, EEPROM, and so forth. One example is ATmega8535. It has a RISC technology with speeds up to 16 MHz makes ATmega8535 faster when compared with MCS51 variants. With complete facilities such as the ATmega8535 microcontroller makes a powerful see figure 1.

### B. Liquid Level Detection

#### a. LED

LEDs are electronic components that are made from semiconductor diode that can disperse light. LED is a product of the other findings after diode. The structure is also similar to the diodes, but later discovered that electrons that hit the connection PN. To obtain light emission in semiconductors,

doping use is gallium, arsenic and phosphida. Different types of doping produce different colors of light.

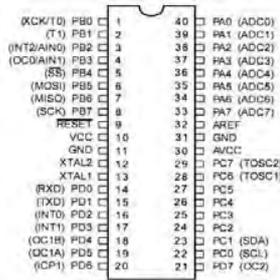

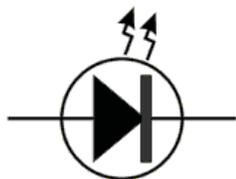

Figure 1. Konfigurasi Pin Mikrokontroler ATmega8535

LEDs have a current or voltage limits are differentiated by color. For example, red = 1.8 Volt, Orange = 2 Volt, Yellow = 2.1 Volt, Green = 2.2 Volt. The standard is 20 mA LED forward voltage and works ranged between 1.4 Volt - 3 Volt. Therefore, the use of LEDs is usually connected in series with a resistance (R) see figure 2a and 2b.

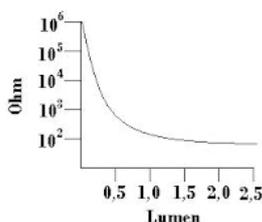

Figure 2.a LED

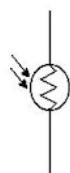

b LED electric symbol

b. LDR (Light Dependent Resistor)

LDR is a resistor resistance value varies whose Because the intensity of the light is absorbed. LDR is also a resistor having a negative temperature coefficient, the resistance value is affected by light intensity. LDR is composed of Cadmium Sulfide (CDS) was generated from ceramic powders. In general, CDS also called conductive photo equipment, as long as the conductivity or resistance of CDS varies with the intensity of the light. If the intensity of the light received high then high barriers would also result in an exit voltage will also be high and vice versa where the mechanism of the process of change light into electricity Occurs. CDS does not have the same sensitivity at each wavelength from ultraviolet to infrared.

( a )

( b )

Figure 3. a . LDR characteristics, b. LDR symbol

C. MODEM

Modem is short for modulator-demodulator. Modulate is the process of translating the data from digital to analog so it can be transmitted. Demodulate the contrary, the process of translating from analog to digital. Modulator is the part that converts the signal information into the signal (carrier) and ready to be delivered, while the demodulator is the part that separates the information signal (which contain data or messages) of the signal (carrier) received that information can be received well.

Modem is a two-way communication tool. Any remote communication devices generally use two-way section called "modem", but the term generally known as the modem hardware is often used for communication on the computer. Data from the computer in the form of a digital signal if it will be given to the modem, to be converted into analog signals. Analog signals can be transmitted through multiple media such as telephone and radio telecommunications.

III. DESIGN SYSTEM

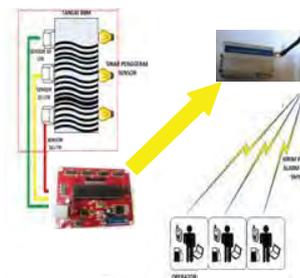

Figure 4. System Design

A. Schematic Sensor Level

Fuel level controller, schematically designed according to Figure 5. below:

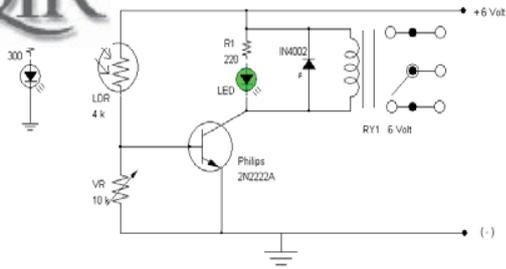

Figure 5. Sensor Circuit Design

Description of figure 5: The circuit is connected to the 5 Volt power supply, if the LDR in exposed conditions, resistance value of LDR will be 500 kilo Ohm so the current can't flow, but if the LDR is exposed to light, in the LDR resistance value will drop to 4 pounds ohm so that current can flow through LDR, toward the base of the transistor 2N2222A, and LED colors used are as in table 1.

Table 1. LED indication on the height of the liquid simulator

No.	LED color	LED Voltage	LED Current
1.	Green	1,5 Volt	20 mA
2.	Yellow	1,5 Volt	
3.	Red	1,5 Volt	

**B. Microcontroller ATmega 8535**

In designing this simulator, controllers used are microcontroller ATmega 8535, as for the pins that was used as in Table 2.

Table 2. Pins Used In Microcontroller ATMEGA 8535

No	pin	function	used for
1.	Pin D. 2	INPUT	Red Lamp
2.	Pin D. 3	INPUT	Yellow Lamp
3.	Pin D. 4	INPUT	Green Lamp
4.	Pin D. 0	OUTPUT	MODEM Fastrack M1306B
5.	Pin D. 1	OUTPUT	MODEM Fastrack M1306B

The algorithm is programmed on the microcontroller are:

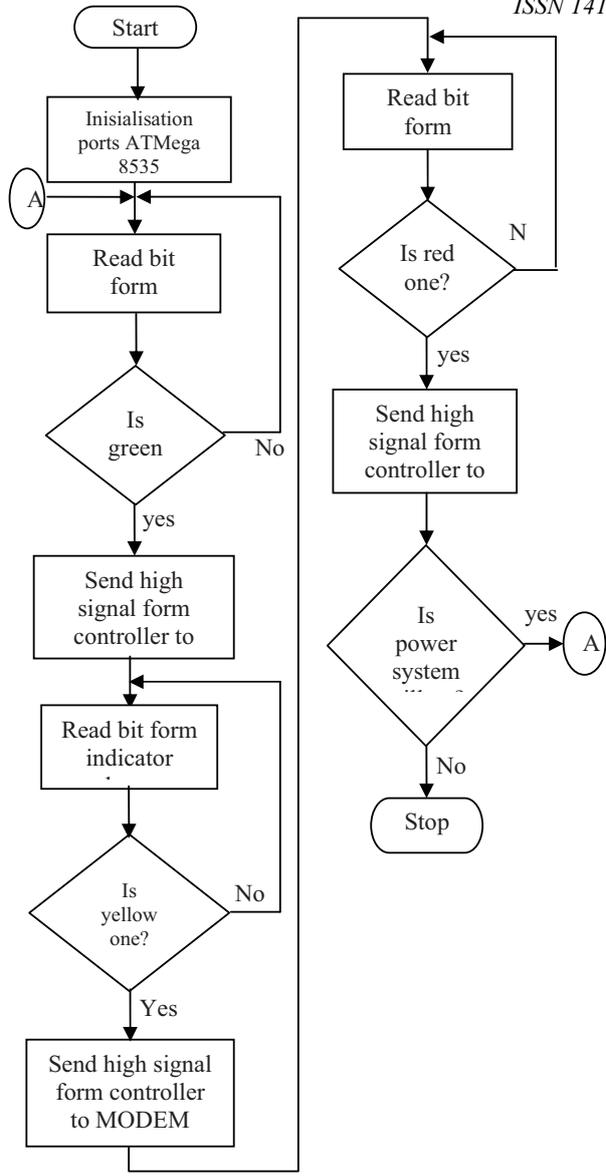

Figure 6. Flowchart Minimum System

**C. MODEM Fastrack M1306B**

FASTRACK Modem M1306B working at the dual frequencies in the 900/1800 Mhz which means that according to the existing mobile frequencies in the Indonesian market, so it fits with the desired characteristics and functions in this paper, namely the media sending data from microcontroller ATmega 8535, i.e. the form of a short message, and then the data is sent to the mobile responsibility tank GENSET. As for the connectivity of the microcontroller ATmega 8535 to 1360 MODEM FASTRACK M 1306b are as in Figure

Figure 7. Fastrack M 1306 Modem

#### IV. SYSTEM TEST AND ANALYSIS

##### A. Sensor Calibration

The results of tests performed by reducing the fluid content that is on the tank, gives the difference between mounting the sensor on the tank with fuel level when testing is done when conditions was detected LDR, as attached in Table 3.

Table 3. Sensor calibration tables for the height of liquid in tank

No	Color	Sensor position (cm)	measurable position (cm)	acuration (%)
1.	Red	9	8,5	94.4
2.	Yellow	20	19,3	96.5
3.	Green	33	32.5	94.6

##### B. Compare between Fuel Level and Volume in the Tank

Table 4. Presentation of the fuel level in the fuel tank volume

No	Color	Tank High Position	Area Tank	Volume
1.	Red	9 cm	531 cm <sup>2</sup>	4,7 liter
2.	Yellow	20,5 cm	531 cm <sup>2</sup>	10,8 liter
3.	Green	34,5 cm	531 cm <sup>2</sup>	12,1 liter

Fuel level sensor can be applied to the alarm system of a company / industry, one of the fuel level sensor application made on cellular systems in BTS in small islands like kepulauan seribu.

##### C. SIM Card

Table 5. Testing sending a message to the MODEM with 4 SIM card in UKI Electrical Laboratory

NO	SIM CARD	TIME
1.	IM3	16 Second
2.	AS	13 Second
3.	3	15 Second
4.	XL	14 Second

#### V. CONCLUSION

There are differences between the measurements of the height sensor installed with fuel level when tested on the boundary conditions, the difference in fuel level LED-level upper limit of 0.5 cm higher than the sensor mounting position, to limit fuel center height difference at the level of 0.7 LED cm lower than the mounting position of the sensor, while the lower limit of the difference in fuel level LED level of 0.5 cm lower than the sensor mounting position.

The use of LED and LDR sensor pair for the fuel level is connected to the generator tank fuel sensor makes it safe to be installed in the generator and fuel system that is inside the tank.

Four times of testing SIM Card, for GSM modems and mobile phones, the time of short messages to each destination on average 14.5 sec. It is still included in the rapid delivery of SMS on GSM.

**Abstract**—Monitoring the engine's performance carried out with the aim of the business process can run smoothly without any process stalled because if the business process stops only a few seconds, the industry will experience a loss. In this research, monitoring of industrial systems using an intelligent system that will do the prognosis of damage to the components contained in the industrial machine is the bearing performance. The method used is the nonlinear autoregressive with exogenous (NARX), based on the linear ARX model, which is commonly used in time-series modeling. This model uses a recurrent dynamic network, with feedback connections and enclosing several layers of tissues. The results of this research remaining useful life (RUL) in machine tools industry. It means the fatal damage in a machine can be avoidable. It is also part of maintenance on industrial machinery, in order to become more efficient in costing and replacement of equipment to be effective.

**Keywords**—bearing damage performance; NARX; recurrent dynamic network; time-series modeling

## I. INTRODUCTION (Heading 1)

Industrial system has rapidly developed. Therefore, to support a success in processing business, industrial system has already computerized. One of the components which operated by a computer is the monitoring of machine usage in industrial system. The purpose of machine performance monitoring is to keep the business process work endless smoothly. There will be a big loss if the business process stops, even only for a second.

In this research, industrial system monitoring used intelligent system that will prognosticate the component damage in the industrial machine, which called by bearing. Bearing is one of the important components in the majority of rotating machine. Because of the damage, bearing is one of the problems in the rotating machine, so it needs the monitoring. Later on, a Feature Extracting Data is used to monitor the

vibration condition. Some of the features are the mean, root mean square (RMS), skewness, kurtosis, and beta kurtosis. The purpose of this monitoring is to detect degradation in the engine. Thus proactive and corrective maintenance can be performed before the worse degradation or failure occurs [9].

Prognosis is a prediction of machine damage at a particular time. Consequently, machine fatal damage can be avoided. It is also a part of industrial machinery maintenance, in order to make expenses and equipment replacement more efficient and effective [18].

NARX model is a method based on the linear ARX model, which commonly used in time-series modeling. Prediction with NARX method is more accurate and consistent [19].

The method used in this research is a nonlinear autoregressive method with exogenous (NARX). This method used for bearing damage prognosis.

## II. FEATURE EXTRACTION AND NARX METHOD

### A. Feature Extraction

Feature extraction is a way to process the data to produce a feature data. In this study, there are 5 features used for prognosis. Those features are the mean, root mean square (RMS), skewness, kurtosis and beta kurtosis. Feature mean is an average or mean value of arrays. Feature root mean square (RMS) is a measure root mean square (RMS) value of the signal. Feature skewness is a measure of the asymmetry of the data around the sample mean.

Kurtosis is the the degree of kurtosis of rolling bearing vibration signal. The equation for kurtosis feature is:

$$K = E(\chi - \mu)^4 / \sigma^4 \quad (1)$$

where  $\kappa$  is the kurtosis,  $E$  is the expected value,  $x$  is the data,  $\mu$  is the average and  $\sigma$  is the standard deviation.

While beta kurtosis is the fourth moment of the beta function. The equation for the beta kurtosis feature is:

$$BK = M_4 / (\sigma^2)^2 \quad (2)$$

where  $BK$  is the beta kurtosis,  $M$  is the moment, and  $\sigma$  is the standard deviation.

### B. Nonlinear Autoregressive with exogenous (NARX)

Method of Method of Nonlinear Autoregressive with exogenous (NARX) is a general model that suitable to represent the dynamics of nonlinear systems. This model uses a repetitive dynamic network, with feedback connections and attaching multiple networks. The equation used in NARX models are:

$$y(t) = f[y(t-1) \dots y(t-ny), x(t-1) \dots x(t-nx)] + e(t) \quad (3)$$

where  $y(t)$  is the output signal at time  $t$ ,  $f$  is a nonlinear function,  $x$  is the external input,  $n$  is the order process, and  $e(t)$  is the error signal (error). Fig. 1, shows the layer of NARX, which two-layer feed forward networks are used for approximation.

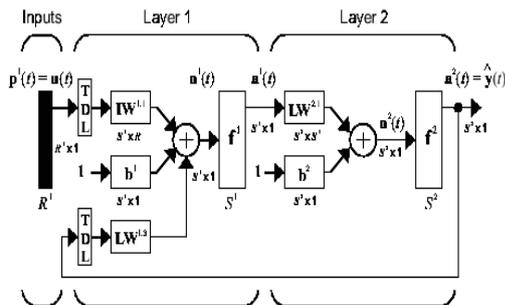

Fig. 1. Layer of NARX

Configuration training is required before demonstrate the training of the NARX network. The output of the NARX network needs to be determined to estimate the output in some nonlinear dynamic system. Fig. 2, shows how to can be accomplished by trying a model of Series-Parallel Architecture for training an NARX.

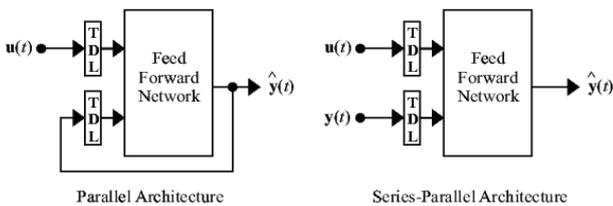

Fig. 2. Series-Parallel Architecture for training an NARX

### III. RESEARCH OBJECTS AND DATA

Research Objects and data used in this study are data on the bearing vibration measurement. These data (from NASA's

Data) are produced by the NSF I / UCR Center for Intelligent Maintenance Systems and supported by Rexnord Corp. in Milwaukee, WI. The data consists of individual files that generated from recorded vibration signals at specific intervals. In addition, each of these file consists of 20,480 points with a sampling rate set at 20 kHz. In this research used 2nd test of NASA's data.

Later, extraction features process these data to produce 5 features, namely mean, root mean square (RMS), skewness, kurtosis and beta kurtosis. The results of extraction feature in the form of the total\_features data with matrix size at 984 x 5. Hence, there are 5 features with each feature consists of 984 data. The fifth feature is used as a dataset 1 to dataset 5. Feature mean as dataset 1. Feature RMS become dataset 2. Feature skewness into dataset 3. Feature kurtosis as dataset 4. And feature beta kurtosis used as dataset 5.

### IV. RESULT AND DISCUSSION

#### A. Data Set 1

Data set 1 using the mean feature. The amount of data on the mean features is 984. The next step performed training data. The data used for the training process is 884 data, that is (1:884,1). Later from first dataset, the prognosis was processed for 100 NARX points of data with NARX method. 100 data of Data Testing Set, in the matrix is (885:984,1). Fig. 3, shows the plot mean feature and prognosis results using mean feature.

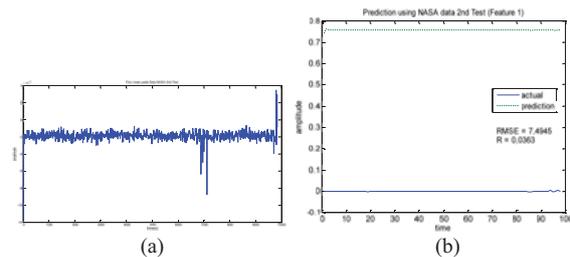

Fig. 3. (a) mean feature. (b) prognosis results using the mean feature

#### B. Data Set 2

Data set 2 using root mean square (RMS) feature. The amount of data on the RMS features is 984. The next step performed training data. The data used for the training process is 884 data, that is (1:884,2). Later from second dataset, the prognosis was processed for 100 NARX points of data with NARX method. 100 data of Data Testing Set, in the matrix is (885:984,2). Fig. 4, shows the plot RMS feature and prognosis results using RMS feature.

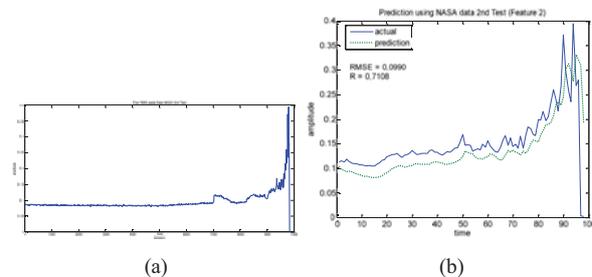

Fig. 4. (a) RMS feature. (b) prognosis results using RMS feature

C. Data Set 3

Data set 3 using skewness feature. The amount of data on the skewness feature is 984. The next step performed training data. The data used for the training process is 884 data, that is (1:884,3). Later from 3rd dataset, the prognosis was processed for 100 NARX points of data with NARX method. 100 data of Data Testing Set, in the matrix is (885:984,3). Fig. 5, shows the plot skewness feature and prognosis results using skewness feature.

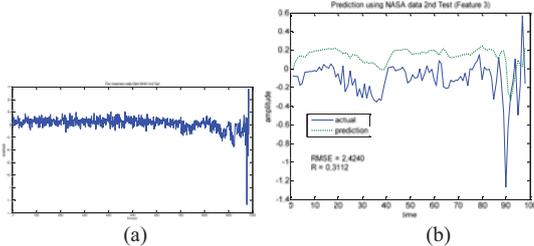

Fig. 5. (a) skewness feature. (b) prognosis results using skewness feature

D. Data Set 4

Data set 4 using kurtosis feature. The amount of data on the kurtosis features is 984. The next step performed training data. The data used for the training process is 884 data, that is (1:884,4). Later from 4th dataset, the prognosis was processed for 100 NARX points of data with NARX method. 100 data of Data Testing Set, in the matrix is (885:984,4). Fig. 6, shows the plot kurtosis feature and prognosis results using kurtosis feature.

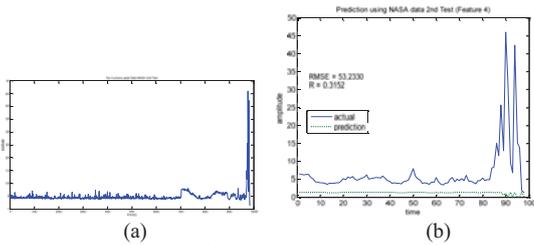

Fig. 6. (a) kurtosis feature. (b) prognosis results using kurtosis feature

E. Data Set 5

Dataset 5 using beta kurtosis feature. The amount of data on the beta kurtosis features is 984. The next step performed training data. The data used for the training process is 884 data, that is (1:884,5). Later from 5th dataset, the prognosis was processed for 100 NARX points of data with NARX method. 100 data of Data Testing Set, in the matrix is (885:984,5). Fig. 7, shows the plot beta kurtosis feature and prognosis results using beta kurtosis feature.

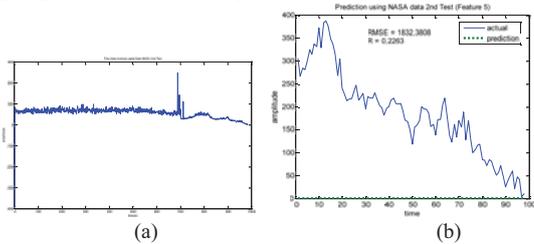

Fig. 7. (a) beta kurtosis feature. (b) prognosis results using beta kurtosis feature

F. Step Ahead Prediction

From the results of the above prediction, a good predictor is RMS feature, because this feature has root mean square error (RMSE) = 0,099 and coefficient correlation (R) = 0,7108. Then the dataset is done step ahead prediction.

- One Step Ahead

For the prediction one step ahead using 10 data, that is (885:894,2). Fig. 8, shows the result plot predicted one step ahead in the features RMS.

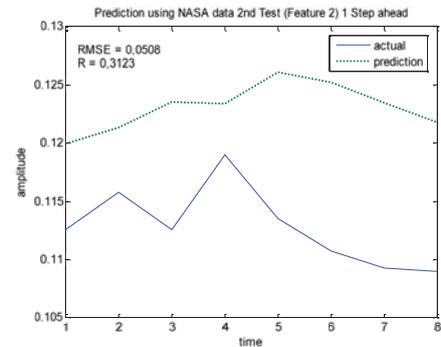

Fig. 8. Prediction one step ahead in the features RMS

- Two Step

For the prediction two step ahead using 20 data, that is (885:904,2). Fig. 9, shows the result plot predicted one step ahead in the features RMS.

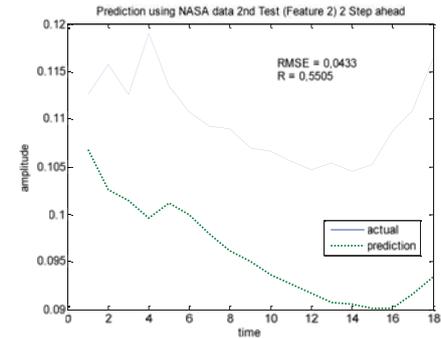

Fig. 9. Prediction two step ahead in the features RMS

- Three Step Ahead

For the prediction three step ahead using 30 data, that is (885:914,2). Fig. 10, shows the result plot predicted one step ahead in the features RMS.

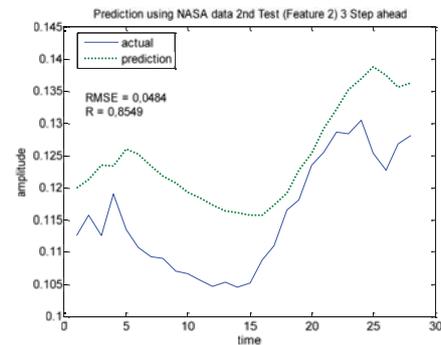

Fig. 10. Prediction three step ahead in the features RMS

## V. CONCLUSION

### A. Remaining Useful Life

Remaining Useful Life calculated using prediction step ahead, that is the amount of data on a step ahead multiplied by the file recording interval. NASA data sets have file recording interval every 10 minutes, so that the data points in the data can be interpreted NASA represents 10 minutes. So when do the predictions One Step Ahead, which 10 points of data in the future, it means that it has been doing predictions for the next 100 minutes. And when do the Two Step Ahead predictions, 20 points of data in the future, it means that it has been doing predictions for the next 200 minutes. Then, if the prediction Three Step Ahead, 30 points of data, means doing the next 300 minutes. Step ahead prediction calculation is :

$$\text{Step Ahead prediction} = \text{amount of data} \times \text{file recording interval} \quad (4)$$

Table 1, shows the table of step ahead prediction.

TABLE 1. STEP AHEAD PREDICTION

Step ahead	Amount of data (points data)	File recording interval (minutes)	Step Ahead prediction (minutes)
One	10	10	100
Two	20	20	200
Three	30	30	300

So if a roller bearing 10 data will be broken in the future, the company still has 100 minutes to replace it. So it can help the company to replace equipment before the equipment suffered fatal damage.

From these five experimental data, starting from the dataset 1 to dataset 5, then the most likely prognosis outcome testing set is RMS feature. Thus, RMS feature can be used as a dataset to predict step ahead for bearing damage prognosis using NARX.

The final results of prognosis aimed to determine the bearing remaining useful life. By knowing the bearing remaining useful life on a piece of equipment in the industrial system, this can help the company to replace equipment before the equipment suffered fatal damage. Therefore, the company can save costs and business processes can be carried out effectively and efficiently.

**Abstract** Power supply is one of the most important thing in mobile telecommunications system. Power quality determine the reliability of telecom equipment, therefore electrical interferences should known as soon as possible to avoid power supply interruption and affecting to the operation of telecommunication system. To keep the power system in any location of base stations could be real time monitor, they invented a remote power monitoring system. It control, monitor and manage all units of rectifier on remote area via microwave radio. As we know there are any weakness of microwave radio, one of them is fading on air due to weather conditions changes. Like a radio communication system in general, it's affects to the reliability of power monitoring system. In this paper, the authors will discuss and analyze the root cause of failure to get information from rectifier in remote area with a case study in a particular location which has been specified by the author.

**Keywords :**

*Path Calculation, RSL, Losses, Gain, Fade Margin*

## 1. INTRODUCTION

Power Element Management System is a centralized power system monitoring which applicable on many industries. The main purpose of PEMs is to ensure the reliability and availability of power supply in any base stations. After check one of the most frequently failure of get electrical information from rectifier in a remote area, the authors investigated an HOP of radio microwave on site Mariana direction to Mato merah site. On this HOP we finding so many failure of radio microwave system which impact of the reliability of power monitoring decrease.

### 2.1. PATH CALCULATION

A calculation of output power levels to ensure the reception power level are greater than or equal to the threshold power level ( $RSL > R_{th}$ ), several parameters that affect to link budget such as Tx Power, EiRP, RSL, FSL, etc. This calculation is to maintain the balancing of gains and losses in order to achieve an ideal parameter link budget.

#### 2.1.1. Tx Power

A radio transmitter usually has an output power which measured by the equations (2.1) and (2.2) with each values as below :

$\text{dBm}$  : Relative power to one (1) milliwatt  
 $W$  : Linear power as Watts

A transmit radio transmit power is not through reinforcement or losses in transmission media. Calculated by the following equations.

#### 2.1.2. Effective Isotropic Radiated Power

An amount that states transmit power of a transmitter that has been through the reinforcement and damping on the transmission line can be calculated by the formula in Equation (2.3) where :

$P_{Tx}$  : Transmit power (dBm)  
 $G_{Tx}$  : Transmitter antenna gain (dB)  
 $L_{Tx}$  : Losses transmitter (dB)

#### 2.1.3. Receive Sensitivity

All radios have a minimum point, where if the signal received is lower than the minimal point of the data sent can not be received well. Minimal point radio sensitivity in dBm or W is known as Threshold. Defined as the limit of tolerance acceptance that can still be tolerated, rec.594 CCIR standards and technical specifications on the level-77dBm.

#### 2.1.4. Receive Signal Level

Receive Signal Level is the level of receptivity in the receiver whose value must be greater than the sensitivity of the receiver ( $RSL \geq R_{th}$ ). The sensitivity of receiver is used as a threshold size (refer to figure 1). RSL value can be calculated by equation (2.4):

Where the values are as below :

$EIRP$  : Effective Isotropic Radiated Power (dBm)  
 $L_{fs}$  : Propagation loss (dB)  
 $G_{Rx}$  : Rx antenna gain (dB)  
 $L_{Rx}$  : Line losses (dB)

Or with equation (2.5) where :

$P_{Tx}$  : Tx output power (dBm)  
 $P_{Tx Loss}$  : Cable loss + Connector loss / insertion loss + Adaptor (dB)  
 $G_{ant1}$  : Antenna Tx Gain (dBi)  
 $L_{fs}$  : Free space loss (dB)  
 $G_{ant2}$  : Antenna Rx Gain (dBi)  
 $Rx loss$  : Rx losses (dB)

#### 2.1.5. Free Space Loss

Free space loss is the wave propagation losses in the air between two isotropic antennas due to the energy spread in the equation (2.6).

where  $D$  = Path distances (km) and  $f$  = Frequency (GHz)

#### 5. DISCUSSION

##### Site Survey

In order to obtain accurate data on the condition of the field, the authors conducted site visits to collect data and information on the data obtained can be seen in (Table 3.1)

##### Cable Loss

Mariana site with length of cable = 48 m  
= 48 x 3.2810 = 157.48ft, The cable losses value is 8.661 dB

Mato merah site with length of cable = 50 m  
= 50m x 3.2810 = 164.050ft, The cable losses value is 9.022 dB

##### Connector Loss

For both station has 2 units of IF connectors , 1 connected to the RFU dan the other connected to the IDU, therefore the insertion loss at those sites as follow :

Mariana site = 2 x 0.15dB = 0.3 dB  
Mato Merah site = 2 x 0.15dB = 0.3 dB

##### Free space Loss

This losses is common in every wave that propagates in air, which is expressed by the LFS refer to the (eq.2.6):

$$L_{fs} \text{ Mariana, } f = 13.143 \text{ GHz}$$

$$= 92.45 + 20 \log (f \times D)$$

$$= 92.45 + 20 \log (13.143 \times 4.16)$$

$$= 127.206 \text{ dB}$$

$$L_{fs} \text{ Mato Merah, } f = 12.877 \text{ GHz}$$

$$= 92.45 + 20 \log (f \times D)$$

$$= 92.45 + 20 \log (12.877 \times 4.16)$$

$$= 127.028 \text{ dB}$$

##### Line Losses

The amount of losses on the transmission line which is calculated in both of location of the biggest losses obtained from free-space loss propagation. This is due to the use of frequency 13 GHz with a distance of 4.16 km. Here are the total transmission losses in both locations as follow :

##### EIRP

Number of additional power in the pentransmission depending on the type and specifications of antennas used. The EIRP values at the location Mariana and Mato merah are :

$$EIRP = P_{Tx} + G_{Tx} - L_{Tx}$$

$$EIRP_{\text{Mariana}} = 22 \text{ dBm} + 30 \text{ dBi} - 9.061 \text{ dB}$$

$$= 42.939 \text{ dBm}$$

$$EIRP_{\text{Mato merah}} = 22 \text{ dBm} + 30 \text{ dBi} - 9.422 \text{ dB}$$

$$= 42.578 \text{ dBm}$$

##### Gains (Refer to the table 3.2)

##### Receive Signal Level

The values of the received power at the receiver side, the good thing is RSL > RTH. RSL value at a receiver can be calculated by using the formula (eq 2.5) :

$$RSL_{\text{Mariana}} = 42.578 \text{ dBm} - 127.028 \text{ dB} + 30 \text{ dBi} - 9.061 \text{ dB} = -63.511 \text{ dBm}$$

$$RSL_{\text{Mato Merah}} = 42.939 \text{ dBm} - 127.206 \text{ dB} + 30 \text{ dBi} - 9.422 \text{ dB} = -63.689 \text{ dBm}$$

##### Fade Margin

For both location, we get the fade margins value as below :

$$FM_{\text{Mariana}} = -63.511 \text{ dBm} - (-75.5 \text{ dBm})$$

$$= 11.989 \text{ dBm}$$

$$FM_{\text{Mato Merah}} = -63.689 \text{ dBm} - (-75.5 \text{ dBm})$$

$$= 11.811 \text{ dBm}$$

Therefore, based on the calculation Fade Margin, it is known that the cause of frequently disruptions radio performance are caused by RSL degraded and fade margin values that has not reach the minimum values. To get it cleared from radio interference such as Fading, Multipaths, then the value should be increase to the over or equals than 15dB.

By the way, with assumes we gonna change the antenna diameters and gain with the values 0.6 (35dB) then change the frequency become 11GHz would be get the best result as follow :

$$EIRP_{\text{Mariana}} = 22 \text{ dBm} + 35 \text{ dBi} - 9.061 \text{ dB}$$

$$= 47.939 \text{ dBm (increase 5 dBm)}$$

$$EIRP_{\text{Mato merah}} = 22 \text{ dBm} + 35 \text{ dBi} - 9.422 \text{ dB}$$

$$= 47.678 \text{ dBm (increase 5.1 dBm)}$$

$$L_{fs} \text{ Mariana} = 92.45 + 20 \log (10.721 \times 4.16)$$

$$= 125.436 \text{ dB}$$

$$L_{fs} \text{ Matomerah} = 92.45 + 20 \log (11.211 \times 4.16)$$

$$= 125.824 \text{ dB}$$

$$RSL_{\text{Mariana}} = 47.678 \text{ dBm} - 125.824 \text{ dB} + 35 \text{ dBi} - 9.061 \text{ dB} = -52.209 \text{ dBm}$$

$$\text{(increase 11.302 dBm)}$$

$$RSL_{\text{Mato merah}} = 47.939 \text{ dBm} - 125.436 \text{ dB} + 35 \text{ dBi} - 9.422 \text{ dB} = -51.919 \text{ dBm}$$

$$\text{(increase 11.77 dBm)}$$

Therefore, the values of Fade Margin would be as follow :

$$\begin{aligned} \text{FM}_{\text{Mariana}} &= -52.209 \text{ dBm} - 75.5 \text{ dBm} \\ &= 23.291 \text{ dBm} \\ \text{FM}_{\text{Mato Merah}} &= -51.919 \text{ dBm} - 75.5 \text{ dBm} \\ &= 23.581 \text{ dBm} \end{aligned}$$

## 6. CONCLUSION

Fade Margin value Mariana to Mato merah not meet the standard, so it is fragile of interferences and impact to the reliability of power remote monitoring system at the location Mariana.

Mato merah to Mariana with 11GHz frequency applications rather than 13 GHz, the added value gained is reduced propagation losses of 2.5 dB free space.

By changing the antenna size with a bigger diameter 0.3 to 0.6 meters would get the result as an increasement of 10 dBm RSL and a power reserve of over than 23 dBm Fade margin.

**Abstract**— In this paper, the bandwidth enhancement of ultra-wideband (UWB) microstrip bandpass filter (BPF) is proposed by utilizing defected ground structure (DGS). The initial UWB microstrip BPF which is designed to have the bandwidth response of 4GHz with the center frequency of 4GHz is deployed on FR4 Epoxy dielectric substrate with overall size and thickness of 11mm x 32mm and 0.8mm, respectively. To enhance the bandwidth response, an attempt is carried out by applying DGS on to the ground plane of initial filter. Here, the proposed DGS is constructed of 3 circular dumbbells. Some parametrical studies to the DGS such as changing the radius of dumbbells and the dimension of bridging-section of dumbbells are conducted intensively to obtain the optimum geometry of DGS with the desired bandwidth response. From the characterization result, it shows that the utilization of DGS on to the ground plane of filter has widened 3dB bandwidth response up to 5.36GHz ranges from 1.84GHz to 7.2GHz yielding an enhanced ultra-wideband response for various UWB applications. The minimum insertion loss and maximum return loss of microstrip BPF with proposed DGS in the passband area are 2.05dB and 6.73dB, respectively.

**Keywords**— Bandwidth enhancement, DGS, dumbbells, UWB microstrip BPF

## I. INTRODUCTION

During last decade, the development of technology for communication and information has been incredibly increasing. This development is principally to satisfy the demand for high speed communication which supports to transmit huge amounts of information [1]-[3]. Some investigation effort to fulfill the demand has also been conducted by improving the existing of device technology. However, the improvement sometimes arises some problems regarding the limited capability of related devices of communication and information technology, including antenna, signal amplifier, coupler, and filter [3]-[5]. From so many mentioned devices, the last device, i.e. filter, is one of the most important and essential parts for application in communication and information technology. As is already well-known, most of devices for communication and information technology could not perform well if they have no adequate quality in filtering system.

In accordance to the development of devices for communication and information technology, the demand of related devices, filters in particular, tends to have wide bandwidth response, compact in size, light in weight as well as adequate electrical characteristic performances. In order to accomplish the requirements above, ultra-wideband (UWB) technology has been one of the most promising solutions for wide range data communication application in future [6]. Several devices that support the UWB system have been theoretically and experimentally investigated including a number of UWB filters which have been developed using some techniques such as microstrip and uniplanar circuits [7]-[9]. However, even though most of devices supported UWB systems, especially filters, have claimed to have wide bandwidth response, another problem often arises regarding to the bandwidth capabilities of devices.

In connection to the attempts for obtaining the wide bandwidth response of filter, in this paper, the bandwidth enhancement of UWB microstrip bandpass filter (BPF) is conducted by changing and/or defecting the ground plane surface of filter called as defected ground structure (DGS). Here, the DGS is intentionally applied to have the BPF with enhanced performance for various UWB applications. The proposed DGS is constructed of 3 uniformly circular dumbbells which are positioned symmetrically between the ports on the ground plane of initial filter. Hence, the BPF itself is composed of dual open stubs and four sections of balanced coupled-lines for obtaining multimode filter responses [10]. The construction of filter and DGS which is deployed on FR4 Epoxy dielectric substrate is designed to have working bandwidth wider than 4GHz as the improvement effect from the original bandwidth response. In the design process, the performance of BPF with proposed DGS is investigated intensively to obtain the optimum design of overall structure. Some parametrical studies upon the DGS are investigated to obtain the optimum geometry of DGS with the desired bandwidth response by changing the radius of circular dumbbells as well as varying the dimension of bridging-section of circular dumbbells. Hence, the filter parameters including return loss, insertion loss, and bandwidth response will be used as key indicators in the evaluation of filter performance.

## II. BRIEF OVERVIEW OF UWB MICROSTRIP BPF

### A. UWB Microstrip BPF without DGS

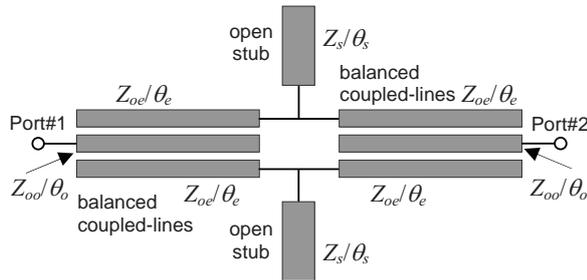

Fig. 1. Transmission line model of initial UWB microstrip BPF

By using the model in [10], the transmission line model of initial UWB microstrip bandpass filter (BPF) is illustrated in Fig. 1. The model is developed with balanced coupled-lines and dual open stubs perturbation to work with the center frequency of 4GHz. It is shown that the line impedance and electric length of every open stub perturbation are  $Z_s$  and  $\theta_s$  respectively. In addition, since the coupled-line is symmetrically structured yielding balanced coupled-line, therefore, the structure has a common line which is connected to the port. Every coupled-line provides the even-mode line impedance and the electric length of  $Z_{oe}$  and  $\theta_{oe}$ , respectively and also the odd-mode line impedance and the electric length of  $Z_{oo}$  and  $\theta_{oo}$ , respectively. Based on the transmission line model, the structure of UWB microstrip BPF is then implemented using microstrip technology on an FR4 Epoxy dielectric substrate with overall size and thickness of 11mm x 32mm and 0.8mm, respectively.

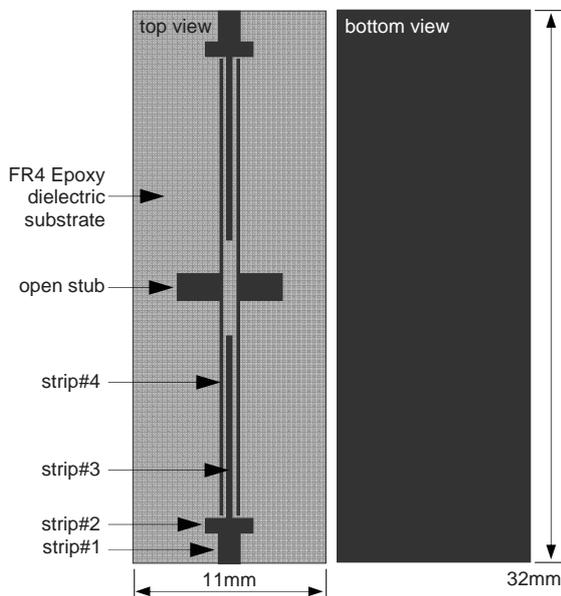

Fig. 2. Structure of initial UWB microstrip BPF.

Figure 2 shows the structure of initial UWB microstrip BPF composed of balanced microstrip coupled-lines with dual open stubs perturbation. Hence, Table 1 summarizes the detail geometry of each filter element, i.e. strips and stubs. The elements are made of metal copper on the top side of dielectric substrate as well as the ground plane on the bottom side. In order to have an accurate design, the losses of dielectric substrate and metal copper conductive for elements and ground plane are taken into account. The input/output signals for initial UWB microstrip BPF are obtained from SMA connectors.

TABLE I. GEOMETRY OF EACH ELEMENTS FOR INITIAL UWB MICROSTRIP BPF

Element	Width (mm)	Length (mm)
Strip#1	1.2	1.8
Strip#2	0.8	2.7
Strip#3	0.4	10.6
Strip#4	0.3	26.4
Open stub	1.5	2.7

### B. DGS-based UWB Microstrip BPF

By using the similar structure of filter elements as applied for the initial UWB microstrip BPF, the bandwidth enhancement to have the filter with improved performance is investigated by employing defected ground structure (DGS). Figure 3 illustrates the utilization of DGS over the ground plane. It shows that the proposed DGS is constructed of 3 uniformly circular dumbbells. The first and the third dumbbell are placed symmetrically each other from the center, while the second one is put at the center underneath open stubs perturbation. To obtain the optimum geometry of DGS, the investigation is carried out by changing the radius of circular dumbbells as well as varying the dimension of bridging-section of dumbbells.

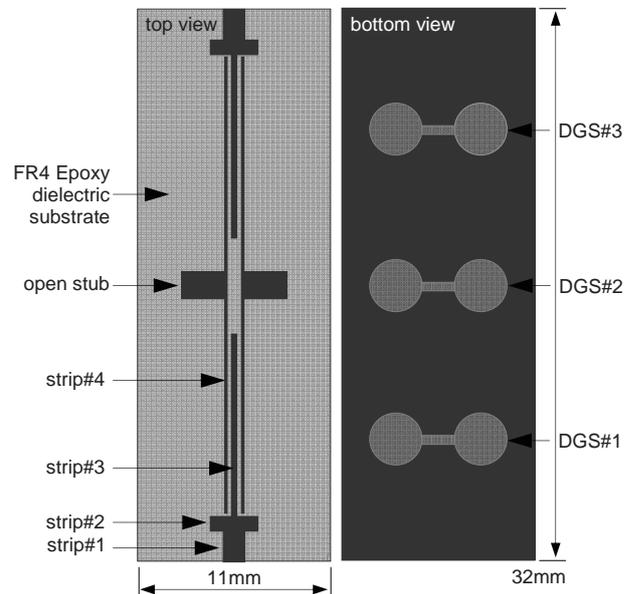

Fig. 3. Structure of DGS-based UWB microstrip BPF.

### III. CHARACTERIZATION RESULTS AND DISCUSSION

Figure 4 plots the characterization result of DGS-based UWB microstrip BPF with the radius of circular dumbbells varied from 1.3mm–1.5mm. The separation between DGS is set to be 7.8mm which is measured from the center of each circular dumbbell. The bridging-section length and width of each circular dumbbell is set to be uniform at 1.0mm and 0.5mm, respectively. From the result, it should be noted that the larger radius of dumbbell yields the better response of passband area at higher frequency bands (6.3–7.8GHz) but the worse response at middle frequency bands (4.6–6.3GHz). The result shows that the variation of circular dumbbell has no effect to the lower frequency bands. This can be understood that the characteristics of dumbbells as DGS affects to the decrease of overall inductance of filter.

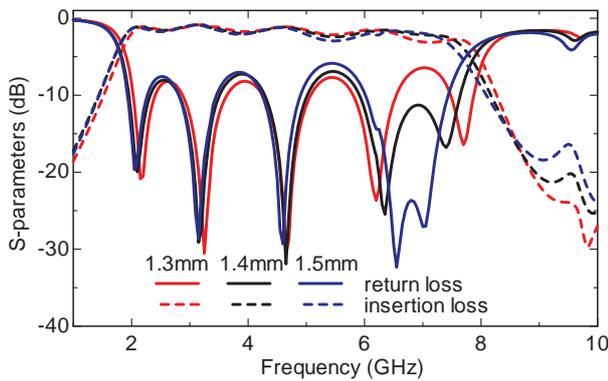

Fig. 4. Characterization result of DGS-based UWB microstrip BPF with the varied radius of circular dumbbells

Next, the characterization of DGS-based UWB microstrip BPF for the varied separation between DGS from 7.7mm–7.9mm and the different value of bridging-section width of circular dumbbell is conducted. The bridging-section width of circular dumbbell for DGS#1, DGS#2, and DGS#3 is 0.3mm, 0.5mm, and 0.3mm respectively, while the length for all is set to be constant at 1.25mm. The result of characterization is depicted in Fig. 5.

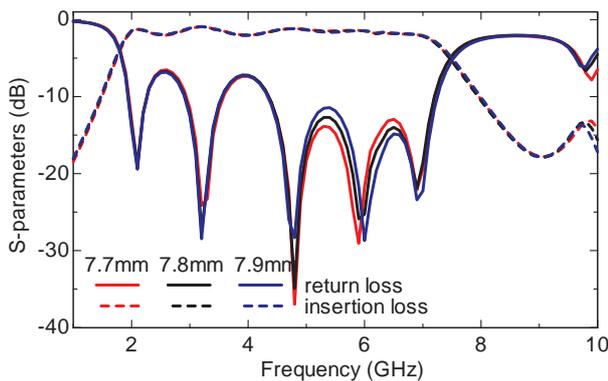

Fig. 5. Characterization result of DGS-based UWB microstrip BPF with the varied separation of DGS and non uniform bridging-section dimension.

From the figure, it shows that the variation of separation between DGS has the similar effect to the variation of radius of circular dumbbell. The similar effect also shows at the lower frequency response which is no discrepancy result. The characteristic response is better at higher frequency bands (6.1–6.9GHz) for the larger distance between DGS but worse for middle frequency bands (4.9–6.1GHz). However, in comparison of 2 results above, the effect of varied radius of circular dumbbell gives more significant change to the characteristics response than the varied distance of DGS. This is probably caused by the lower coupling between the DGS and the filter itself for the larger distance of DGS.

Finally, to demonstrate the enhancement bandwidth, the DGS-based UWB microstrip BPF is characterized with the radius of each circular dumbbell of 1.4mm, separation between DGS of 7.8mm, bridging-section length of 1.25m, and bridging-section width for DGS#1, DGS#2, and DGS#3 of 0.3mm, 0.5mm, and 0.3mm, respectively. The characterization result which is shown in Fig. 6 is plotted together with the characterization result of initial UWB microstrip BPF. It shows that the initial UWB microstrip BPF filter has 3dB bandwidth response up to 4GHz ranges from 2.15GHz to 6.15GHz. The minimum value of insertion loss in passband area is 1.47dB which occurs at 5.54GHz. On the other hand, the maximum value of return loss in passband area is 11.81dB at 2.98GHz. Whilst from the characterization results of proposed DGS-based UWB microstrip BPF, it has 3dB bandwidth response up to 5.36GHz ranges from 1.84GHz to 7.2GHz. In the passband area, the minimum insertion loss is 2.05dB which occurs at 4GHz and the maximum return loss is 6.73dB at 2.6GHz.

From the characterization results, it should be noted that the proposed DGS-based UWB microstrip BPF has the bandwidth response 1.36GHz wider than the initial filter, or in other term, the utilization of DGS can successfully enhance the bandwidth response up to 34% compared to the initial UWB microstrip BPF. The bandwidth enhancement occurs both at the lower and the higher frequency bounds of the DGS-based UWB microstrip BPF, where the lower frequency bound is shifted lower than the lower frequency bound of initial UWB microstrip BPF, as well as the higher frequency bound which is also shifted higher.

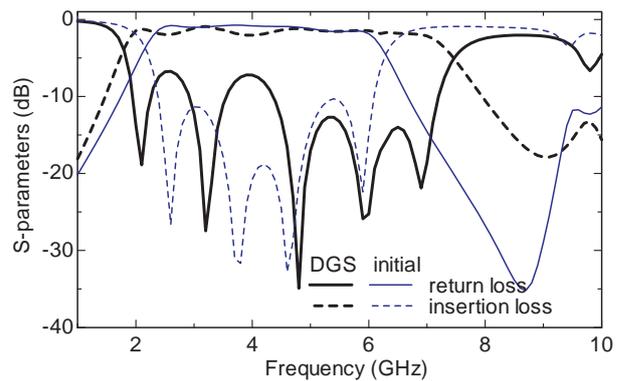

Fig. 6. Characterization result of proposed DGS-based UWB microstrip BPF in comparison with initial UWB microstrip BPF.

On the other hand, the initial UWB microstrip BPF has the lower value of maximum return loss and the higher value of minimum insertion loss compared to the DGS-based UWB microstrip BPF. This can be figured out the utilization of DGS to the initial UWB microstrip BPF has probably changed the characteristic filter type from the Butterworth response in initial filter to the Chebyshev in proposed filter. Due to the change of characteristic, the ripple is discovered in the passband area of proposed filter evokes the change of return loss and insertion loss values.

#### IV. CONCLUSIONS

The bandwidth enhancement of UWB microstrip BPF has been investigated by utilizing DGS on the ground plane surface. The used DGS was constructed of 3 uniformly circular dumbbells. From the characterization results, it has been shown that the variation of some DGS parameters has significant effect but not for all frequency responses at passband area. Hence, from the comparison of characterization results between the initial filter and the proposed DGS-based filter, it has been demonstrated that the utilization of DGS has successfully enhanced the bandwidth response up to 34% from the initial filter of 4GHz 3dB bandwidth response. It has also been shown that the utilization of DGS has probably changed the characteristic of filter, i.e. from Butterworth to Chebyshev, which is indicated by appearance of ripple in the passband area. Although some values of return loss and insertion loss of DGS-based UWB microstrip BPF is not better than the initial one, however, the proposed DGS-based filter has shown an improved and acceptable performance which can be applied for various UWB applications.

#### ACKNOWLEDGEMENT

The authors thank to Dr. M. Ridwan Effendi, School of Electrical Engineering and Informatics, Institut Teknologi Bandung (ITB) for the useful discussion and support.

 Tarumanagara University  
 Jakarta, Indonesia  
 lely@fti.untar.ac.id

**Abstract**—University Course Timetabling Problem (UCTP) belongs to Constraint Satisfaction Problems (CSPs), which are the set of objects whose state must satisfy a number of constraints. The constraints, in this case, are related to characteristics and regulations of a particular university. Certainly, these will vary from one university to the other. A number of approaches have provided feasible and optimal solutions for UCTP. However, their solutions are still based certain university's constraints. Our approach has given another way to occupy various constraints for various universities. Dynamic Constraint Matching (DCM) consists of constraints logical formulation, collision matrix generation, and validation using the collision matrix. Our experiment, using 93 subjects offered in Faculty of Information Technology Tarumanagara University, has shown that all constraints, taken from the characteristics and regulations of the Faculty, can be formulated successfully. When DCM were integrated with Vertex Graph Coloring (VGC) as one of the guaranteed optimal solutions for UCTP, the approach results a course schedule that does not contain any hard or soft constraints violations. The processing time can be said fast, which is less than 1 minutes.

**Keywords**—Dynamic Constraint Matching, Vertex-based Graph Coloring, University Course Timetabling Problem, Constraint Satisfaction Problem, Constraint Based Reasoning

## I. INTRODUCTION

UCTP is consisting of allocating a set of subjects within a given domain. UCTP model must accommodate characteristics and regulations of specific university. Certainly, these will vary from one university to the other. These characteristics and regulations define what we call later as constraints in generating a feasible and optimal course schedule.

Corne et.al [1] stated that constraints in UCTP can be classified into five categories:

1. Unary Constraints, involving one event, such as the constraint “event  $a$  must not take place on Tuesday”, or the constraint “event  $a$  must occur in timeslot  $b$ ”,
2. Binary (Event Clash) Constraints, concerning pairs of events, such as the constraint “event  $a$  must take place before event  $b$ , which must take place before  $c$ ”, etc,

3. Capacity Constraints, governed by room capacities, etc. For example, “all events should be assigned to a room which has a sufficient capacity”,
4. Event Spread Constraints, concerning requirements such as the “spreading-out” or “clumping together” of events within the timetable in order to ease student or lecturer workload, and to agree with university timetabling policy.
5. Agent Constraints, imposed in order to promote requirements or preferences of the people who will use the timetables, such as the constraint “lecturer  $x$  likes to teach event  $a$  on Mondays” or “lecturer  $y$  must have  $n$  free mornings per week”.

Constraints can be said to be hard constraints or soft constraints [2]. Hard constraints are those which must be satisfied in order to have a feasible schedule. For example, no lecturer may be scheduled to teach two subjects during the same timeslots. Soft constraints are request that should be fulfilled, if it is not fulfilled, the schedule is still considered feasible provided that all hard constraints have been satisfied. For example, a lecturer may request a particular timeslot free during the week.

There are two different points of view for UCTP [2]. One could assume that a particular set of courses will be offered during a term by particular lecturers, and first assign them times and rooms, and then allow students to register only for courses whose times do not conflict. The second approach would be to decide which courses would be offered, allow students to register for them, and then assign times and rooms to each course, so that the number of students who have course conflicts is minimized. Our research looks at the UCTP from the first point of view.

Based on our observation, characteristic of UCTP, in general, consists of a set of course subjects, a set of constraints and a two-dimensional scheduling domain (timeslots and rooms). Let consider a course subject as an object. Each object has a number of attributes, for example class, lecturer, time slot and room. A University might have other specific attributes which will vary from one university to the others. If we closely observe, a constraint basically defines a logical relationship between two different objects in terms of their attributes. One constraint may involve more than one logical relationship.

Thus, relations of AND and OR can be used to join those relationships. Using these basic ideas, we proposed Dynamic Constraint Matching (DCM) technique for dynamically defining constraints based on any characteristic and regulation of various universities.

Our proposed DCM, currently, focuses more on the Binary (Event Clash) Constraints. This particular constraint can be found in almost all UCTPs, and it presence allows parallels to be drawn with the well-known graph coloring problem [1]. For the Capacity Constraint, which is mainly on the room capacities, is also considered, but directly integrated in our subject-domain allocation step.

Optimization-based scheduling approaches that have lots of attention recently is the meta-heuristics approaches, such as graph coloring, simulated annealing, tabu search, genetic algorithms, and particle swarm optimization [3]. These approaches have been proven to give feasible results. However, if they were implemented alone, near-optimal solution cannot be obtained by them [4][5][6][7]. Some studies have shown that by incorporating constraint based reasoning, a near-optimal solution can be obtained [3].

A Hybrid Genetic Algorithm and Constraint Based Reasoning (GA-CBR) [8][9][10] and A hybrid Particle Swarm Optimization and Constraint Based Reasoning (PSO-CBR) [3] give feasible and near-optimal solution. DCM basically performs the same tasks that CBR do, but in more effective and flexible way. The success of PSO-CBR [3] is our main reference to incorporating DCM into Vertex-based Graph Coloring (VGC). We choose VGC because this technique is simple and guaranteed to provide feasible and optimal solution. However, since the scheduling domain is limited to a number of timeslots and a number of rooms with their own capacities, the solution of VGC still will have some constraint violations. Thus, incorporating the DCM will ensure less to no constraint violation with regard to domain limitation.

The rest of this paper is organized as follows. Section 2 describes more detail DCM. Section 3 discusses the incorporation of DCM into VGC. Section 4 reports and discusses our experimental results. Section 5 concludes in Section 5.

## II. DYNAMIC CONSTRAIN MATCHING (DCM)

DCM consists of three steps. The first step defines logical formulations of constraints. The second step matches the constraints with the attributes' value of two objects and generates a collision matrix. Finally, the third step is validation step that utilizes the collision matrix. This section describes the first two steps. The third step discussed in Section 3.

### A. Constraint Logical Formulation

UCTP, based on CSPs' model, is consisting of the following sets: [1][3]

1. A set of subjects,  $X = \{x_1, x_2, \dots, x_N\}$
2. A set of two-dimensional domain, consisting of timeslots and rooms,  $D = \{d_1, d_2, \dots, d_M\}$
3. A set of constraints,  $C = \{c_1, c_2, \dots, c_L\}$

Each subject,  $x_i$  for  $i = 1, 2, \dots, N$ , consists of a set of attributes or properties,  $A = \{a_1, a_2, \dots, a_K\}$ . In UCTP, these attributes of each subject could be room, timeslot, lecturers, subject's credits, room capacity, semester distribution, and others, depending on the characteristics and regulations of university operational curriculum.

UCTP domain,  $D$ , is viewed by timeslot and room dimensions. One timeslot is equal to one credit of a subject. For example, one credit is equal to one hour, then each timeslot is equal to one hour. So, if in one day, the course time schedule starts from 08.00 to 17.00, then in one day there are nine timeslots. In one week, with five days for face-to-face lectures, the total timeslots is 45 slots. Fig. 1 depicts the data structure of  $D$  in form of matrix. Each element in the matrix is called the position slot. In this case, each subject can take more than one slot. Two subjects are said to be parallel, if their position slots are overlapped. For Room  $r_i$  and Timeslot  $t_j$ , where  $i = 1, 2, \dots, R$  and  $j = 1, 2, \dots, T$ , the slot position index, can be defined using  $d_{(j-1)*R+i}$ .

	Room $r_1$	Room $r_2$	...	Room $r_R$
Timeslot $t_1$	$d_1$	$d_2$		$d_R$
Timeslot $t_2$	$d_{(R+1)}$	$d_{(R+2)}$		$d_{2R}$
.				
.				
Timeslot $t_T$	$d_{(T-1)*R+1}$	$d_{(T-1)*R+2}$		$d_{(T-1)*R+R}$

Fig. 1. UCTP Domain in a Form of a Matrix

Mathematically, a constraint can be defined as follows:

Definition 1: there exist one or more logical relations between subject  $x_i$  for  $i = 1, 2, \dots, N$  and subject  $x_j$  for  $j = 1, 2, \dots, N$  and  $i \neq j$  resulting true relationship, or

Definition 2: subject attribute for  $x_i$ ,  $i = 1, 2, \dots, N$  equal or not equal to certain value, or

Definition 3: combination of Definition 1 and Definition 2.

For example, a lecture cannot teach two subjects in the same time. This constraint is defined in the form of logical formulation as follow:

$$c_q = (x_i, a_k == x_j, a_k), \text{ where } 1 \leq q \leq L$$

Hence,  $a_k$  is assumed as lecture attribute, related to each different subject ( $i \neq j$ ). If  $c_q$  is true, then the relationship of  $x_i$  and  $x_j$  is marked with hard constraint violation value. This is done to prevent the  $x_i$  and  $x_j$  are being placed in the overlapped position slots.

### B. Constraint Matching and Generation of Collision Matrix

Assuming a set of subjects along with their attributes  $X = \{S_1, S_2, \dots, S_N\}$  and a set of related constraints  $C = \{c_1, c_2, \dots, c_L\}$ . If  $S_i$  is a subject  $x_k$  with its defined attributes, it is always possible for  $S_j$  to be a presentation of a subject  $x_k$  having different attributes with  $S_i$ . Collision Matrix consists of values ordered in rows and columns to describe the constraint violation (collision relation) value between  $S_i$  and  $S_j$ . If the value is equal to 0, it means that  $S_i$  and  $S_j$  can be placed in overlapped timeslots. If the value is equal to 1, it means that

possible. The minimum number of colors used is called chromatic number ( $\chi(G)$ ) [11]. There are many VGC algorithms can be used. In this paper, we use *Recursive Largest First* (RLF) algorithm [12] shown in Fig. 7.

A vertex in the graph represents a subject,  $S_i$ . After all vertices have been colored, each color, which will consists of a number of vertices with the same color, will be allocated to position slots in domain  $D$ , with same timeslots but different rooms. Initially, the allocation starts from  $t_1$ , continued until  $t_7$ , and each allocation considers room capacity. If the number of vertices in certain color exceeds the number of rooms, the vertices that cannot be allocated are collected in *unallocated particles* (*unP*). After all vertices have been placed to their positions in  $D$ , randomly, each vertex in *unP* is allocated to  $D$ . The allocation considers the constraints violations and room capacity.

Table I. Constraint Formulation of FTI Untar

Constraints	Logical Formulation	Type of Constraints
The same lecturer cannot teach in the same time	$(S[i].dosen.nik == S[j].dosen.nik)$	Hard Constraints
Single class of subject $S_i$ cannot be scheduled in the same time with other single or parallel class of subject $S_j$ , if $S_i$ and $S_j$ in the same semester distribution.	$(S[i].jenis.id_jenis == 1) \ \&\& \ (S[i].semester.id_sem == S[j].semester.id_sem) \ \&\& \ (S[i].prodi.id_prodi == S[j].prodi.id_prodi)$	Hard Constraints
	$(S[j].semester.id == 1) \ \&\& \ (S[i].semester.id_sem == S[j].semester.id_sem) \ \&\& \ (S[i].prodi.id_prodi == S[j].prodi.id_prodi)$	Hard Constraints
Parallel class of subject $S_i$ cannot be scheduled in the same time with other parallel class of subject $S_j$ , if $S_i$ and $S_j$ have the same class name and semester distribution.	$(S[i].jenis.id_jenis == 2) \ \&\& \ (S[i].semester.id_sem == S[j].semester.id_sem) \ \&\& \ (S[i].kelas.id_kelas == S[j].kelas.id_kelas) \ \&\& \ (S[i].prodi.id_prodi == S[j].prodi.id_prodi)$	Hard Constraints
Single class of subject $S_i$ is better not to be scheduled in the same time with other single or parallel class of subject $S_j$ , if semester distribution of $S_i$ and $S_j$ are different in exactly 1 semester, based on the even or odd period of academic semester.	$(S[i].jenis.id_jenis == 1) \ \&\& \ (S[i].semester.id_sem == 1) \ \&\& \ (S[j].semester.id_sem == 3) \ \&\& \ (S[i].prodi.id_prodi == S[j].prodi.id_prodi)$	Soft Constraints

### I. DISCUSSION

We developed an application to implement the approach. The application is developed using PHP and MySQL. Our experiment uses real data from Faculty of Information Technology Tarumanagara University (FTI Untar). There were 93 subjects offered in period of odd semester in academic year

2012/2013. To run the application to process the data, we used CPU Intel Centrino 1.83GHz Dual Core with 3MB RAM.

	TK12027	TK12026	TK12028	TK12030	TK12031
TK12027	-1	3	0	3	0
TK12026	3	-1	0	3	0
TK12028	0	0	-1	0	1
TK12030	3	3	0	-1	0
TK12031	0	0	1	0	-1

Fig. 8 Example of Collision Matrix of Several Subjects

The implementation of DCM for course scheduling problem in FTI Untar successfully accommodates all its constraints. TABLE I shows the formulation of hard constraints and one example of soft constraints for FTI Untar. Fig. 8 depicts the result portion of Constraint Matching in a form of Collision Matrix. We use logical expression evaluation function of PHP, `eval()`, to implement the Constraint Matching. Fig. 9 shows the screenshot of part of scheduling output resulted from VGC that utilizes the Collision Matrix.

We run VGC for 10 times, and the results show that no hard and soft constraints are violated. Time spend to output the schedule using VGC in average is less than 1 minute. Thus, our DCM incorporation to VGC can provide feasible and optimal solution with fast processing time.

### II. CONCLUSION

We have proposed Dynamic Constraint Matching (DCM) to occupy various constraints of UCTPs and integrate it with Vertex Graph Coloring (VGC) approach. Based our experiment, all constraints, taken from the characteristics and regulations of Faculty of Information Technology Tarumanagara University, can be formulated successfully by DCM. When the formulations were integrated with VGC, the approach results a course schedule that does not contain any hard or soft constraints violations. The processing time can be said fast, which is less than 1 minute. It can be concluded that our approach can provide feasible and optimal solution, with fast processing time.

Next research will take a look at several approaches to optimize the use of available rooms. Current solution although has given feasible and optimal solution in terms of constraints, it still has problem in room distribution. As can be seen from Fig. 9, certain positions of the same timeslots are allocated with just a number of subjects. Some approaches that we are going to consider are heuristic VGC, Particle Swarm Optimization, and Simulated Annealing.

# Handwritten Word Segmentation Using Kaiser Window

Linggo Sumarno

Faculty of Science and Technology  
Sanata Dharma University  
Yogyakarta, Indonesia  
E-mail : lingsum@usd.ac.id

**Abstract**—In the field of handwritten word recognition field, word segmentation into letters is an approach that could be used. Using this approach, word segmentation would be a complicated task, especially when dealing with a cursive handwritten word. A simple method in word segmentation called oversegmentation could be used. This paper discusses a simple method using Kaiser window. In general, the word segmentation process in this paper can be described as follow: Input - Preprocessing - Segmentation - Output. The input is an image of isolated handwritten word in binary format, while the output is images of letter segment. The main purpose of preprocessing is to correct slant and slope. This preprocessing is necessary since the segmentation method used is sensitive with slant and slope. The main purpose of segmentation is to divide a word into some letter segments. Based on a subjective test result, it was shown that the minimum parameters for the Kaiser window that can be used effectively for oversegmentation are 8 points in window's length and 10 in beta value. As its window's length is getting longer and its beta value is getting bigger, it can also be used effectively for oversegmentation. However, it must be noted that if the letter size is getting bigger, there will be more letter segments resulted.

**Keywords**— Handwritten word, segmentation, Kaiser window

## I. INTRODUCTION

In the field of handwritten word recognition, recognizing a word by means of letter-by-letter recognition is a way that can be carried out. If the word is written in handprinted style, the word recognition will be simple, since the segmentation of the letters is obvious. However, if it is written in cursive style, the word recognition will be difficult, since the segmentation of the letters is not obvious. This difficulty is in line with Sayre's Paradox [1]: a word cannot be segmented before being recognized and cannot be recognized before being segmented.

According Bunke [2], segmentation is a process by which a given word was segmented into smaller entities. Before that, in line with Bunke, Bozinovic and Srihiari [3] have proposed a simple segmentation approach using possible segmentation points, which results the number of entities that greater than the number of letters in a word image, that called oversegmentation.

A simple method in oversegmentation can be carried out by dividing a word image uniformly, as proposed by Senior [4]. However, it tends to produce too many segments.

Sumarno [5] has proposed a simple method in oversegmentation that divides a word image not uniformly, which based on vertical projection histogram, by using stationary wavelet. However, since the stationary wavelet can only process the input that has  $2^n$  in length, so, it is less practical. Sumarno *et al* [6] have proposed another variation of oversegmentation that divides a word image not uniformly, which based on vertical projection histogram, by using a Gaussian filter. By using this filter, the segmentation results were similar with the stationary wavelet, but it was more practical since it have no  $2^n$  limitation.

A Kaiser window [7] is a window that usually used in the design of FIR filters and spectrum analysis. If a Kaiser window is convoluted with a signal, so, the detail components of the signal will be reduced. On the other hand, a Kaiser window can be used as a low pass filter.

This paper proposes a new variation in handwritten word segmentation, which based on vertical projection histogram, by using Kaiser window. The segmentation method that will be discussed is the oversegmentation that divides a word image not uniformly.

## II. THEORY

### A. Segmentation

A simple strategy of segmentation is to use of explicit segmentation based on the dissection. In this strategy, a word image is divided into letter segments where the number of segments is equal to or greater than the number of letters in the image, without analyzing the class information or the shape of the letters. If the number of letter segments is greater than the number of letters in the word image, the segmentation is called oversegmentation. According Bunke [2], in oversegmentation there are some rules as follow.

- The image of a letter that occurs within a word may be broken into several segments.
- Merging two adjacent letters into the same segment must be avoided.
- Merging parts of two adjacent letters into the same segment must be avoided.

A strategy in explicit segmentation based on the dissection is to use vertical projection histogram of a word image. For example, Fig. 1(b) shows the shape of the histogram “hills” that represent the letter segments of the word image of Fig. 1(a). As a hypothesis, if the basic shape of the histogram hills can be made more obvious, the separation of letter segments can be made easier. The shape of the histogram hills in Fig. 1(b) still shows the rough shape (i.e. its basic shapes are less obvious), since there are details components shown. In order to make its basic shapes more obvious, a low pass filter is needed to remove the detail components. According Sumarno *et al* [6], a low pass filter for that purpose should have the following properties.

- It must be able to remove many detail components.
- It must be able to maintain histogram hills, which represent letter segments. On the other hand, it must have high localization property.

As shown in Fig. 1(c), the detail components have been removed by using a low pass filter. Fig. 1(d) shows the vertical lines that indicate the local minimum places. Finally, Fig. 1(e) shows the segmentation result where the segmentation places are based on the local minimum places.

### B. Kaiser Window

Kaiser window  $w(n)$  with the length  $N$  is defined by

$$w(n) = \begin{cases} \frac{I_0(\beta) \sqrt{1 - ((n - 0.5N)/(0.5N))^2}}{I_0(\beta)}, & 0 \leq n \leq N \\ 0, & \text{otherwise} \end{cases} \quad (1)$$

where  $I_0(\cdot)$  is the zero-th order Modified Bessel function of the first kind, which can be computed using

$$I_0(x) = 1 + \sum_{k=1}^{\infty} \left[ \frac{(0.5x)^k}{k!} \right]^2 \quad (2)$$

### C. Convolution

As described above, the Kaiser window can be used as a low pass filter. Low pass filtering of the signal  $x(n)$  with a Kaiser window  $w(n)$  is the convolution process between  $x(n)$  with  $w(n)$ . Since the signal  $x(n)$  has finite length, there will be distortion at the edges of filtering results. In order to overcome that problem, Misiti *et al* [8] have proposed a method by lengthening the signal  $x(n)$  by means of signal repetition which called periodization. For example  $x(n) = \{x(1), x(2), \dots, x(M)\}$  is the signal to be convoluted with Kaiser window  $w(n) = \{w(1), w(2), \dots, w(N)\}$ , where  $N$  is an even number, and  $M > N$ , so the signal repetition by means of periodization will be

$$x_{per}(n) = \{x(M - n + 1), \dots, x(M), x(1), \dots, x(M), x(1), \dots, x(N - 1)\} \quad (3)$$

The convolution of lengthen signal  $x_{per}(n)$  with Kaiser window  $w(n)$  will give output signal

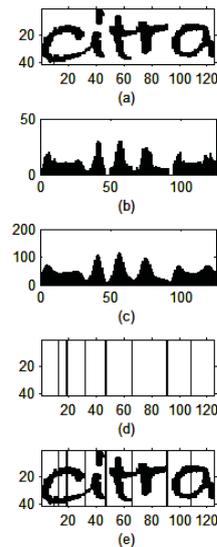

Fig. 1. An example of segmentation using vertical projection histogram; (a) Input image; (b) Vertical projection histogram; (c) Filtering result using Kaiser window 12 points with  $\beta$  value 10; (d) Vertical lines that indicate local minimum places; (e) Segmentation result. (Notes: Vertical and horizontal axes units are in pixels)

$$y(n) = x_{per}(n) * h(n) \quad (4)$$

or

$$y(n) = \sum_j x_{per}(j) h(n+1-j) \quad (5)$$

where the length of  $M+N-1$  is greater than the length of  $x(n)$ . In order that the output signal has the same length with the input signal, so, only the certain parts of the output signal are selected. For example, the output of the convolution above is  $y(n) = \{y(1), y(2), \dots, y(L)\}$ , where  $L=M+N-1$ , so, the selected certain parts of  $y(n)$  are

$$y_{keep}(n) = \{y(N+1), \dots, y(N+M)\} \quad (6)$$

## III. RESEARCH METHODOLOGY

### A. Materials and Equipments

Materials in this research were isolated handwritten word images in binary format. These materials came from the data acquisition sheets scanned at a resolution of 300 dpi. Data were taken from 10 writers from different ages and genders. They wrote the word “citra” as they usually write, i.e. handprinted, cursive, or mixed handprinted and cursive styles. Equipment in this research was a set of computer based on Intel processor Core2Duo E7500 (2,93GHz) and 2GB of RAM, which equipped with MATLAB software.

### B. System Development

By using materials and equipments above, a handwritten word segmentation system has been developed (see Fig. 2). In this system, the input is an image of isolated handwritten word in binary format, while the output is images of letter segment.

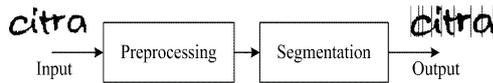

Fig. 2. A word segmentation system.

The main purpose of preprocessing is to correct slant and slope of the input image. This preprocessing is necessary since the segmentation process that uses vertical projection histogram is sensitive with slant and slope variation [6].

### C. Preprocessing

Preprocessing steps in Fig. 2 are shown in Fig. 3 [6]. The slope and slant corrections are carried out by using the linear transform for shearing. See Halmos [9] for the detail of the linear transform. The slope and slant corrections will make the image template become bigger than its image. (Note: for the word image input, the image and its template have the same size). To overcome this, a cutting according to bounding box was applied.

The slope and slant correction in Fig. 3 are carried out sequentially by simultaneous slant correction method, as proposed by Slavik & Govindaraju [10]. Fig. 4 [6] shows the slant correction steps for the slope and slant correction. By using this method, first, slope correction using the horizontal projection histogram carried out. Then, followed by slant correction using the vertical projection histogram. Determining of shearing coefficient  $k_s$  is carried out by searching a highest variance value in the vertical/horizontal projection histogram. See TABLE I.

### D. Segmentation

Segmentation steps are shown in Fig. 5 [6]. Low pass filtering is a convolution process between Kaiser window and vertical projection histogram, which has undergone periodization (see equations (3) to (6)). Letter segments cutting are a cutting of the input image in order to get letter segment images. The cutting places are based on the places of the local minimums in the vertical projection histogram that has undergone low pass filtering. An example of the segmentation steps is shown in Fig. 1.

## IV. RESULTS

### A. Segmentation results on various Kaiser window parameters

Segmentation results on various Kaiser window parameters, for an example of the word "citra", shown in Fig. 6 and 7. It can be shown in Fig. 6 and 7, for all Kaiser

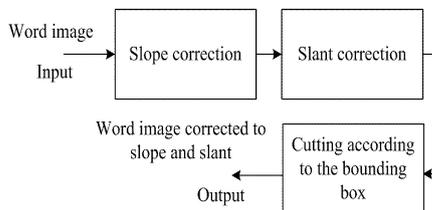

Fig. 3. Preprocessing steps.

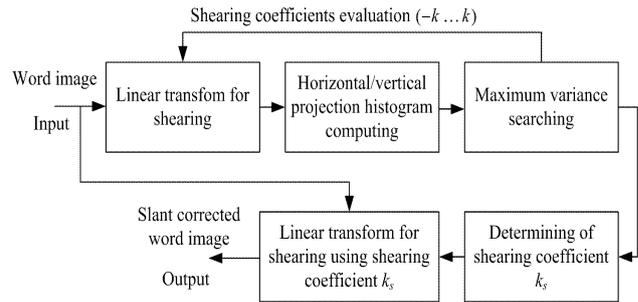

Fig. 4. Slant correction steps.

TABLE I. PARAMETERS FOR SLOPE AND SLANT CORRECTIONS.

Correction	Parameters
Slope	Shearing coefficient values for the evaluation of horizontal projection histogram at slope correction $\{-0.2, -0.15, \dots, 0.2\}$ . In this case it is assumed that the slope of horizontal projection histogram is in the range of $-0.2 \dots 0.2$ .
Slant	Shearing coefficient values for the evaluation of vertical projection histogram at slant correction $\{-0.4, -0.35, \dots, 0.4\}$ . In this case, it is assumed that the slope of vertical projection histogram is in the range of $-0.4 \dots 0.4$ .

windows with  $\beta$  value 0 and also with window's length 4 points, the segmentation results show parts of letter "c" and "i", or "i" and "t", or "r" and "a" are in the same segment. It means segmentation errors have been occurred, since they do not follow the oversegmentation rules [2].

As shown in Fig. 6 and 7, in order that oversegmentation can be effectively carried out, the minimum parameters of Kaiser window are 8 points in length and 10 in  $\beta$  value. As its window's length is getting longer and its  $\beta$  value is getting bigger, the oversegmentation can also be effectively carried out. In summary, the segmentation results from Fig. 6 and 7 can be seen in TABLE 2.

### B. Segmentation results on various writing styles and sizes

The segmentation results on various writing styles and sizes of 10 words of "citra" which uses a sample of 12 points Kaiser window with  $\beta$  value 10 shown in Fig. 8(a). As a note, the 10 words came from 10 writers who wrote as they usually write. For comparison, segmentations results for the same 10 words of "citra", which uses 16 points Gaussian filter with standard deviation 4 which proposed by Sumarno *et al* [6] are shown in Fig. 8(b). As shown in Fig. 8(a) and 8(b), no segmentation errors occurred since they follow the oversegmentation rules.

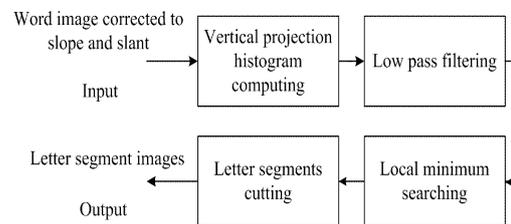

Fig. 5. Segmentation steps.

Fig. 6. Segmentation results on various parameters of Kaiser window; (a) – (f) Length: 4 points,  $\beta$  values: 0, 10, 20, 40, 80, and 160 respectively; (g) – (l) Length: 8 points,  $\beta$  values: 0, 10, 20, 40, 80, and 160 respectively; (m) – (r) Length: 12 points,  $\beta$  values: 0, 10, 20, 40, 80, and 160 respectively; (s) – (x) Length: 16 points,  $\beta$  values: 0, 10, 20, 40, 80, and 160 respectively. (Notes: Vertical and horizontal axes units are in pixels)

## V. DISCUSSIONS

As shown in Fig. 6 and 7 there are three tendencies that started from 8 points window's length. First, if  $\beta$  value is getting bigger, it will lower the occurrence of segmentation errors. As an example, from Fig. 7(s) – 7(x), if  $\beta$  value is getting bigger, the occurrence of segmentation error will be lower. This one indicates that the histogram hills localization is getting lower, since the number of detail components in the vertical projection histogram that removed also getting lower. Therefore, basic shapes of letter entities which represented by histogram hills become more unobvious (since too many component details), so that, the separation between letter entities become more obvious.

TABLE 2. SUMMARY OF THE SEGMENTATION RESULTS FROM FIG. 6 AND 7.

$\beta$	Window's length							
	4	8	12	16	20	24	28	32
0	x	x	x	x	x	x	x	x
10	x	√	√	x	x	x	x	x
20	x	√	√	√	x	x	x	x
40	x	√	√	√	√	√	x	x
80	x	√	√	√	√	√	√	√
160	x	√	√	√	√	√	√	√

Notes: a. "x" indicates there are segmentation errors.  
 b. "√" indicates there are no segmentation errors.

Second, if window's length is getting longer, it will raise the occurrence of segmentation errors. As an example, from Fig. 6(h), 6(n), 6(t), and 7(b), if window's length is getting longer, the occurrence of segmentation error will be raise. This one indicates that the histogram hills localization is getting higher, since the number of detail components in the vertical projection histogram that removed also getting higher. Therefore, basic shapes of letter entities which represented by histogram hills become more unobvious, so that, the separation between letter entities become more unobvious also.

Third, if window's length is getting longer and  $\beta$  value is getting bigger, there is no segmentation errors occurred. As an example, from Fig. 6(n), 6(u), 7(d), and 7(k), if window's length is getting longer and  $\beta$  value is getting bigger, there is no occurrence of segmentation errors. This one indicates that the histogram hills localization can be maintained (not too high nor too low), since the number of detail components in the vertical projection histogram that removed can also be maintained. Therefore, basic shapes of letter entities which represented by histogram hills can be maintained obvious, so that, the separation between letter entities can also be maintained obvious.

Fig. 7. The Segmentation results on various parameters of Kaiser window; (a) – (f) Length: 20 points,  $\beta$  values: 0, 10, 20, 40, 80, and 160 respectively; (g) – (l) Length: 24 points,  $\beta$  values: 0, 10, 20, 40, 80, and 160 respectively; (m) – (r) Length: 28 points,  $\beta$  values: 0, 10, 20, 40, 80, and 160 respectively; (s) – (x) Length: 32 points,  $\beta$  values: 0, 10, 20, 40, 80, and 160 respectively. (Notes: Vertical and horizontal axes units are in pixels)

A summary of the segmentation results in TABLE 2 are come from a subjective test results, since they only use one writing variety of the word "citra". In order to get a more objective test results, the segmentation needs to be tested on even more writing variety of the word "citra". However, if the segmentation results were observed visually, it would be impractical, since we have to observe it one by one. Therefore, in order to make it more practical, it is not done visually, but by observing the results of the recognition rate of the whole handwritten word recognition. It can be assumed that at the highest recognition rate, the number of segmentation errors is the lowest. Milewski [11] has shown an example of recognizing a word by means of character segment by character segment, which made use of a graph.

Fig. 8(a) and (b) show the segmentation results of the 12 points Kaiser window with  $\beta$  value 10 and the 16 points Gaussian filter with standard deviation 4 respectively. They can be used effectively to segment nine various writing styles and sizes of the word "citra", since there are no segmentation errors. However, Fig. 8(a5), (a8), and (a10) show one additional segment compared to Fig. 8(b5), (b8), and (b10) respectively, which indicates that 12 points Kaiser window with  $\beta$  value 10 a bit worse than 16 points Gaussian filter with standard deviation 4. This case shows that if it is compared with Kaiser window, the Gaussian filter is a bit more able to conserve "small hills" at vertical projection histogram, which represent character entities.

In general, Fig. 8 shows that if the letter size is getting bigger there will be more letter segments resulted. For example, at Fig. 8(a9), (a10), (b9), and (b10), a low pass filtering that made use of the 12 points Kaiser window with  $\beta$  value 10 and also the 16 points Gaussian filter with standard deviation 4 were not "strong" enough to smooth the "big hills" at projection histogram which represent character entities, so that, more letter segments are resulted. Therefore, in order to deal with the letter sizes it is suggested to introduce some size correction steps in the segmentation system.

## VI. CONCLUSION AND SUGGESTION

Based on what has been described above, it can be concluded the following.

- Based on the subjective test result, it was shown that the minimum parameters for the Kaiser window that can be used for oversegmentation effectively are 8 points in window's length and 10 in  $\beta$  value.
- For the Kaiser window, as the window's length is getting longer and its  $\beta$  value is getting bigger, it can also be used for oversegmentation effectively.
- If the letter size is getting bigger, there will be more letter segments resulted.

Here are some suggestions to further develop the segmentation system.

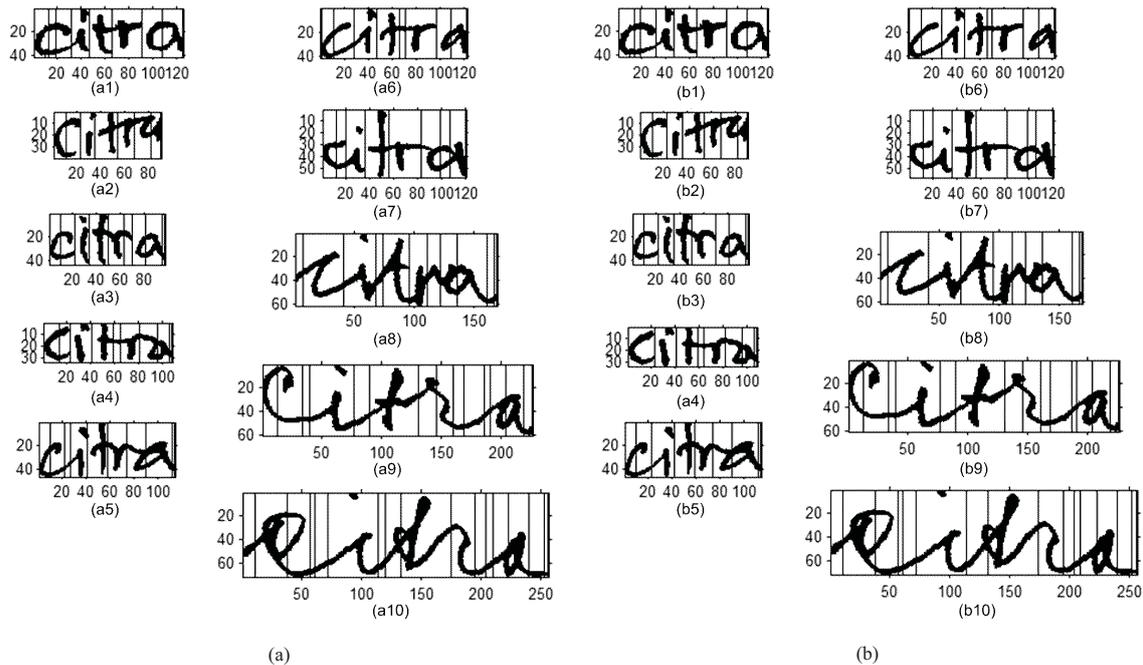

Fig. 8. Segmentation results for 10 writing styles and sizes of "citra"; (a) Using 12 points Kaiser window with  $\beta$  value 10; (b) Using 16 points Gaussian filter with standard deviation 4. (Notes: Vertical and horizontal axes units are in pixels)

- In order to obtain a more objective segmentation results, it is necessary to test more writing varieties and sizes of the word "citra" and for other words.
- In order to be more practical, it is suggested that the segmentation results are observed by observing the results of the recognition rate of the handwritten word recognition, which is the next process after the process of segmentation.
- In order to deal with the letter sizes it is suggested to introduce some size correction steps in the segmentation system.

**Abstract-** The existing system has the ability to yet lack the ability to control indoor humidity. Green House Monitoring and Controlling is a complete system designed to monitor and control the humidity inside a green house. This software uses an Android mobile phone, connected using Wifi to a central server which connects via serial communication to a microcontroller and humidity sensor. The result shows that the condition specified in sensor's datasheet and system in reality is appropriate. The achieved test result concludes that the system is working properly.

**Keyword:** green house, arduino uno, wireless network, embedded system, SHT 11 sensor

## I. INTRODUCTION

Green house farmers cannot precisely detect level of level of humidity inside the green house. They only know the condition inside the green house manually and by feel it by themselves. Ultimately, experiences play a bigger part on their daily operations. If the condition is too dry, they will give water to the plants or soil, but if it is too humid, they will open the rooftop of the green house, especially in the daylight.

In designing this device, there is limitation to problems, to see how far this system can do its tasks. This limitation according to the situation where this system will be used later. The limitation is the system can detect the humidity of air in the building. When the humidity sensor reach a certain threshold, the humidity sensor will send a signal to microcontroller which will then process the signal, to be sent into connected computer. Computer functions as a server which connects to the android platform.

There are 3 kinds of activity that are designed in the system. First, monitor the humidity level in

the green house. Secondly, if the green house is too dry, the water sprayer can be activated, to increase the humidity level. It also can deactivated water sprayer. Third, if the green house is too humid, the rooftop can be opened to lower the humidity level. The third function can be use to open or close the rooftop based on the needs.

## II. DESIGN OF GREEN HOUSE MONITORING AND CONTROLLING SYSTEM

This embedded system for monitoring and controlling the green house is based on measuring the humidity and temperature by sensor that located at different places. The monitoring and controlling is conducted through Android Smartphone.

### A. Hardware Description

Design of hardware for green house monitoring and controlling are used to control the environment condition of green house to get a good condition. The parameters are humidity and temperature in the greenhouse. The monitoring and controlling of greenhouse component consists of sensor for the humidity, Arduino UNO microcontroller, serial communication, wireless connection, LED module change for water sprayer, stepper motor, model of greenhouse, personal computer as server, and power supply unit. The output for the sensor become an input to microcontroller and sent to computer through serial communication. The task of the computer is to transfer the data through wireless communication to application software at Android Smartphone. The task of the Android Smartphone to control the microcontroller and the components, such as, LED module and stepper motor, sent to the computer.

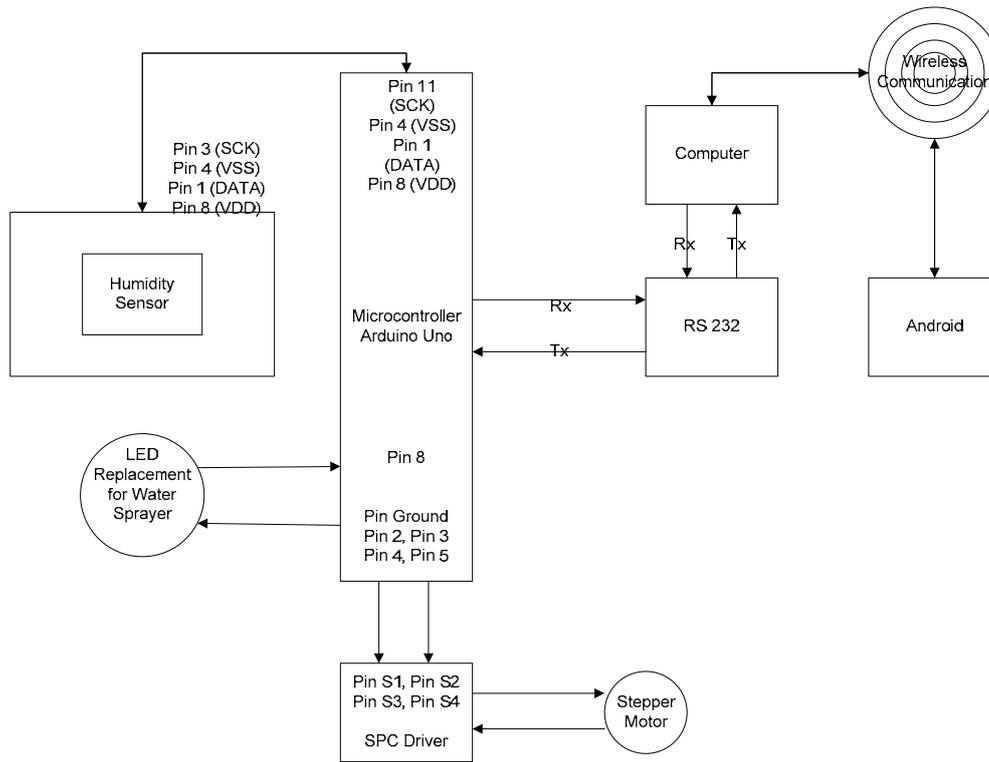

Figure 1. Schematic Diagram Showing The Green House Monitoring and Controlling System

The microcontroller will read the sensor periodically and updates the value of sensor to android. Figure 1 show the schematic diagram of greenhouse monitoring and controlling system.

### B. Software Description

The software is designed to process the humidity value, monitoring and controlling the green house. The software includes the various measurements of the sensor, analog to digital converters, send humidity value from sensor to microcontroller. Then continue to display the value in application at Android, control the microcontroller from the application in Android and update to user by sending the value of sensor for monitoring the green house. The microcontroller Arduino UNO is to convert analog to digital, send the value of sensor through serial communication to PC, control the stepper motor, water sprayer, and updating the user. The program is written in Arduino 1.0.1 IDE. The server used to process the value from the sensor, serial, and wireless communication by PHP serial programming and PHPmyadmin to transfer and receive the input for controlling and output for monitoring.

The hardware system is divided into 3 part. There are microcontroller arduino, a sensor, and IEEE wireless 802.11g. The microcontroller arduino used for monitoring and controlling the green house. It is used to read the measurement value of sensor, write an input to control the stepper motor and LED module, analog-digital converter and serial communication for the flow of value from sensor. First, microcontroller get the analog voltage signal from the sensor and convert it to digital signal. After microcontroller receive the digital signal, microcontroller send the value from sensor to the Android via computer through serial communication and wireless connection.

Figure 2. Architecture of AT MEGA 328 for Microcontroller Arduino[1]

The reading program, the converter and also program to controlling is done in C Language for Arduino. The value from read the sensor, analog to digital converter, and for controlling is done in Microcontroller Arduino that use AT MEGA 328. Figure 2 shows the architecture of AT MEGA 328.

For sensor we use SHT 11 to measure humidity and temperature. This sensor is interfaced to the stamp over two I/O pins. Through a two-wire serial interface, both temperature and humidity can be read with excellent response time and accuracy. Figure 3 shows the module of SHT 11 sensor: [4]

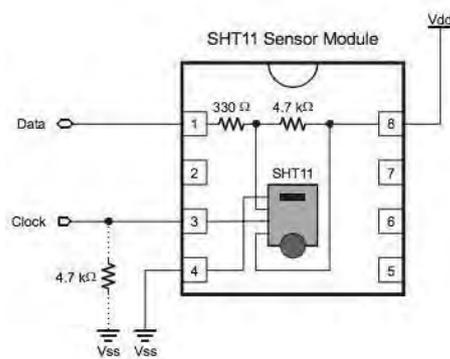

Figure 3. SHT 11 Sensor Module [2]

Each SHT 11 is individually calibrated in a precision humidity chamber from the manufacturer. The calibration coefficients are programmed into an OTP memory on the chip. These coefficients are used to internally calibrate the signals from the sensors. The 2 wire serial interface and internal voltage regulation allows for easy and fast system integration. SHT 11, for which datasheet applies-features a version 4 Silicon sensor chip. Besides the humidity and temperature sensors the chip contains an amplifier, A/D converter, OTP memory and a digital interface. Dimensions in mm (1mm = 0,39 inch). The type of sensor is SHT 11 and contacts are assigned as follows: 1:GND, 2:DATA, 3:SCK, 4:VDD.[5]

The features of SHT 11 sensor are:

- Temperature range: -40° Fahrenheit (-40° to +254,9°F (123,8°C)
- Temperature accuracy: +/- 0,5°C - 25°C
- Humidity Range: 0 to 100 %RH
- Low power consumption (typically 30W) [3]

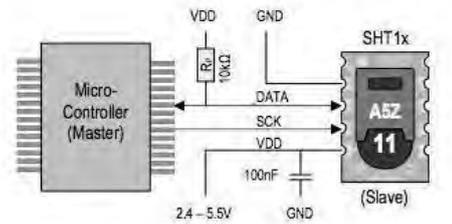

Figure 4. Schematic of SHT 11 Wire to Microcontroller [2]

Because the sensor built in resistors, the pins that should be connected,

- SHT-11 PIN 3 (SCK) -> Arduino PIN 11 (SCK)
- SHT-11 PIN 4 (VSS) -> Arduino's Ground
- SHT-11 PIN 1 (DATA) -> Arduino PIN 9 (data)
- SHT-11 PIN 8 (VDD) -> Arduino +5V

Arduino is process signal from this sensor, where the result will take in the right value. In this sensor, there is a LED to show whether the sensor is on or off.

For wireless transfer, we use IEEE 802.11g-2003 or 802.11g or Wireless G is an amendment to the IEEE 802.11 specification that extended throughput to up to 54 Mbit/s using the same 2.4 GHz band as 802.11b. This specification under the marketing name of Wi-Fi has been implemented all over the world. 802.11g is the third modulation standard for wireless LANs. It works in the 2.4 GHz band (like 802.11b) but operates at a maximum raw data rate of 54 Mbit/s, or about 19 Mbit/s net throughput (identical to 802.11a core, except for some additional legacy overhead for backward compatibility). 802.11g hardware is fully backwards compatible with the 802.11b hardware. Details of making b and g work well together occupied much of the lingering technical process. In an 802.11g network, however, the presence of a legacy 802.11b participant will significantly reduce the speed of the overall 802.11g network. Wireless G is used in our system as a communication path from Android to server and vice versa. [6]

#### IV. ANDROID APPLICATION SYSTEM

In developing the software, Eclipse Indigo. The method that used is created to make monitoring activity. It is called kosong.java with layout\_kosong.xml, controlling activity that called MainActivity.java with activity\_main.xml, main menu window that called MainMenu.java with layout\_mainmenu.xml, timer activity that needed to update data that received from database that called MyTimerTask.java.

Table 1. List of Class used in the System

Class Name	Methods	Description
kosong.java	DefaultHttpClient getThreadSafeClient()	Used to connecting & receiving data from android to PHP
	onBackPressed()	Used to disconnecting the update that received from PHP if we change to another window
MainActivity.java	setOnCheckedChangeListener(new CompoundButton.OnCheckedChangeListener())	Used to make what need to do with toggle button
	sendDataSpray()	Used to sending data water sprayer from android to PHP
	sendDataRooftop()	Used to sending data rooftop from android to PHP
MainMenu.java	setOnClickListener(new OnClickListener())	Used to change the window in main menu layout
MyTimerTask.java	MyTimerTask extends TimerTask {}	Used to handling timer that used for updating data that received from PHP

In the system, Kosong.java used to receiving data from PHP that has delay every three seconds. It will be shown in TextView on android window. MainActivity.java is the main class for controlling microcontroller. It send data from toggle button into database. Then it will get the string if the data get to database. If it doesn't get string, it will not receive any string because it is not connected to database that will send an echo into android. On MainMenu.java it is used to choose which window, whether it is monitoring or controlling. For MyTimerTask.java it is used to run the timer to control for updating data that received from PHP.

made through serial communication and computer as a server. The computer as a path for receive and transfer value from sensor for monitoring and input for controlling.

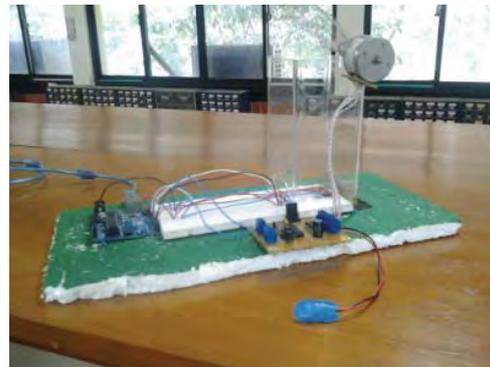

Figure 5. Actual Hardware Implementation

## V. IMPLEMENTATION OF GREENHOUSE MONITORING AND CONTROLLING SYSTEM

### A. Hardware Implementation

In the hardware implementation, it has wired components sensor to microcontroller arduino by jumper cable and use protoboard as a board for the components like stepper motor and LED module in the hardware. The 5V DC power is provided for microcontroller arduino UNO, stepper motor and also the sensor. Then, the connection between for microcontroller arduino, sensor circuit, stepper motor, water sprayer replace by LED module are

### B. Software Implementation

For software implementation, Figure 6 shows the flow of the software in monitoring and controlling the green house. C program for arduino to measure humidity, send the value to computer then to Android Smartphone through serial communication. Next receive input from Android Smartphone then control the stepper motor and LED module. PHP code use for communication path. Last, Modules for application in android are written in C program.

#

#

Figure 9. Controlling System

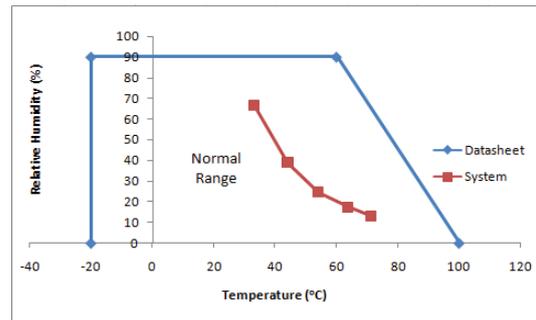

Figure 11. Comparison of Sensor Work Characteristic with Datasheet

In the test, the system is tested whether it is working properly or not. Table 2 shows that system is running properly.

### VI. ANALYSIS

Based on datasheet, sensor works stable within recommended normal range (see Figure 10). Long term exposures to conditions outside normal range, especially at humidity >80%RH. After return to normal range it will slowly return towards calibration state by itself. Prolonged exposure to extreme conditions may accelerate ageing. [5]

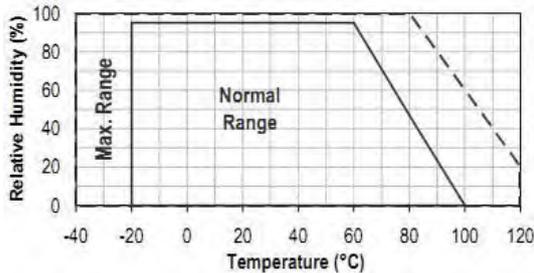

Figure 10. Operating Condition of SHT 11 Sensor [5]

In testing of work characteristic sensor, it used heat from GPU core of a computer through GPU ventilation to increase the temperature in environment. This test used a closed box to put the computer and sensor.

Figure 11 shows the graphic of sensor working characteristic in this system (shown in red) compared to ideal sensor characteristic (shown in blue), where the comparison between temperature and humidity is in normal range SHT 11 sensor. In the red line, the tests are from 30°C until 70°C. In conclusion, sensor works fine and fit with the value in datasheet. The system shows that the sensor works properly.

Table 2. Technology Acceptance Modeling

No	Parameter	Yes	No
1.	Android received humidity data from sensor	√	
2.	Android send data and received in PHP	√	
3.	Android send data for water sprayer to microcontroller and water sprayer's indicator is turned on	√	
4.	Android send data for motor stepper to microcontroller and motor stepper work	√	
5.	There is no error in the whole application	√	
6.	There is no error in the whole system	√	

### VII. CONCLUSION

The prototype of the system is successfully built and run in reality based on Technology Acceptance Modeling that shows in Table 2. The output for the given analog input values are visualized in android application system. The analog value given by the sensor changes it into a digital value.

The android software is already working properly and appropriate with the purpose in the beginning, that is to get humidity value from green house and give input to control components in green house. After development is finished, test for sensor's work is done and device is working properly.

#

#

The testing that has done shows that condition in datasheet of sensor and in system is appropriate. The test result shows in temperature 30°C to 70°C, humidity is still in normal range area. If temperature gets higher and more, relative humidity will be decrease and goes near to zero.

Looking into the Table 2 about Technology Acceptance Modeling, it can be conclude that the whole system, which are software and hardware is working fine.

# Task Execution Reliability of Resource Allocation with Tasks Replication in Mobile Ad Hoc Grid

Sri Chusri Haryanti, Riri Fitri Sari  
Departement of Electrical Engineering,  
Faculty of Engineering, University of Indonesia,  
Depok, Indonesia  
[sri.chusri@ui.ac.id](mailto:sri.chusri@ui.ac.id), [riri@ui.ac.id](mailto:riri@ui.ac.id)

**Abstract**— This paper reviews task execution reliability in mobile ad hoc grid. We consider resource allocation for mobile ad hoc grids with centralized architecture in the presence of dependent tasks. Allocating appropriate resources for the tasks can avoid uncompleted tasks and ensure the service reliability. With the aim to increase service reliability, resource management can assign the same tasks to different resources for parallel execution (tasks replication). Analytical example is given to illustrate the reliability. The result reveals that assigning the same tasks to more than one resource nodes has increased the reliability. Assigning the same tasks to 4 or 3 resource nodes provides superior reliability than that of just 2 resource nodes.

**Keywords**— resource allocation, mobile ad hoc grid, reliability, tasks replication, dependent tasks

## I. Introduction

In recent years, mobile ad hoc computational grid is a challenging research topic. Mobile ad hoc computational grid allows collaboration of mobile nodes to build a Grid, join existing Grid or contribute in a Grid spontaneously. Nodes can dynamically request and receive a sharing of resources in a Grid computing system, and be active in the services offered by other nodes in the Grid. Mobile Ad hoc computational grid facilitates autonomous interaction without requiring pre-configuration or policy management [1].

Resource allocation plays a crucial role in determining the performance of the overall grid system. Resource allocation algorithm that is suitable for mobile ad hoc environment is expected to minimize task completion time. Mobile ad hoc environment is characterized by lack of infrastructure in the network, nodes mobility and limited power of mobile nodes. Thus, it is highly critical to provide a reliable resource allocation scheme that ensures the completion of the tasks.

One simple, but potential method for obtaining fault resilience is task replication. In a grid with network infrastructure, task replication is primarily used as a fault tolerance technique in case of a system outage [2]. Replication is a technique based on an assumption that the success probability of completing the task will increase when it is done by multiple resources. In case of a task running on an unreliable execution environment, multiple replicas of the task

run on different machines. As long as not all replicated tasks fail, the task will be successfully executed [3].

## II. Resource Allocation With Tasks Replication On Mobile Ad Hoc Grid

### A. Problem context and Objectives

Grid Computing is a system that allows computational resource sharing between nodes that are connected in one network in completing specific tasks [4]. Originally, it has been used to solve huge and complex problems in science and engineering areas.

Rapid advancement in mobile computing systems has enabled the use of mobile nodes as a contributing entity to Grid. Recently, several methods have been proposed for integrating mobile nodes with grid computing systems, in which mobile nodes can share computing resources in mobile and ad-hoc environments. It is called mobile ad hoc computational grid. As the complexity of human life increased, the problem size becomes relative. People may require computing resources from others to solve computationally-intensive common problems.

Unpredictable node mobility across the coverage area in mobile ad hoc grid may lead to a task failure. Node mobility across the coverage area will not only affect the task execution on a node but also affects dependent tasks execution on the other nodes. Therefore, mobility of a single node can have a large effect on an application performance. This paper presents two approaches for avoiding a task failure due to node mobility. First, selecting nodes, which have corresponding mobility as the resource nodes. This will ensure the use of nodes with long-term connectivity for executing the tasks. The second is task replication which is expected to increase service reliability.

### B. Resource Allocation Scheme

In grid computing systems, Resource Management System (RMS) controls sharing resources among the nodes [5]. This paper considers resource allocation for mobile ad hoc grids

with centralized architecture. The resource allocation service process in a star topology as depicted in Fig. 1. The RMS is in the center which is directly connected with the node resources through communication channels. Here, the node which requires resources from other nodes is responsible of resource allocation service.

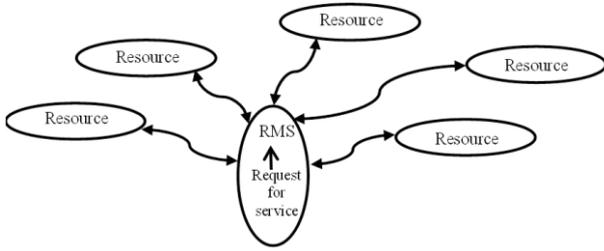

Fig. 1. Mobile ad hoc grid with a star architecture

We consider a number of nodes that could connect and communicate in a mobile ad hoc network. When a user needs resources from other users to execute an application, it will send the application to resource allocation service. Then, resource allocation service will enable resource discovery service which afterwards broadcasts a discovery message. Nodes within a range that are willing to share computing resources will send a reply message. In the reply message, characteristics such as processing power, memory, and remaining battery power are enclosed. These attributes could be used to select nodes. The execution of tasks depends on the application's type. If the mobile resource nodes are not enough to execute an application, the resource allocation service may wait for other nodes to join the grid. When tasks execution has finished, the results will be gathered by the requesting node that submitted the application.

Before allocating the tasks, all nodes that are willing to share resources are mainly selected based on their mobility. Nodes which have a certain degree of corresponding mobility pattern are selected into a cluster of resource nodes. The idea is allocating the tasks only to the nodes belong to this cluster. Only these nodes will execute the existing tasks to ensure that most of the tasks will be properly resolved. Furthermore, we apply tasks replication as a failure tolerance method. Here, we investigate resource allocation service for different tasks replication number. However, it should be a limitation of replication number, due to the scarcity of resources in constrain environment of mobile ad hoc grid.

### III. Resource Allocation Reliability Analysis

Resource allocation is certainly critical for a reliable mobile ad hoc grid. There have been papers investigating the reliability of resource allocation for grid with infrastructure including [6-9] and likewise reliability of mobile ad hoc network including [10-13]. However, reliability of resource allocation for mobile ad hoc grid has not been studied.

As stated in [9], the services in existing grid systems are usually organized in a hierarchical manner. They contain

different layers that are interconnected through a set of interfaces. Those are program, resource, request, network and management layer. The discussion of grid service reliability analysis with hierarchical model includes reliability of request layer, reliability of management layer, and reliability of network, program and resource layer [9]. This paper will only present reliability of program layer. It is task execution reliability portion of centralized resource allocation service with tasks replication.

#### A. Reliability of Task Execution

Built upon [7], the reliability of tasks execution depends not only on the reliability of each tasks, but also on the reliability of the execution dependencies of them. In the tasks execution phase, tasks will be undertaken in different resources. Each resource can only handle one task when it is available. However, the same task will be assigned to several resources. If the same task is done by several resources, it is considered completed when the first output is arrived back to the RMS.

It is assumed that RSM is totally reliable. The time of task processing by the RMS is also assumed to be ignored. This is because it is very small when compared with the tasks processing time.

In this paper, a job is composed of  $m$  tasks with  $c_j$  complexity and the amount of data that will be interchanged between RMS and a resource  $a_j$  ( $1 \leq j \leq m$ ). If task  $i$  needs an output data from task  $k$ , then task  $i$  can be executed only if task  $k$  has been completed. The task execution time is defined as the time from the beginning of the input data transmission from the RMS to a resource, to the end of output data transmission from the resource to the RMS [7].

The task execution time of task  $i$  by resource  $j$ ,  $t_{ij}$  has two possible values. If the task has been failed,  $t_{ij} = \infty$ . Otherwise, if the task has been completed successfully, then

$$t_{ij} = \hat{t}_{ij} = \frac{c_i}{x_j} + \frac{a_i}{s_j} \quad (1)$$

where  $c_i$  is the computational complexity of task  $i$ ,  $x_j$  is the processing speed of the resource, and  $s_j$  is the data transmission speed (bandwidth) of communication channel.

If failure rates of resource and communication link is constant, the probability of successful task execution is :

$$p_j(\hat{t}_{ij}) = e^{-(\lambda_j + \pi_j)\hat{t}_{ij}} \quad (2)$$

where  $\lambda_j$  is the failure rate of the resource  $i$  and  $\pi_j$  is the failure rate of the communication channel  $i$ , with  $Pr(t_{ij} = \hat{t}_{ij}) = p_j(\hat{t}_{ij})$  and  $Pr(t_{ij} = \infty) = 1 - p_j(\hat{t}_{ij})$ .

It is assumed that for every task  $i$ , RMS allocates a set of resources  $\omega_i$  ( $\omega_i \cap \omega_j = \emptyset$ ). RMS can initiate every execution of task  $j$  after task  $k \in \phi_i$  is successfully completed. Thus, it can be determined that the random time of the start of task  $i$  execution,  $T_i$  is

$$T_i = \max_{k \in \phi_i}(\tilde{T}_k) \quad (3)$$

where  $T_k$  is the random completion time for task  $k$ . If  $\emptyset = \emptyset_i$ , task  $i$  can be immediately commenced :  $T_i = 0$ . If  $\emptyset \neq \emptyset_i$ , so the value becomes  $\tilde{T}_{il}$  ( $1 \leq j \leq m$ ).

With the start of execution  $T_i$  and execution time  $t_{ij}$  of task  $i$  by resource  $j$ , the random execution of task  $i$  by resource  $j$  is :

$$\tilde{t}_{ij} = T_i + t_{ij} \quad (4)$$

To obtain the distribution of  $\tilde{t}_{ij}$ , the probability of any realization of  $\tilde{t}_{ij} = \hat{T}_{il} + \hat{t}_{ij}$  has to be considered. It is equal to the product of three occurrences :

1. Task  $i$  execution starts at  $\hat{T}_{il} : q_{ij} = Pr(T_i = \hat{T}_{il})$
2. Resource  $j$  has not failed before task  $i$  execution starts :  $p_j(\hat{T}_{il})$
3. Resource  $j$  has not failed during task  $i$  execution :  $p_j(\hat{t}_{ij})$

Accordingly, the distribution of  $\tilde{t}_{ij}$ , with task  $i$  execution at  $\hat{T}_{il}(T_i = \hat{T}_{il})$

$$\begin{aligned} Pr(\tilde{t}_{ij} = \hat{T}_{il} + \hat{t}_{ij}) &= p_j(\hat{T}_{il})p_j(\hat{t}_{ij}) \\ p_j(\hat{T}_{il} + \hat{t}_{ij}) &= e^{-(\lambda_j + \pi_j)(\hat{T}_{il} + \hat{t}_{ij})} \\ Pr(\tilde{t}_{ij} = \infty) &= 1 - p_j(\hat{T}_{il} + \hat{t}_{ij}) = 1 - e^{-(\lambda_j + \pi_j)(\hat{T}_{il} + \hat{t}_{ij})} \end{aligned} \quad (5)$$

Random time execution of task  $i$ ,  $\tilde{T}_i$  is equal to the fastest a resource from  $\omega_i$  finishing the task,

$$\tilde{T}_i = \min_{j \in \omega_i}(\tilde{t}_{ij}) \quad (6)$$

In case that the number of tasks is  $m$ , the start time of task  $m$  is  $T_m$ , knowing the distribution of  $T_m$  in the form of  $q_{ml} = Pr(T_m = \hat{T}_{ml})$  for  $1 \leq l \leq L_m$ , the reability of service performance can be evaluated.

In estimating service reliability and performance, one can use different measures depend on the application. In the application where the execution time of each task is critical, the system reliability  $R(T^*)$  is defined as the probability of the correct output in time less than  $T^*$ .

$$R(T^*) = \sum_{l=1}^{L_m} q_{ml} \cdot 1(\hat{T}_{ml} < T^*) \quad (7)$$

### B. Illustrative Example

This analytical example illustrates  $R(T^*)$  for resource allocation on mobile ad hoc grid. Assume that there are eight resource nodes in the grid. The analysis of  $R(T^*)$  will be conducted for two, three and four tasks replication. The replication number of tasks for each scenario is fixed.

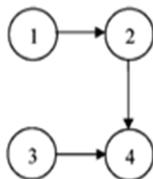

Fig. 2. Task execution precedence for the analytical example.

Assume that the RMS divides job into three tasks. Tasks 1 & 3 get the input data directly from the RMS; task 2 needs the output of subtask 1, and the job is completed when the RMS gets the outputs of both tasks 2 & 3. These task sequence is shown by the directed graph in Fig. 2.

Table 1 contains a summary of the failure rates of the resources, communication channels, and task execution times. If it is assumed that all resources are reliable, the failure rate of the resource ( $\lambda$ ) is 0. Considering that the mobility model of nodes is random point group mobility (RPGM), the failure rate of communication channel obtained from [14] is 0.0064. So  $\lambda_j + \pi_j$  is 0.0064.

TABLE I. PARAMETERS OF THE MOBILE AD HOC GRID SYSTEM FOR THE ANALYTICAL EXAMPLE.

No. of resource $j$	$\lambda_j + \pi_j$	$\hat{t}_{ij}$
1	0.00164	100
2	0.00164	130
3	0.00164	150
4	0.00164	180
5	0.00164	220
6	0.00164	300
7	0.00164	180
8	0.00164	150

In the first scenario, the first task is assigned to resources 1 & 2, the second task is assigned to resources 3 & 4, and the third task is assigned to resources 5 & 6.

$$\omega_1 = \{1,2\}, \omega_2 = \{3,4\}, \omega_3 = \{5,6\}$$

For the second scenario, the first task is assigned to resources 1, 2 & 3, the second task is assigned to resources 4, 5 & 6, and the third task is assigned to resources 2, 3 & 4.

$$\omega_1 = \{1,2,3\}, \omega_2 = \{4,5,6\}, \omega_3 = \{2,3,4\}$$

And in the last scenario, the first task is assigned to resources 1, 2, 3 & 4, the second task is assigned to resources 3, 4, 7 & 8, and the third task is assigned to resources 5, 6, 7 & 8.

$$\omega_1 = \{1,2,3,4\}, \omega_2 = \{3,4,7,8\}, \omega_3 = \{5,6,7,8\}$$

To evaluate the distribution of service time of each scenario, universal generating function (u-function) as in [7] is used. This technique is using a fast algebraic procedure and effectively proven for evaluating the reliability of multi state system [15]. Then calculating reliability using (7), it is obtained as:

The 1st scenario,	$R(T^*) = 0.3928$	for $250 < T^* \leq 280$ ;
2 task replica	$R(T^*) = 0.5239$	for $280 < T^* \leq 300$ ;
	$R(T^*) = 0.663$	for $300 < T^* \leq 310$ ;
	$R(\infty) = 0.8632$	

The 2nd scenario,	$R(T^*) = 0.5371$	for $230 < T^* \leq 250$ ;
3 task replica	$R(T^*) = 0.7004$	for $250 < T^* \leq 280$ ;
	$R(T^*) = 0.7611$	for $280 < T^* \leq 300$ ;
	$R(T^*) = 0.8006$	for $300 < T^* \leq 310$ ;
	$R(T^*) = 0.8032$	for $310 < T^* \leq 330$ ;

$$R(T^*) = 0.8033 \quad \text{for } 330 < T^* \leq 360;$$

$$R(\infty) = 0.8636$$

The 3rd scenario,  
 4 task replica

$$R(T^*) = 0.6629 \quad \text{for } 150 < T^* \leq 180;$$

$$R(T^*) = 0.8019 \quad \text{for } 180 < T^* \leq 220;$$

$$R(T^*) = 0.8381 \quad \text{for } 220 < T^* \leq 300;$$

$$R(\infty) = 0.8661$$

Fig. 3. Service Reliability for different replication number

The result of all scenarios can be seen in Fig. 3. It is shown that the service reliability increases as the number of task replica is increased. It is also shown that the increasing number of task replica will decrease the required service time, because the probability of successful task increases as the number of replica increases.

#### IV. Conclusion

The severe environment of mobile ad hoc network requires a fault-tolerant resource allocation for mobile ad hoc grid. One of the methods for obtaining fault resilience in a grid with infrastructure is task replication. Here, we analyze the reliability of task execution on resource allocation with tasks replication in mobile ad hoc grid. An analytical example has been delivered to show the reliability analysis. In line with a grid with infrastructure case, the result shows that assigning tasks replication provides superior reliability in mobile ad hoc grid. However, due to mobile ad hoc network characteristic the number of task replica has to be limited. In the future, we will use comprehensive hierarchical model in analyzing the reliability of resource allocation in mobile ad hoc grid. The optimum number of task replica for a certain failure probability will also be studied.

**Abstract**— The main actor of the game is based on non-playable character (NPC) behavior to respond the environment based on artificial intelligent method. This research simulates the behavior of buyer-seller agent on purchasing computer goods in computer game. The buyer agent has price and specification variable which is reacted in satisfaction factor of agent. The seller agent has price and profit variable which is took effect in Join Utility (JU) of agent. In this case, there is usually no single optimal solution, but a set of alternatives with different trade-offs. This research describes buyer-seller agent behavior by multi objective optimizations approach using Multi Objective Evolutionary Optimization (MOEA) Non Sorted Dominated Genetic Algorithm II (NSGA II). NSGA II provides pareto fronts value to the minimum and maximum functions. Based on simulation result, we generate 3 kinds of scenarios of buyer and seller agent. First, the seller agent with profit oriented behavior provides the value of JU twice from the buyers function. Second, the seller agent with customer oriented behavior provides balance JU from the buyer function. Third, the buyer agent with satisfaction oriented behavior. Stability results of simulation is evenly attained after the fifth generation with simulation parameters: chromosome/pop=1000, crossover probability (pc)=0.9, mutation probability (pm)=0.005, index of distribution crossover ( $\eta_c$ )=20, index of distribution mutation ( $\eta_m$ )=20, value of pool=pop/2 and number of tour=2.

**Keywords**— *intelligent agent, multiobjective, NSGA II, NPC behavior*

## I. INTRODUCTION

Computer game have several type of *Non-Playable Characters* (NPCs) agent. Two of them are buyer and seller NPCs. If NPC have human-like behavior, the buyer NPC must have intelligent when make decision to buy some thing. The NPC should choose from several selection of goods base some criterias, like minimum price and maximal quality.

Research of the buyer-seller agent relationship had researched by some researchers [1, 2, 3, 4, 5, 6, 9]. Imam [1] design buyer agent based on *hierarchical finite state machine* (HFSM) to simulate *Supply Chain Management* Procurement decision. Seller agent's strategis to select buyer in face of limited stock matematically formulated [2]. Still correlates of buyer agents, buyer agents developed based on fuzzy logic for automated negotiation in e-commerce[3]. Also Li[4] investigated the use of multi-objective optimization approach

to the buyers and sellers agents using techniques based priority matchmaking genetic algorithms. Methods of *Constraint Satisfaction Problems* (CSP) can also be used to measure the negotiations between buyer-seller [5]. Anon[6] investigate the approach to form buyer coalition with bundles of items by using the genetic algorithm. *Multi Objective Evolutionary Optimization* (MOEA) *Non Sorted Dominated Genetic Algorithm II* (NSGA II) had been employed by Adianto[7] to badminton agent using stamina and player action criteria. Asto[8] employed MOEA NSGA II agent on electricity supply serious game.

In this research, we proposed buyer-seller agent's decision behavior based multi objective optimizations approach using MOEA NSGA II to employ it for NPCs, from our previous research [9].

The paper is organized as follows. A brief description about buyer-seller behavior scheme is presented in section II. Discussions about multiobjective design for buyer-seller behavior described in section III. The experimental results are shown in section IV and conclusion in section V.

## II. BUYER-SELLER BEHAVIOR

We design Finite State Machine (FSM) for buyer agent in our novelty game, a REOG PONOROGO game. The job of buyer agent is find the best offer from several seller. Buyer do scoring function ,based on NSGA II, is to assess what is offered by the seller until the deal with the seller. Conversely the seller also have considerations with the profit taking , so as long still have profit, the seller also did the scoring from the buyer offers to end up doing a deal with a buyer.

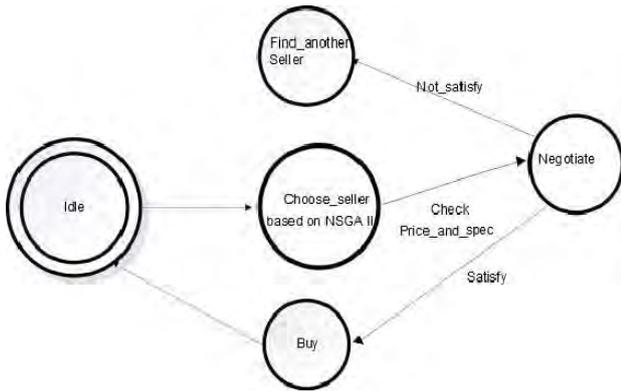

Figure 1 FSM of buyer agent

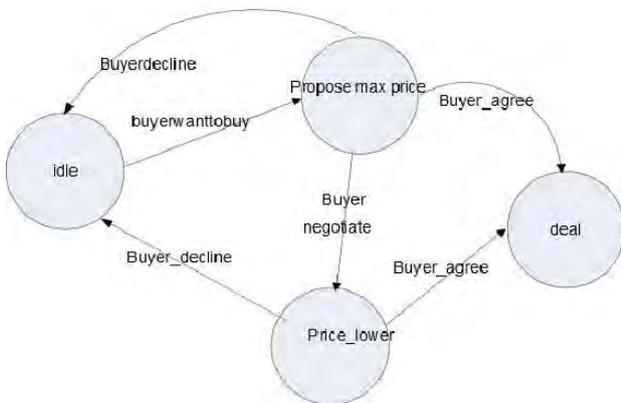

Figure 2 FSM of seller agent

### III. MULTIOBJECTIVE DESIGN

#### A. NSGA II

Nondominated Sorting Genetic Algorithm II (NSGA II) developed by Kalyanmoy Deb [10] which is a modification of the procedure of rank in NSGA. The algorithm of the original NSGA is first, initialize population. Once the population has initialized the population sorted by non-domination into each front. Each individual in each front rank rated (fitness) or by front where they belong. The individuals at the first front were given a fitness value is 1, while for individuals on second fronts given fitness value 2 and so on for the next.

#### B. Buyer seller multiobjective design

Population initialization is done by forming a population. In this study determined the amount of maximum population is 1000 chromosomes. chromosome generated from database laptop purchase. Chromosomes consist of 19 objective variables which offer sellers (processor, memory, hard drive, price), the minimum expected price from seller, expectations of buyers (processors, memory, hard drive, price), minimum capability buyers (processors, memory, hard drive) the maximum capacity buyer (price), the weight of interest /

preference buyers (processors, memory, hard drive) cumulative weight (specifications, prices) and quantity.

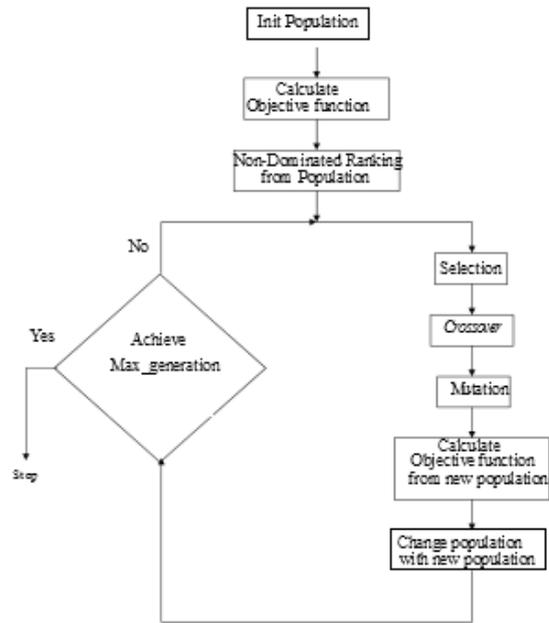

Figure 3 NSGA II Flowchart

#### C. Join Utility function

Li[4] use the matchmaking mathematical model for novel method to match buyers and suppliers in B2B e-marketplace. We use the matchmaking mathematical model [4] to form buyer and seller function. The buyer-seller functions then used by NSGA II [10] to make *pareto front*. From *pareto front* we calculate Join Utility (JU), which is *bargaining value* from the seller to the buyer's agent.

- Buyers function (f1),

QBigf is variable assessment (scoring) of the quality products offered, i is a buyer, g is the product

$$Qb_{ig} = \begin{cases} 1 & , agf \geq eif \\ \frac{agf - eif_{min}}{eif - eif_{min}} & , eif_{min} \leq agf \leq eif \\ -1 & , agf \leq eif_{min} \end{cases} \quad (1)$$

Where:

Eif = the expectation value of the buyer

Agf = bid price sellers

Eif min = minimal value ability of the buyer

Pbigf is variable assessment (scoring) of the price of products offered,  $i$  is a buyer,  $g$  is the product

$$Pb_{igf} = \begin{cases} \frac{eif_{max} - agf}{eif_{max} - eif} & 1, agf \leq eif \\ -1, agf \geq eif_{max} \end{cases} \quad (2)$$

Where:

Eif = the expectation value of the buyer

Agf = bid price sellers

Eif max = maximal value ability of the buyer

Then scoring of buyer (Bij) calculated by:

$$Bij = \sum W_i \times bigf \quad (3)$$

Finally the buyer function affected by the quantity of sales (Q), so the f1 become:

$$f1(x) = Bij \times Q \quad (4)$$

• Seller function (f2)

First we calculate the value of seller scoring:

$$S_{ji} = \begin{cases} \frac{Pbi - PSj_{min}}{PSj - PSj_{min}} & 1, Pbi \leq PSj \\ -1, Pbi \geq PSj_{min} \end{cases} \quad (5)$$

Where:

Sji: Seller scoring

Pbi: Bid price from buyer

PSj: the expectation value of the seller

PSjmin: maximal value ability of the Seller,

Then we calculate the seller function, affected also by bargaining value(JU) and quantity (Q):

$$f2(x) = JU \times S_{ji} \times Q \quad (6)$$

which on normal scenario, bargaining value JU is defined:

$$JU = 1 - f1(x) \quad (7)$$

#### IV. EXPERIMENT

We find the best value of the agents with consideration of maximizing buyer (cheap price, good specs, purchase quantity lots) and maximize the seller (profits, a lot of customers, big sales quantity). By implementing equation 1 to equation 7 in NSGA II, we generate 3 kinds of scenarios of buyer and seller agent.

1. First, the seller agent with profit oriented behavior provides the value of JU twice from eq.7 :

2. Second, the seller agent with customer oriented behavior provides balance JU, using eq.7

3. Third, the buyer agent with satisfaction oriented behavior: The value of JU halved from eq. 7.

The three category of scenarios is tested to NSGA II with simulation parameters as follows: chromosome/pop=1000, crossover probability (pc)=0.9, mutation probability (pm)=0.005, index of distribution crossover ( $\eta_c$ )=20, index of distribution mutation ( $\eta_m$ )=20, value of pool=100 and number of tour=2.

The experiment has a *pareto front* result as follows:

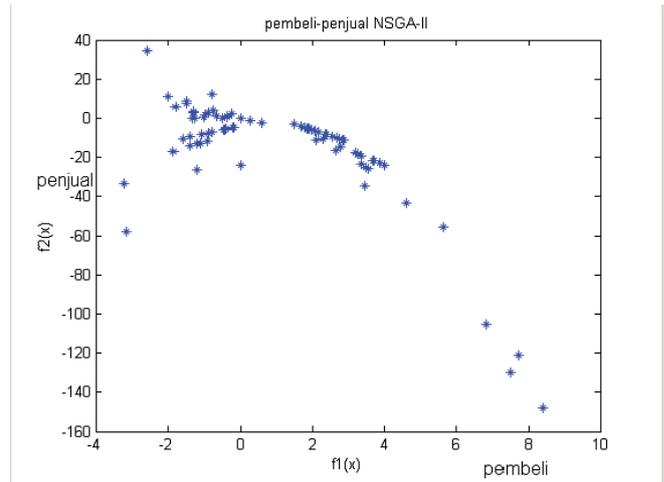

Figure 4. Value JU twice from normal JU

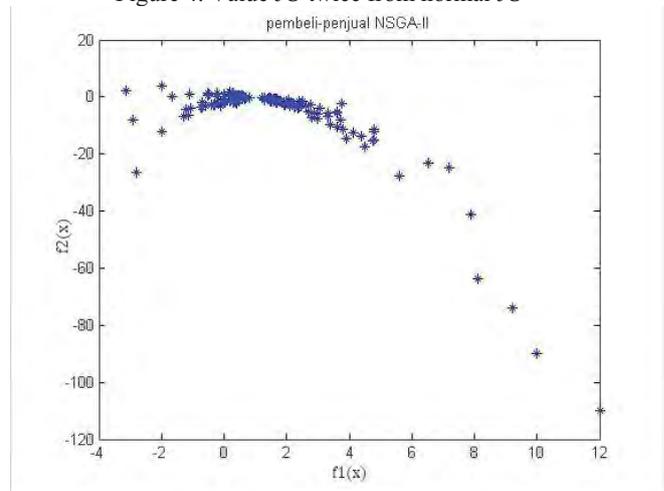

Figure 5. The simulation results with generation = 75

On generation =50 and 75 crowded points still in the same range as previous simulations (fig. 5), so it can be concluded for the generation of = 50 and thereafter obtain stable results. So that the pareto fronts of generation 50 can already be used to find a solution or the best value.

## V. CONCLUSION

We present NSGA II optimization method for seller agent decision in computer game. Employed to buyer-seller FSM, the buyer-seller agents can interact more immersive. Using NSGA II, we have the best result after 50 generation.

**Abstract**—Machinema is a system that allows making movies in virtual environment created in real-time. In the process of making machinema movie, the camera position plays an important role in the process of cinematography. In the real world, the cameraman receives direction from the director to put the camera accordance with the desired viewpoint. Machinema works in real-time, it would a real camera system that can perform the roles of a director and cameraman in determining perspective on every scene in the film making. In the real world cinematography, the director used a variety of viewpoints such as establishing shot, track shot, bird eye, and close up to get an interesting story. If machinema is used to make a film resembling as in the real world then machinema should be possible to take shoot with various position. We designed an intelligent camera system that can accommodate the needs of the virtual cinematography by observing the rules of traditional cinematography in the real world. An intelligent camera system is capable of assisting in the process of making machinema movies. Our method uses behavior trees. The system we made allows the camera to perform as a director in terms of deciding the proper perspective based on priorities and possibilities to make the camera moves automatically and shoots like a cameraman in the real world. In this paper we implement the system we've created in virtual world using unreal engine.

**Keywords**—component; machinema; cinematography; behavior trees; unreal engine

## I. INTRODUCTION

Movies, television, and video games are among the most popular form of entertainment in these days. Of these movies has been around the longest, followed by television. It follows that video games can benefit from lessons learned from the movie and television industries. Creating the film, however, is a costly and time consuming endeavor that requires trained writers, producers, directors, actors, and others. Recently many hobbyists have turned to a portmanteau of machine and cinema, machinema or machinima.

Machinema refer to the innovation of leveraging video game technology and used pre rendered 3D images to greatly ease the creation of computer animation. Rather than creating complex graphical word, machinema artist manipulated the behavior of 3D games. By choreographing the characters as

the avatar or create their own character, they can “perform” the actions according to the script they are creating.

Filmmaking using machinema is a complex visual medium that combines virtual cinematography, avatars controlling, and editing to convey a story. The camera must film the right event at the right time to produce the right picture. Cinematography and editing are both complex art form in their own right.

In this paper we focus on the problems of selecting secondary camera placement and angles to capture the action of an event based on behavior trees. There are a number of challenges therein including visual composition, event triggering action, and coordination between main camera and the secondary camera. We described a secondary camera placement system for machinema movies.

## II. BACKGROUND

Cinematographers over time developed a rich canon of conventions for filming commonly recurring types of shots (A continuous take of camera recording) and sequences (an ordered series of shots). For example, cinematic convention suggests that in filming two characters facing one another in conversation, alternating shots of the two characters should depict one gazing left-to-right and the other right-to-left. In filming the rest shot of such a sequence, the camera is placed on one side of an imaginary line-of-interest passing through the characters, and successively placing the camera on the same side of this line preserves continuity by repeating the established facing directions of the characters. [1].

In composing the visual properties of a shot, a cinematographer may vary the size of a subject in the frame or the relative angle or height between camera and subject. Shot sizes include extreme close-up, close-up, medium, long, and extreme long in which a subject's size in the frame appears progressively smaller or more distant. A filmmaker can also use editing decisions such as shot duration and the frequency of cuts to artful effect. [1].

Many researchers have focused on integrating cinematographic principles into automatic camera control. These approaches provide sophisticated control to a user.

Christianson et al. [2] divide cinematography into simple fragments in a “Declarative Camera Control Language”. They also develop a “Camera Planning System” that partitions a character’s movement into individual actions. He et al. [3] encode a finite state machine that controls the camera’s position and parameters. This implementation does not work in real-time and is limited to simple scenarios involving two characters. Our approach works for multiple simultaneous events, operates in real-time, and expands to more robust scenarios, such as crowds, tracking an object/character, and conversations.

### III. CINEMATOGRAPHY

In the process of film-making cinematography play an important role to make the movie feels great not just a sequence of images. The angles, the frame and the other main cinematography principles must be applied to a movie.

Cinematography means Light and camera settings when recording photographic images for the cinema. Camera settings in cinematography consist of camera movement, camera placement, and camera angle. The developments of commercial game at the recent days have brought the good story telling almost the same as the movie. This requires a proper camera placement to increase player emotions that plays the game. Taking a particular point of view is expected to improve emotional player such as player to watch movies. However, for placing a camera in cinematography principle, we need a basic knowledge about creativity in cinematography

#### A. Framing the Scene

In the game, framing and composition are essential to communicate the situation. The depth of a particular frame may provide different information for each player. If frames are taken very close to the actor game such as close-up shot of the information obtained will be less and it could make the player confuse but can provide emotional closeness, for example, when a character is in a state of anger. Conversely, if the frames are taken tend to widen as establishing shot, the players will get more information from the surrounding environment but will get less emotion as shown in Figure 1.

Figure 1. Shot idioms in cinematography principles

#### B. Shots Idiom

- *Extreme Close up* : Generally refers to a shot showing only the eyes and mouth, but can also

indicate an even tighter Shot showing only one feature that is important to the current scene.

- *Medium Close up* : Sometimes referred to as two T’s (for teeth and throat), this shot shows the head down to the top Of the throat.
- *Full Close up*: Also known as a chocker, this contains the head and full throat.
- *Wide Close up*: Similar to Close Up, but thus shot includes the full shoulders.
- *Close Shot* : Sometimes referred to as three T’s (teeth, throat and ...), this shot is from breast area to up
- *Medium Close Shot* : This shot goes from just above the belt to the top of the head
- *Medium shot* : This shot is from the waist up, including the belt
- *Full Shot*: This shot is a full body shot with little or no space above or below in the frame.
- *Two Shot* : A Shot framing the two central character of the scene
- *Long shot* : Also known as a wide shot, this shot encompasses an entire scene.
- *Extreme long shot* : A shot that includes more than the scene, usually to establish location or geography that is Important to the scene

#### C. Camera Movement

The camera movement shapes and informs a shot’s meaning. Basic camera moves include three actions: pans, tilts, and tracks. In general, most complex camera moves are simply mixtures of these basic components. A camera pans when it rotates horizontally, either from left to right or from right to left, normally establishing a scene. The camera rotates vertically to tilt, either from up to down or from down to up. In a tracking shot, the entire camera moves, rather than simply changing the direction of its focus to provide detail. These moves provide 6 degrees of freedom allowing the camera to position correctly as shown in Figure 2.

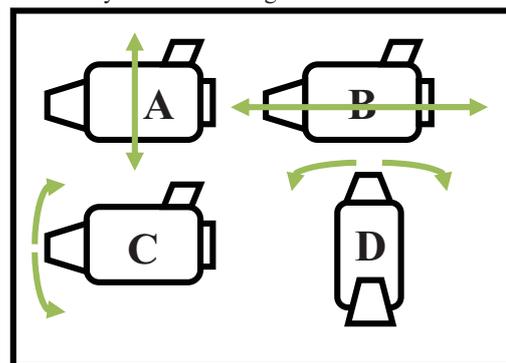

Figure 2. Camera movement, A Boom Movement, B Dolly, C Tilt, and D Pan

#### IV. IMPLEMENTATION

##### A. Methodology Overview

In this paper, we perform several step to process the behavior trees for camera in our machinema system.

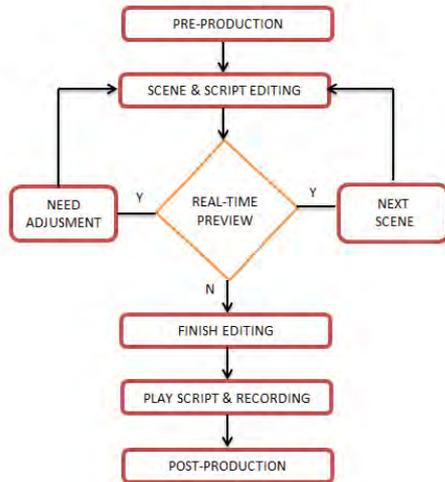

Figure 3. Machinema Workflow Process

Figure 3 shows how our system works. Pre-production process includes the 3D character modeling, material editing, texturing and pre-render process. Scene and script editing are the process creating the 3D environment and story line. In the real time preview we implemented the behavior trees for camera using trigger for our actor and camera system.

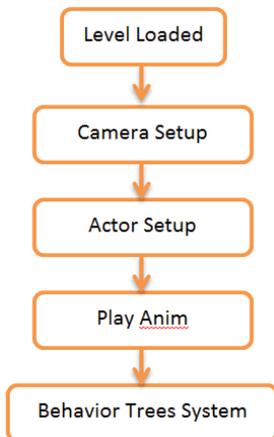

Figure 4. Sub System in Real Time Preview Process

While we created level for 3D environment scene for machinema production we also set up camera and actor according to the script created before. After all of the camera and actor ready, we can play animation according to the script, while animation is playing if some actor triggered special events, and then behavior trees are executed.

##### B. Behavior Trees for Single Camera

To accommodate the diverse needs of shot, the camera will have a complex movement. A behavior tree is a simple data structure that contains a chart or image to describe a complex action. We have used the Behavior trees to set the camera movement. The Chart of Behavior trees using the logic "AND / OR" in action, it's have a form of a statement Node and various commands to implement a variety of complex actions, in this situation like our project that means a wide range of idioms shot that can be taken by the cameramen.

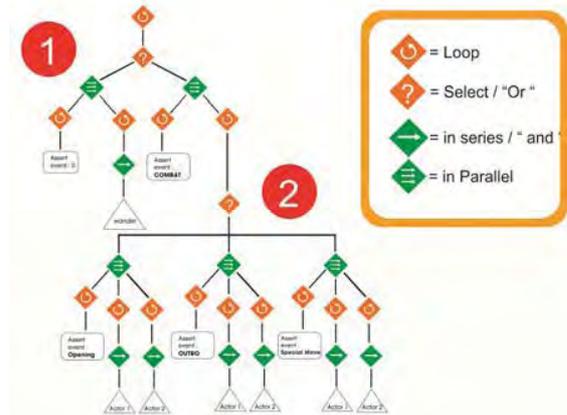

Figure 5. Behavior trees for single camera

Figure 5 shows the Behavior trees on one camera. Chart begins with the loop "and then followed by a" selector ". In the first condition, the camera is in condition to choose which of the branches that will be run. White diagrams mean that there are certain conditions that must be checked, in this case a camera that behaves as an agent will check what events are happening and give report to the selectors both conditions fail or succeed. Selector will attempt to execute each branch, and will stop if no condition report successful at every level. In the first condition, the left diagram is an example of where the camera does not accept assignment and the camera do the right diagram assignment of "Combat". Parallel Box indicates that the l execution run together, so the first condition in the picture above, on the left diagram when there is the assertion that there is no event happens then the camera will "Wander" until white box success in sending report selector. This enforces constraints on the cameras that the parallel node has one child that is constantly enforcing some constraints on the execution of its other child.

An object used in our study is the placement of the camera in a fighting game, the fighting game, usually beginning with the opening shot - a particular shot to make things more dramatic in accordance with the rules of Cinematography. When the character fight each other, sometimes can use a special moves that require the camera takes a particular shot, as well as closing the game. From Figure 5 on the condition that the two subsidiaries, Selector will select the conditions which will be run by the camera, the

camera will decide whether to take a shot for the Opening, Special move or for closure.

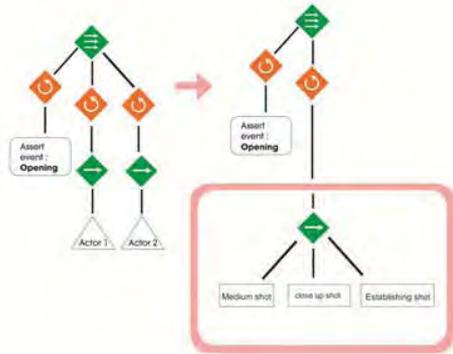

Figure 6. Behavior trees flow for shoot selection

Figure 6 is a graph that describes the behavior continued flow tree of figure 5, in Figure 6 we can see more detailed exposition of the camera, when “opening” event turn on the camera will run shot against the actor 1, then the camera will perform sequential range of idioms such as Medium shot, Close up shot, and establishing shot. Behavior trees also allow us to add the action to be selected with ease so that action will become more complex. After doing shot to actor 1, according to the graph, then the execution behavior also proceed to Actor 2.

### C. Behavior Trees for Secondary Camera

The use of behavior trees for secondary camera has the same principle behavior trees for one camera. The event triggered by the actor processed by behavior trees to select appropriate camera angle and camera shot for the action.

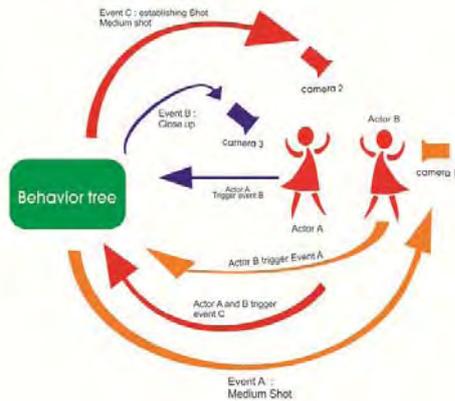

Figure 7. Behavior trees flow for shoot selection

Figure 7 above shows us how behavior trees work for multiple cameras. When actor A, triggered event B, its told the behavior trees system to select the appropriate camera angle

and placement during that event, in example when actor A has dialog event, the behavior trees select the Close-up shot for dialog event.

Actor B triggered event A, which is an “Ultimate” movement for actor B, so the camera select the medium shot for that action. Same when both actors triggered an opening event so the best shot for that event is Establishing shot.

## V. RESULT

Figure 8 shows screenshots of our test with two actors and two cameras. Using smart events, the shot is called depends on its priority for the scene. At the opening of the scene, the “establish shots” take place before any other shots. Camera 1 cuts to Camera 2 when another shot occurs. If the line of action happens to suitable for camera movement idioms, our system will automatically assign the movement to camera as transition between two shots. Figure 9 shows alternate shot from our camera system that shows close up and long shot camera shot.

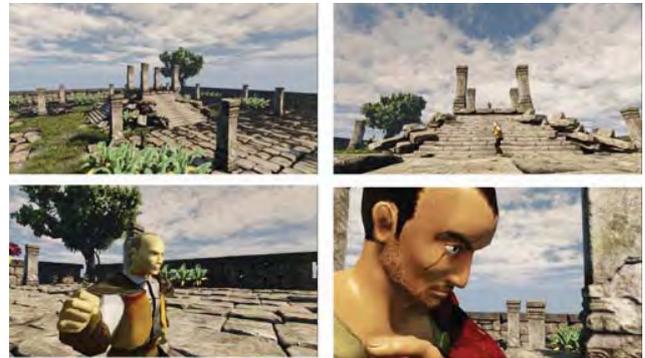

Figure 8. Screenshots of our test with two actors and two cameras

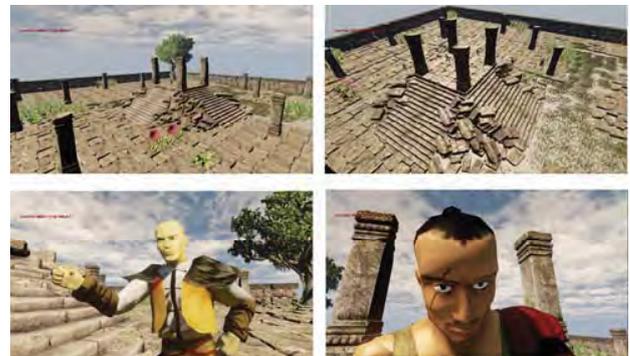

Figure 9. Alternate shots from the scene

**Abstract**—Simple-O, an automated essay grading application was developed at the Department of Electrical Engineering University of Indonesia. This application used MD5 + salt algorithm to perform protection for authentication password of users stored in its database. Unfortunately, due to a number of flaws contained in the MD5 algorithm, SHA-1 + salt algorithm was implemented in this application and then the comparison was carried out between those two algorithms. The experiments include time measurements and estimation of brute force attack for each algorithm. Processing time and CPU usage were also measured. In the brute force hash code scenario, it was tried to find plaintext from the ciphertext. In this scenario, both MD5 and SHA-1 was implemented and tested using Hashcat tool. The better the algorithm, the more time needed to brute force the ciphertext. In this scenario the password tested has 8 to 10 characters. The result from this testing shows that the implementation of SHA-1 algorithm is more robust against brute force attacks than MD5. The difference in processing time between SHA-1 + salt and MD5 + salt ranged from 0.001 seconds to 0.002 seconds for each length variation of the password from 8 to 10 character. While the difference in CPU usage is 0.545%, 0.985%, and 1.69% respectively for the password with 8, 9, and 10 characters length. These results indicate that while giving better security the implementation of the algorithm SHA-1 + salt does not impose on the performance of Simple-O application.

## I. Introduction

Development of web-based applications in the field of education has been growing rapidly. Various types of educational activities have been carried out by utilizing this technology. E-learning is the education system that uses electronic applications to support learning and teaching with

the use of the Internet media, computer network, or standalone computer. Along with the development of the current web technology, e-learning which originally only focused on distance learning system, has now been developed and has a broader scope, such as sites that provide a variety of learning materials, facilitates discussion, conduct online examination, etc.

With the continued development of e-learning today, the need for security systems is also increased. Therefore, various security methods has been applied to e-learning application, which aims to prevent attacks from outside or from inside that may be committed even by users of e-learning application itself.

Simple-O is one example of e-learning applications that is used to conduct online essay examination. This application was developed in the Department of Electrical Engineering, University of Indonesia. In this application, several methods were implemented, including in the authentication system which provide protection against username and password data. This system used MD5 algorithm to hash the password that was stored in the database. But with the increasing number of vulnerabilities found in the use of the MD5 algorithm, then the use of the MD5 algorithm in this system should be reviewed further. In this research we analyze the performance of SHA-1 algorithm in Simple-O authentication system and then compared with the implementation of the previous algorithm.

## II. Simple-O Authentication System and Hash Function

### A. Simple-O [1][2]

Simple-O is a web-based application, which is used to perform online examination as well as grading the testing

result automatically. To access the system, examinees or students must access the Simple-O Web and going through the authentication system by providing a correct username and password at first. To give security to the system, the passwords are stored in the database not in their original form, but encrypted. Encryption is needed so that if someone can penetrate the database, he/she will not be able to see all password stored in the database.

Simple-O implements hash function to protect its user passwords. With the implementation of hash algorithm, when a user logs in to the system, the system will find the hash code of the password, then the results will be compared with the value of the hash code that are stored in the database to authenticate the user. If it has the same hash code, then the user will be able to go to the home page of the Simple-O application.

**B. Hash Function [3]**

Hash function is one branch of cryptography, like encryption and message authentication code (MAC). The difference is that hash function does not require any special key to do the coding like on encryption and MAC. Hash function is a function that maps any message with the variety of length, into a fixed-length hash value, called a hash code, which is used as authenticators. Hash code is a function of all bits in any message, which is used to detect errors of the message. One bit changes in original message will produce a different hash code.

There are two approaches that can be used to attack the security of a hash function. Two kinds of approaches are cryptanalysis and the brute-force attack. A cryptanalysis attacks will exploit the logic weaknesses of the hash algorithm that are being used. While the strength of a hash function can be tested by brute force attack, depends on how long the hash code generated by an algorithm and the complexity of the process of the algorithm.

Hash algorithm is usually combined with the use of salt. Salt is an additional scrambler with a specified value that usually combined with the hash code in a form of a specific function. Value and function in salt can be determined freely. The use of salt is aimed to increase the complexity of the ciphertext hash result, making it more difficult to brute force. There are various types of hash function algorithms, while the MD5 and SHA-1 algorithm are the two most commonly used algorithms.

**1) Message Digest 5 [4]**

Message digest 5 or MD5 is one of message-digest algorithm that was developed by Ron Rivest in 1991. MD5 algorithm takes an input in any of length and produces an output in the form of a digest with the length of 128 bits. Input received by this algorithm will be processed in a block size of 512 bits, which will then be divided into 16 sub-blocks, each is 32 bits. Fig. 1 shows the processing of input on MD5 algorithm.

MD5 is an algorithm developed to replace its predecessor, the MD4 algorithm. At the beginning of its publication, the MD5 hash algorithm is one of the nicest, but at 2004 the

weaknesses contained in these algorithms began to be found [5] [6]. The weakness contained on this algorithm is the collision that easily discovered on the results of the MD5 hash. The collision is the existence of two different inputs but have the same hash result ciphertext. This weakness is caused by a wrong design of the MD5 algorithm itself, and then exploited so collision in this algorithm can be found quickly.

Since the MD5 algorithm is used in Simple-O applications, the MD5 weakness could also have an impact on applications Simple-O. If there is someone who actually does not have the right of access to the account as a lecturer, then by brute force attack against the application he could have discovered the password of the account of a teacher, and when he managed to find the account, he will have all privileges held by a lecturer on a variety of information contained in the system.

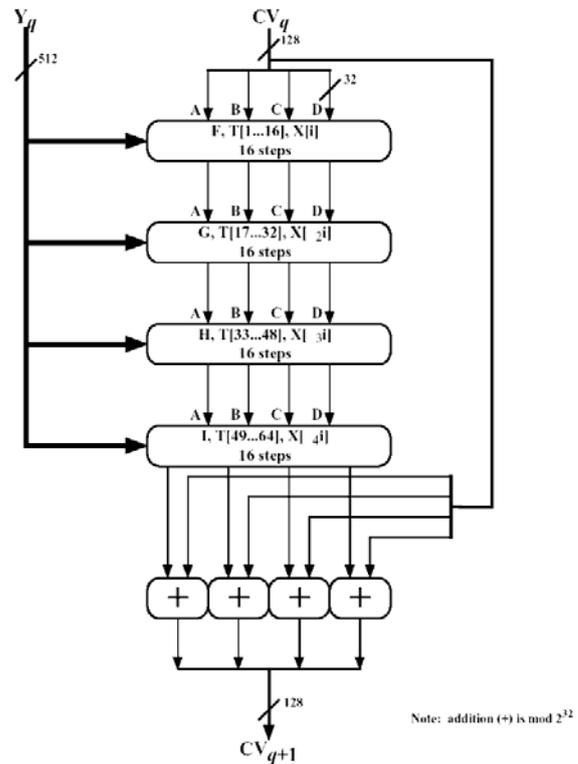

Fig. 1. The processing of the input at 512-bit block of the MD5 [3]

**2) Secure Hash Algorithm – [3] [6]**

SHA was developed by the National Institute of Standards and Technology (NIST) and published as a Federal Information Processing Standards (FIPS 180) in 1993. When the weakness of the algorithm is found, then the various revisions made to make a better algorithm, and the revision is published in FIPS 180-1 in 1995 and became a reference to the manufacture of the new algorithm called SHA-1.

SHA-1 input can accept a maximum of less than 64 bits, and 160 bits long output. This input restrictions that became one of the strengths of this algorithm, because the number of

input restrictions will reduce collisions that may occur in the use of these algorithms. SHA-1 processing input in a block size of 512 bits, and then divide it into 16 sub block that each measuring 32 bit. Fig. 2 displays the input processing algorithm SHA-1.

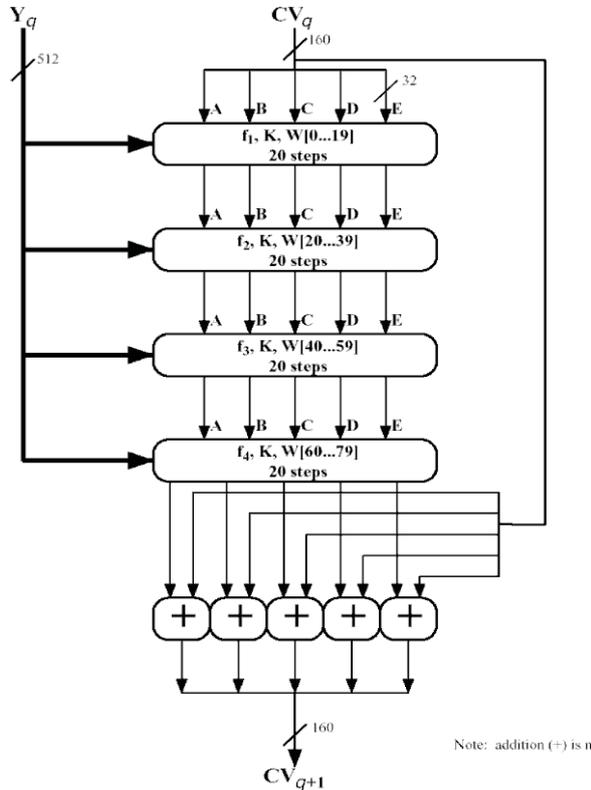

Fig. 2. The processing of the input at 512-bit block of the SHA-1 [3]

### 3) MD5 and SHA-1 Comparison

MD5 codes any stream of bytes into a 128 bit value while SHA1 codes any stream of bytes into a 160 bit value. Therefore the SHA1 will provide more security compared to MD5. The MD5 algorithm is **cheaper** to compute, however MD5 is found to be more vulnerable for collision attacks [5]. Comparison of both algorithms in terms of output length, memory usage, processing time, variance and time to brute force can be seen in more detail can be seen in Table I.

TABLE I. MD5 AND SHA-1 ALGORITHM COMPARISON [6]

Analyzing Subject	MD5	SHA-1	Better Algorithm
Output length	128 bit	160 bit	SHA-1
Memory usage	30060 byte	30267,6 byte	MD5
Processing time	17,233 ms	17,633 ms	MD5
Variance	$0,9013 \times 10^{-3}$	$0,4857 \times 10^{-3}$	SHA-1
Time for brute force	$6,8841 \times 10^{29}$ years	$2,8825 \times 10^{39}$ years	SHA-1

## III. Experimental Design

In this experiment we used two desktop PCs using as a local server and a client. Both PCs are connected in a local network. Both server and client PCs using AMD Athlon CPU, 3GHz and DDR1 memory, 1 GB. Besides these two PC, also used a standalone PCs that are not connected to the network. This PC is used to perform brute-force testing of the ciphertext of the algorithm MD5 and SHA-1 so that it can find the original plaintext from the ciphertext. This PC uses Intel® Core™ 2 Duo E7400, 2.8GHz, and DDR3 memory, 2 GB.

From the software side, some of the supporting software is used to establish a testing system and used during the test. The software is the OS Ubuntu 11.10 - Oneiric Ocelot and LAMP, which is used to form a local network for testing, and Hashcat to brute force a hash code.

## IV. Comparison and Analysis

### A. Brute Force Testing

In this scenario, we conduct brute force attack against the ciphertext from various passwords with a length of six to nine characters. The goal is to measure how long it took to find the plaintext from a ciphertext when a brute force attack is performed against the hash code stored in Simple-O database. The test was performed by using Hashcat software.

There are two kinds of results from this testing—the testing time and the estimated time of the brute force attack. The testing time is the time when the test results obtained from the process of brute force until it gained the original plaintext from the ciphertext that was brute forced. The testing time results are obtained from the process of brute force to plaintext with a length of 6 characters, both hashed with SHA-1 or MD5 algorithm. For plaintexts which are greater than six characters, we took the estimated time only. This is because the process for brute force attack from the password which is longer than six characters will takes a very long time.

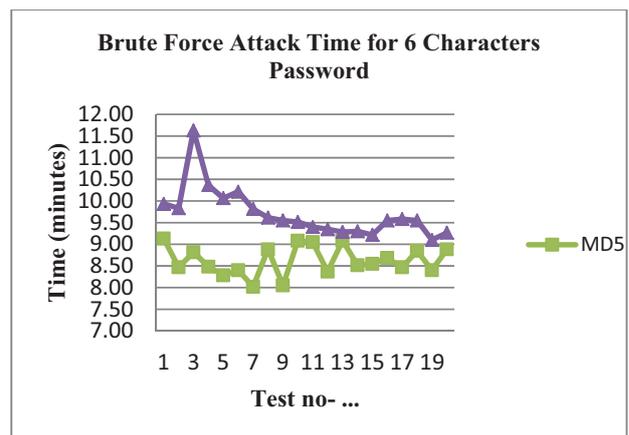

Fig. 3. Time comparison of brute force testing against 6 characters password

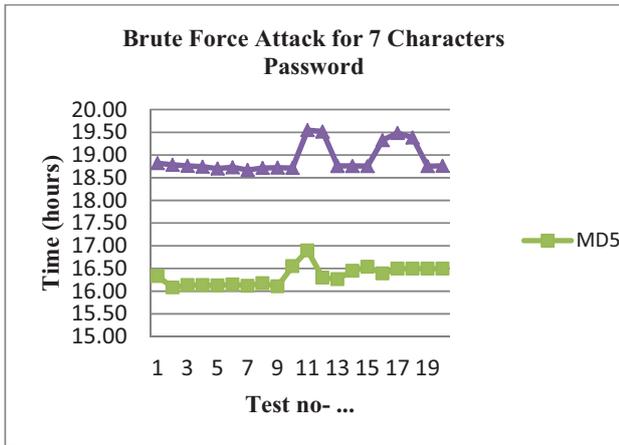

Fig. 4. Time comparison of brute force testing against 7 characters password

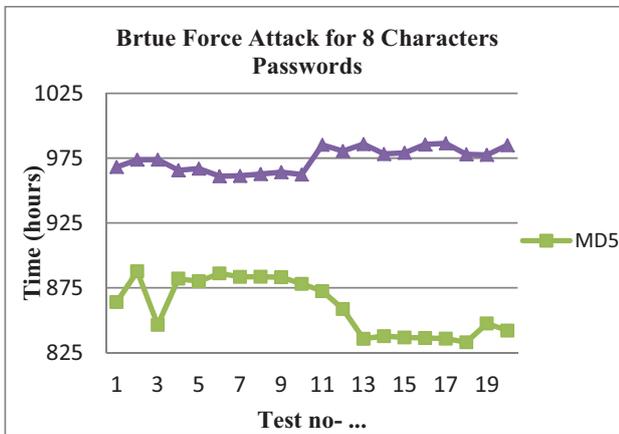

Fig. 5. Time comparison of brute force testing against 8 characters password

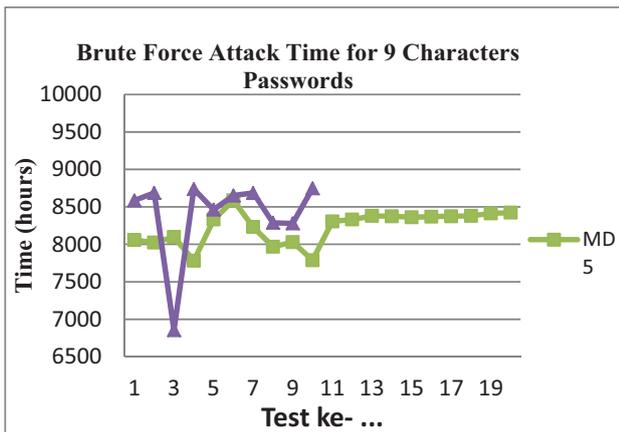

Fig. 6. Time comparison of brute force testing against 9 characters password

TABLE II. AVERAGE AND DIFFERENCE OF TIME AND ESTIMATION TIME FROM BRUTE FORCE TESTING

Characters Long	Average Time		Differences	Explanation
	MD5	SHA-1		
6 characters	8.62	9.71	1.08	In minutes
7 characters	16.34	18.92	2.59	In hours
8 characters	860.51	974.06	113.54	
9 characters	8229.95	8397.80	167.86	

Fig. 3 displays the time to brute force the password of 6 characters. Fig. 4 to Fig. 6 show the estimated time for a brute force password each 7, 8, and 9 characters. While Table II displays the average and the difference in estimation time to brute force. It can be seen that in the testing for 6 characters, the time difference is not too long, though the results still indicate that a brute force for SHA-1 takes longer. When performing a brute force password with a length of 7, 8 and 9 characters, the brute force time is getting longer. The difference in estimation time becomes the parameter that shows the complexity and strength of SHA-1 algorithms which is better when compared with MD5.

One thing that should still be considered, the process of a brute force itself is not necessarily in accordance with the estimation time. It could be faster or even longer than the estimation time. But estimation time can be used as a parameter to indicate the strength of each algorithm.

*B. Processing Time Measurement*

This scenario aims to measure the length of processing time for a user to log in to the Simple-O applications. This testing shows a comparison results from the implementation of MD5 and SHA-1 in Simple-O. This scenario was conducted with 4 kinds of combinations of hash, which are MD5, SHA-1, MD5 with salt, and SHA-1 with salt. In each implementation of the algorithm, we used a combination of three combinations of password length; 8, 9, and 10 characters as in the previous scenario.

TABLE III. AVERAGE AND DIFFERENCE OF TIME AND ESTIMATION TIME FROM BRUTE FORCE TESTING

Algorithm	Average Times (seconds)		
	8 Characters	9 Characters	10 Characters
MD5	0.02846675	0.02860271	0.02885417
MD5+salt	0.02817892	0.02812147	0.02806399
SHA-1	0.02948047	0.02920856	0.02929798
SHA-1+salt	0.02957196	0.03002721	0.03001589
<b>Differences of SHA-1+salt and MD5+salt</b>	<b>0.00139304</b>	<b>0.00190574</b>	<b>0.0019519</b>

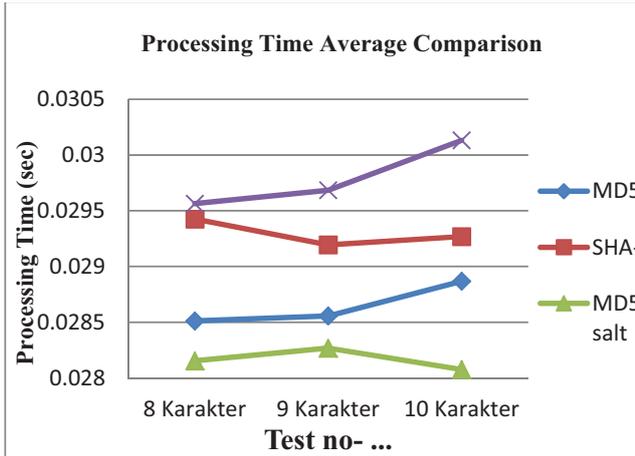

Fig. 7. Comparison of average processing time

Table III and Fig. 7 show the average and the difference of processing time. Based on the above test results, the time difference that occurs in every variation, both algorithms and passwords have margin in the range of  $10^{-4}$  seconds. Due to the very small difference, it can be concluded that the processing time required for the implementation of the MD5 algorithm, salt + MD5, SHA-1 and SHA-1 + salt tend to be similar. Therefore we conclude that the implementation of SHA-1 with salt in Simple-O will not overload the system.

### C. CPU Usage Measurement

In this testing we measure the CPU usage when a user log in to Simple-O. This testing will show a comparison of CPU usage in the implementation of MD5 and SHA-1 in Simple-O application. Same as the previous scenario, this scenario conducted with 4 kinds of combinations of hash algorithms which are MD5, SHA-1, MD5 with salt, and SHA-1 with salt. In each implementation of the algorithm, we used three combinations of password length; 8, 9, and 10 characters as in the previous scenario.

TABLE IV. AVERAGE AND DIFFERENCE OF CPU USAGE

Algorithm	Average CPU Usage (%)		
	8 Characters	9 Characters	10 Characters
MD5	9.555	9.955	10.565
MD5+salt	9.845	10.285	10.96
SHA-1	10.355	10.955	12.4
SHA-1+salt	10.39	11.27	12.65
<b>Differences of SHA-1+salt and MD5+salt</b>	<b>0.545</b>	<b>0.985</b>	<b>1.69</b>

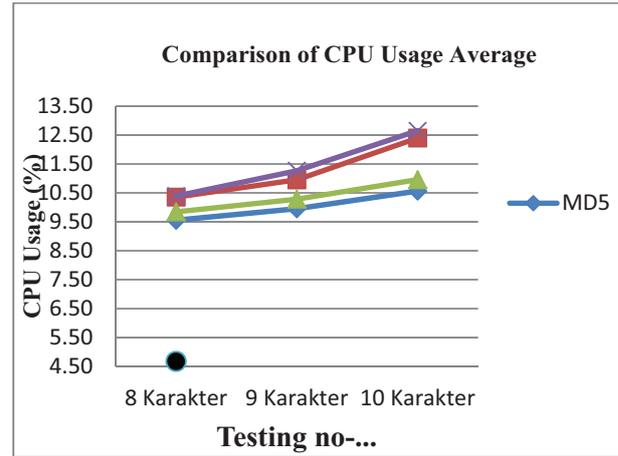

Fig. 8. Comparison of Average CPU usage

Table IV and Fig. 8 display the average and the difference in CPU usage for each password character length used, in any variation of hash algorithm for the login process. In this graph, we mark the idle processor which took CPU usage of 4.68%. This idle processor CPU usage can be considered as reference point. From Fig. 8 it can be seen in the graph that the MD5 algorithm used the lowest CPU resource for every variation of the average length character password, which is then followed by a MD5+salt, SHA-1 and SHA-1+salt.

The testing result shows that the use of SHA-1+salt will increase CPU resource usage when the login process. The difference between SHA-1 + salt compared to MD5 + salt in CPU usage for log in process is 0.56% for 8 character password, 0.99% for 9 character password, and 1.69% for a 10 character password. It is shown that the percentage difference increases along with password length. But the differences are not too significant for a password up to 10 characters long, which is 1.69%.

For passwords with more than 10 characters in length, the difference is predicted to increase. This may indicate that the use of the algorithm SHA-1 + salt will weigh Simple application-O, especially when many users are accessing the same time. However, the server load is predicted not going to be too big, given the length of the character of the password of each user will vary greatly, because not all users use passwords with a length of 10 characters or more, there are also users who use a password that is less than 8 characters.

## v. Conclusion

From the test results and analysis, we can conclude that test results and comparison of brute force attack for passwords of length 6, 7, 8, and 9 characters, indicating that the algorithm SHA-1 algorithm is stronger than MD5. The brute force attack time for 6 characters in SHA-1 was 9.71 minutes in average while in MD5 was 8.65 minutes. The estimated time of brute force attack for SHA-1 for 7, 8, and 9 characters passwords was 18.92 days, 974.06 hours, and 8397.8 hours each, while for MD5 was 16.34 hours, 860.51 hours, and 8229.95 hours.

SHA-1 has a processing time that is not much different than MD5, even relatively the same. MD5 algorithm has a processing time 0.029 seconds for each variation of the password length (8, 9, 10 characters), MD5 + salt for 0.028 seconds, SHA-1 for 0.029 seconds, while SHA-1 + salt has 0.03 seconds. While for the use of CPU resources, SHA-1 uses more resources than MD5, but the differences were not so big. MD5 algorithm used 9.56%, 9.96%, and 10.57% CPU resource for password length of 8, 9, and 10 characters respectively. While MD5 + salt used 9.85%, 10.29%, and 10.96%, SHA-1 used 10.36%, 10.96%, and 12.4%, and SHA-1 + salt used 10.39%, 11.27%, and 12.65 % respectively.

From the three testing's conducted, we can conclude that SHA-1 + salt gives better security for password protection in Simple-O compared to MD5 + salt while not overload the performance of existing systems, and the use of SHA-1 for securing authentication system hopefully can be used widely in the future to replace the use of MD5.

# Software Requirements Specification Analysis Using Natural Language Processing Technique

Agung Fatwanto  
Informatics Department  
UIN SunanKalijaga  
Yogyakarta, Indonesia  
agung.fatwanto@uin-suka.ac.id

**Abstract**—Understanding software requirements has been widely acknowledged as a crucial task in software development projects. This problem emerges since software requirements, which are originally specified using a particular natural language, are often ambiguous and incomplete. The condition will be completely different if the requirements are specified using formal language in which ambiguity and incompleteness could be obviously found and thus quickly anticipated. Transforming “natural” software requirements into a more formal specification may therefore reduce their ambiguity and incompleteness. This paper hence proposes a method to transform software requirements specified in a natural language to formal specification (in this context is object-oriented specification). The proposed method uses natural language processing technique.

**Keywords**—*software requirements specification; natural language processing; object-oriented*

## I. INTRODUCTION

Understanding software requirements during software development projects is an effortful task. It is common for requirements, which are normally specified using a particular natural language, adorned with ambiguity and incompleteness. Forming a shared view between stakeholders or potential users and developers hence requires significant works. Both parties have to share their internal view regarding the system under consideration in order to obtain a common understanding.

Technical difficulties, which normally occur during the understanding process, usually come from the fact that software requirements are specified in a particular natural language. Specifying requirements in a natural language frequently make them prone to ambiguity and incompleteness. Specifying requirements using a formal language, in the contrary, could raise their clarity and completeness. In most practices, however, software requirements are specified using a particular natural language due to its flexibility and simplicity.

This paper therefore proposes a method to transform software requirements that originally specified using a natural language to more formal specification in order to minimize ambiguity and incompleteness and, at the same time, maintaining the flexibility and simplicity of the old ways of specifying requirements using natural language. This paper is structured as follows: i) Section I discusses the background of this study, ii) Section II presents the other works on this subject, iii) Section III describes the proposed

method, and iv) Section IV discusses the applicability of the proposed method.

## II. LITERATURE REVIEW

A number of works on utilizing the natural language processing technique for analyzing software requirements specification have been conducted. These studies related to the translation of software requirements specified in natural language to formal specification. These studies mainly deal with the translation of software requirements specified using natural language that does not consider the dynamic aspect of software system. My proposed method, on the other hand, offers a translation of a dynamic requirements specification (written in a scenario-like format) to formal specification (in this case is object-oriented model).

The methods as proposed by these studies, based on their utilized translation approach, can be classified into two category: translation using artificial intelligence theory (rule-based approach) and translation based on grammatical analysis (natural language processing approach).

The rule-based approach uses artificial intelligence theory as the tool for analyzing software requirements specification written in free (unconstrained) natural language. The objective of this approach is to derive formal from informal specification. Specification Acquisition From Expert (SAFE) [3], the Requirements Apprentice (RA) [4], and Specifier [5] are the example of method applying the rule-based approach. These methods use no linguistic analysis in translating the informal into formal specification.

Different from the rule-based approach, the natural language processing approach uses grammatical knowledge to analyze the software requirements specification written in free (unconstrained) natural language. The objective of this approach is also to derive a formal specification from the informal one. Conceptual Model Builder (CM-Builder) [6], LIDA [7], Language Extended Lexicon (LEL) [8], Metamorfosis [9], and Natural Language Processing (NLP) [10] are the example of method applying the natural language processing approach.

All of these methods, however, do not consider the dynamic requirements specification, which is actually an inherent part of software requirements specification.

## III. THE REQUIREMENTS SPECIFICATION ANALYSIS

As an effort to bridge the gap between flexibility and simplicity of “natural” requirements specification with clarity and completeness of formal specification, I propose a

requirements specification analysis method using natural language processing approach. Within this method, requirements specification text will be analyzed using syntactic analysis (or parsing) technique.

A stream of text from requirements specification will be parsed using a particular syntactic analysis method. The parsing activity is performed to sentences that compose requirements specification. This activity is conducted in order to classify a sentence into its grammatical constructing elements.

Requirements specified in natural language will be parsed using Reed-Kellogg sentence diagramming system [11]. According to the Reed-Kellogg system, a sentence can be analyzed to obtain its simple structure following the particular schemata:

*Sentence* ← *Subject* + *Predicate*

The predicate must contain a verb that requires other sentence elements (object) in order to complete the predicate. The object is normally a direct object. Nevertheless, the object can be in the form of a predicate noun or adjective. In cases where other sentence composing elements (such as adverb, adjective (including article), or prepositional phrase) are found, these elements are only act as the descriptor for the main elements. A sentence, based on the Reed-Kellogg system, can further be analyzed according to the following schemata:

*Sentence* ← *Subject* | *Verb* | *Direct Object*; or

*Sentence* ← *Subject* | *Copula* | *Predicate*

An example for the first type of sentence is "PDA searches elector" while an example for the second is "PDA is expensive".

By adopting the Reed-Kellogg system, requirements that are specified in a natural language will then be filtered into a constrained natural language. The format is as follows:

*Requirement* ← *Subject* + *Verb* + *Target* + [*Way*]

A requirement represents an action, an activity performed by an agent who affects/changes one state of an entity/object (an agent or a resource). Subject represents the agent who executes the behavior (the activity prescribed by the verb). Verb describes the activity taken by the agent (subject). Target can be physical or conceptual entity (object). The entity (object) has a number of properties (attributes), which will be affected by the activity. Meanwhile, way defines the way in which an action will be taken. Way can either defines a manner or a utilized instrument (a means) to take the prescribed action. In this specification format, the subject, the verb, and the target are required whereas the way is optional.

Requirements specification example, which describes a system for tracing electors' participation in a particular election using handheld devices called as the Voter Tracking System (VTS), is used for this paper. The example is taken from a real-world industrial project. A snippet of the VTS requirements specification example is written as follows:

*"Normally when an elector attends a polling place to vote, a polling official will search a paper copy of the electoral roll for the name and address of the elector. Once the elector's details are found the polling official places a small black mark next to the name, and/or rules through the name, to*

*show that the elector has attended to vote. The copy of the electoral roll issued to each official is called a certified list.*

*Once the election is complete, the Electoral Commission compares all the certified lists to establish who has voted. In recent elections, the certified lists have been scanned to improve the accuracy and time taken for the comparison. After the 2004 election the ACT Electoral Commission engaged a company to scan all 918 certified lists. The cost of printing and storage of these certified lists was considerable and the use of large paper lists was becoming cumbersome. Further, after the 2004 ACT election, the ACT Electoral Commission experienced accuracy problems with the scanning of the lists, resulting in a much higher number of non-voter notices being issued than was necessary. (Note: Voting is compulsory).*

*The Commission identified two key business problems:*

- *The need for a faster, more efficient and cheaper method of searching for and marking voter's names on the electoral roll, and*
- *The need for a more cost effective technique to accurately and efficiently access information as to who has voted, post election"*

Using the filtering format as previously proposed, the "natural" requirements specification will then need to be analyzed and re-specified in order to be aligned with the proposed specification system. An example that can be derived from the "natural" VTS requirements specification is written as follows:

*(PDA)<sub>s</sub> (searches)<sub>v</sub> (elector)<sub>t</sub> (based\_on\_family\_name)<sub>w</sub>*

In this example, PDA (personal digital assistance) acts as the subject. It executes the behavior as prescribed by the verb (in this case is searching). Elector is the entity (object) that will be affected by the searching activity. Meanwhile, the term "based\_on\_family\_name" prescribes the way in which searching activity will be performed.

The proposed method also further defines the structure for specifying software requirements, in addition to the specification of clause or sentence, by adopting a scenario-like structure. There are two reasons why a scenario-like structure was adopted. *First*, it can incorporate the dynamic aspect of software systems. It is important since the study aims to accommodate the way to specify the dynamic parts of software systems within the proposed method. *Second*, scenario-like structure is an intuitive and familiar medium even for novices.

The proposed method also defines that, beside specified in a scenario-like structure, requirements also have to be expressed in the form of event-state-action structure. This kind of structure can be used to specify the dynamic parts of software systems. It was designed following the way to specify scenario. In this case, event is an incident that causes the activation of one or more actions. An action is an activity performed by an agent who affects/changes one state of an entity/object (an agent or a resource). Meanwhile, a state is a condition of a particular entity/object (an agent or a resource). Each state represents a phase in the lifecycle of an entity/object. A state can be categorized as initial and final

state. An initial state defines a pre-condition that has to be attained prior to the execution of an action. Meanwhile, a final state defines a post-condition that is attained after the execution of an action. This type of specification format describes that an action is triggered by an event whereas an event causes one or more actions. An action changes the condition of a state.

An example for software requirements specification following this format is provided in Table 1. In this table, an initial scenario for identifying elector during a particular election using PDA is specified. If we analyze the requirements as specified in Table 1, we can see that it forms a flow of a scenario. Taken from the example, when the current state of the system is PDA shows home screen and if there is an event that PO enters name then the action taken is that PDA will search elector. Next, if there is an event that PDA found elector at the time when the PDA searching elector, then the system will take an action to show elector. This flow of scenario can be easily followed from the event-state-action list specification.

TABLE I. SCENARIO SPECIFICATION FOR IDENTIFY ELECTOR

Event	State	Action		
		Agent	Activity	Object
PO enters name	{PDA} shows  home_screen	{PDA}	searches	elector
{PDA} found elector	{PDA} searches elector	{PDA}	shows	elector
PO clicks  home_button	{PDA} shows elector	{PDA}	shows	home_screen

There is a rule that needs to be imposed when using this specification format. *First*, any agent or object which represents the system being developed, such as PDA in this example, must be written between curly bracket ({...}). *Second*, any agent or object that represents the interface, such as home\_button and home\_screen in this example, has to be written between vertical bar (|...|). The reason for having this rule is to distinguish the elements of the system from the systemic objects (the system being developed and the interface) which will be crucial during the translation process. The translation method is, however, beyond the scope of this paper.

As the specification written in Table 1 is a type of initial version, hence it needs to be revised in order to come up with a more complete, consistent, and unambiguous requirements. According to the proposed method, the initial scenario should be: (i) elaborated and refined, (ii) its conflicts need to be identified and resolved, and (iii) its feasibility needs to be studied. The result of these refining processes is provided in Appendix A.

#### IV. DISCUSSION

The proposed method was designed to transform software requirements specified in natural language format into more formal specification. Using the proposed set of rules adopted from the Reed-Kellogg system, a "natural" requirements specification can be transformed in order to

obtain a set of formal requirements specification written in a scenario-like format.

The proposed method is actually an extension of work from [12] and [13] in which these studies face a couple of limitations. The particular limitation that is related to this study is that the methods as specified in these papers can only translate software requirements specified in a specific format (in this context is the Concern-Aware Requirements Engineering format). The capability to translate software requirements specified in any other formats is beyond the scope of these papers. This study therefore proposes a method to transform "natural" requirements specification into a more formal format that hopefully can be further translated into object-oriented models as specified in [13]. This study, however, still lacks of a clear procedure on how to map from a "natural" requirements specification written in a very flexible (loose) format into their associated formal specification.

As a recommendation for future work, a study on how to clearly map a sentence found in the "natural" requirements specification with their counterpart in the transformed formal specification should be conducted.

# P2P Locality Awareness Architecture In Ethernet Passive Optical Networks

Andrew Tanny Liem  
Department of Computer Science  
Klabat University  
Manado, Indonesia  
andrew.t.liem@gmail.com

**Abstract**— The P2P live streaming nowadays becomes more popular and begins to take a larger share of bandwidth together with the Internet video calling. Furthermore, a large scale peer-to-peer (P2P) live streaming has recently been successfully and commercially deployed to provide either live streaming or on-demand video streaming. Cisco predicts that 60% of video traffic worldwide will be consumed by these P2P applications in 2015, which is enough to make any Internet Service Provider (ISP) straitened. In particular, the major challenge that has received significant attention is that many network oblivious P2P applications without locality awareness of ISP boundaries that lead to inefficient Internet resource utilization due to the Inter-ISP traffic cost. Consequently, we propose P2P locality awareness architecture in Ethernet Passive Optical Network (EPON) that mitigates Inter-ISP traffic by optimizing peering locality for P2P live streaming. We design mechanisms in ONU. These mechanisms can reduce inefficient Internet resource utilization at the server sides and improve each peer QoS.

**Keywords**—P2P Live streaming; Locality Awareness; EPONs; QoS;

## I. Introduction

In recent times, peer-to-peer (P2P) system begins to generate huge amount of bandwidth due to their popularity and nature. Among P2P applications, the P2P live streaming applications whose resilience and performance depend on the random connections across the network, consume the biggest part of the available resources provided by the Internet Service Providers (ISPs) infrastructure and increase the market demand for more stable and faster broadband services [1]. Recently P2P live streaming systems are becoming the next Internet killer applications as testified by the growing success of commercial systems, such as PPLive, SopCast and UUsee [2]. They allow to “watch television” over the Internet, granting to anyone to become a content provider by limiting the infrastructure costs, while giving the chance to break broadcasting constraints so that anyone can watch any content anywhere, at any time. Although it gives huge opportunities for the ISPs, however it comes together with the large network engineering problems such as costly routes and infrastructure.

The Inter-ISP connections could have been avoided if the P2P systems would not choose random neighbors [3] and another

aspect of the problem should be considered is that P2P live streaming application is becoming popular with highly sensitive QoS and Quality-of-Experience (QoE) requirements. In order to tackle aforementioned problems that arise with P2P live streaming in particular, a solution could be reached if the P2P systems would get modified and adopt an ISP-friendly behavior. ISP-friendliness means that the network applications show low levels of redundancy and costly traffic. The level of ISP-friendliness is often traded with system performance if pushed too far. It simply means that the choice of neighbors in P2P overlays should be designed carefully to exploit the locality for the underlying routing strategy. Therefore, many network service providers begin to control P2P traffic by implementing the ISP-friendly design approach in order to reduce the Inter-ISP traffic cost. ISP-Friendly approaches aim to mitigate Inter-ISP traffic by optimizing peering locality since the peers from the same ISP (i.e., Intra-ISP traffic) respond faster to the requesting peer. This also in conjunction with current studies showing that in P2P live streaming more than 80% of a peer’s downloaded streaming traffic in popular channels are served by peers in the same ISP whereas the unpopular channels are less than 50%. In other words, most of the P2P live streaming applications have achieved strong ISP-friendly awareness since the level of traffic locality with respect of popular channels is very high. This fact is also somehow connected to the study in [4] that the localized P2P is projected to grow 65% of IP video traffic and 60% of all Internets by 2013. Figures 1 and 2 show the total predicted localized P2P video until 2013 and the localized P2P that traverses in the access network only, respectively. It can be observed that in 2013 the total localized P2P video is exceeding 20 Exabytes/month. It is also shown that with the increasing number of P2P video titles available from each subscriber the bandwidth utilization is also increasing.

However, up until now, most studies in EPONs have not addressing the the traffic locality awareness, which very important issue since P2P live streaming traffics that served by peers in the same EPON are gradually increasing. By keeping the P2P streaming traffic localized, it can vastly decrease the bandwidth load at the server side and Inter-ISP traffic cost. To our knowledge, there are few studies discuss on implementing the Intra-ISP traffic mechanism in the EPONs system. Thus, architecture with sophisticated resource management that

supports not only Intra-ISP traffic mechanism but also provides better QoS and QoE, particularly for P2P live streaming is required. Consequently, we propose P2P locality awareness architecture in Ethernet Passive Optical Network (EPON) that mitigates Inter-ISP traffic by optimizing peering locality for P2P live streaming. We design mechanisms in ONU which consists of a buffer-map with a routing table. These mechanisms can reduce inefficient Internet resource utilization at the server sides and improve each peer QoS. Moreover, we exploit the passive splitter in order to support Intra-ISP traffic communications (i.e., ONU-to-ONU or Peer-to-Peer) in the same ISP. Simulation results have shown that our propose architecture has lower packet delay and bandwidth waste.

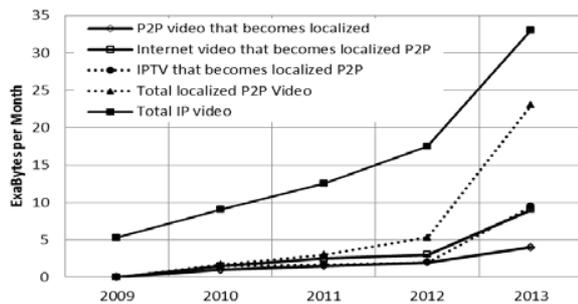

Figure 1(a) Localized P2P Projected [4]

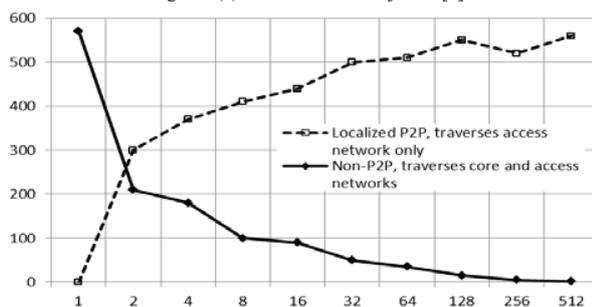

Figure 1(b) Localized P2P Traverses in Access Network [4].

However, up until now, most studies in EPONs have not addressing the the traffic locality awareness, which very important issue since P2P live streaming traffics that served by peers in the same EPON are gradually increasing. By keeping the P2P streaming traffic localized, it can vastly decrease the bandwidth load at the server side and Inter-ISP traffic cost. To our knowledge, there are few studies discuss on implementing the Intra-ISP traffic mechanism in the EPONs system. Thus, architecture with sophisticated resource management that supports not only Intra-ISP traffic mechanism but also provides better QoS and QoE, particularly for P2P live streaming is required. Consequently, we propose P2P locality awareness architecture in Ethernet Passive Optical Network (EPON) that mitigates Inter-ISP traffic by optimizing peering locality for P2P live streaming. We design mechanisms in ONU which consists of a buffer-map with a routing table. These mechanisms can reduce inefficient Internet resource utilization at the server sides and improve each peer QoS. Moreover, we exploit the passive splitter in order to support

Intra-ISP traffic communications (i.e., ONU-to-ONU or Peer-to-Peer) in the same ISP. Simulation results have shown that our propose architecture has lower packet delay and bandwidth waste.

## II. RElated Work

According to [5], the ISP-friendly approaches can be divided into three taxonomies i.e., ISP-Friendly P2P approach, ISP approach and ISP-P2P cooperation approach. In ISP-Friendly P2P design the construction of P2P overlay topologies is one of the primary concerns. This affects both Inter-ISP traffic and user perceived service quality, since overlay connections among peers are determined by the way peers obtain content from its neighbors. In general, ISP-friendly P2P schemes attempt to direct peers to connect to adjacent neighbors within the same ISP for traffic localization. As for the ISP approach simply means that the ISPs can proactively help to regulate and guide P2P applications to reduce Inter-ISP traffic cost and increase the desired network efficiency. Lastly, the ISP-P2P cooperation approach is the collaborative traffic control between P2P applications and ISPs in achieving efficient utilization of network resources without sacrificing application performance, given that ISPs are best positioned to determine the locality, link costs, and ISP policies. Relevant information including topologies, policies, routing, and traffic pattern are accessible for P2P application trackers or peers via the information interfaces provided by ISPs.

On the other hand, recently optical network is regarded as one of the best solutions in the access networks due to large amounts of bandwidth only in one single fiber. By 2015, fiber will cover 20-30 percent of all households and 30-50 percent in 2020 [6]. Currently, Japan, China and Korea are developing large-scale EPON deployments, which are built by multiple system operators [6]. By the end of 2011, Japan already has 21 million subscribers, followed by Korea and China, respectively. As for 2012, EPON networks have passed more than 60 million households, and more than 20 million broadband subscribers are served by EPON [6]. China Telecom has the fastest and biggest growing fiber-to-the-x (FTTx) network operators in the world, which on track to pass additional 30 million subscribers in 2012 [15]. EPONs representing the convergence between Ethernet and Fiber infrastructure have been discussed in IEEE 802.3ah as one of the extensions of Gigabit-Ethernet [7].

The EPON architecture consists of a centralized optical line terminal (OLT) and a number of splitters. The OLT connects to multiples associated optical network units (ONUs) over point-to-multipoint topologies to deliver broadband packets and reduce costs relative to the maintenance power. In addition, the OLT has the entire channel bandwidth to broadcast the control messages and data packets to each ONU since the directional properties of the splitter or coupler is used. However, in the upstream direction, the entire ONUs

must share the common transmission channel towards the OLT, and only a single ONU may upload upstream data in its transmission timeslot to avoid data collisions. Therefore, the IEEE 802.3ah standard has developed a Multipoint Control Protocol (MPCP), thus each ONU transmits within a dedicated timeslot and the OLT receives a continuous stream of collision-free packets from each ONU.

MPCP is merely a supporting protocol that facilitates the implementation of various bandwidth allocation algorithms in EPON. The MPCP relies on two Ethernet control messages, GATE and REPORT, to allocate bandwidth to each ONU. The GATE message is used by the OLT to allocate the upstream transmission window to each ONU and the REPORT message is used by ONUs to report its local queue-length to the OLT. An ONU can support up to eight priority queues as defined in 802.1q [8]. After receiving all the report messages based on queue state information from entire ONUs, the OLT executes a Dynamic Bandwidth Allocation (DBA) to calculate and allocate the timeslots to each ONU. The DBA plays a key role to provide more efficient bandwidth allocation for each ONU to share network resources and offer the better Quality of Services (QoS) for the end users.

Despite the abovementioned advantages of EPONs, there are still many challenges to supporting P2P live streaming in the EPONs. One of the issues is that due to the ISP-friendly approach, the traffic locality awareness becomes a key concern. Since 80% of most popular downloaded P2P live streaming channels are served by peers in the same ISP (i.e., Intra-ISP traffic). Moreover; video bandwidth will increase due to the evolution from HDTV formats towards super HD and ultra HD and 3D formats [9]. Nonetheless, recently most studies in EPON [10-13] only discussed on how to allocate the bandwidth without considering the importance of Intra-ISP traffic localization mechanism that can reduce not only the resource consumption at the server side, but also decrease the Inter-ISP traffic cost.

### III. System ARchitecture

Our high-level architecture contains three modules that are ONU modules, Star Coupler modules, and OLT modules. The architecture consists of  $N$  ONUs with extra receivers: one is to accept the downstream signal from OLT to ONUs tuned at 1550nm, the other is to accept the loop-back signal coming from the upstream direction tuned up at 1310nm; the 3:N star coupler (SC) with isolator for redirecting the packets among ONUs connected to the end users and the OLT.

#### A. OLT Modules

In OLT, the ISP information interface and P2P Locality Awareness DBA scheme for P2P lives streaming are proposed. The ISP information interface is the collaboration between ISP and P2P providers so that they can start exchanging messages such as the neighbor list that P2P providers send, newly join peers and so on. They also should

form the relationships satisfying the demands for inter/intra-domain reduction of ISP and guarantee the P2P streaming QoS. By implementing ISP Information interface, the OLT will try to reduce the traffic from each peer within its domain by discovering their Autonomous System (AS) number and Round-Trip-Time (RTT) estimation (e.g., hop time, distance, load balancing, etc). In other words, the peer most likely will prefer to connect with a local peer in the same AS or ISP with a small upload capacity than external peer with higher upload capacity. Therefore, the OLT will filter or block the inter-ISP traffic if there are local supplier peers for the request, thus reducing the inter-ISP cost yet increasing the QoS and QoE. Moreover, at every given time the OLT will send a signaling traffic to the ONU using the Single Copy Broadcast (SCB) so that each ONU can update its peers list for the routing mechanism.

The Dynamic Bandwidth Allocation (DBA) scheme can be distinguish into two paradigms, which are offline-paradigm and online-paradigm. In online-paradigm, although it has less control of channel transmission time, however the ONU is scheduled for upstream transmission as soon as the OLT receives the REPORT without waiting to receive the request from the rest of the ONUs. In contrast, the offline-paradigm has the capability to allocate the bandwidth fairly; however the OLT will begin bandwidth allocation computation after collecting the REPORT messages from all ONUs, thus introduce the idle period problems. Nonetheless, we prefer offline-paradigm since the OLT takes into account all ONUs request, and therefore the process of bandwidth allocation can be globally optimized. Based on aforementioned advantages of offline-paradigm, we propose offline limited-DBA scheme that support the Inter-ISP traffic with four priority queues at each ONU, which are EF, AF, BE and intra-ISP queues, respectively

#### B. Passive Splitter

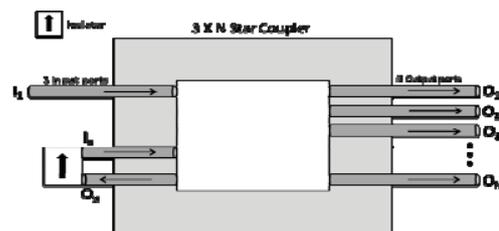

Figure 2. 3xN Star-Coupler (SC)

The passive splitter module is shown in Figure 2. An optical signal introduced into any input port is distributed to all output ports. Our SC design consists of 3:N ports, where two input ports (i.e.,  $I_x$  and  $O_x$ ) of it are connected to each other through an optical isolator as shown in Figure 6. The function of this is to redirect the upstream traffic back from  $O_x$  to  $I_x$  and broadcast to all ONUs through the  $N$  output ports.  $I_1$  is used for the downstream input port channel from OLT to all ONUs and vice versa. The  $O_1, O_2, \dots, O_N$  output ports are also used to broadcast signals to each ONU from the OLT. Finally,

the optical isolator is used to allow the transmission from  $O_x$  to  $I_x$  in only one direction and to prevent unwanted feedback.

### C. ONU Modules

Figure 3 shows the working principle of ONU mechanisms that an ONU has six different modules - packet classifier, ingress rules, buffer-map management, routing mechanism, uplink scheduling and reporting queue mechanism. First, when the user request arrives at the ONU, the packet classifier will check the request; whether it is Intra-ISP traffic or Inter-ISP (i.e., EF, AF and BE queue) traffic based on the routing table and ingress rules. Afterwards, all the requests will be mapped into the queues (i.e., EF queue, AF queue, BE queue and Intra-ISP queue). Finally, the intra-uplink scheduling will decide when to send all the queues report to the OLT to satisfy all the traffic types. In this paper, the Priority-Queuing (PQ) is used for the intra-uplink scheduling. In a PQ, traffics are divided into  $K \geq 2$  classes numbered 1; 2;...;K. The lower the priority, the higher the class number would be. In other words, priority  $i$  traffics are given preference over priority  $j$  traffics if  $i < j$ . In the case of our proposed intra-uplink scheduling, the EF traffic have the highest priority along with intra-ISP traffic, followed by AF and BE traffic, respectively.

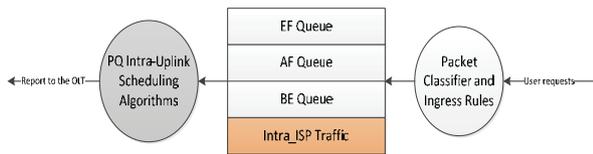

Figure 3. PQ Scheduling Mechanism at ONU

## IV. Performance evaluation

TABLE I  
SIMULATION PARAMETERS

Parameters	Value
Number of ONUs in the system	32
Upstream/ Downstream link capacity	1Gbps
OLT-ONU distance (uniform)	10-20km
ONU buffer size	10MB
Maximum transmission cycle time	1ms
Guard time	5μs
DBA Computation time	10μs
Control message length	0.512μs

In this section, we show the results of our simulation experiments conducted to evaluate the packet delay of Intra-ISP and Inter-ISP as well as the system throughputs. The scenario of the simulation includes the downstream and upstream channels that are set to 1 Gb/s; the distance from ONU to OLT ranges from 10 to 20 km and each ONU has a finite buffer of 10 Mbytes up to 20 Mbytes; and the traffic modeling is self-similarity and long-range-dependence (LRD) to generate highly bursty BE and AF traffic classes with the Hurst parameter of 0.7 and packet sizes are uniformly distributed between 64 and 1518 bytes. Moreover, the high-priority traffic (e.g., voice application) is based on Poisson distribution and the packet size is fixed to 70 bytes [14].

Finally, we the traffic proportions of aforementioned traffics are followed [15], which stated that approximately 40% of total traffics are used for video data. In this paper, we just assumed that 14% of the AF traffics are Intra-P2P-live streaming. Table I summarizes the simulation parameters.

### A. Packet Delay

Figure 4 shows the packet delay for 32ONUs with “244” traffic proportion (i.e., 20% of EF, 40% of AF, and 40% of BE) versus the offered load. It can be observed that the Intra-ISP packet delay has the highest packet delay. The reason is that in our proposed DBA as mentioned above, the Intra-ISP traffic will be postponed until a given cycle time condition is satisfied (i.e., ten percent of cycle time). Although it has higher packet delay compared to the AF Inter-ISP traffic, however, the packet delay is kept below 3ms which still can satisfied the P2P live streaming packet delay requirement. Finally, our proposed scheme can also reduce the AF inter-traffic load, thus decreasing the packet delay. This is because in the proposed architecture some packets are redirected back due to the locality awareness in ONUs.

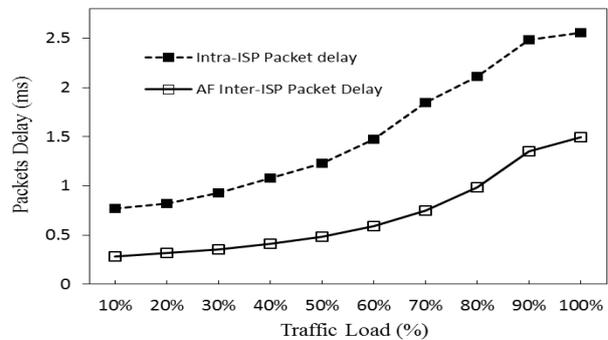

Figure 4. Packet Delays

### B. Bandwidth Waste

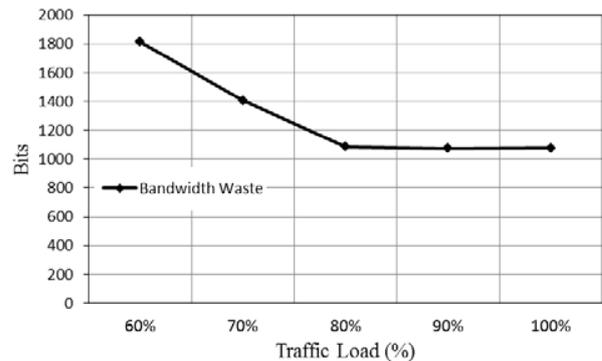

Figure 5. Bandwidth Waste

Bandwidth waste is occurred because there are differences between the grant and report timeslots. It means that the OLT could grant more than the requested timeslots from each ONU. As can be seen in Figure 5, when the network load is high the bandwidth waste is decreasing. This fact might happen because we adopt the limited DBA for our proposed DBA (i.e., limit the maximum timeslots for each

ONU). Therefore, when the offered load is high most of each ONU timeslot will be filled, thus the bandwidth waste is reduced. Moreover, bandwidth waste also might happen since we calculated the intra-ISP traffic based on the RTT between ONU to OLT, although it's supposed to be ONU to ONU which is less than the distance between ONU to OLT. Noted that the grant message is calculated as: report timeslots of  $ONU_i + RTT(ONU_i \text{ to OLT}) + \text{guard time}$ . The reason why we used the RTT between ONU to OLT instead of RTT between ONU to ONU is that we want to keep the conventional DBA working principles. Nevertheless, the bandwidth waste is approximately below 1200 bits when the traffic load is 100%.

### Conclusion

This paper has proposed P2P Locality Awareness Architecture in Ethernet Passive Optical Networks. In the proposed architecture we implemented the ISP Information interface in the OLT. This interface will try to reduce the traffic from each peer within its domain by discovering their Autonomous System (AS) number and Round-Trip-Time (RTT) estimation so that the peer most likely will prefer to connect with a local peer in the same AS or ISP with a small upload capacity than external peer with higher upload capacity. Simulation results have shown that our architecture has good system performance in terms of packet delay and bandwidth waste.

# On Robotic/Tactical Behavioral Layer of an Agent in a Continuous Topography Agent Base Model for Traffic Simulation

Ade Jamal

Department of Informatics, Faculty of Science and Technology  
 University Al Azhar Indonesia  
 Jakarta, Indonesia  
 adja@uai.ac.id

**Abstract**—Development of traffic simulation software has been being interest of scientist and engineer from different field since the year '50. Various approaches have been used to model the simulation, from the very old one, the macroscopic model to the relatively new model, namely agent based mode in the framework of microscopic model where every single vehicle processes as function of time. Hybrid microscopic approach by incorporating cellular automata with agent based model has got many attentions in the last decade. The most recent technique, namely a continuous topography where agent based model is combined with finite state automata gain, is discussed here. Layer architecture for agent model is invoked here to make the complex system more clearly to understand. One of the layers will represent the tactical behavioural layer on which the finite state machine will be applied. The dynamic process of a sample of complex manoeuvre will be discussed briefly using statechart and sequence diagram.

**Keywords**—traffic simulation; agent based model; finite state machine;

## I. Introduction

In the earlier phase of research and development of traffic simulation software, a macroscopic model based on continuum hydrodynamic kinematic law was used where traffic flow is described as continuum. Modern traffic simulation has been being studied and developed based on microscopic model where trajectory of every single vehicle is calculated as function of time. Since the influences of mathematicians and computer scientist on the traffic simulation research are getting more significant, two important techniques, namely the cellular automata (CA) and the agent based model (ABM) have been incorporated in this research area. CA was first time used in the microscopic traffic model by introducing the two lane model with periodic boundary conditions [1]. The combination of CA and ABM was later on incorporated to model pedestrian movement using regular square structured multi-grid topography [2].

Traffic participant movements are directed by topography model of the traffics environment. In the CA based two- or multi-lane model, vehicle's movement can take place in two ways, first completely unrealistic sideway and forward [1]. On the more complex regular grid structured topography using

CA and ABM combination, traffic participants basically can move in any direction depending on the grid cell shape and size. Using hexagonal shaped cell gives more possibilities of movement direction than using square shaped cell. Furthermore, the smaller the cell size, the more accurate the movement trajectory can be modeled. Making more complex cell shape and smaller cell size requires significantly extra computational resources in term of power and memory.

The CA based traffic model is received many interests during 90's as it can run large and relatively complex traffic simulations such urban traffic with only comparatively low computational resources [3]. As the strength of CA model is efficiently used of computer resources, then the previously improvement by increasing cell shape complexity and using smaller cell size should not be followed. Ulf Lotzmann [4] has proposed a completely other approach by introducing a continuous topography model. In this model, agent based system is still retained but cellular automaton principle is thrown away. The finite state automata takes place the role of CA to control the agent behavior.

The present research will study this new model of topography as has been shown in the previously published paper that the model of lane changing movement in the new approach needs more complex mathematical model comparing that the old CA based model [5]. This paper will focus more in the finite state machine of the tactical agent's behavioral layer where all physical layer of agent will be determined autonomously.

## II. A Continuos Topography Agent Based Model Traffic Simulator

The traditional approach of microscopic model based for traffic simulation was modelled as single lane, i.e. the system consists of a one dimensional grid with periodic boundary. Two basic models are very often used i.e. car-following model [6, 7, 8, and 9] and lane-changing model [6] in the microscopic single lane model. Later on a mathematicians and physician scientist [1] has incorporated cellular automata (CA) to introduce a two lane model consisting of two parallel single

lane models with periodic boundary conditions and additional rules defining the exchange of vehicles between the lanes. This CA approach lasts not longer than one decade in the year 90's, until software scientists introduced the so called agent based model (ABM) to traffic simulation software [10]. The ABM approach has been a successful technique in the recent traffic simulator software in the last decade [11,12].

Dijkstra [2] has combined CA and ABM to model pedestrian movement using a regular grid based topography model. While in the single or multi-lane microscopic model, traffic participant can only move forward or lateral only in every (sub)-step, in the regular grid structure CA based topography, any traffic participant can move in any direction as long as no obstacles blocking the movement depending on the grid shape and size. In contrary to CA model where its topography is characterized by regular grids in various forms e.g. square or hexagonal shape, the current approach takes a continuous topography hence the agent is able to move more freely and independent from any restriction such as grid shape or grid size.

An agent is an autonomous entity that cannot be controlled by external interference but and it perceives events from its environment and then react accordingly. How agent perceives and reacts to this perception must be governed by a logical system. In the case CA and ABM combination, a simple CA algorithm is invoked since the perception area covers only the neighbouring grid cell of the agent. In the continuous topography model, a communication system like a sensor system is used to receive any event's data only in the perception area as shown in Fig. 1 two agents are out of communication areas. In this case the simple algorithm incorporated by CA must be replaced by more complex finite state automata or finite state machine (FSM) as explained in [13].

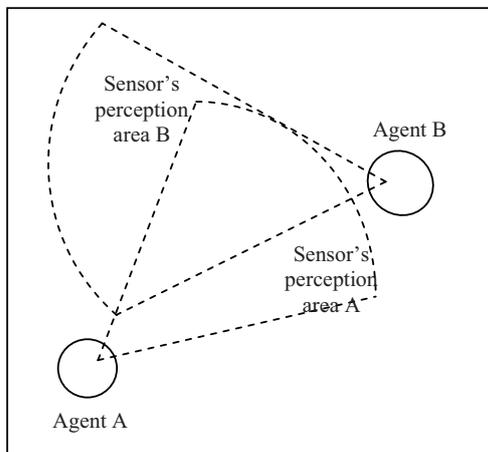

Fig. 1. Agent's communication system

Following the footprint of works in [4, 11, 14], the ongoing research [5, 15] distinguishes the agent model in two abstract layers, i.e. a physical layer and behavioural layers. The physical layer depicts the real-world attributes of an agent such as location coordinates, velocity, direction and other

physical parameters attached to the agent's entity. This physical layer is the only layer that has interface to outside world of agent, either for dynamic process or for visualization.

The behavioural layers model how the agent will behave in response to its environment. This layer is further separated into two functional layers, namely the operational behavioural layer and the strategic behavioural layer. The first layer is also called the robotic operative behavioural layer in [4, 14] or tactical layer in [11]. This tactical behavioural layer will interact directly with the physical layer describing the perception and reaction of the agent in a very short time. The second layer is the strategic layer which has an intelligent behaviour for decision making such as route selection. The strategic layer will perceive the robotics perception and then will provide an intelligent action to be performed by tactical layer accordingly. This intelligent layer is called Artificial Intelligent (AI) layer in [4, 14]. Figure 2 shows the agent model and the interaction within agent's layers and the topography. This article as described in the title will focus only in the tactical behavioural layer.

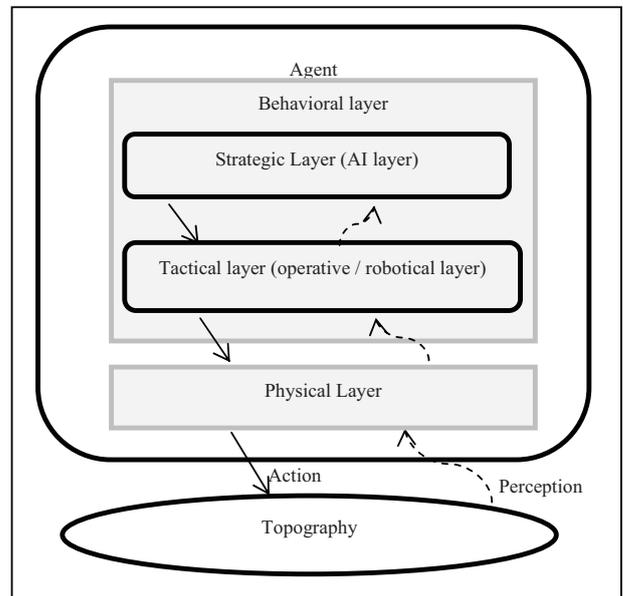

Fig. 2. Layer wise agent model and interaction with each layer and topography

### III. Agent's Tactical Layer

In [4] an agent can be taught as a reactive agent who has ability to interact with other agent but can only passively communicate. Hence the name "reactive" means that this type of agent cannot recognize its environment actively. The specialization of this reactive agent is a proactive agent that defined as subclass of reactive agent. The sub-class proactive agent is the most important agent as the most of traffic vehicles fall in this agent category. This type extends the reactive agent with capability to perceive events from the agent's environment and then react accordingly. In the present research, an agent will be distinguished in different manner,

i.e. passively immobile agent and actively mobile agent. The difference lies in the structural relationship where these two type agents are both sub-classes of a common abstract agent. Some of physical attribute will belong to the abstract class of agent, such as shape, position and sensors. Their capability will be different for each type, for sure the passive agents will not occupy a strategic behavior, but do have a tactical behavior however much simpler than the actively mobile agent.

The more complex tactical layer of actively mobile agent requires Finite State Machine (FSM) approach to model the autonomous dynamical process as can be represented by nested state chart diagrams [13].

#### A. Finite State machine

Finite State machine is an abstract machine that can be in one of a finite number of states but in only one state at a time, called current state. By a triggering event or condition, the state can be changed from one to another state; this process is called a transition. A particular FSM is defined by a number of its states and triggering event for each transition. For a complex machine, a particular state can consist of many sub states which form complete FSM in a hierarchy level. The state activity and action in the more complex state (super state machine), will trigger an event for a transition on the state machine below (sub-state machine) by supplying the state transition function and its input parameters. However, when the transition function cannot handle the input information for instance because of missing or unknown data, a trigger signal for state change on the automaton at the level above (its super state machine [13]) might be fired by the sub state machine.

The tactical layer of actively mobile agent is further split into three sub-layers, namely:

- Level one (the lowest level) represents basic actions which are usually conducted without thinking by humans (e.g. turning the steering wheel).
- Level two deals with activities composed of basic actions (e.g. hold the center of a lane).
- Level three subsumes all required plans for complex activities a human is aware of when executing (e.g. lane change operation).

The state activities on the lowest level directly modify the physical agent attributes during the lapse of time. Due to the time-discrete simulation model, the activities are adjusted for the duration of a discrete time step. Furthermore, state activity and transition function are executed at every time step. The transition functions for level three are provided by the AI strategic behaviour layer.

Each layer of robotic behaviour is equipped with a sensor communication and a perception filter processor. The filter is used to reduce the input data that are not significant to the state machine and in order to decide whether the information from the perception input data is not sufficient for underlying level.

#### B. Level One FSM

The first level of tactical layer consists of states that represent four basic actions which are normally done without thinking by human driver, namely:

- Idle: the vehicle remains steady in the current state. Speed  $v$  and heading direction  $\phi$  remain constant.
- Accelerated: the driver accelerates or decelerates the vehicle by accelerating intensity  $a$  to the desired speed  $v$ .
- Bent: the driver turns the steering wheel with the angular radius  $m$  in order to gain a new direction  $\alpha$  where linear speed  $v$  remains constant and the heading direction  $\phi$  is modified accordingly.
- Unsteady bent (accelerated and bent): combination of accelerate and bend where both linear speed  $v$  and the heading direction  $\phi$  are modified.

Fig. 3 shows the state chart diagram of the level one FSM for the four basic action, where for each underlying movement action a mathematical model based on Newtonian governing equation are given in [5, 15].

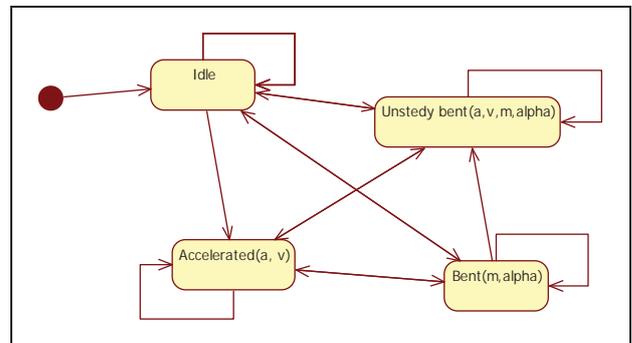

Fig. 3. Statechart diagram FSM Level One

#### C. Level Two FSM

The state at level two describes various basic driving manoeuvres, namely:

- Lane-Centered: the driver steers the vehicle in the center of a lane.
- Lane-Bordered: the driver steers the vehicle in the direction of the (left or right) lane border with the angle  $\alpha$ .
- Off-Lane: the driver steers the vehicle onto a topographic region not marked as a road (e.g. crossing, parking etc.), heading towards a target "tg" decelerated to desired velocity  $v$ .
- Turned: the driver steers the vehicle into a bend.
- Lane-Center & Lane-End-Ahead: the driver steers the vehicle in the center of a lane and reaches the end of the lane.

Fig. 4 shows the state chart diagram of the level two FSM for the five basic manoeuvres that in turns composed of basic actions from the level one FSM. Before each activity from level two will be triggered, a moderate calculation must be performed to determine some input parameters from the level one basic action based on the result of perception data from the environment. For instance Lane-Centred manoeuvres calculation is presented in [5], and the other manoeuvres will be presented in [15].

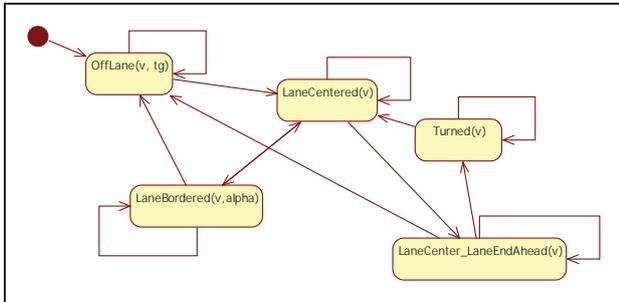

Fig. 4. State chart diagram FSM Level Two

#### D. Level Three FSM

Level three FSM will cover various complex driving manoeuvres, such as:

- Go-Ahead: the driver follows the course of the road with intended velocity  $v$  considering traffic rule and road situation.
- Lane-Changing: the driver performs a lane change to the left or right side according to parameter “direction”
- Cross: the driver passes an intersection with intended velocity  $v$ , heading towards outbound lane “out”
- Drop-Off: the driver stops the vehicle for short time along shoulder of the road (border lane), usually to drop off or pick up passengers.

Fig. 5 shows these four samples of complex manoeuvres in the state chart diagram of level three FSM. The level three manoeuvres can consist of one or more level two activities and will be explained later using sequence diagram.

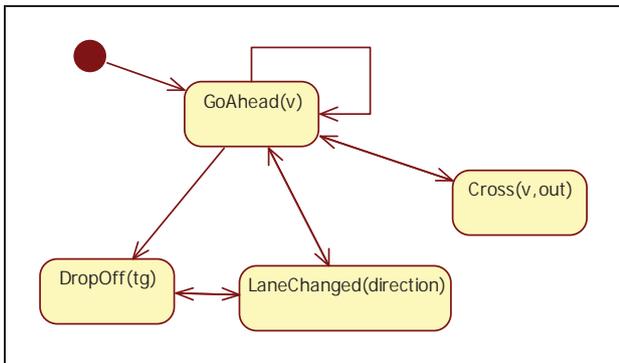

Fig. 5. State chart diagram FSM Level Three

## IV. Dynamic Process of tactical Behaviour Layer

In [14], an example of the complex manoeuvres of level three robotic layer, in this case the crossing capability of an agent. Here the other manoeuvres will be briefly discussed. The Fig. 6 shows a picture of a situation for a car traffic where agent a1 hindered by slower moving agent a2 ( $v_2 < v_1$ ). The current state of a1 is {L1: Idle; L2: Lane-Centred; L3: Go-Ahead}. The agent a1 have two possible actions i.e. changing lane to b2-b3 or following car agent a2. Fig. 7 depicts the dynamic process of lane changing movement as sample complex manoeuvres.

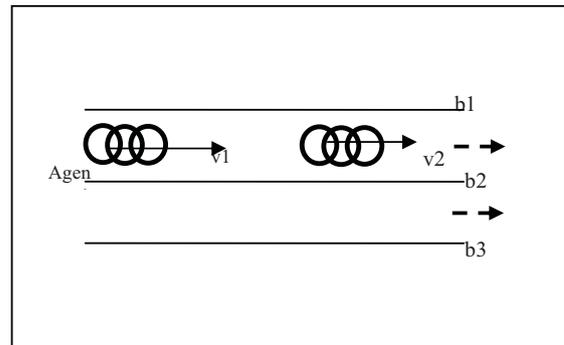

Fig. 6. Sample traffic situation two agents in one lane

## V. Conclusion

A new approach of agent based model traffic simulation software was discussed in this paper. There are two important differences in the new technique i.e. continuous topography in compare with the traditional cellular grid based topography and utilization of finite state automata in place of cellular automata. These two issues yield more complex mathematical model and computational model. A layered architecture is invoked in the agent model to make the model definition easier to develop and applying nested finite state machine gives a successful result.

The layer which describes how the agent will perceive and react to environment’s event and situation is named a behavioural layer. This layer is divided into tactically operative behavioural and intelligent strategic behavioural layer. The tactical behavioural layer, also called robotical layer is further split into three level of nested finite state machine, from the simplest movement, e.g. accelerating, in level one up to the most complex manoeuvres in the level three such as lane changing movement. How these three sub layers of tactical behavioural layer interact in the dynamic process of simulation are clearly described using sequence diagram.

**Abstract**—Transportation systems are complex dynamic systems that hard to be modeled exactly. The correct model need model verification and validation. This paper presents an improved discrete event simulation model of traffic light control on a single intersection. Model is developed using SIMULINK / SimEvent toolbox provided by MATLAB. We proposed the improved model using controller with two input switches and two output switches combined with traffic signal logic block. In this research, the fixed time controller algorithm is located within traffic signal logic block. The intersection model uses four approaches, and each approach consists of one through stream and one right turn stream. Each stream is modeled as an M/M/1 queue. FIFO discipline is applied to the vehicles queue in each stream. Inter arrival time between vehicles is modeled using exponential distribution. Model validation is done in two different scenarios of inter-arrival time between vehicles 15 s (for low traffic volume), and 5 s (for high traffic volume) respectively. Experiment results show that the number of vehicles in queue and average waiting time of low traffic volume is lower than high traffic volume. That means the model has functioned correctly.

**Keywords**—discrete event model; traffic light control; single intersection; validation; distribution

## I. INTRODUCTION

Transportation systems are complex dynamic systems that hard to be modeled exactly [1]. For this reason, many current methods do not have good theoretical bases. However, without modeling the system appropriately, the characteristic of transportation system cannot be identified correctly. Furthermore, it is hard to evaluate existing algorithms and to recognize potential problems and improve them. The model needs to be verified and validated. A model should be developed for specific purpose and its validity determined with respect to that purpose [2]. So far as we know most existing research works [3,4,5,6,7,8,9,10,11] have developed the single intersection model for implementation of the specific algorithm. Moreover those research works did not describe how to develop the model and how to perform validation.

Consider the simplified version of the model development process in Fig. 1 [2]. The problem entity is the system (real or proposed), idea, situation, policy, or phenomena to be modeled; the conceptual model is the mathematical / logical / verbal representation of the problem entity developed for a particular study; and the computerized model is the conceptual model implemented on a computer. The conceptual model is developed through analysis and modeling phase, the computerized model is developed through a computer

programming and implementation phase, and inferences about the problem entity are obtained by conducting computer experiments on the computerized model in the experimentation phase.

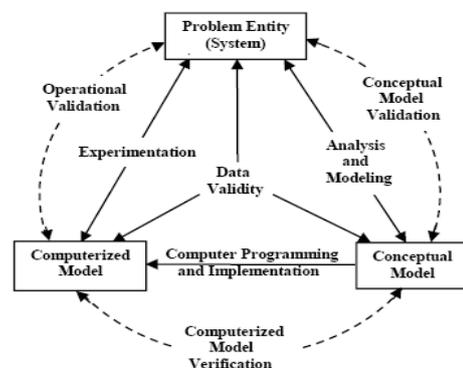

Fig. 1. Simplified version of the modeling process [2].

This research has two goals:

- Propose the improved traffic light discrete event simulation model using controller with two input switches and two output switches combined with traffic signal logic block. In this research, the fixed time controller algorithm is located within traffic signal logic block. The advantage of this model is that it can be used to test any traffic light algorithm without major modification and also can be modified to fit for real system.
- Validate model through evaluation the number of vehicles in queue and average waiting time.

## II. DESCRIPTION AND MODEL OF SINGLE INTERSECTION

### A. System

The real common intersection consists of four approaches (east, west, north and south) [3,4,5,6,7,8,9,10,11] with two or three streams in each approach. The approach that consists of three streams [3,6,8,9] are one through stream, one right turn stream and one left stream while the approach that consists of two streams [4,5,7,11] are one through stream and one right turn stream. The signalized intersection is equipped with a fixed time traffic control system.

### B. Conceptual Model

The traffic light control on a single intersection model shown in Fig. 2 is designed based on the real traffic light system. In this model, there are four approaches (east, west, north and south) with total 8 streams. Each approach consists of two streams are one through stream and one right turn stream. At this time pedestrian crossing and the left turn stream are not considered. The input flow rates in each stream are assumed to be provided by sensors accurately.

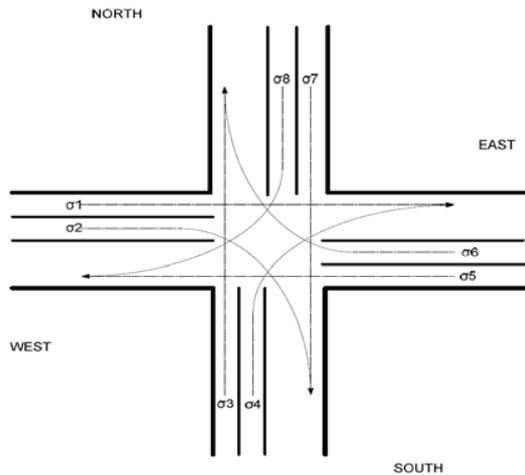

Fig. 2. Single intersection traffic stream model.

Each stream is modeled as an M/M/1 queue (based on Kendall notation) and it is built based on the three main concepts in queuing theory which are customers, queues, and servers. The first and the second M in M/M/1 stand for “memoryless” distribution of interarrival time and service time, respectively. The “1” indicates that the single intersection has single server with specific service time.

First-In-First-Out (FIFO) discipline is applied to the vehicle queue in each stream. From queuing theory, the vehicles in this model are known as customers while service time is the time for the vehicles to depart from queue and to cross the intersection in their own stream.

Based on research works [4,6,8,12], the characteristic of arrival traffic according to Poisson process. Many other models have been used for describing the arrival process of vehicles on the approach. However, most of them are more complex, but the Poisson model is still used for most practical purposes [12]. With Poisson flow, the probability of arrival of  $m_i$  vehicles of traffic stream  $\sigma_i$  to an intersection, during interval  $\tau$ , is expressed by the equation [12]:

$$P_{m_i}(\tau) = p[m_i \text{ vehicles arrive in interval } \tau] = \frac{(q_i \tau)^{m_i}}{m_i!} e^{-q_i \tau} \quad (1)$$

$q_i$ : constant, arrival rate

The interarrival times for a Poisson process with rate  $q_i$  are IID (Independent and Identically Distributed) exponential random variables with mean  $1/q_i$ . The Poisson model is good for describing the real arrival process on an intersection

approach in the case when the ratio between volume and approach capacity is not high [12].

Modelling each stream as an M/M/1 queue is still suitable for real traffic system that observed, since the intersections or network that we are observed is a single intersection with not too high traffic volume. If the network is large with huge traffic volume then the suitable model is Stochastic Fluid Model-SFM [13]. Based on research [1,3,4,5,6,8] and much more, the number of vehicles and the average waiting time in each stream are popular performance indices for traffic light signal control.

Traffic light control is divided into four signal groups (D1, D2, D3, D4), that are D1: for approach west (stream 1 and stream 2), D2: for approach south (stream 3 and stream 4), D3: for approach east (stream 5 and stream 6) and D4: for approach north (stream 7 and stream 9). A signal group is the set of traffic streams that are controlled by identical traffic light indication. If a signal group is active it means green light indication. Green light indication for vehicles means allowed passage the intersection, while red light indication means forbidden passage. In this research, sequence and duration for signal groups is determined using fixed time algorithm.

Fig. 3 shows the sequence and duration of signal groups. Label “1” indicates the signal group is active while label “0” is not active. The durations of signal group are labeled  $t_1, t_2, t_3,$  and  $t_4$  for signal group D1, D2, D3, and D4 respectively. In this simulation the durations of each signal group are 100 s.

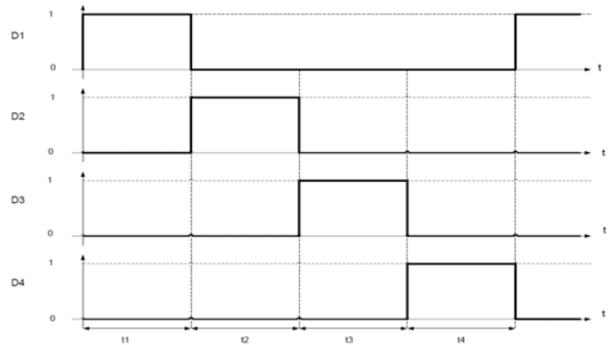

Fig. 3. Signal group

### C. Computerized Model

The single traffic intersection model developed in MATLAB using SIMULINK and SimEvent toolbox is shown in Fig. 4. SimEvents software incorporates discrete-event system modeling into the Simulink time-based framework, which is suited for modeling continuous-time and periodic discrete-time systems [14]. In time-based systems, state updates occur synchronously with time. By contrast, in discrete-event systems, state transitions depend on asynchronous discrete incidents called events. Since we are interested in the number of vehicles and the average waiting time in each stream and we are not interested in the details of how an vehicle move and cross the intersection-for example-then we can use discrete-event simulation.

The discrete event simulation model of traffic light control on a single intersection in this research is an improvement model from discrete event model that developed by Devdatt Lat [15]. The improvement that we are proposed is using two input switches and two output switches that controlled by Traffic Signal Logic block as implementation of traffic light control algorithm, and modeling each traffic stream in each approach (see also Fig. 2) with using a time based entity generator (for generation of customers), a queue and a server. As describe at paragraph above, each stream is modeled as an M/M/1 queue and traffic arrival is modeled by inter arrival between vehicles using exponential distribution. First-In-First-Out discipline is applied to the vehicles queue.

Fig. 4 shows the signal group D1, D2, D3 and D4 are implemented using input port IN1, IN2, IN3 and IN4 at input switch 1 and input switch 2 respectively. The sequence of input port of input switch 1 and 2 is controlled by the output signal of traffic signal logic block that connected to the input port "p" of input switch. Output switch 1 and 2 have function so that the customer (vehicle) can arrive at the approach destination.

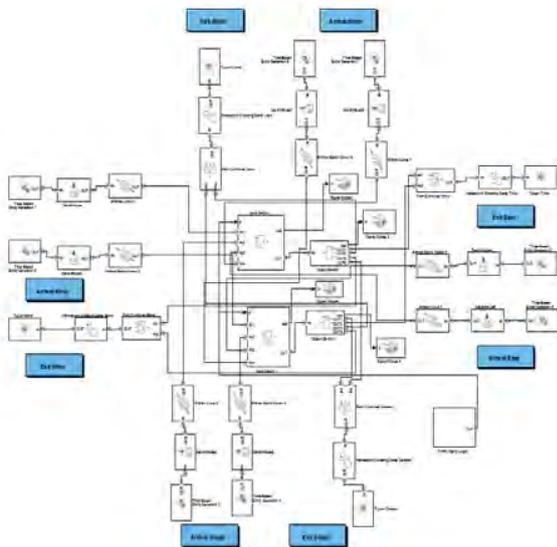

Fig. 4. Simulink / SimEvent block diagram of single intersection traffic model.

Inside Traffic Signal Logic Block (in Fig. 5), the duration of green time is determined by Event Based Sequence block and then executed by server block. The sequences of Signal Group activation are determined by another Event Based Sequence 1 block. The output signal of traffic signal logic block (from output port of the signal latch block) will control the sequence of input port activation of input switch 1 and input switch 2. Since the model implemented using Simulink / SimEvents, model verification through with ensuring that an error free simulation language has been used.

The advantage of this model can be used to test any traffic light algorithm without major modification of the model since traffic light algorithm located within a traffic signal logic block.

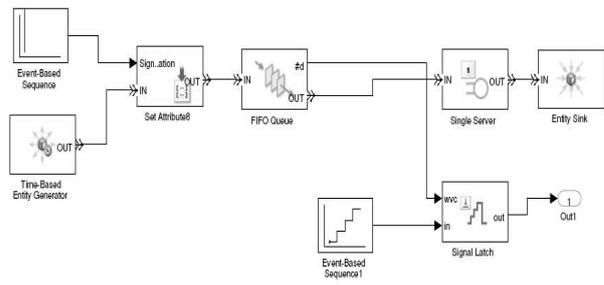

Fig. 5. Traffic signal logic block diagram

### III. RESULTS AND DISCUSSION

The objective of this simulation is to validate the model that has been built if the output simulation of the model has the same characteristic with the real traffic light control system. The outputs of the simulation that we evaluated as performance indices are the number of vehicles in queue and average waiting time in each stream. The simulation time is 1000 s. Duration each signal group D is 100 s and two different scenarios of inter arrival time between vehicles are 15 s (for low traffic volume), and 5 s (for high traffic volume) for all stream respectively.

Fig. 6 shows the numbers of vehicles in each queue using inter arrival time 15 s in stream 1 (red curve) and 5 (blue curve). From the figure it looks if the signal group of stream is active, the number of vehicles in the queue will be reduced compared to the inactive group signal. For clarity we take an example, stream 1 gets an active group signal (D1) for a duration of 100 s first, then the number of vehicles in the queue a bit. For time 100 s to 400 s where the signal group of stream 1 is not active (see also Fig. 3), the number of vehicles continues to grow. At the time of 400 s to 500 s, when the signal group is active, the number of vehicles is reduced. The number of vehicles increased again when the time 500 s to 800 s are currently no active signal group again and so on. The same characteristics were obtained for the other streams.

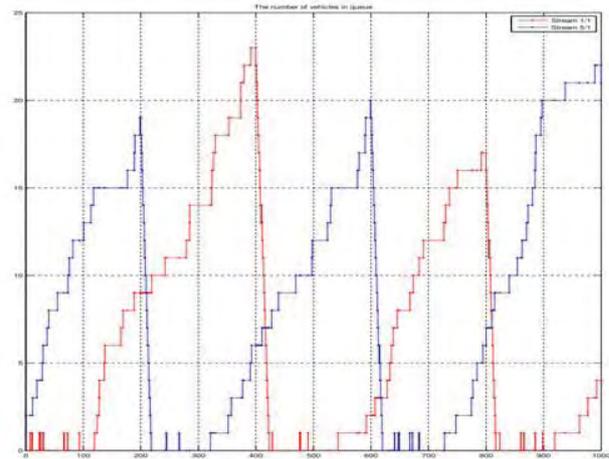

Fig. 6. The numbers of vehicles in each queue using inter arrival time 15 s.

If the inter arrival time between vehicles converted to 5 s, then the number of vehicles coming into the queue increasingly or high traffic volume. It resulted in the number of vehicles in queue greater than if inter arrival time between vehicles 15 s or low traffic volume. These characteristics are shown in Fig. 7. For example again, few the number vehicles in the queue of stream 1 (red curve in Fig.7) at time 0 s to 100 s. For time 100 s to 400 s when the signal group of stream 1 is not active the number of vehicles continues to grow. At the time of 400 s to 500 s, when the signaling group is active, the number of vehicles is reduced. The number of vehicles increased again when the time 500 s to 800 s are currently no active signal group again and so on. The same characteristics were obtained for the other streams. In Fig. 7 shows that the decrease of the number of vehicles in the queue (at the time of signal group is active ) is lower than in the scenario inter arrival 15 s (see Fig. 6). It is caused to the addition of vehicles to the queue is greater than the speed of vehicles crossing the intersection that simulated by setting service time 5 s.

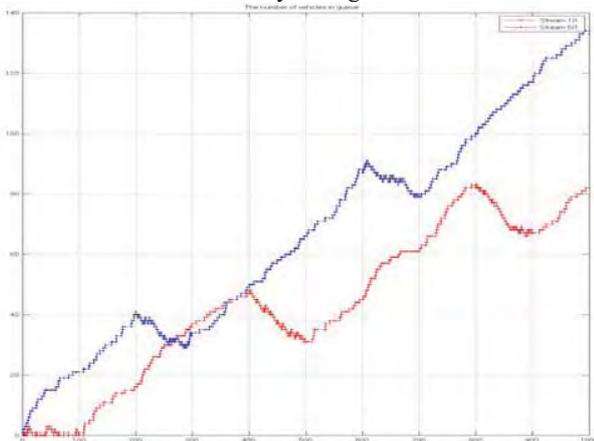

Fig. 7. The numbers of vehicles in each queue using inter arrival time 5 s.

Fig. 8 shows the average waiting time in each queue using inter arrival time 15 s in stream 1 (red curve) and 5 (blue curve). The MATLAB will update the average waiting time in queue for all entities (customers) that have departed from the queue. The customers will depart the queue if the signal group of the stream is active. For an example, stream 1 gets an active signal group (D1) for a duration of 100 s first, then the waiting time in that queue is very short. For time 100 s to 400 s where the signal group of stream 1 is not active, MATLAB does not update the average waiting time. At the time of 400 s to 500 s, when the signal group is active, it appears waiting time increases as the number of vehicles from the 100s to 400 s to grow. That increasing of the waiting time is till to a certain limit and then decreases again. Same characteristics occur at time 800 s to 900 s. The same characteristics were obtained for the other streams.

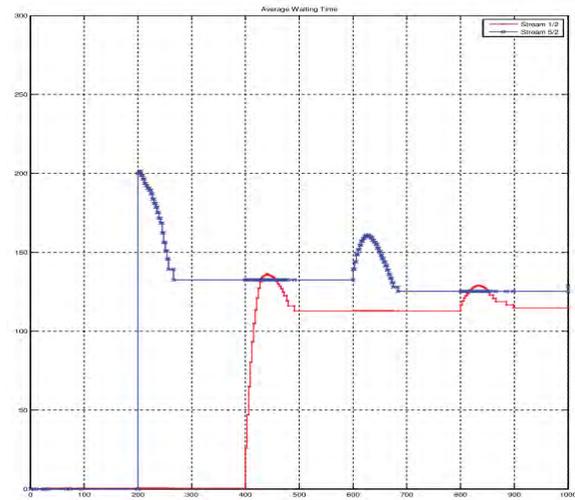

Fig. 8. The average waiting time in each queue using inter arrival time 15 s.

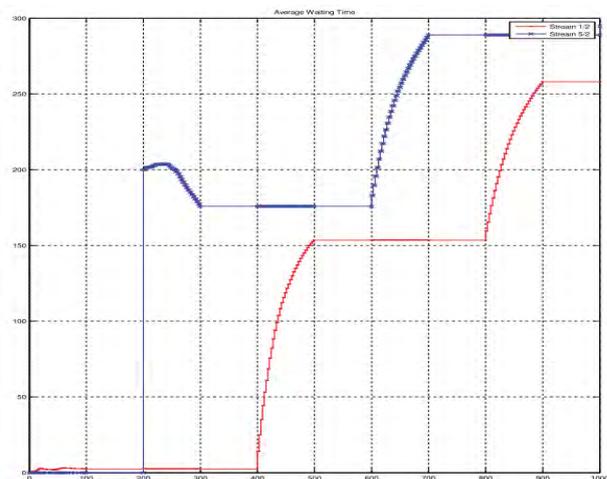

Fig. 9. The average waiting time in each queue using inter arrival time 5 s.

Fig. 9 shows the average waiting time in each queue using inter arrival time 5 s in stream 1 (red curve) and 5 (blue curve). As described for Fig. 7, if the inter arrival time between vehicles converted to 5 s, then the number of vehicles coming into the queue increasingly or high traffic volume. It resulted in the average waiting time in queue is greater than if the inter arrival time between vehicles 15 s or low traffic volume. For example, it is clear the waiting time in the queue of stream 1 at time 800 s to 900 s longer than the waiting time in the scenario of inter arrival time 15 s (see also Fig. 8). The same characteristics were obtained for the other streams.

#### IV. CONCLUSION

This paper proposed an improved discrete event simulation model of traffic light control on a single intersection. The improvement of the model is to use the controller with two input switches and two output switches combined with traffic signal logic block. Based on queuing theory, the model is easy

to develop using SIMULINK / SimEvent toolbox in MATLAB.

The simulation has shown that the model has functioned correctly. Experiment results also have shown that the number of vehicles in queue and average waiting time of low traffic volume is lower than high traffic volume. But it has to be configured carefully for service time at each server. The model can be extended further for multiple intersection and will be extended further in our ongoing research on using adaptive traffic light control algorithm.

**Abstract** — Roller element bearings is one of the vital parts of the machine elements that hold an important role. A machine can be very dangerous if a defect occurs on the bearing performance during the operation. Therefore a fault detection is important to prevent damage to other components of a machines. Various technique have been proposed for fault diagnostic of rolling element bearings. This paper investigate the fault detection and diagnosis for rolling element bearings from the vibration datas that are classified based on similarity of the data. An Intelligent system using Radial Basis Function Neural Network (RBFNN) created. RBFNN is a method used for data classification. It works faster than the back propagation that takes time. Furthermore RBFNN is appropriately used to large data. Gaussian is used as activation function of this RBFNN. The result shows the extent of the fault that occurs in rolling element bearing.

**Keywords**—*Intelligent System; Fault diagnosis; Rolling element bearings; RBFNN; vibration data.*

## I. INTRODUCTION

The usage of rotating machines increases in industrial world recently. Roller element bearings is one of the vital part of rotating machines. Roller bearings are normally used in heavy duty applications such as conveyor belt rollers, where they must hold heavy radial loads (Rao et al.,2012). Machine failure can lead to economic loss and safety problems due to unexpected and sudden production stoppages, therefore an early detection become important for rolling element bearing failure to prevent the damage to the other components in an industrial machine (Yang et al., 2004).

The object of this paper is enrich the study about Radial Basis Function Neural Network (RBFNN) in diagnosing rolling element bearings failure for the performance of the machine. Implementation of the artificial intelligence technology should be considered as investment in science especially in industrial world that provide the benefits for the company.

Following this introduction, section 2 of this paper presents defect problem and literature survey. Section 3 explain why choosing RBFNN and building the classifier.

Section 4 prepare data, training and testing, while section 5 is the conclusion.

## II. LITERATURE SURVEY AND PROBLEM DEFECT

### A. Literature Survey

Data used for classification is rolling bearing vibration data were measured using Acceleometer. The process of traditional condition monitoring and fault diagnosis can be summerized as : data acquisition, data processing, data analysis and decision making. Data represented as features that provides a best solution for classification problem that greatly reduces the requirement of transfer number and save storage space. that data are compressed as feature from many domain with keeping data information as high as possible. relative technique come out such as feature representation, feature extraction and feature selection (Widodo, 2005). Fig .1 below is illustrated the typical feature –based condition monitoring and fault diagnosis structured.

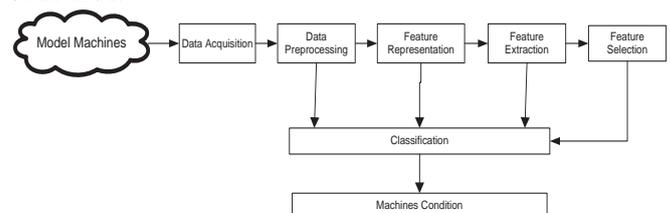

Figure 1: feature-based condition monitoring and fault diagnosis system

Data acquisition is a process of collecting and storing useful data from targeted engineering assets for the purpose of condition monitoring and diagnosis. After collecting the data, we go to data preprocessing, data preprocessing is a purge of the data that has been measured before it is processed. It aims to create a better quality of data. Feature extraction is an important step in recognition system, which directly depends on the classification performance of feature selection and extraction. The main benefit of feature extraction is to eliminate redundancy or repetition of data that represent a form of character by a set of numerical feature (wiley, 2005).

B. Problem Defect

The diagnosis of rolling element is based on inspection defect that occur. Defect in rolling element bearing can be categorized as localized and distributed defect. Localized defects include cracks, holes and fragments which is caused by fatigue in the round surface. Other categories are distributed defects, including surface roughness, waves on the incorrect surface and track and the rotary elements that have been worn.

Bearing faults can be categorized into distributed and localized defects. Distributed defects affect a whole region and are difficult to characterize by distinct frequencies. In contrast, single-point defects are localized and can be classified according to the following affected element (Vas (1993), Tandon and Choudhury (1997), Nandi and Tolitat (1999), Stack, Habetler and Harley (2004).

- Outer raceway defect
- Inner raceway defect
- Ball defect and Cage fault
- Surface irregularities, misaligned races, cracks, pits and spalls on rolling surfaces

III. BUILDING CLASSIFIER

Several methods known in the statistical classification of machine learning method. Neural network is one of the methods in machine learning which has a better capability than the statistical method.

Radial Basis Function Neural Network (RBFNN) is a neural network model with one unit in the hidden layer. Radial basis function neural network is a feed forward neural networks that are specific to transform a non-linear input to the hidden layer is further processed linearly at the output layer. The architecture of RBFNN can be seen in figure 2 below :

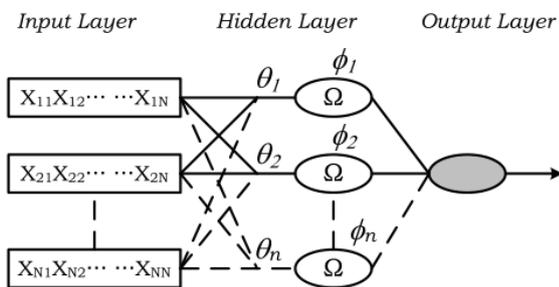

Figure 2 : Architecture of RBFNN

RBFNN can be applied to various domains such as modeling problems like time series data, classification, etc. RBFNN has advantages such as considering the overlap between training data vectors from different categories, so bias can be avoided. Moreover for a large training data are

not slowing its ability. So that's why RBFNN is suitable for the classification process that involves large data sets

Data obtained from the rolling bearings vibration data can be divided into 8 classes. 8 class selected based on the fault condition that often occur in rolling element bearings. 8 damage are Broken rotor bar, Bowed rotor, Faulty bearing, Rotor unbalanced, Eccentricity, phase unbalance, misalignment and normal motor data. Normal motor data is not kind of fault condition in a rolling element bearing, its just a normal data that aims to compare fault and normal data.

The use of RBFNN method above is to classification process. There are some of radial basis functions, such as Thin Plate Spline Functions, Multikudratik Functions, Inverse Functions and Function Multikudratik Gaussian. Radial basis function chosen is Gaussian Function, because it has a local nature that is if the input is close to the average (center), then the function will return the value 1, while if the input away from the average then the function will give a 0 value. Gaussian function is one of the radial basis function that gives the best results in pattern recognition.

The following is the equation of Gaussian Function :

$$\phi(z) = \exp\left[-\frac{(z-\mu)^2}{\sigma^2}\right] \quad (1)$$

Where,  $z$  is the data,  $\mu$  is the means and  $\sigma$  is the variance / standard deviation.

The classification procedure using the trained RBF is describe in figure 3:

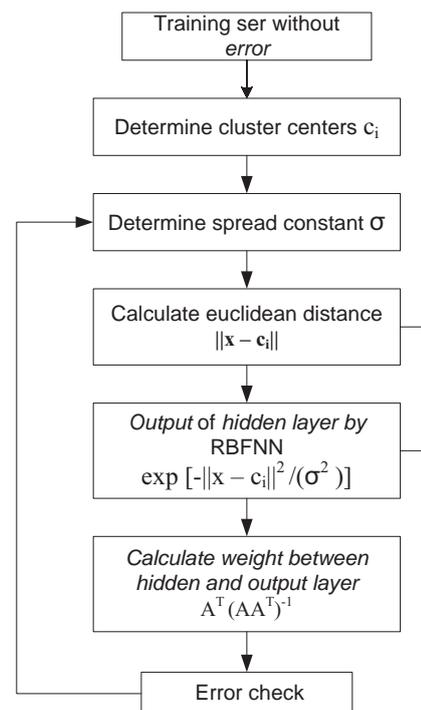

Figure 3: Flowchart of RBFNN

By looking at the model design RBFNN (figure 2), then the output can be defined by equation (2) below :

$$y = F(x) = \exp [-\|x - c_i\|^2 / (2\sigma^2)] \quad (2)$$

Where  $\mathbf{x}$  is the input vector of the network,  $\mathbf{c}_i$  is the  $i$ -th center vector, then  $\|\mathbf{x} - \mathbf{c}_i\|$  is the distance between the input vector to the center vector.  $\|\cdot\|$  is the euclidean norm distance, while  $y$  is the output of radial basis function.

Figure 3 explain how to get output of hidden layer. Cluster center  $\mathbf{c}_i$  can be found using k-means clustering algorithm. Since the used of gaussian function, the value given that are close to cluster center is 1 and the value that are far from cluster center is 0. Euclidean distance can be found by input vector minus cluster center. Output layer can be calculated with eq.2 while the weight of neuron calculated using eq.3.

Weights of neurons between the hidden and output neuron is calculated using equation (2). Where is the pseudo inverse has the same role as the network with the method of least mean square (LMS).

$$y = \mathbf{W}\mathbf{A}(\mathbf{x}, \mathbf{c}), \quad \mathbf{W} = \mathbf{y}\mathbf{A}^T (\mathbf{A}\mathbf{A}^T)^{-1} \quad (3)$$

Where  $\mathbf{W}$  is the weight matrix,  $\mathbf{A}$  is the output of the hidden layer and  $y$  is the output of the output layer.

This 2 figures below (fig.4 and fig. 5) are shown the results plot of random data and real data are classified into 8 classess

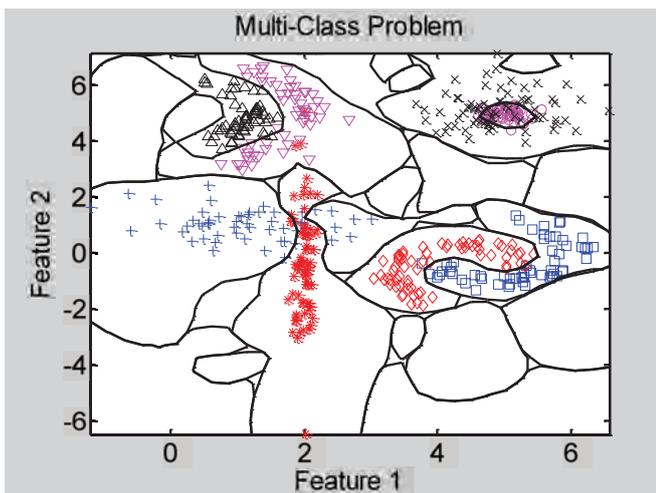

Figure 4 plot of random data

Figure 5 shows the result plot of real data are classified into 8 class.

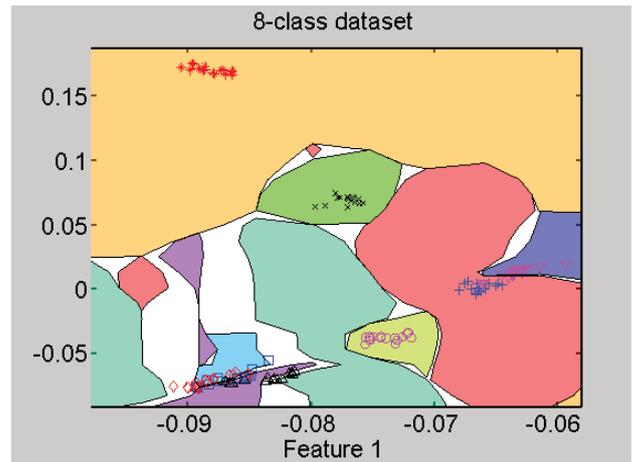

Figure 5 plot of real data

Figure 5 is 2 dimensional plot of vibration datas of rolling element bearing that already classified using RBFNN. From the figure we know that data are classified into 8 classes.

#### IV. DATA TESTING AND ANALYSIS

##### A. Data Testing

Obtained form the matrix data format is [160x5], where 160 is the data and 5 is a feature that has been reduced from 21 features using PCA. of 160 data classified into 8 classes where each class contains 20 datas. From the 20 datas then selected 16 datas for training and 4 datas to testing.

The error system can be detected by processing the data testing using RBFNN algorithm, where the valid data is divided by the number of data and then multiplied by 100%.

$$e = \frac{\text{number of misclassify}}{\text{number of data test}} \times 100\% \quad (4)$$

The accuracy is  $1 - e$

##### B. Analysis

By testing the process it was found that there are data that misclassify or out of the target class. Result shows that from the 8 classes, 3 classes have 100% accuracy and 5 classes shows different misclassification in a class. Overall the number of misclassify data is 5. Accuracy can be found by getting the number of error data first, and the result is 1 minus number of error data. The accuracy is 84,375%.

#### V. CONCLUSION

Rolling bearing damage can be fatal and resulted in an expensive termination fees. Therefore the process of rolling bearing monitoring is important for the maintenance of machinery and process automation. The process of monitoring the condition of the bearing

performance becomes something important for diagnosis. With the diagnosis of the damage is expected to facilitate the action or the treatment of the machine. Thus, the next will be able to improve the effectiveness, efficiency on machine performance. RBFNN has advantages such as considering the overlap between training data vectors from different categories, so bias can be avoided. Moreover for a large training data are not slowing its ability. RBFNN is suitable for the classification process that involves large data sets. From the result that the accuracy is 84,375% we can conclude that using RBFNN is quite good for fault diagnosis rolling element bearing.

#### ACKNOWLEDGMENT

The authors would like to thank Ir. Toni Prahasto, M.ASc, Ph.D and Dr. Achmad Widodo, ST, MT for the assistance in developing research in rolling element bearing fault diagnosis.

**Abstract-** The pqr-coordinate in the mapping matrices model of Kim-Akagi developed in order to find a solution to the problems of harmonic caused by non-sinusoidal power system and non-linear loads. This model is designed for the active/reactive power filter under energy balance and compensation condition. The pqr-coordinate is developed as well as space-vector transformation of the active/reactive power by using Euler angle rotation. The mapping matrices model of Kim-Akagi revisited by the Euler angle rotation method.

By using the Euler angles methods of twice rotation the available mapping matrices model of Kim-Akagi is resulted. Furthermore, the Euler angles methods of three times rotation will result in a correction factor. Also conducted to orthogonal test and invariant transformation properties and the results obtained show that space-vector transformation is part of Clarke transformation.

**Keywords-** Active/reactive power, mapping matrices model, Euler angle rotation method.

## I. INTRODUCTION

In general understanding, the active-reactive power on the electric power system with sinusoidal source and linear load has long been understood. In a single phase case, as the quantity of electric power produces average equal to zero. Average power produced does not contribute to the transfer of energy from source to load. However, if the source is non-sinusoidal and the load is non-linear then this concept does not apply [1]. The theory of instantaneous active-reactive power, otherwise known as the pq-theory, first published by Akagi, Kanazawa and Nabae in 1984 [2] and then refined into a pqr-theory in advanced research conducted by other researchers [3]-[4]. This theory was developed to overcome the problems caused by harmonics of non-linear loads on the 3-

phase 4-wire system. The term is also used for filtering power theory because problem cover all issues such as damping harmonic harmonics, harmonic isolation, harmonic termination, load balance, voltage regulation, power factor correction, and power flow control. In pq-theory gives explanation a definition of instantaneous active-reactive power in the time domain because there is no limit imposed on voltage or current. This theory applies to steady state and transient system for 3-phase 4-wire as a unit so it's not a superposition or sum of the single-phase to three. Clarke transformation is used to transform the system 3-phase 4-wire from coordinate-abc to coordinate- $\alpha\beta 0$ .

Analysis for the sinusoidal voltage or current source to the linear and non-linear load resulted shape of the power generated tetrahedron [5]-[6], is not triangular like the concept of average power, which is already understood that led to an understanding of the pqr-coordinate. The existence of r-axis in the pqr-coordinate related by neutral component (zero current), R-axis as the imaginary axis in the pr-plane together with axis-q-generating reactive power ( $Q_r$ ,  $Q_q$ ) affecting to the active power.

The mapping matrices model of Kim-Akagi [7] deals with instantaneous active-reactive power and voltage-current source is orthogonal vectors in a tetrahedron shape. In the pqr-coordinate transformation, Kim-Akagi made two consecutive transformation goals for voltage vector projection axis-q and axis-r is zero. Instantaneous active power generated from the multiplication dot product between voltage-current and cause condition the flow of energy between the two sub-systems. While the instantaneous reactive power resulting from the multiplication cross product between voltage-current and does not cause condition the flow of energy. Instantaneous active power is linearly independent, while instantaneous reactive

power depends on linearly three components to each other.

Power transformation in space-vector is the transformation of coordinate matrix-vector in reference frame stationary or rotating reference frame. Stationary reference frame (coordinate- $\alpha\beta$ ) called the Clarke transformation and rotating reference frame (coordinate-dq) is called the Park transformation. This transformation can be used to analyze the active-reactive power (PQ).

The research objective is to develop of pqr-coordinate on the mapping matrices model of Kim Akagi by Euler angle rotation method with twice and three times the rotation angle, and for certain boundary conditions can be applied to coordinate-pqr (Kim-Akagi model), coordinate- $\alpha\beta 0$  (Clarke transformation), and coordinate-dq0 (Park transformation).

## II. REVIEW THE MAPPING MATRICES MODEL OF KIM-AKAGI

Power transformation in a space-vector is stationary reference frame transformation (coordinate-  $\alpha\beta 0$ ) and a rotating reference frame (coordinate- dq0). This transformation can be used for analysis of the active-reactive power (PQ) and the control system on induction generator.

Transformation on coordinate-  $\alpha\beta 0$  (Clarke) is given as follows;

$$\begin{bmatrix} X_{\alpha} \\ X_{\beta} \\ X_0 \end{bmatrix} = \sqrt{\frac{2}{3}} \begin{bmatrix} 1 & \frac{2}{\sqrt{3}} & -\frac{2}{\sqrt{3}} \\ 0 & \frac{1}{\sqrt{3}} & \frac{1}{\sqrt{3}} \\ \frac{1}{\sqrt{3}} & \frac{1}{\sqrt{3}} & \frac{1}{\sqrt{3}} \end{bmatrix} \begin{bmatrix} X_a \\ X_b \\ X_c \end{bmatrix} \quad (1)$$

Transformation on coordinate- dq0 (Park) is given as follows;

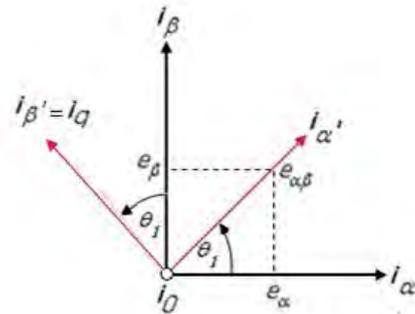

$$\begin{bmatrix} X_d \\ X_q \\ X_0 \end{bmatrix} = \begin{bmatrix} \cos \theta & \sin \theta & 0 \\ -\sin \theta & \cos \theta & 0 \\ 0 & 0 & 1 \end{bmatrix} \begin{bmatrix} X_{\alpha} \\ X_{\beta} \\ X_0 \end{bmatrix} \quad (2)$$

The X-parameter can be in a voltage vector or a current vector. So far, researchers have to understand many phenomena of electric power system, especially in the analysis on the induction generator using a coordinate-  $\alpha\beta 0$  and / or coordinate- dq0. To overcome the problem of harmonics and non-linear loads then Kim-Akagi, based on research in [5], proposed a new coordinate transformation as a refinement of the coordinate-dq0 where the presence of a neutral component considered.

The pq-theory as an approach to the instantaneous active-reactive power in the time domain is developed from the Clarke transformation and applies to steady state or transient condition. The pqr-theory is

development of the pq-theory for the shunt active power filter system on 3-phase 4-wire. In pqr-theory analysis of active-reactive power (PQ), especially for the compensation components must use the neutral p-axis, q-axis and r-axis.

Kim-Akagi made two times transformation is from axis- $(\alpha\beta 0)$  to axis- $(\alpha'\beta'0)$ , and from axis- $(\alpha'\beta'0)$  to axis-(pqr) becomes stationary reference frame to rotating reference frame for instant active power ( $P_p$ ) and reactive power ( $Q_q, Q_r$ ). Elimination of neutral currents also conducted on r-axis with reactive power ( $Q_q$ ) derived from the q-axis.

Picture-1: Transformation plane-  $\alpha\beta$  to plane-  $\alpha'\beta'$ .

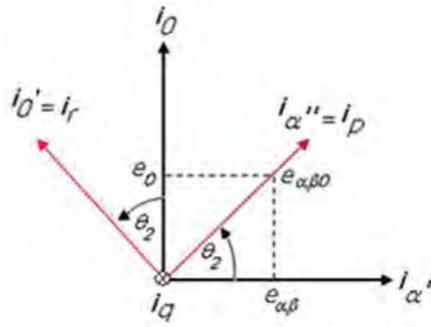

The first time is the transformation of the coordinate-  $\alpha\beta 0$  to coordinate- $\alpha'\beta'0$ . In the picture-1 transformation from coordinate- $\alpha'\beta'0$  to coordinate- $\alpha\beta 0$  is rotation by angle- $\theta_1$  and referred to as Park transformation, that is a transformation from coordinate-  $\alpha\beta 0$  to coordinate- dq0, where the axis- $\beta'$  is the q-axis.

$$\begin{bmatrix} i_{\alpha'} \\ i_{\beta'} \\ i_0 \end{bmatrix} = \begin{bmatrix} \cos \theta_1 & \sin \theta_1 & 0 \\ -\sin \theta_1 & \cos \theta_1 & 0 \\ 0 & 0 & 1 \end{bmatrix} \begin{bmatrix} i_{\alpha} \\ i_{\beta} \\ i_0 \end{bmatrix} \quad (3)$$

in this case  $\cos \theta_1 = \frac{i_{\alpha}}{e_{\alpha\beta}}$ ,  $\sin \theta_1 = \frac{i_{\beta}}{e_{\alpha\beta}}$

and  $e_{\alpha\beta} = \sqrt{i_{\alpha}^2 + i_{\beta}^2}$

$$\text{thus obtained } \begin{bmatrix} i_{\alpha'} \\ i_{\beta'} \\ i_0 \end{bmatrix} = \begin{bmatrix} \frac{i_{\alpha}}{e_{\alpha\beta}} & \frac{i_{\beta}}{e_{\alpha\beta}} & 0 \\ -\frac{i_{\beta}}{e_{\alpha\beta}} & \frac{i_{\alpha}}{e_{\alpha\beta}} & 0 \\ 0 & 0 & 1 \end{bmatrix} \begin{bmatrix} i_{\alpha} \\ i_{\beta} \\ i_0 \end{bmatrix} \quad (4)$$

Picture-2: Transformation plane-  $\alpha'0$  to plane- $pq$ .

And then the subsequent transformation is from  $\alpha'\beta'0$ -coordinate (or  $\alpha'q0$ -coordinate) to  $pqr$ -coordinate. In the picture-2, the transformation from plane-  $\alpha'0$  to plane-  $pq$  by rotation angle  $\square_2$ , that mean  $i_\alpha$  current on position of the  $\alpha'$ -axis to be  $i_p$  current on position of the  $p$ -axis in form of a tetrahedron shape.

$$\begin{bmatrix} i_p \\ i_q \\ i_r \end{bmatrix} = \begin{bmatrix} \cos \theta_2 & 0 & \sin \theta_2 \\ 0 & 1 & 0 \\ -\sin \theta_2 & 0 & \cos \theta_2 \end{bmatrix} \begin{bmatrix} i_{\alpha'} \\ i_{\beta'} \\ i_0 \end{bmatrix} \quad (5)$$

in this case

$$\cos \theta_2 = \frac{e_{\alpha\beta}}{e_{\alpha\beta\gamma}}, \quad \sin \theta_2 = \frac{e_{\alpha\gamma}}{e_{\alpha\beta\gamma}}$$

$$\text{and } e_{\alpha\beta\gamma} = \sqrt{e_{\alpha\beta}^2 + e_{\alpha\gamma}^2 + e_{\beta\gamma}^2}$$

thus obtained

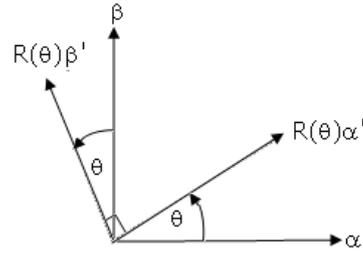

$$\begin{bmatrix} i_p \\ i_q \\ i_r \end{bmatrix} = \begin{bmatrix} \frac{e_{\alpha\beta}}{e_{\alpha\beta\gamma}} & 0 & \frac{e_{\alpha\gamma}}{e_{\alpha\beta\gamma}} \\ 0 & 1 & 0 \\ -\frac{e_{\alpha\gamma}}{e_{\alpha\beta\gamma}} & 0 & \frac{e_{\alpha\beta}}{e_{\alpha\beta\gamma}} \end{bmatrix} \begin{bmatrix} i_{\alpha'} \\ i_{\beta'} \\ i_0 \end{bmatrix} \quad (6)$$

If equation-4 is substituted into equation-6 is obtained as follows:

$$\begin{bmatrix} i_p \\ i_q \\ i_r \end{bmatrix} = \begin{bmatrix} \frac{e_{\alpha\beta}}{e_{\alpha\beta\gamma}} & \frac{e_{\beta\gamma}}{e_{\alpha\beta\gamma}} & \frac{e_{\alpha\gamma}}{e_{\alpha\beta\gamma}} \\ \frac{e_{\alpha\gamma}}{e_{\alpha\beta\gamma}} & \frac{e_{\alpha\beta}}{e_{\alpha\beta\gamma}} & 0 \\ -\frac{e_{\alpha\gamma}}{e_{\alpha\beta\gamma}} & -\frac{e_{\beta\gamma}}{e_{\alpha\beta\gamma}} & \frac{e_{\alpha\beta}}{e_{\alpha\beta\gamma}} \end{bmatrix} \begin{bmatrix} i_{\alpha'} \\ i_{\beta'} \\ i_0 \end{bmatrix} \quad (7)$$

### III. OVERVIEW OF EULER ANGLE ROTATION METHOD

Principle of Euler angle rotation on the group theory [7].

Picture-3: Rotation in  $\square$  angle

Projection of  $R(\theta)$  to the vector- $\alpha, \beta$  can be written as follows:

$$\alpha = R(\theta)\alpha' \cos \theta - R(\theta)\beta' \sin \theta$$

$$\beta = R(\theta)\alpha' \sin \theta + R(\theta)\beta' \cos \theta$$

in matrix form

$$\begin{bmatrix} \alpha \\ \beta \end{bmatrix} = \begin{bmatrix} \cos \theta & -\sin \theta \\ \sin \theta & \cos \theta \end{bmatrix} R(\theta) \begin{bmatrix} \alpha' \\ \beta' \end{bmatrix}$$

By doing the inverse matrix can be explained as follows:

$$R(\theta) \begin{bmatrix} \alpha' \\ \beta' \end{bmatrix} = \begin{bmatrix} \cos \theta & \sin \theta \\ -\sin \theta & \cos \theta \end{bmatrix} \begin{bmatrix} \alpha \\ \beta \end{bmatrix} \quad (8)$$

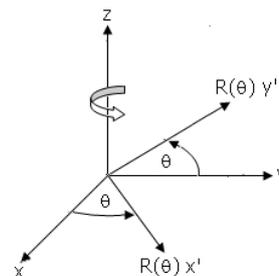

For the boundary condition  $\alpha = \alpha'$  and  $\beta = \beta'$  obtained matrix rotation  $R(\theta)$  as follows:

$$R(\theta) = \begin{bmatrix} \cos \theta & \sin \theta \\ -\sin \theta & \cos \theta \end{bmatrix} \quad (9)$$

Some important properties of the matrix rotation  $R(\theta)$  in the Euler angles are as follows:

1.  $R^{-1}(\theta) R(\theta) = I$  (Identity)
2.  $\det R(\theta) = 1$  (Identity)
3.  $R(0) = I$  (Identity)

In the same, for three dimensional projections way the matrix rotation of the  $z$ -axis can be described as follows:

Picture-4: Plane- $xy$  rotated  $z$ -axis direction where the rotation matrix is in the  $z$ -axis;

$$R_z(\theta) = \begin{bmatrix} \cos \theta & \sin \theta & 0 \\ -\sin \theta & \cos \theta & 0 \\ 0 & 0 & 1 \end{bmatrix} \quad (10)$$

By using the principle of rotation of the equilateral triangle can be obtained rotation matrices for each axis, like a rotation about the  $x$ -axis,  $R_x(\theta)$ , and the  $y$ -axis,  $R_y(\theta)$ .

The rotation matrices in the  $x$ -axis as follows:

$$R_x(\theta) = \begin{bmatrix} 1 & 0 & 0 \\ 0 & \cos \theta & \sin \theta \\ 0 & -\sin \theta & \cos \theta \end{bmatrix} \quad (11)$$

and the rotation matrices in the y-axis s follows:

$$R_y(\theta) = \begin{bmatrix} \cos\theta & 0 & \sin\theta \\ 0 & 1 & 0 \\ -\sin\theta & 0 & \cos\theta \end{bmatrix} \quad (12)$$

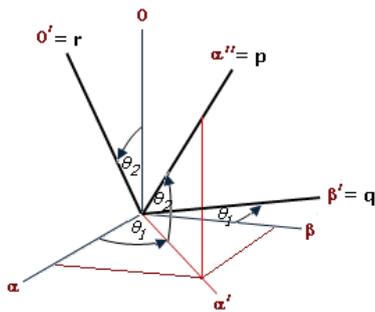

Euler angle rotation matrix formed by multiplying each axis rotation and can be described as follows:

$$R(\theta_1, \theta_2, \theta_3) = R_z(\theta_3) R_y(\theta_2) R_x(\theta_1) \\ = \begin{bmatrix} \cos\theta_3 & \sin\theta_3 & 0 \\ -\sin\theta_3 & \cos\theta_3 & 0 \\ 0 & 0 & 1 \end{bmatrix} \begin{bmatrix} \cos\theta_2 & 0 & \sin\theta_2 \\ 0 & 1 & 0 \\ -\sin\theta_2 & 0 & \cos\theta_2 \end{bmatrix} \times \\ \begin{bmatrix} 1 & 0 & 0 \\ 0 & \cos\theta_1 & \sin\theta_1 \\ 0 & -\sin\theta_1 & \cos\theta_1 \end{bmatrix} \quad (13)$$

A coordinate rotation can be done with continuous configuration between two Cartesian coordinate. The coordinate- $(\alpha, \beta, 0)$  as a stationary reference frame and coordinate- $(\alpha', \beta', 0)$ ,  $(\alpha'', q, r)$ ,  $(p, q, r)$  as a frame of reference rotating. Rotation, noted as,  $R(\theta_1, \theta_2, \theta_3)$  is performed to move the rotation axis of the stationary reference frame into a frame of reference rotating with the boundary condition,  $0 < \theta_1, \theta_2 < 2\pi$  and  $0 < \theta_3 < \pi$ .

It can be seen that the rotation of the reference frame is carried out rotating continuously from a stationary reference frame. Method of Euler angle rotation is the rotation in each coordinate- $(\alpha, \beta, 0)$  in a stationary reference frame into the coordinate- $(\alpha', \beta', 0)$ ,  $(\alpha'', q, r)$ ,  $(p, q, r)$  reference frame spin axis so that it can be done in a systematic incorporation. Thus, the principle of rotation can be used to the mapping matrices model of Kim-Akagi in solving problems related to pqr-coordinate.

The process of two-times rotation on the angles  $\theta_1, \theta_2$

Picture-5: The rotation of two Euler angles.

In figure-5, the two simple rotation in Euler angles where the  $\square_1$ -angle must be shift the  $\alpha$ -axis into  $\alpha'$ -axis along with it's  $\beta$ -axis shifted to q-axis, and  $\square_2$ -angle raise  $\alpha'$ -axis be the p-axis, and along with it's the 0-axis shifted to r-axis.

Multiplication Euler angles for 2 variable angles  $\theta_1, \theta_2$  are as follows:

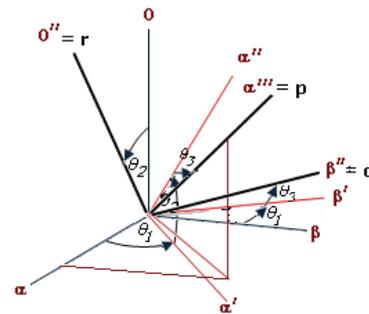

$$R(\theta_1, \theta_2) = R_N(\theta_2) R_z(\theta_1)$$

$$= \begin{bmatrix} \cos\theta_2 & 0 & \sin\theta_2 \\ 0 & 1 & 0 \\ -\sin\theta_2 & 0 & \cos\theta_2 \end{bmatrix} \begin{bmatrix} \cos\theta_1 & \sin\theta_1 & 0 \\ -\sin\theta_1 & \cos\theta_1 & 0 \\ 0 & 0 & 1 \end{bmatrix} \\ = \begin{bmatrix} \cos\theta_2 \cos\theta_1 & \cos\theta_2 \sin\theta_1 & \sin\theta_2 \\ -\sin\theta_2 \cos\theta_1 & -\sin\theta_2 \sin\theta_1 & \cos\theta_2 \\ \sin\theta_1 & \cos\theta_1 & 0 \end{bmatrix} \quad (14)$$

in this case the  $R_N(\theta_2) = R_y(\theta_2)$  is the rotation in the direction of the y-axis as equation-12. These results together with model Kim-Akagi mapping matrices are as in equation-7 above shall be as follows:

$$R(\theta) = \begin{bmatrix} \frac{r}{\sqrt{p^2+q^2}} & \frac{q}{\sqrt{p^2+q^2}} & \frac{p}{\sqrt{p^2+q^2}} \\ \frac{r}{\sqrt{p^2+q^2}} & \frac{q}{\sqrt{p^2+q^2}} & 0 \\ \frac{r}{\sqrt{p^2+q^2}} & \frac{q}{\sqrt{p^2+q^2}} & \frac{p}{\sqrt{p^2+q^2}} \end{bmatrix}$$

The process of three-times rotation on the angles  $\theta_1, \theta_2, \theta_3$

Picture-6: The rotation of three Euler angles.

In figure-6, the  $\square_1$ -angle shift  $\alpha$ -axis into axis- $\alpha'$  along with it's  $\beta$ -axis shifted to the  $\beta'$ -axis, the  $\square_2$ -angle raise  $\alpha'$ -axis be the  $\alpha''$ -axis, and along with it's the 0-axis shifted to axis-r, and last time  $\square_3$ -angle shift  $\alpha''$ -axis to the p-axis along with it's  $\beta'$ -axis shifted into q-axis.

Multiplication Euler angles for 3 variables angles  $\theta_1, \theta_2, \theta_3$  are as follows:

$$R(\theta_1, \theta_2, \theta_3) = R_3(\theta_3) R_N(\theta_2) R_3(\theta_1)$$

Applicability of the transformation is when angles  $\theta_1, \theta_2, \theta_3 = 0$ , that is not the case then the Euler angle rotation event multiplication results in the transformation Clarke (coordinate- $\alpha\beta 0$ ) as follows:

$$\begin{bmatrix} X_{\alpha} \\ X_{\beta} \\ X_0 \end{bmatrix} = \begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix} \begin{bmatrix} X_{\alpha} \\ X_{\beta} \\ X_0 \end{bmatrix} = \frac{1}{\sqrt{3}} \begin{bmatrix} 1 & \frac{1}{\sqrt{2}} & \frac{1}{\sqrt{2}} \\ 0 & \frac{1}{\sqrt{2}} & -\frac{1}{\sqrt{2}} \\ \frac{1}{\sqrt{2}} & \frac{1}{\sqrt{2}} & \frac{1}{\sqrt{2}} \end{bmatrix} \begin{bmatrix} X_{\alpha} \\ X_{\beta} \\ X_0 \end{bmatrix} \quad (14)$$

For the angles  $\theta_1, \theta_2 = 0$ , there is one variable rotation Euler angles, namely rotation about the z-axis to obtain the equation-2 transformation Park (coordinate-dq0) as follows:

$$\begin{aligned} \begin{bmatrix} X_p \\ X_q \\ X_r \end{bmatrix} &= \begin{bmatrix} \cos \theta_1 & \sin \theta_1 & 0 \\ -\sin \theta_1 & \cos \theta_1 & 0 \\ 0 & 0 & 1 \end{bmatrix} \begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix} \begin{bmatrix} X_{\alpha} \\ X_{\beta} \\ X_0 \end{bmatrix} \\ &= \sqrt{\frac{2}{3}} \begin{bmatrix} \cos \theta_1 & \sin \theta_1 & 0 \\ -\sin \theta_1 & \cos \theta_1 & 0 \\ 0 & 0 & 1 \end{bmatrix} \begin{bmatrix} 1 & \frac{2}{\sqrt{3}} & -\frac{2}{\sqrt{3}} \\ 0 & \frac{2}{\sqrt{3}} & \frac{2}{\sqrt{3}} \\ \frac{1}{\sqrt{3}} & \frac{1}{\sqrt{3}} & \frac{1}{\sqrt{3}} \end{bmatrix} \begin{bmatrix} X_{\alpha} \\ X_{\beta} \\ X_0 \end{bmatrix} \end{aligned} \quad (15)$$

For the angle  $\theta_3 = 0$ , occurs Euler angle rotation 2 variables, namely rotation about the z-axis and the continued rotation of the y-axis as a description of the equation-14 model of Kim-Akagi mapping matrices is obtained as follows:

$$\begin{aligned} \begin{bmatrix} X_p \\ X_q \\ X_r \end{bmatrix} &= \begin{bmatrix} \cos \theta_2 \cos \theta_1 & \cos \theta_2 \sin \theta_1 & \sin \theta_2 & 1 & 0 & 0 \\ -\sin \theta_1 & \cos \theta_1 & 0 & 0 & 1 & 0 \\ -\sin \theta_2 \cos \theta_1 & -\sin \theta_2 \sin \theta_1 & \cos \theta_2 & 0 & 0 & 1 \end{bmatrix} \begin{bmatrix} X_{\alpha} \\ X_{\beta} \\ X_0 \end{bmatrix} \\ &= \sqrt{\frac{2}{3}} \begin{bmatrix} \cos \theta_2 \cos \theta_1 & \cos \theta_2 \sin \theta_1 & \sin \theta_2 \\ -\sin \theta_1 & \cos \theta_1 & 0 \\ -\sin \theta_2 \cos \theta_1 & -\sin \theta_2 \sin \theta_1 & \cos \theta_2 \end{bmatrix} \begin{bmatrix} 1 & \frac{2}{\sqrt{3}} & -\frac{2}{\sqrt{3}} \\ 0 & \frac{2}{\sqrt{3}} & \frac{2}{\sqrt{3}} \\ \frac{1}{\sqrt{3}} & \frac{1}{\sqrt{3}} & \frac{1}{\sqrt{3}} \end{bmatrix} \begin{bmatrix} X_{\alpha} \\ X_{\beta} \\ X_0 \end{bmatrix} \end{aligned} \quad (16)$$

and by incorporating the boundary conditions of each axis as follows:

- $\alpha \rightarrow p : f(\theta_1, \theta_2, \theta_3)$  as a function from angles  $\theta_1, \theta_2, \theta_3$
- $\beta \rightarrow q : f(\theta_1, \theta_3)$  as a function from angles  $\theta_1, \theta_3$ .
- $0 \rightarrow r : f(\theta_2)$  as a function from angle  $\theta_2$ .

The matrix rotation is obtained as follows;

$$R(\theta_1, \theta_2, \theta_3) = \begin{bmatrix} \cos \theta_2 \cos(\theta_3 + \theta_1) & \sin(\theta_3 + \theta_1) & \sin \theta_2 \\ -\sin(\theta_3 + \theta_1) & \cos(\theta_3 + \theta_1) & 0 \\ -\sin \theta_2 & 0 & \cos \theta_2 \end{bmatrix} \quad (17)$$

With using equation-2 (Clarke transformation) to obtain a matrix transformation as follows:

$$\begin{aligned} \begin{bmatrix} X_p \\ X_q \\ X_r \end{bmatrix} &= \begin{bmatrix} \cos \theta_2 \cos(\theta_3 + \theta_1) & \sin(\theta_3 + \theta_1) & \sin \theta_2 \\ -\sin(\theta_3 + \theta_1) & \cos(\theta_3 + \theta_1) & 0 \\ -\sin \theta_2 & 0 & \cos \theta_2 \end{bmatrix} \begin{bmatrix} X_{\alpha} \\ X_{\beta} \\ X_0 \end{bmatrix} \end{aligned} \quad (18)$$

in this case  $X \equiv i, V$  (as current or voltage)

## CONCLUSION

The instantaneous active-reactive power theory in the theory-pq or theory-pqr developed as an effort to solve the problem of harmonic and non-linear loads caused by sources that are non-sinusoidal, by using the model of mapping matrices, Kim-Akagi attempting to solve the problem. Active power filter also developed to support the theory. The pqr-coordinate on the model mapping matrices of Kim-Akagi is a refinement of the coordinate-dq0.

The pqr-coordinate as the mapping matrices model of Kim-Akagi is two times of rotation in Euler angle method. Rotation also developed three times of rotation in Euler angles as a correction factor. This transformation is a part of the Clarke transformation. With Euler angle rotation method, the mapping matrices model Kim-Akagi can be described and the result of the rotation of the 2 (two) Euler angles. Furthermore, rotation of the 3 (three) points generate a new transformation matrix for the coordinate-pqc. In certain circumstances the transformation matrix can be applied to coordinate- $\alpha\beta 0$  (Clarke transformation), coordinate-dq0 (Park transformation), and coordinate-pqr (Kim-Akagi).

**Abstract**—The use of renewable energy source (RES) in meet the demand of electrical energy is getting into attention as solution of the problem a deficit of electrical energy. Application of RES in electricity generation system is done in a variety of configurations, among others in microgrid system. Implementation of microgrid systems provide many advantages both from the user and from the electric utility provider.

Many microgrid development carried out in several countries, because microgrid offers many advantages, including better power quality and more environmentally friendly. Microgrid development concern in technology generation, microgrid architecture, power electronics, control systems, protection systems.

This paper reviewing various technological developments related to microgrid system and case study about microgrid system development using grid tie inverter (GTI). Microgrid system can implemented using GTI, power transfer can occur from GTI to grid when GTI has power excess and grid supplying power to GTI when GTI power shortage.

**Keyword** : microgrid, microgrid architecture, microgrid control and managemen, grid tie inverter

## I. INTRODUCTION

The use of renewable energy source (RES) in meet the needs of electrical energy is getting into attention as solution of the problem a deficit of electrical energy, particularly for areas that are difficult to reach existing power grids. A variety of development related to the use of RES continues. Start from optimizing the use of energy sources, the development of the power conversion system up to the electrical power system architecture. Application of RES in electricity generation systems performed in a variety of configurations. Starting from the most simple systems such as the utilization of PV in solar home systems (SHS) to the application of RES in the microgrid system.

Production of electric power from RES such as solar power generation varies greatly depending on the source of the sun received at the time. This raises concerns on quality of generated power, especially if it is connected to the grid system, where solar power would be seen as a negative expense by net system because it has characteristics associated with uncontrolled fluctuation from energy sources [1]. This problem can be addressed by adding another generation systems more controlled, such as, the addition of energy storage systems (batteries) or forming a hybrid system by adding diesel generators or micro turbines[2].

Implementation of microgrid systems provide many advantages both from the user and from the electric utility provider. From the user's application of the microgrid is connected to the grid, it can improve network quality, reduce emissions and can reduce the cost to be incurred by the user.

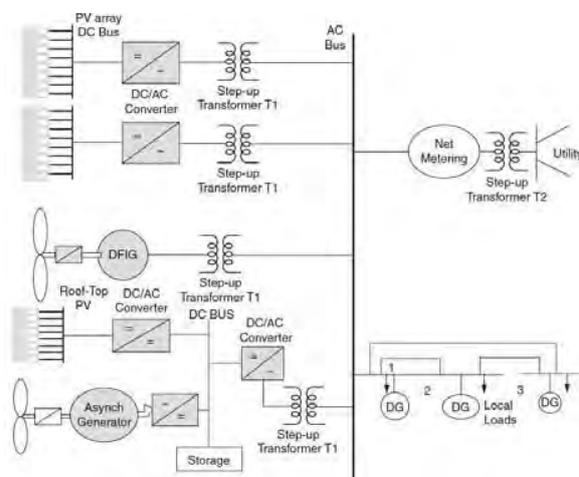

From the electric utility provider implementation of distributed generation systems with the ability microgrid can reduce the power flow on transmission and distribution lines, so as to reduce losses and reduce costs for additional power. Moreover microgrid can also reduce the load on the network by eliminating the impasse in meeting electricity needs and help repair network in case of errors[3]. Implementation of microgrid system will also help improve the reduction of emissions and the threat of climate change.

Microgrid development done by many countries since microgrid offers many advantages such as better power quality and more environmentally friendly. Moreover the economic potential that may still be used from this system is the opportunity to utilize the waste heat from the engine generator using a combined heat and power (CHP). Application of this system with RES as an alternative generation system in the future. Surely this system requires the operating mechanism and a sophisticated control system to make the finger with a reliable and efficient, and it can all be met by the microgrid[4].

## II. ARCHITECTURE OF MICROGRID

Microgrid system operate at a low voltage distribution, and has several distributed energy resources. Microgrid system also has the ability to operate connected to the grid (on grid) or disconnected to the grid (off grid/islanded) [5].

The microgrid structure consists of several types of distributed energy sources (DER) such as solar panels, wind turbines, microturbine, thermal power plant each in the form of distributed generation (DG), including energy reserves from battery (Distributed Storage/DS).

(a)

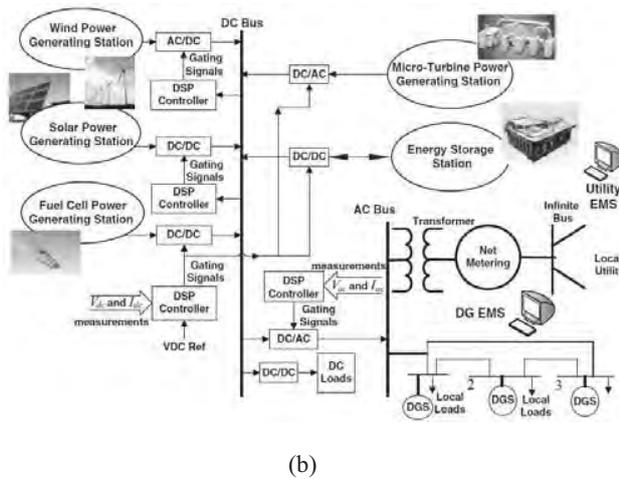

Figure 1. Architecture of Microgrid (a) AC microgrid (b) DC microgrid

Microgrid electrical connection points that connected to the low voltage network in the PCC (point of common coupling) that connected to the DG, DS and loads, which consist of several types of loads such as residential, commercial buildings, campuses and industrial complexes. As shown in Figure 1, architecture of microgrid organized as AC microgrid (AC bus) or DC microgrid (DC bus) or combine of both [6].

### III. TECHNOLOGY OF MICROGRID

Operation of microgrid system can not be separated from technologies that support from each part that make up the microgrid system, as the source of energy (distributed generation), energy storage, interconnect switches and microgrid control system. Technologies in energy sources distributed generation include the utilization of renewable energy sources such as photovoltaic, wind turbines, and fuel cells. Several power systems improve efficiency by implementing the use of flue gas using CHP technology (combined heat and power) as microturbine, figure 2.

Figure 2. Microturbine

Technologies in energy storage microgrid systems which include battery, super capacitor and flywheels. Energy storage in microgrid system is used among others to:

- Stabilization of the microgrid system in the face of fluctuating energy sources and load changes.
- Enables load sharing operation in microgrid system.
- Reduce the loads spikes and electrical interference
- Backup energy source

Switch interconnection technology in microgrid system utilizing digital technology using Digital Signal Processor (DSP) and equipped with communication devices, while meeting the IEEE 1574 standard network interconnection. To improve the response speed semiconductor switch used technologies such as thyristors and IGBT, Figure 3.

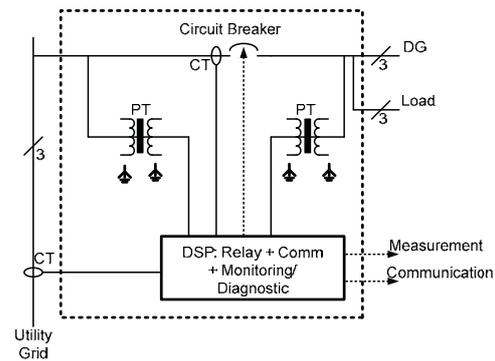

Figure 3. A schematic diagram of circuit breaker on connection to the grid

Control system technologies in microgrid can be grouped in two modes of operation are connected to the network mode and isolated mode (islanding). The control system is intended to regulate the stability of microgrid operation particularly in frequency and voltage to maintain stability in face of changes in load and interconnection with other networks. The control system is applied to power converter technology in regulating active and reactive power supply, applying droop control and frequency control [7].

### IV. CONTROL AND MANAGEMENT OF MICROGRID

Control system in microgrid contrast to conventional power systems, this is due to several reasons, among others:

- Steady state and dynamic characteristics of microgrid different from conventional plants
- microgrid possesses inherent unbalanced load due to one phase loads
- The supply of power from microgrid can come from uncontrolled sources such as wind
- The role of energy storage is very large in the control mechanisms used
- microgrid accommodate disconnection and connection mechanisms to maintain expenses during its operating
- microgrid requires initial requirements of power quality or service preferences for certain types of loads

TABLE I. SEVERAL TYPES OF MECHANISMS CONTROL USED IN DER

	Main Energy Sources	Interface/inversion	Power Flow Control
DG conventional	reciprocating engine small hydro Wind Turbin fixed speed	synchronous generator induction generator	AVR Control and Governor (+P,±Q) stall or pitch control of turbine (+P,-Q)
DG Non conventional	Wind Turbin variabel speed Microturbine	Power electronics converters (conversion AC-DC-AC)	Turbine speed control and DC link voltage control (+P,±Q)
	Solar Panel Fuel cell	Power electronics converters (conversion DC-DC-AC)	MPPT Control and DC link voltage control (+P,±Q)
Long time storage (DS)	battery storage	Power electronics converters (conversion DC-DC-AC)	state of charge and / or control output voltage / frequency (±P/±Q)
Short time storage (DS)	Flywheel	Power electronics converters (conversion AC-DC-AC)	state of charge (±P,±Q)
	Super Capacitor	Power electronics converters	Speed control (±P,±Q)

As described previously microgrid consists of DER configuration, loads with classified characteristics and management control systems and microgrid. DER may include distributed generation (Distributed Generation/DG) or distributed storage systems (Distributed Storage/DS). Diagram of DG on the microgrid system consists of primary energy sources, media interface and interconnect switches. A DS can be a major energy source for the DG. Moreover main energy source can be generated using a rotary machine /spinning and generating device that consists of power electronics converters.Both provide concepts, strategies and characteristics of different controls. Moreover control strategy and operation of interconnect system, as well as energy/power management used largely determined the type of DER technologies in use, the type of load demand and the expected operating scenarios. Several types of control mechanisms used in DER described in Table I.

In context of power flow control DER units can be grouped into unit dispatchable energy (power output can be regulated) and non-dispatchable (power output can not be adjusted). In dispatchable energy unit output power setting is set externally using supervisory control such as AVR, while for non-dispatchable energy unit output power settings based on the maximum power that can be generated using MPPT concept. A non-dispatchable energy units can be converted into dispatchable energy units using additional energy storage systems and power electronic circuit converter dc-de-ac. In addition to provide faster response electronic converters also able to limit short circuit contribution not less than 200% from current capability and to prevent damage due to currents, figure 4.

Stability of microgrid operation was also obtained by setting the loads connected to the network, especially on non-critical loads. Critical loads more attention than the other loads that are not critical. Settings done in several ways including termination control loads in order to maintain the stability of the voltage and frequency. The distinction between loads service, improved power quality and reliability for certain expenses.

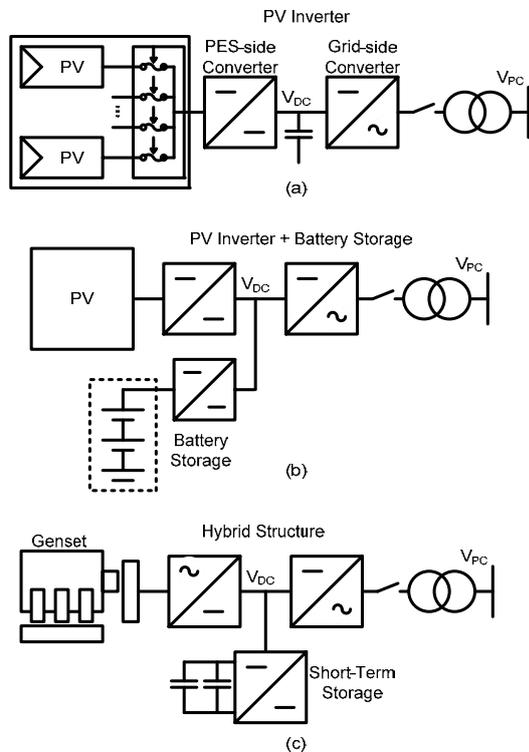

Figure 4. Configuration of non dispatchable (a) and dispatchable (b) and (c)

Control Method of microgrid

The aim control mechanisms of microgrid is to regulate voltage and frequency, as well as reactive and active power output, to fit the setting. Microgrid control strategies can be grouped into several alternative control as shown in table II.

TABLE II. CLASSIFICATION OF DER UNIT CONTROL METHOD

Control method	Grid following control	Grid forming control
Non-interactive control method	Power Export (with/without MPPT)	Voltage and frequency control
Interactive control method	Power dispatch real and reactive power support	Load sharing (droop control)

In non-interactive control strategies, output power settings carried out independently while at interactive control strategies output power setting performed as command from control unit. Each control strategy is divided into grid-following and grid-forming control. In grid-following control, settings power output including voltage and frequency are determined by the microgrid. Setting output active power and reactive power can use a synchronization

control strategy framework "dq0". In this control strategy current in each phase is used as an input to determine PWM voltage that will regulate power output. Magnitude of input current is transformed into massive d axis and q axis which then transformed into  $V_{abc}$  voltage magnitude. Mechanisms of active and reactive power dispatch by an energy management system to perform optimization strategy based on potential energy profile. Moreover setting output power is also determined by load profile, Figure 5.

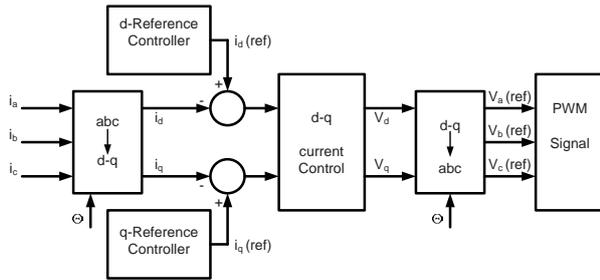

Figure 5. dq control on DER unit inverter

In grid-forming control power settings, including output voltage and frequency, by DER units and will be followed by another DER units. DER units that implement grid-forming should have a greater energy potential. Droop control strategies made using voltage and frequency droop control. Determination of allowable output power according to droop characteristics given parameters, as shown in figure 6,

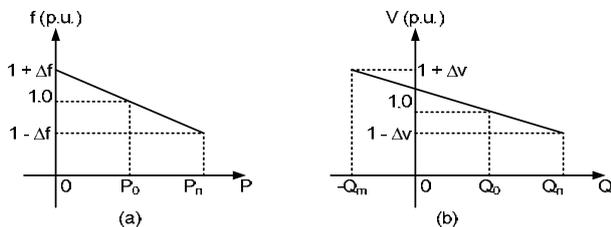

Figure 6. DER unit droop diagram on grid-forming control

Amount change in voltage and frequency of droop characteristics are used as input to dq transformation in order to determine amount of active and reactive power output. To ensure microgrid operation mechanism works as expected then the operation of each DER unit must be coordinated properly for it required method of supervisory control strategy microgrid operation. Microgrid operation supervisory control strategies can be centralized or decentralized [8].

#### Managing control of microgrid

On centralized supervisory control strategy, amount of power output from each LC (Local Control) is determined by MCC (Microgrid Control Center) based on input (bidding) production capacity owned by each LC. MCC based on inputs of LC and operating policy that covers current energy market prices, estimates needs and production as well as consideration of infrastructure conditions other microgrid,

determine LC operations include setting LC production capacity. The amount of loads to be served and amount of market price for energy optimization of LC in determining bidding further production capacity to MCC.

In decentralized supervisory control strategies each LC has ability to determine operating autonomy of energy production that will be generated by LC. The main purpose of control strategy in each LC is not aimed at increasing financial income but rather to overall performance of microgrid. So at each LC already has economic parameters, environmental conditions/ potential energy (weather) and the estimated load. One method of control that can be applied to this system is using Multi Agent System (MAS). MAS is a evolution form of classical control of distributed control systems with the ability to control large and complex entity. The main feature of MAS is the ability to incorporate elements of intelligence in each local control (LC). Configuration of MAS system on a microgrid as shown in figure 7.

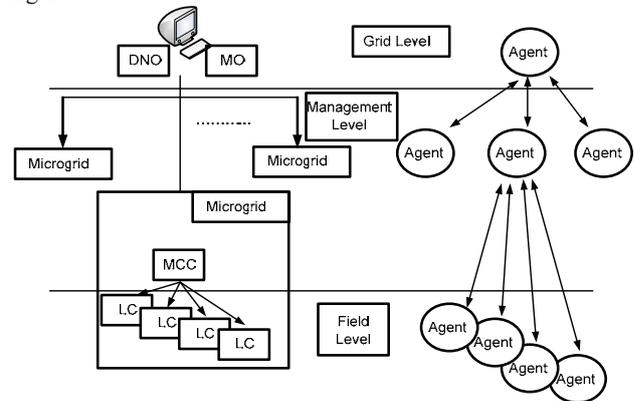

Figure 7. Multi Agent System configuration on microgrid

In the centralized and decentralized systems both require reliable data communications facilities. Data communication network can be radio, telephone or power line carrier. Through this communication networks microgrid operation mechanism arranged between each DER unit or the main control system in form of energy management system applications.

#### V. TECHNICAL CHALLENGES ON MICROGRID

As a new paradigm of power systems, implementation of microgrid still face many obstacles. Less understanding about microgrid and unfavorable government policies become an obstacle in applying microgrid technology. In general, in addition can be applied as a solution to electricity in remote areas, microgrid technology can also be used as electrical solutions such as urban residential complexes, offices, schools and others. In which implementation of microgrid technology will provide advantage compared if have to build a new transmission and distribution network. Advantages and disadvantages in applying microgrid technology among others [9]:

*Microgrid Advantages*

- Microgrid, have ability, during a utility grid disturbance, to separate and isolate itself from the utility seamlessly with little or no disruption to the loads within the Microgrid.
- In peak load periods microgrid can prevents utility grid failure by reducing the load on the grid.
- Microgrid have environmental benefits made possible by use low or zero emission generators.
- In microgrid to increasing energy efficiency, the use of both electricity and heat is permitted to get closer the generator to user.
- Microgrid can act to mitigate the electricity costs to its users by generating some or all of its electricity needs.

*Microgrid Disadvantages*

- In microgrid, that must be considered and controlled voltage, frequency and power quality parameters to acceptable standards whilst the power and energy balance is maintained.
- Electrical energy needs to be stored in battery banks thus requiring more space and maintenance.
- The difficulty of resynchronization with the utility grid.
- Microgrid protection is one of the most important challenges facing the implementation of Microgrids.
- Issues such as standby charges and net metering may pose obstacles for Microgrid.
- Interconnection standards needs to be developed to ensure consistency. IEEE P1547, a standard proposed by Institute of Electrical and Electronics Engineers may end up filling the void.

*Future Direction On Microgrid Research*

Future direction which require further investigation in the context of microgrid research are [10]:

- To investigate full-scale development, field demonstration, experimental performance evaluation of frequency and voltage control methods under various operation modes
- Transition between grid connected and islanded modes on interaction phenomena between distribution generation and high penetration of distributed generation
- Analysis the issue of black starting in an unbalanced system on the control, protection and power quality
- Transformation of microgrid system today into the intelligent, robust energy delivery system in the future by providing significant reliability and security benefits.

*VI. MICROGRID DEVELOPMENT USING GTI*

Microgrid systems can be implemented using grid tie inverter (GTI). The weakness of this system is when there is no grid, the system can not work because GTI will work if there is a power from grid that is used as a reference of GTI operation. microgrid trials using GTI have been conducted in laboratory.

In this experiment, PV source simulated with variable DC source. a set of Configuration tests looks like in figure 8

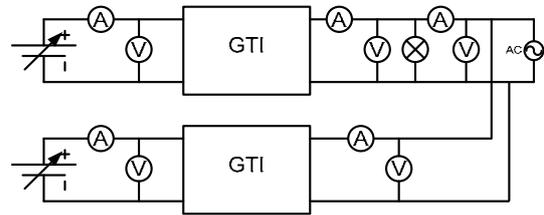

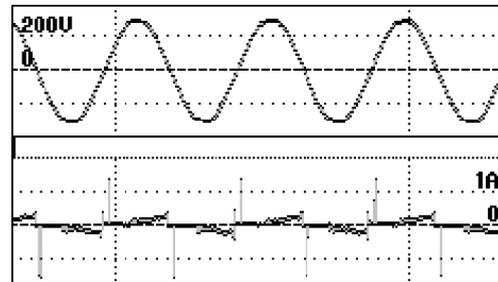

Figure 8. Microgrid system using GTI

In this trial used 2 pieces of GTI and a local load. Measurements were taken to see the distribution of power flow of each GTI and power flow from PLN in meeting needs of power required by load.

Gambar 9. GTI output voltage on grid condition

The measurement results of GTI output voltage shown in Figure 9. The form of GTI output voltage in accordance with PLN. Power measurements performed on each output of inverter, load and line to PLN. The measurement begins by activating the GTI without being connected to the PLN, characterized by value of PLN power = 0W as shown in table III.

TABLE III. POWER FLOW IN MICROGRID SYSTEM

$P_{GTI1}$ (W)	$P_{GTI2}$ (W)	$P_L$ (W)	$P_{pln}$ (W)
0	0	0	0
122	0	170	55
120	40	170	14
120	40	0	-158
0	0	0	0

From the data presented can be seen that when there is no supply from PLN then both the GTI does not generate power to the load. When GTI 1 (PGTI1) supplied power to load and GTI 2 (PGTI2) has not been issued, then power to load (PL) supplied by GTI 1 and PLN (PPLN). When GTI2 start generating power then the power of the PLN decreases proportional to the input power of GTI2. When there is no power supplied to load (load disconnected) power of both GTI supplied to PLN. Minus sign indicates direction of power flow towards PLN grid. When the source of PLN disconnected (isolated/islanding), as seen in last data table, PLN power = 0W, then both the GTI no output power again. The measurement results show that the number of power

does not show balance of power, this can caused each power output measurements performed using different tools.

### VII. CONCLUSION

Microgrid system is an alternative electricity network that can be used to meet the electricity needs of the future. In the microgrid system consists of multiple power sources, which can use renewable energy sources. Microgrid system works autonomously so it requires a complex control system to regulate the operation of microgrid.

Implementation of microgrid can be done using the inverter GTI. Microgrid with GTI can transferring power to/from grid. Power transfer can occur from GTI to grid when GTI has power excess and grid supplying power to GTI when GTI power shortage. Power sharing between parallel GTI based on input power of each of GTI, if there is shortage of power will be supplied from grid.

**Abstract** – Neodymium magnets are permanent magnets, which have high strength. Magnets can exert a force push or repel as powerful motor. The method in this study through the stages in the preparation of materials and research tools. Magnet is used N42 grade neodymium magnet with a diameter of 12.5 mm, thickness 1.5 mm thick composed of six pieces so that the whole 9 mm. In the attached magnet stator magnets are 48 pieces divided in 2 rows with the north pole facing into, and the magnet attached dictator a divided by 44 pieces also in the second row with the north pole facing out. The position of the stator magnet attached at an angle of 25° facing perpendicular magnetic rotor with 5 mm distance between the poles. Houses magnet drilled at an angle of 25° as deep as 9 mm, to install as many as 40 holes magnet is divided into 2 rows aligned with the row spacing of 15 mm. The results obtained by the occurrence of a failure in the magnetic shield systems to reduce the magnetic field, so it has been done in the selection of formulation shield Co-netic AA-Alloy, with the hypothesis magnet motor will work with power of 0.173 kW, torque of 1.81 Nm and motor rotation speed of 911 rpm.

**Keywords:** Magnet Neodymium, energy, power, torque, rotation speed

## 1. Introduction

### 1.1 Background

Electrical energy demand in Indonesia is needed, and the government should subsidize the operation so that the community can be met. In Indonesia is still very lacking supplies of energy resources, so that frequent electric power crisis that occurs mainly remote and isolated areas. Magnetic power generator is one of the ideas of alternative energy development, to maximize the potential energy that can be used as well as the fuel and mining. A large investment, but operating costs are very small, a power advantage is. By utilizing the energy of the magnetic poles repel without additional charge at each operation. Achievement of the preservation of nature can also be maintained as independent power against the pollution.

### 1.2 Objectives of Research

This magnetic power is assumed to be working optimally, without limitation too focused on the potential energy

required in its performance, because it relies on magnets repel force used. The power plant is expected to be helpful in terms of saving of minerals that are getting reduced due to excessive use of energy needed to obtain. The plant also preserve nature a clean, safe and comfortable without pollution, waste, noise, and other adverse effects.

In the village is not like the city of the electrical energy needs could be met, in villages sometimes do not work as a result electricity is not an unqualified company to always supply the electricity provider, so the policy was taken as a precaution. In anticipation long before the current energy crisis is to use water and wind. As the potential energy that can not be discharged, but the conditions and other support remains a limitation, not always where there is a large flow of water and there was always a strong wind pressure velocity, so this step can only be done in certain areas only, differently to magnets that can perform operations without the need to worry about where that does not support. In addressing these conditions, the researchers wanted to test the specimens will be obtained and the values of the necessary steps in planning a magnetic power generator. So that the future results of this study are expected to greatly help both in terms of science, the economy, and especially in the field of energy.

## 2. Magnetic

Neodymium magnet made from an alloy of neodymium, iron, and boron to form Nd<sub>2</sub>Fe<sub>14</sub>B tetragonal crystalline structure has a very high magneto crystalline uniaxial anisotropy (H<sub>A</sub> ~ 7 tesla). These compounds provide the potential to have high coercivity (resistance to be demagnetized). This compound also has a high saturation magnetization (J<sub>S</sub> ~ 1.6 Tesla or 16 kg). Therefore, the maximum energy density comparable to J<sub>s2</sub> magnetic phase has the potential to store a large amount of magnetic energy (~ 512 kJ/m<sup>3</sup> BH<sub>max</sub> or 64 MG · Oe). Unit poles in the system are MKS Ampere meter, symbol m and q as well as for electrical charge. If at any point we place a power pole m 'of magnetic thin and long, while at another point as far as r of m' well we put m a power pole the interaction style both poles are:

Figure 1 : The interaction of the two poles Style

$$F = \frac{\mu_0}{4\pi} \frac{m m'}{r^2} \quad (1)$$

Where:

F = force of attraction / repel force in newton

R = distance in meters

$m_1$  and  $m_2$  strong magnetic poles in Ampere-meter.

$\mu_0$  = permeability of vacuum.

$$\text{Value} \quad \frac{4\pi}{\mu_0} = 10^7 \quad \text{Wb/A.m}$$

(2)

This formula is the same as the interaction of two electric charge formula proposed by Coulomb.

If B is the magnetic induction wire cutting, the force experienced by the wire is  $F = 2\pi I B r$ , if  $2\pi r$  is the length of the wire windings. Flow of radius r there with the induction field of  $B = \mu_0 I / 2r$ , so that the power poles U experiencing a force of  $F = m B'$

$$F = \frac{m \mu_0 I}{2r} \quad (3)$$

Both styles in the last equation is the interaction force between the poles of a magnet with current N on the circuit, so that:

$$2\pi I B r = \frac{m \mu_0 I}{2r} \quad (4)$$

or

$$B = \frac{\mu_0 m}{4\pi r^2} \quad (5)$$

Magnetic induction is induced by the magnetic poles of the magnet poles so far r. Comparison of magnetic induction B with permeability of vacuum  $\mu_0$   $H = B / \mu_0$ ,  $\mu_0 = 12,5 \times 10^{-7}$ . Called the magnetic intensity of the room is empty, so the intensity of the generated magnetic pole strength m to r point extent of the poles are:

$$H = \frac{1}{4\pi} \frac{m}{r^2} \quad (6)$$

If B is measured dalam Wb/m<sup>2</sup> unit, the magnetic intensity H in Amp/m. Comparison between the power poles with cross-sectional area is called the power of the magnetization, as well as the charge per unit area is called the charge density.

$$J = \frac{m}{A} \quad (7)$$

Known as magnetic flux ( $\Phi_B$ ), which is the result of the projection of the magnetic field in all extents, penetrate. Magnetic field flux ( $\Phi_B$ ) that penetrates the area  $d\vec{S}$  is zero. This is due to a net magnetic charge magnetic dipole is zero so the number of lines entering the B value as the path out of the area it. This means the overall magnetic field magnetic flux is:

$$\Phi = B \cdot A \quad (8)$$

Where:

$\Phi$  = magnetic flux

A = area (surface) copy

B = strong magnetic field or magnetic

## 2.1 Style That Works On Portable Power Magnet Motor Mechanism

### 2.1.1 Rotation Kinematics

In Motion Straight subject, we know some scale, such as velocity, displacement and acceleration. Called angle because the rotational motion of each particle on a rigid body moving in a circle and take a certain angle. Quantities are also called angular velocity, angular acceleration and angular displacement.

When the disc rotates, each part of the disc moving at a different pace. Point near the axis (S), moving more slowly than the point located at the edge of the disc, however, because the rate of each point alias every part of the disc is different. However, when a point located on the edge of doing a full rotation, then the point near the axis also did a full turn. If discs do one lap, then all parts of the disc that also did one round.

### 2.1.2 Displacement Angle

In rotational motion, the easiest way is to measure angles using radians. Radian can be expressed in degrees, and vice versa. A full circle = 360°. Arc length around the circle =  $2\pi r$ . Thus:

$$\theta = \frac{l}{r} = \frac{2\pi r}{r} = 2\pi \text{ rad} \quad (9)$$

To help demonstrate the change in the position of rotational motion, set an imaginary line as a reference point to see the change in location of the position. When the disc rotates, a point which at first coincides with the reference line moves through an angle  $\theta$  l along the arc so far. A point is said to do the rounds as far as one radian if the length l = length r. In other words, if  $l = r$ , then  $\theta = 1$  radian. Mathematically, the angle  $\theta$  is expressed as follows (in radians):

$$\theta = \frac{l}{r} \quad (10)$$

where:

r = radius,

l = length of arc

$\theta$  = Angular displacement

### 2.1.3 Corner speed

If speed is the ratio of the displacement and the lapse of time, it is the ratio of the angular velocity and the angular displacement interval.

### 2.1.4 Average angle speed

The position angle is measured from the reference line. At the time  $t_1$ , part the wheels are marked with dotted lines in the position so far  $\theta_1$  from reference line. At time  $t_2$ , the wheels are marked with dotted lines in the position of the reference line as far  $\theta_2$  from line. Difference between  $\theta_2$  and  $\theta_1$  an angular displacement ( $\Delta\theta$ ). Mathematically average angular velocity is expressed as follows:

$$\omega = \frac{\theta_2 - \theta_1}{t_2 - t_1} = \frac{\Delta\theta}{\Delta t} \quad (11)$$

Where:

$\omega$  = angular velocity

t = time taken

$\Delta\theta$  = delta theta or angular displacement

$\Delta t$  = time interval or period

### 2.1.5 Average acceleration angle

Mathematically, the average angular acceleration is defined as follows:

$$a = \frac{\omega_2 - \omega_1}{t_2 - t_1} = \frac{\Delta\omega}{\Delta t} \quad (12)$$

where :

$a$  = average angular acceleration

$\omega_2$  = final angular velocity

$\omega_1$  = initial angular velocity

### 2.1.6 Frequency

The equation that connects between the frequency and the angular velocity is described as follows:

$$\omega = \frac{2\pi}{\Delta t} \quad (13)$$

Because  $\Delta t = 1/f$ , the angular velocity equation can be written as:

$$\omega = 2\pi f \text{ or } f = \frac{\omega}{2\pi} \quad (14)$$

where

$f$  = frequency (hertz)

### 2.1.7 Period

The period is the time it takes to do one lap

$$\Delta t = \frac{1}{f} = \frac{1}{\omega/2\pi} = \frac{2\pi}{\omega} \quad (15)$$

### 2.1.8 Relations between Linear Speed and Velocity Angle

When the disc rotates during the time interval  $\Delta t$ , the point of A cover corner as far as  $\Delta\theta$ , along the arc  $\Delta l$ . A point linear velocity direction given by the arrow to the end. Large linear velocity is:

$$v = \frac{\Delta l}{\Delta t} \quad (16)$$

because  $\theta = \frac{l}{r} \rightarrow l = r\theta$ , then the above equation can be written as:

$$v = \frac{\Delta l}{\Delta t} = r \frac{\Delta\theta}{\Delta t} = r\omega \quad (17)$$

The following equation expressing the relation between the tangential acceleration with angular acceleration.

$$a = \frac{v_2 - v_1}{t_2 - t_1} = \frac{\Delta v}{\Delta t} = r \frac{\Delta\omega}{\Delta t} = ra \quad (18)$$

### 2.1.9 Torque or moment of force

Newton's Second Law, that a body can move straight to a certain acceleration when given style. Changes in velocity = acceleration. The greater the force applied, the greater the acceleration of motion of an object. Mathematically, the relationship between torque to angular acceleration expressed as follows:

$$a \propto Fr \propto \tau \quad (19)$$

description :

$a$  = acceleration angle

$\propto$  = comparable

$F$  = force

$r$  = radius

$\tau$  = torque

### Big torque

Torque is the product of the force  $F$  and sleeve style  $l$ . Mathematically, the torque is formulated as follows:

$$\tau = Fl \rightarrow l = r \sin \theta = r F \sin \theta \quad (20)$$

description :

$\tau$  = torque and moment of force

$F$  = force

$L$  = sleeve style

### 3. Research methodology

The magnets used are grade N42 neodymium magnets with a diameter of 25.4 mm, 25.4 mm thick. In the magnet rotor magnet mounted as many as 30 pieces, 1 row with the north pole facing into, and the magnet-attached distator as many as 34 pieces, 1 row with the north pole facing out. The position of the stator magnet attached at an angle of 25°, facing perpendicular magnetic rotor. Planned home magnet rotor has a diameter of 360 mm with a thickness of 35.4 mm made that does not have an influence on the magnetic field, in order to eliminate the influence of the resistance in the future as well as other effects.

Hold the magnet or drilled with a variety of angles, to attach the magnet by 30 holes divided into rows of slits. Similarly to the stator magnet, only differentiated diameter, number of holes and the drill angle holes to adjust the rotor magnet. In the process works, rotor positioned at the beginning of the side, will be shifted towards the position of the stator, which is supported by a retaining bolt as well as sliding sab.

After shifting toward rotor stator, rotor magnet is in or distator, will face each other and provide a repulsive force refused to move the stator is connected to the shaft. Varied angles before seen performance comparisons occur. In a shift towards rotor stator hub is planned to be a component of slip, with the rotary system as well as on the clutch was still attached to the stator grinding machines hand.

### 3.1 Test tools

The shape and construction of the test apparatus is shown in the following figure:

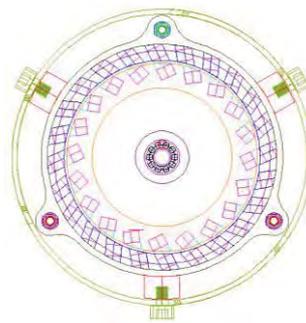

Fig 2 instrument testing looks ahead

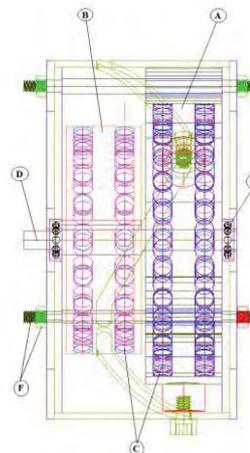

Fig 3 instrument testing looks aside

A: The house magnet stator, B: House magnet rotor, C: Magnet, D: Axis, E: Bearing / bearings, F: Bolts and nuts retaining

#### 4. Analysis and Discussion

Has been taken into account and planned for portable power magnet motors of performance, torque, rpm, power up component-supporting components, but on the ground the motor may not work as expected, with the review that the components of the magnetic material made of teflon, with a diameter of holes made of 12.5 mm with a depth of 9 mm, with a total hole / hold as many as 40 pieces in 2 rows of rotor, and the composition of each magnet is attached at an angle of 25 ° right upright faces in 48 holes in 2 rows on the stator, the distance between 5 mm, and the north pole is a pole of mutual dealing.

##### 4.1 Calculation of Magnetic Shielding And Planning

###### 4.1.1 Calculation Results:

magnetic data

Magnetic induction (B) = 0.1599 Wb/m<sup>2</sup> = 1599 Gauss

Strong magnetic field (m) = 39.978 amp.m

The intensity of the magnetic

(H) = 127920 amp/m = 1606.6315 Oersted

Magnetic flux (Φ) = 1.962 Wb

Magnet diameter (d) = 12.5 mm = 0.49213 in

data Shield

Co-netic AA-Alloy

The maximum magnetic induction (B<sub>max</sub>) = 7500 Gauss

Magnetic coercivity (H<sub>c</sub>) = 0.015 Oersted

Netic S3-6 Alloy

The maximum magnetic induction (B<sub>max</sub>) = 21 000 Gauss

Magnetic coercivity (H<sub>c</sub>) = 1.0 Oersted

###### 4.1.2 Magnet Shield Plan.

Based on the data above, the calculated thickness and damping material owned by comparing material Co-netic AA-Alloy and Alloy netic S3-6, so it can be selected to suit the needs. Planning With Material Co-netic AA-Alloy

Counting thick magnetic shield (t) can be found by the equation:

$$t = \frac{1,25 \cdot d \cdot H}{B_{max}} \quad (21)$$

Having acquired a thick shield, the shield can be searched damping (A) by a magnetic force, by the equation:

$$A = \frac{\mu \cdot t}{d} \quad (22)$$

Magnetic flux density is obtained by comparing the style of the magnetic field has shield calculated by the equation:

$$B = \frac{H}{A} \quad (23)$$

From the calculation results obtained:

Shielding Co-netic AA-Alloy

Shield thickness (t) 0.13 in, the damping rate (A) 36189.63 and the remaining influence of magnetic force intensity (B) 0.044 gauss.

Netic shield S3-6-Alloy

Shield thickness (t) in 0.047, the level of attenuation (A) 147.08 and the residual effect of the intensity of the magnetic force (B) 10.92 gauss. It can be concluded that material suitable for use on portable power magnet motors is the shield of the type Co-netic AA-Alloy, due to the influence of a magnetic shield once fitted are assumed to reduce the magnetic force very well, but the thickness of the field size on the market only in 0014, in 0020, 0.025 in, 0.030 in, 0.040 in, 0.050 in and 0.062 in, so based on the information stretcher, whichever is the thickest in the 0.062 to take into account the damping rate of return.

Planning with Co-netic material Alloy AA-size 0.062 in

Measured values for the remaining influence of the intensity of the magnetic force is small enough so that the magnets on the rotor and stator are expected to work optimally as desired. Because of the reduced resistance force, although of little value, still the necessity of calculating whether these changes are affecting the performance of the rotor and the stator, the returns obtained by the calculation of the force experienced.

###### 4.1.3 Calculation of Influence Remaining Prisoners Of Style Magnet

Consider the case that occurred due to force prisoners so that the rotor cannot rotate or does not move, which means that the force between repulsion and prisoners alike than or equal to zero. It can be concluded that the calculation can then be calculated on the basis of the failure.

Calculating the effect of magnetic force prisoners obtained from the equation:

$$F_{working} = m \times B_{working} \quad (24)$$

$$F_{resistance} = m \times B_{resistance} \quad (25)$$

$$F = F_{working} - F_{resistance} \quad (26)$$

#### 5. conclusion

From the measurement results based on the equations and literature obtained in simulation planning power magnet has specification power (P) 0173 kw, torque (τ) 1.81 Nm, rotation speed (n) 911 rpm. For the election to choose the magnetic shield material that has a high level of permeability to obtain maximum damping, but the thickness and material used in the planning should be adapted to the product in the market, as well as in the selection of the bearing, in order to facilitate the work. In this plan still need measurements of the magnet to be used that will be very helpful if you are using an accurate measuring tool, especially in the calculation of static magnets. On subsequent research, it is necessary variation to variable angle position magnet mounted on the rotor, so the comparison of power, torque and rpm of the angle formed can be seen clearly performance.

E-mail : rskmura@ipc.shizuoka.ac.jp

Dye sensitized solar cells, as an alternative for fossil fuel, has gain a reasonable interest among researchers because of its low cost of production and environmental friendliness. Although the efficiency of Dye sensitized solar cells (DSSCs) reaches 11~12%, various attempts have been still taken to improve the efficiency. The conventional fluorine doped tin oxide (FTO) layer used in DSSCs is a flat transparent thin film.

In this research, the FTO nanorods were fabricated to be used as the front electrode as shown in Fig.1. Rather than the conventional flat FTO film, the nanorods will have a comparatively large surface area. The high area of TiO<sub>2</sub>-FTO interface leads more charge collection and less charge recombination in the TiO<sub>2</sub> film due to a fast charge transportation through the FTO. The nanorods also could work as a charge-collecting probe inside the TiO<sub>2</sub> film, so that the effective path length that an excited electron has to travel before reaches the FTO can be shortened. In addition, because of the low resistance in FTO, the overall internal resistance of the cell will be decreased.

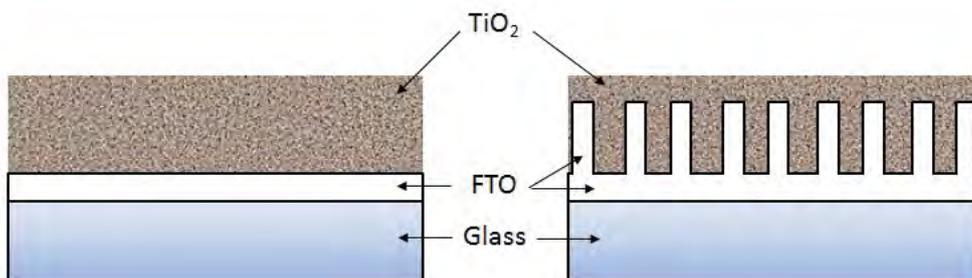

Figure 1: FTO thin films used in DSSC; conventional structure (left), new structure using nanorods (right)

To fabricate the FTO nanorods film, a solution mixture of SnCl<sub>4</sub>.5H<sub>2</sub>O and NH<sub>4</sub>F is sprayed on to a plain glass at 500°C using a specially designed and improved spray pyrolysis deposition apparatus. An ultra-fine mist is injected into a closed chamber, in which the heated substrate is kept. The spraying is done in 8 different spraying durations (15, 30, 45, 60, 75, 90, 105 and 120 min) and the transmittance, conductivity and morphology of the film are characterized.

The conditions for the well aligned FTO nanorods with higher conductivity and transmittance must be optimized before utilizing the films in DSSCs. For that, the spray duration, precursor solution concentrations, temperature, spray pressure and other physical parameters have to be altered and studied further.

Finally, it is expected that the FTO nanorods films could give a high efficiency for DSSCs comparing with those made with conventional FTO thin films.

**Abstract**—To be able to interact with humans, robot made as much as possible in order to have similar movement to human. Imitation Learning or often called Motion Capture is one of the humanoid robot control techniques with human as an actor and the robot as an agent who will imitate the movement of the actor. This method offers flexibility and ease to modify robot system. This paper explores the method of designing whole body imitation in Humanoid Robot. Robot motion was controlled by Joint Space Control with reference motion captured by natural human motion through Microsoft Kinect. The motions are also preserved in database for later used on robot motion generation and teaching as well. Finally, the effectiveness of the proposed method is illustrated by the experiment of imitating Indonesia Traditional Dances motion using humanoid robot with 18 DOF.

**Keywords**—Inverse Kinematic, Imitation, Kinect, Dynamixel, Humanoid Robot

## I. INTRODUCTION

The roboticist always trying to get the robot to approach the form and abilities like human, so that the robot can interact with human as well. Humanoid robots are without question a hot topic in research today. Humanoid robots may prove to be the ideal robot design to interact with people [1]. The most challenging problem in humanoid robot development is joint trajectory control. There are some ways to generate humanoid robot motion. For industrial need, robot motion is generated though complex computation code to achieve high precision. This is done in off-line mode through engineering software. Other method uses straightforward approach. Here, the operator drive robot to certain pose either by moving manipulator tool-tip with hand or remotely. Once the desired pose achieved, the current pose is saved to memory. However, these methods are time consuming especially for long-duration motion. Each pose may takes in minutes. Thus, these methods are not effective for more than hundred poses. In spite of that, an easy and quick approach is by imitating an object motion to robot with sensing device, or often called motion capture [5]. There have been numerous efforts for motion imitation either by using position sensitive detector (PSD) or by using stereo camera. Unfortunately, initial preparation is required such as mounting detector on object along with cabling or calibrating camera position for each measurement.

Programming by demonstration, or also known as imitation learning or motion capture is an answer to a problem how to control humanoid robot joints. This method offers flexibility and easy modification of the robot control. Humans as the actor would make a move, and then the robot as an agent will perform the movements performed by humans. Imitation is the best way to make the robots do some humanlike motion. The system is very useful to train the robot to make movements and in the future can be used to create a natural human-like motion of humanoid robot motion that can do housekeeping, dangerous work, and even entertain humans. Human motion imitation also can be used to record some traditional dance. The need for traditional dance preservation especially in Indonesia is unavoidable. There have been numerous claims on National traditional dances by other country while teenagers are starting to loose appetite in learning national cultures such as traditional dance. For that purpose, there have been national robot competitions on national dancing performance since three years ago. Here, the dancing should be carried out by humanoid robots since this kind of robot is more similar to human being. Also, interesting challenge in humanoid robot is how to design trajectory control for each joint. Obviously, the robot should have generated motion in memory.

Previous researches on robotic imitation have been done among others by Nakaoka research group to perform Japanese traditional dances by imitate motion to robot [7]. Imitation process has done by used 8 cameras to obtain three-dimensional information of 30 points on the actor body. Another imitation research is also done through markless tracking by Marc Rosanes to imitate the human arm movement on the Bioloid robot with TOF (Time of Flight) capture device Camera: Swiss Ranger 3000 [8]. Nevertheless, motion capture devices such as multi-camera capture or stereo camera are still expensive and have difficult algorithms to tracking human motion.

In this paper, realistic motion imitation by capturing human motion by markless method through Kinect is proposed. Kinect that usually used along with Xbox games has a stereo camera system. With certain library, the captured human pose is translated to quaternion form of each human joints. This is

done naturally without marking human body. Robot Operating System (ROS) used as work platform in this research. In the same time, the 18DOF humanoid robot imitates human motion. In addition, the extracted human motion is preserved in database for later used on robot motion generation and teaching as well. In this paper, only the upper part of humanoid robot is used. Moreover, to achieve realistic motion, the operation is made in rate 20Hz, which is close for human eye that has ability to see up to 25Hz.

## II. PROPOSED METHOD

There are three steps for doing imitation learning in this paper. First, we did human tracking to get important skeleton vectors. Second is mapping human motion to robot, joint position and velocity control. Finally, designed database motion, and then extract database to repeated movements that have been made.

### A. Human Tracking

Microsoft Kinect is used as capturing device to get human joint positions data. Microsoft Kinect is an accessory for Microsoft's Xbox 360 platform. Kinect is motion sensing unit device that was developed to interpret human gestures. It has sensors connected to a motorized pivot based. This device has a RGB camera, depth sensor, and multi-array microphone. With these sensors, Kinect can provide the ability to capture full-body 3D motion, facial recognition and voice recognition. Kinect has a good performance, small dimensions, and open source libraries that are able to make Kinect used on multiple OS platforms (Windows, Linux, and Mac), and also kinect is cheaper than other capture device. In this paper, human motion will be captured using kinect with markless method. With the skeleton tracking software from the Open NI, three-dimensional vectors of the joints in humans are achieved.

Fig. 1. Skeleton Tracking Node

To track the human skeleton, `openni_tracker` node from `stack openni_kinect` in Robot Operating System (ROS) is employed. This node will provide three-dimensional vector of 15 points on the human body. To perform tracking, someone needs to stand up and do "surrender" pose in front kinect (raise both hands). After the tracking process calibrated done, the `openni_tracker` node will publish 15 vectors which representing position of 15 main joints from the tracked body. Here is calibration pose picture and 15 vectors which `openni_tracker` published from this node.

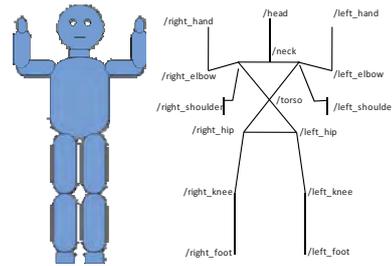

Fig. 2. Calibration Pose and Vectors Published by `openni_tracker`

### B. Mapping Human Motion

In mapping process, firstly, kinematics model of the robot must be identified which used to find the inverse kinematic solution of the model later. The used model robot consists of two arms with each arm consists of four degrees of freedom and two legs which consist 5 DOF in each leg. Humanoid robot model (each joint at 0°) and joint configuration of the robot model is shown in the figure below.

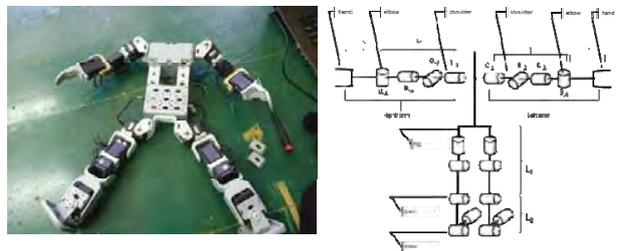

Fig. 3. Robot Model and Joint Configuration

Dynamixel AX-12 used as joint actuator in the robot. The advantages of using this actuator is feedback position, speed, voltage, temperature, and load. Here is Dynamixel AX-12 configuration movements and position constraint in the robot:

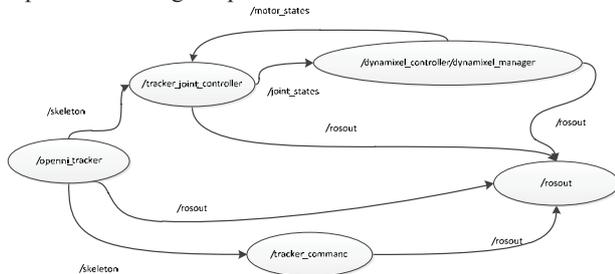

TABLE I. DYNAMIXEL AX-12 CONFIGURATION MOVEMENTS AND POSITION CONSTRAINT IN THE ROBOT

Right Body		
ID	Movement	Constraint
1	Flexion-Extension Shoulder	-90° to 90°
3	Abduction-Adduction Shoulder	-90° to 90°
5	Hand Internal Rotation	-90° to 90°
7	Flexion-Extension Elbow	-90° to 0°
9	Hip Yaw Rotation	-150° to 150°
11	Hip Pitch Rotation	-89.06° to 90°
13	Flexion-Extension Knee	8.20° to 143.26°
15	Ankle Pitch Rotation	-26° to 102.25°
17	Ankle Raw Rotation	-19.92° to 21.09°

Left Body		
ID	Movement	Constraint
2	Flexion-Extension Shoulder	-90° to 90°
4	Abduction-Adduction Shoulder	-90° to 90°
6	Hand Internal Rotation	-90° to 90°
8	Flexion-Extension Elbow	0° to 90°
10	Hip Yaw Rotation	-150° to 150°
12	Hip Pitch Rotation	-89.06° to 90°

14	Flexion-Extension Knee	-143.26° to -8.20°
16	Ankle Pitch Rotation	-102.25° to 26°
18	Ankle Raw Rotation	-19.92° to 21.09°

The complete process of real time imitation in ROS node is shown in following figure, ellipse shapes is node (process in ROS) and between two nodes, there is a topic which represents message or packet data:

First, /openni\_tracker node send /skeleton topic which contain 3D position of human joints. The position of human joints are computed in /tracker\_joint\_controller to generate the angular position and speed for dynamixel motor with inverse kinematic transformation. The /joint\_states topic contain data of position and speed which computed before. After that, we send the topic to dynamixel and dynamixel will give position feedback. Speed control Block diagram is shown in the following figure.

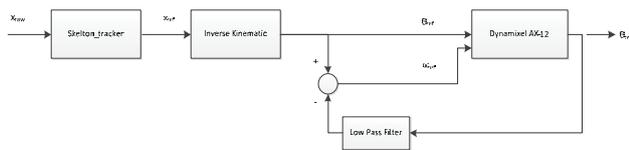

Fig. 4. Position and Speed Control Diagram

### C. Record Database Motion

Motion database is needed in order the robot can be able to repeat the results of imitation motions. In this paper, human motion is saved in a .csv extension by writing in the following format.

time	$\theta_1$	$\theta_2$	...	$\theta_{18}$
Goal Position				

secs.nsecs

Fig. 5. Motion Database Format

With that format, less memory is saved because there is no need to keep the speed memory of each joint. Velocity of each joint can be derived from the subtraction of the current and previous angle position divide by time difference.

### III. RESULT

The result of the real time imitation is a good, mapping algorithm with inverse kinematic show the robot can imitate human motion, and has conducted multi-solution anticipation of weakness in the method of inverse kinematic mapping

process. The video of the dance imitation result can be seen in this url: <http://www.youtube.com/watch?v=qIWyny3vqds>. Balancing method is still in development so that when doing imitation it still required hanger. Real time imitation process with Microsoft Kinect performed at frequency of 20 Hz.

Fig. 6. Real Time Dance Imitation Result

### IV. CONCLUSION

A real time motion imitation is realized in this paper. The imitation is done by capturing motion through Kinect and mapping the motion to robot's arms and legs. At the same time the motion also can be recorded in database motion. By tuning Robot Operating System, the proposed method has been validated in rate of 20Hz which is close to human eye ability. Here, the ROS package that has been developed, successfully solve the challenges of the imitation process as well humanoid robot capable of performing database extraction and storage and motion that has been done by humans.

**Abstract**— Prepaid electricity which is using prepaid digital kWh metre is one of the programs of PT PLN to enhance the quality of their services. They make these programs to avoid errors reading the meter, the uncertainty of the Bills, arrears and disconnection. The problems occurred in the consumer side is whether prepaid electricity consumption more efficient than postpaid electricity consumption. In this research we perform the measurement of electric energy consumption using postpaid and prepaid kWh meter with the same load and the same time, so that we able to know which is more efficient. The measurements performed on 1300 VA, R1 customers with 4 types of load (resistive load 500 Watts and 1000 watts, household expenses 407 Watts and 1235 watt), testing was carried out for 6 hours per day, 6 days per week for 1 month. The research result obtained from measurement and calculation of energy consumption. Technically at the time and the same loads, prepaid kWh meter more efficiently than postpaid kWh meters. Economically, according to TDL 2010, for consumption under 52 kWh kWh Meter prepaid more efficient, whereas for consumption above 52 kWh showed similar results.

**Keywords** :Pre paid electricity, Post paid electricity, Pre paid kWh meters, Post Paid kWh meters.

## I. INTRODUCTION

Electricity has become a fundamental requirement for a wide range of human activities, which are used for a variety of functions in the future. Electricity reliance would make man its existence. PLN was aware of society's reliance on electricity, so continue to conduct various studies to improve the quality of service by offering a variety of service programs. Forms of innovation created by PT. PLN is by issuing prepaid electricity program. The Program has issued prepaid electricity since 2008, prepaid electricity has the advantage that electricity use is more restrained, with no termination penalties, not fines imposed delays, there is no fixed monthly fees and so on. Additionally prepaid electricity created in order to avoid any incident read meter, erratic utility bills, the delinquent accounts, and any disconnection on electricity postpaid. With this program the community invited to better appreciate the existence of electric power and wiser in consuming electricity. Now the question is whether the use of prepaid electricity can be the solution of the existing problems at the moment? Is it true that prepaid electricity more efficient than postpaid

electricity? Therefore the authors conducted a study to analyze the comparative measurement of the electric energy with postpaid and prepaid meters kWh kWh meters with a load and the same time in the laboratory of State Polytechnic of Sriwijaya.

## II. THEORY

### A. Power<sup>[1]</sup>

Electric power is the amount of energy per unit of time, where work is in progress or the work done the Union time. From this definition, then the electrical power (P) can be formulated:

$$P = W / t \quad (1)$$

$$P = V \cdot I \cdot t / t \quad (2)$$

$$P = I^2 \cdot R \quad (3)$$

Whereas Power (P, Watt or Joule/detik), Electrical Energy (W, Joules), time (t, second), voltage (V, Volt), Resistance (R, Ohm).

### B. Electrical Energy<sup>[2]</sup>

Electrical energy is the ability to generate electricity. Electrical energy is represented by w. Where as the formulation is used to determine the electrical energy is:

$$W = Q \cdot V \quad (4)$$

$$W = (I \cdot t) \cdot V \quad (5)$$

$$W = V \cdot I \cdot t \quad (6)$$

Whereas Electric charge (Q, Coulomb)

### C. Current<sup>[3]</sup>

Current, depicted with the symbol i (derived from the French word: intensite), defined as the change of velocity with respect to time charge. Or, other sense is the charge flows in a unit of time. So, the current that is actually moving charge. As long as this charge is moving it will pop up the flow, but when the charge is stationary then the flow will also be lost. The charge will move if there's energy out that affected it. The charge is the smallest unit of an atom or a subsection of the atom. In the modern atomic theory, stated that atoms consist of a nucleus of particles (protons are positively charged (+)

and neutrons are neutral) surrounded by loads of electrons (-). So, is normally electrically neutral atoms.

The charge consisted of two types i.e. positive charge and the negative charge. Electric current direction in line with the direction a positive charge and the opposite direction with a flow of electrons. A particle can be a positive charge when it loses an electron, and a negative charge when accepts electrons from other particles.

Coulomb is the basic unit of the International System of Units (SI) is used to measure the electric charge. Mathematically, the current defined:

$$i = \frac{dq}{dt} \quad (7)$$

Symbol: Q = a constant charge, q = electric charge

#### D. Voltage<sup>[3]</sup>

Voltage or often called potential difference, is the work done for a charge of one coulomb moves from one terminal to another terminal. Or, in other words, if a charge of one coulomb is driven or moved, there is a potential difference on either Terminal.

#### E. Measurement<sup>[4]</sup>

The measurement is determination of quantity, dimensions, or capacity, usually against a standard or unit of measurement. In the study of measurement known a few terms, among other things:

- The instrument is measuring instrument for determining the value of a quantity or quantities or variables.
- Precision is a price closest to a reading of an instrument approach the true value of the measured variable.
- Precision is a measure of the ability to measure results that are similar.
- Sensitivity is a comparison between the output signal or instrument responses to changes in input or variables that are measured.
- Resolution is the change in the value of the smallest measured which instruments will give a response or a response.
- Error is the deviation of the measured variable price (value) which is actually

Measurement of electrical quantities no one produces perfect precision. Need to know the actual cause of the sensitivity and the occurrence of errors of measurement Errors in measurement can be classified into three types, namely: Error –common mistakes, Systematic error mistakes Random Errors Are Not Intentional.

### III. METHODOLOGY

The measurement of electric energy in kWh meters postpaid and prepaid using a measuring instrument of Power and Harmonics Analyzer. The measurement was carried out in

the laboratory of electrical engineering State Polytechnic Sriwijaya Palembang. The comparative testing of electrical energy in both postpaid and prepaid kWh meter is done with 4 different types of loads for 1 month and each load test performed within 6 hours per day for 6 days. Testing process performed with 4 different types of loads each week, namely:

1. The first week, the resistive load 5 incandescent lamps with a total power of 500 Watt.
2. The second week, the resistive load 10 pieces of incandescent lamps with a total power of 1000 Watts.
3. The third week, the load of household consisting of energy-efficient lighting, TV, fan, refrigerator, and water pumps with a total power of 407 Watts.
4. The fourth week, the load of household consisting of incandescent bulbs, television, fan, fridge, and water pump with a total power of 1235 Watts.

#### A. Measurement Equipment

##### Power and Harmonics Analyzer

Power Harmonics Analyzer is a combination of several functions measurement of electrical such as voltage, current, active power, reactive power, power factor, frequency, all power, and the other harmonics in one device. Power Harmonic Analyzer 6830 used to measure the current (total, phase motors and metal), voltage (total, ph-ph and ph-neutral), frequency, power factor (total and per phase), power/phase (active, reactive and apparent), total power (active, reactive and apparent), energy (active, reactive and apparent), THD (currents and voltages).

##### Analogue KWH Meter (Postpaid)<sup>[6]</sup>

kWh meter PLN postpaid used to calculate the power consumption of consumer kWh meter is analogous to the power of 1300 VA. This tool works using magnetic induction method in which a magnetic field to move the dish is made of aluminum. The rotation will move counter shows the number of digits as his kWh. The disc rotation will move counter shows the number of digits as his kWh

Kwh meter is a device used to measure the large power consumption by consumers. This tool is very common in the community. The main part of a kWh meter is, the coil voltage, the coil current, aluminum disc, fixed magnet whose task of induction aluminum disc to neutralize the magnetic field and mechanical gear that records the amount of rotation of the aluminum disc.

This tool works by using method of induction of the magnetic field in which the magnetic field moving the aluminum disc. The disc rotation will move the counter digits as the number of kWh display

##### Digital KWH Meter (Prepaid) 2R<sup>[7]</sup>

Prepaid kWh meters type of Star 2S-2R DDSY23S with a power of 1300 VA is the latest service from PLN with a range

of advantages in regulating the use of electric energy through the Prepaid Meters (CDM).

The electricity will be streamed to households (load), it first flowed through the MCB who serves as the current delimiter is at once in case of short circuit protection. Then streamed into kWh Meters which functions to calculate the energy used. This prepaid system using a special Meters kWh with keypad and have sensors to detect electrical energy used with impulse output of the lights flicker.

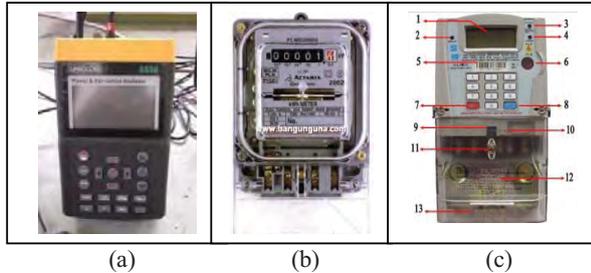

Figure 1. (a) Power and Harmonics Analyzer 6830, (b) analogue kWh meter, (c) Digital kWh Meter

### B. Load Measurement

Comparison of measurement of power on postpaid and prepaid meters kWh using a simulated series of module 1 simple phase consisting of load incandescent lighting (purely resistive), energy saving lights, water pump, TV, refrigerator and fan.

TABLE I. LIST OF LOAD

No.	Type of Load	Specification	Cos φ	Number	Power
1.	Incandescent lighting	100W/220V	1	10 pcs	1000W
2.	Energy Efficient lighting	18W/220V	0,64	4 pcs	72 W
2.	Water pumps	125W/220V	0,46	1 pcs	125W
3.	TV	70W/220V	0,53	1 pcs	70 W
4.	Refrigerator	90W/220V	0,81	1 pcs	90 W
5.	Fan	50W/220V	1	1 pcs	50 W

## IV. DISCUSSION

### A. Comparative Analysis of Measurement Results and Calculations

Comparison of the test results of electrical energy on average per hour within 6 hours for 6 days for each load on postpaid and prepaid kWh meter, obtained electric energy comparison on average for 6 days as follows :

TABLE II. COMPARING THE RESULTS OF MEASUREMENTS AND CALCULATIONS OF ELECTRICAL ENERGY PER HOUR

Type of Load	Type of Metre	Energy Used
--------------	---------------	-------------

		Measurement Result	Calculation Result
500 Watt (a pure resistive load)	Pospaid	0,446 kWh	0,4488 kWh
	Prepaid	0,443 kWh	0,4461 kWh
	<b>Difference</b>	<b>0,003 kWh</b>	<b>0,0027 kWh</b>
1000 Watt (a pure resistive load)	Pospaid	0,874 kWh	0,8758 kWh
	Prepaid	0,871 kWh	0,8723 kWh
	<b>Difference</b>	<b>0,003 kWh</b>	<b>0,0035 kWh</b>
407 Watt (Load of household)	Pospaid	0,380 kWh	0,4699 kWh
	Prepaid	0,376 kWh	0,4668 kWh
	<b>Difference</b>	<b>0,004 kWh</b>	<b>0,0031 kWh</b>
1235 Watt (Load of household)	Pospaid	1,101 kWh	1,1351 kWh
	Prepaid	1,088 kWh	1,1327 kWh
	<b>Difference</b>	<b>0,013 kWh</b>	<b>0,0024 kWh</b>

Technically, the use of electrical energy in kWh meter postpaid and prepaid using the same load and the same time, energy consumption electricity kWh meter postpaid larger or faster than electrical energy consumption spent electric energy in prepaid kWh meter. Each of kWh Meter have different working principles, where in principle work on postpaid kWh meters have a coil inductance, which had resulted in consequential kWh meters more quickly heat so it's more quickly spend electrical energy. whereas Prepaid kWh meters just an electronic device with keypad keys which has sensors to detect electrical energy used with impulse output of the lights flicker. Thus in technical measurements prepaid kWh meters more efficient than postpaid kWh meter.

### B. Economic Analysis

From the results of calculations performed in accordance TDL 2010, Rp 790 for 1300 VA. Then can be calculated economically postpaid and prepaid electricity.

TABLE III. THE ECONOMICAL CALCULATION RESULTS OF PREPAID AND POSTPAID ELECTRICITY

Usage (kWh)	Amount of Postpaid Electricity bills	Amount of Prepaid Electricity Bills
49	Rp 41,080	Rp 38,710
50	Rp 41,080	Rp 39,500
51	Rp 41,080	Rp 40,290
52	Rp 41,080	Rp 41,080
53	Rp 41,870	Rp 41,870
54	Rp 42,660	Rp 42,660
55	Rp 43,450	Rp 43,450

Customers of R1 1300 VA according to TDL 2010, total electricity bill for prepaid than postpaid more efficient for use of <52 kWh and it is same for the use of ≥ 52 kWh. For calculation of postpaid tariff, electric energy consumption limits enforced minimum is 40 hours. When taking electrical energy under 40 hours, for the calculation of the rates will still be counted 40 hours of usage. While prepaid tariffs, electrical energy consumption is calculated according to the amount consumed, do not impose minimum limit the consumption of electrical energy. postpaid Bill for not including VAT and the

use of street lighting. While the bills for prepaid is already included VAT and the use of street lighting.

### CONCLUSION

From the results of measurements and calculations for R1 customers 1300 VA technically, electric energy consumption in postpaid and prepaid kWh meter with the same and the same time, prepaid kWh meters are more efficient than postpaid kWh meters. While economically, for the consumption of electrical energy under 52 kWh prepaid kWh meter more efficient than postpaid kWh meters. for usage above 52 kWh will both alike.

The advantages and disadvantages of Prepaid Electricity and Postpaid Electricity are as follows.

- Prepaid Electricity, has advantages over the postpaid electricity, energy prices: kWh "ALONE" (without the cost burden), no minimum account limit, the registrar meter no need to record the number of usage, there is no potential for arrears, and most importantly, the customer able to manage and control the use of electricity to be more efficient in a month. The disadvantage if the usage limit is over then the power turns off immediately no matter the time of day or night, you are using electricity or not it is being considered by the consumer to change the way electricity consumption by using electricity vouchers.
- Postpaid Electric, Has the disadvantage compared to prepaid ie, price of energy: additional kWh cost burden (power 450 and 900 VA), is limited to the "minimum bill" (40 hours minimum), need to recording kWh rate, potential delinquent "big enough". While the advantages are electrical disconnection the connection manually.

 canisius\_donra@yahoo.com, basyarie@eng.ui.ac.id, yuli@eng.ui.ac.id, eko@eng.ui.ac.id

**Abstract**— Radio Frequency Identification (RFID) is one of the developed technologies, which is used in several applications, including for medical field applications. For patient monitoring purpose, the RFID system is consisted of a medical tag that is implanted into the human body and a reader unit that is installed away from the human either in proximity or far away from the human body. By this communication system, it can reduce medical error, the risk of the tag being lost, and can be used for uncooperative patient. The monitoring device will be connected to the existing network (wireless LAN and so on) allowing to provide the mobility of patient, the physicians or caregivers can get easily patient's medical information without spending a lot of time via such a network connection. In this study, it will propose a tiny dipole antenna for RFID tag that will be implanted into the body following it is enclosed by a silica glass to reduce the radiation effects on the human body. The antenna is numerically simulated by using a human arm model in the frequency of 924 MHz according to the RFID band allocation in Indonesia. This study also investigates two other different surrounding environment of the antenna in order to precisely understand about the antenna characteristics, i.e. antenna placed in free space and enclosed in silica glass material. Each environment gives effects on the antenna's resonant frequency including its bandwidth. Following the simulation, the antenna is fabricated and validated by the basic measurement. This paper will show the current results of the antenna characteristics in free space environment in order to validate its basic manner. The antenna is relatively very small dimension compared to the band wavelength with good performances in S parameter, sufficient bandwidth, and omnidirectional radiation pattern.

**Keywords**— Implanted dipole antenna, medical tag, patient monitoring system, RFID, short range communication

## I. INTRODUCTION

Patient monitoring system in the hospital still uses a conventional monitoring, where nurse or doctor needs to go to the patient's room to examine and check the current physical condition of the patient. This condition is quite impractical if the number of available medical personnel is fewer than the number of patients in the hospital. In order to overcome such a drawback, an automated monitoring system that is able to instantaneously display the state of the patient's physical condition.

The concept of the monitoring system will allow for monitoring the patient's condition without the patient itself coming to the nurse's room. Currently, most of hospitals in Indonesia have applied a cable-based monitoring system. Along with the current wireless technology especially the RFID (Radio Frequency Identification) system, most of cable-

based application systems tend to shift into wireless-based technology, in order to ease the equipment's installation and reduce its cost. The RFID is a tremendously adopted wireless technology in very wide applications that uses radio frequency to send data from a device called RFID tag, which is placed on the object, and will be recognized by a reader or recipient for the purpose of identification or tracking the object [1].

The development of wireless technology for health sector today has greatly attracted both academic and industrial researchers as the needs of the world (especially in developed countries) and associated with rising health care costs and the demand for hospital resources [2].

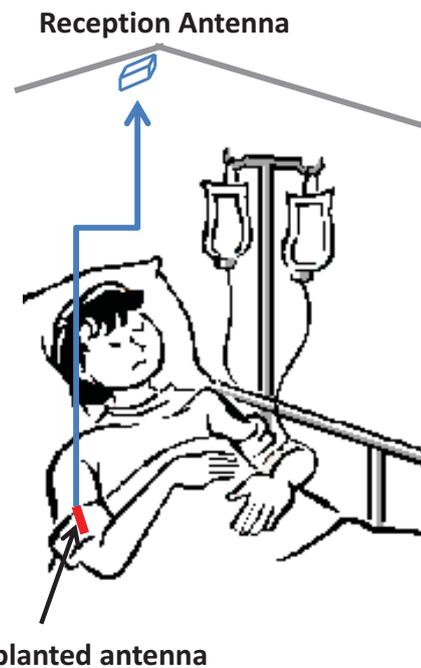

Fig. 1. An example of monitoring system of the patients in hospital.

One of the technologies with interestedly studied is the RFID technology, which offers a promising solution in building health care with wireless technology [3] and has a potential point to reduce medical errors and improve the quality of life of the patients in hospitals [4]. Figure 1 shows an example of RFID application for patient's monitoring system. Most of antennas researches for medical applications still focus on hyperthermia for cancer treatment and diagnostics on physical parameters of a patient [5], even though currently some researchers has been interested to study

on antennas for medical communication. In the past, the RFID technology is usually used by planting a tag on animal's body. However, current developments have allowed for putting a RFID tag or implantation in the human body [6]. The use of tags in the body (not the outside of the body) is aimed to reduce the risk of losing the tag and yet it looks suitable for patients who are less willingness to cooperate with the doctor [7].

Earlier RFID technology typically uses low frequency, since it has no signal attenuation and less significant effect to the human body. However, the existing system is limited to have a short distance coverage and very low data transmission rate. In order to overcome these drawbacks, UHF frequency band (Ultra High Frequency) is sometimes used to have the possibility of further transmission distances, higher data rate although the damping (loss) is greater, especially in the layers inside the human body because the nature of the material body man is very lossy [8]. Currently, some of RFID tags are widely designed for medical applications in the form of loop antennas, which work at frequencies 402–405 MHz to determine the effect of a human head to the signal transmission frequency. Another tag is also designed for transmitting patient data such as temperature, blood pressure, heart rate, and so on in real time operation. The tag antenna works at frequencies 951 – 956 MHz implanted in the human upper arm model [5]. However, this operating frequency band is not recommended to use in Indonesia, since the regulation of Indonesia government recommends to use RFID frequency at 923 – 925 MHz [9]. In addition the use of the frequency 923 MHz is intended to reduce the effects of SAR in the human body. In this paper, it will be proposed a RFID tag antenna operates at frequency of 923 – 925 MHz aiming at patient monitoring system.

## II. ANTENNA CONFIGURATION

The configuration and dimension of the proposed antenna is shown in Fig. 2. The antenna is fabricated by using a copper wire that is folded in such a way it will be appropriate design for 50 ohm-port. The antenna element (without silica glass cover) is made by the size of 33.3 mm × 1.8 mm × 1.8 mm (L × D × H). The antenna will be implanted in the human body at the upper arm, which the arm model is represented by three layers consist of skin, fat and muscle. The antenna is implanted at the position between the skin and fat layer. The thickness of skin, fat and muscle layers is 2 mm, 4 mm and 54 mm, respectively [10]. Each layer electrical property is shown in Table 1. Hence, by this design it is expected to establish communication in range of 10 m coverage as predicted in link budget [10]. The fabricated antenna is shown in Fig. 3.

TABLE 1: ELECTRICAL PROPERTIES OF TISSUES AT 924 MHz

Tissue	Electrical Properties	
	Permittivity	Conductivity
Skin	41.284523	0.874705
Fat	5.458249	0.051615
Muscle	56.824448	1.004436

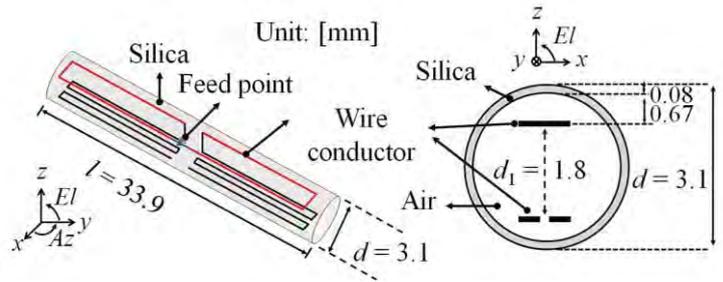

Fig. 2. A proposed antenna's structure

Fig. 3. Fabricated Antenna

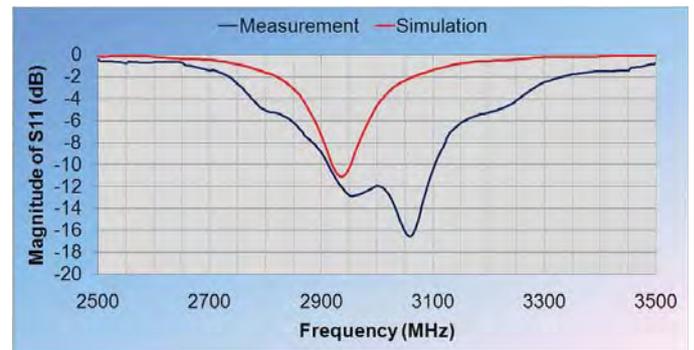

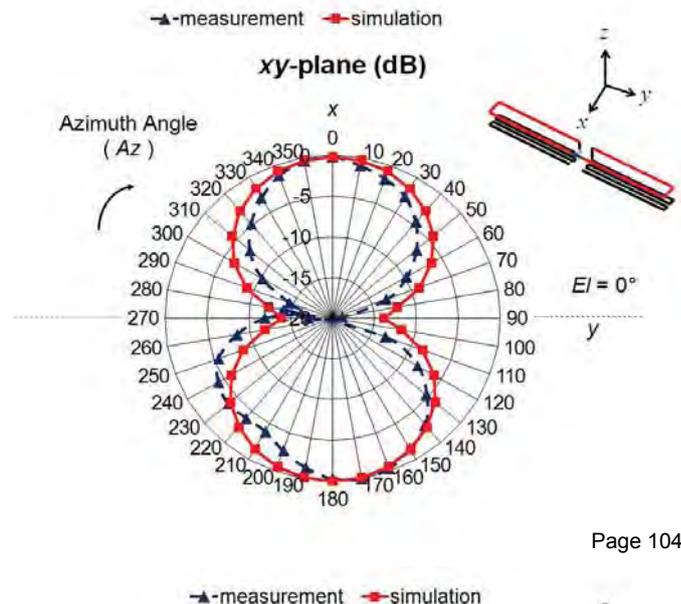

Fig. 4. S11 performance

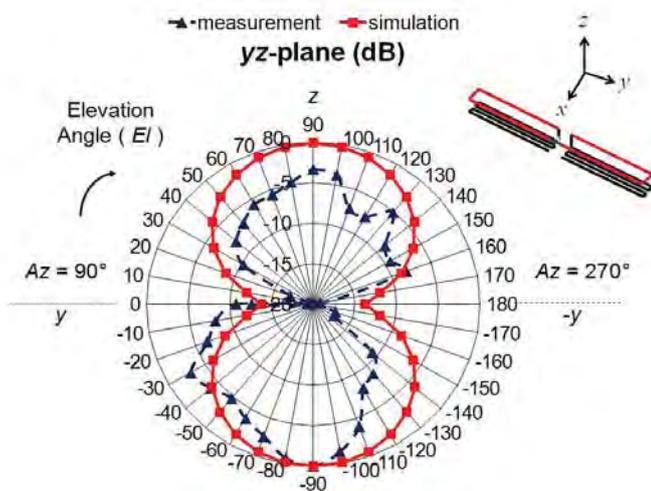

Fig. 5. Radiation pattern characteristics of the antenna

### III. MEASUREMENT RESULTS

The fabricated antenna is validated by measuring basic characteristics such as coefficient reflection and radiation pattern. In present validation, the antenna is measured in free space environment, where at least it can be known the basic performance of the antenna before it will be inserted in the phantom model or animal tissue.

In accordance to the measurement results, it can be seen that the fabricated antenna has large enough bandwidth from 2915 – 3100 MHz in the standard of  $S_{11} \leq -10$  dB, which is very sufficient bandwidth. The result agrees with the simulation result as shown in Fig. 4.. In addition, the radiation pattern of the antenna is evaluated in three different planes, namely  $xy$ -,  $yz$ - and  $xz$ -plane. In comparison to the simulation results, the measured radiation pattern meets the simulation at the resonant frequency 2.94 GHz as shown in Fig. 5. Moreover, the antenna has omnidirectional pattern in H-plane and 8-number shape as the basic pattern of the electric dipole antenna.

### IV. CONCLUSION

In this study, we have proposed a tiny dipole antenna for RFID tag that will be implanted into the body following it is enclosed by a silica glass to reduce the radiation effects on the human body. The antenna is numerically simulated by using a human arm model in the frequency of 924 MHz. The distance

between the tag and reader is expected by 10 m with the minimum gain of the antenna is -30 dBi. Then, the antenna is simulated using the finite integration technique (FIT) software in three different conditions; those are when the antenna is implanted, when it is enclosed in silica glass, and in free space environment, in order to understand the antenna characteristics in each given condition. The dimension of the antenna is  $33.3 \times 1.8 \times 1.8$  mm<sup>3</sup> at operating frequency 924 MHz with very sufficient bandwidth. When the antenna is enclosed in silica the resonant frequency is shifted to the frequency 2.69 GHz and it becomes 2.94 GHz in free space condition. In this paper, the antenna's characteristic is evaluated in free space environment in order to validate its basic manner. The antenna is fabricated and measured in anechoic chamber including the reflection coefficient and radiation pattern to validate the simulation results. The antenna has good coefficient reflection, sufficient bandwidth, and omnidirectional radiation pattern as it is expected in the simulation.

**Abstract**— The Fokker-27 remains one of logistics and military transport aircraft to the Indonesian Air Force. With age and life-time aircraft components, the components have been and often damaged during the flight. One of the important equipment is the alternator Fokker 115/208 Volt 400 Hz 15 KVA generating power.

This paper was discussed, about first our research on the alternator, and performed at the Air Squadron 2, this is done one of which is due by the Fokker Industry. Alternator type in Fokker 27, is not produced anymore, given the alternator and its function as a supplier of electricity, converting DC voltage into AC and as a voltage divider is used to keep the generator excitation and round on the Fokker 27 be a constant and airworthy.

The result showed that the alternator Fokker 27 with 15KVA power, with small dimensions, can be used 12 KVA at 0.9 lagging power factor as alternative substitutes and have similar characteristics to the alternator Fokker 27, and now the stage is made up paper being conducted routine flight air force in particular at SKADRON 2nd.

**Keywords** Electricity on the Fokker 27, alternator, voltage regulator

## I. INTRODUCTION

Indonesia is an archipelago with numbers of islands, it has considerable natural potential of developing countries. To preserve and defend the territory of Indonesian from the threat of the other countries, so we need a strong military component.

The Air Force as one of the major elements of the military who have the task of carrying out air defense to protect the territory of Indonesia and also provide support for rapid transit assistance in addressing the situation of natural disasters in Indonesian.

We need aircraft with maintained well condition, so when the Air Force have assignment they able for move quickly and then have the high mobility, especially to reach the long distances areas that have in a rapid relatively. The one entity that is in the Air Force is the Air Squadron 2 as a union that supports the assignment routinely done every day. Currently Air Squadron 2 only has 6 units Fokker 27 (F27) whit the highest mobility, so we need a good condition of the aircraft and ready to perform their duties

It is necessary for both routine maintenance aircraft structures, engines, avionics and electrical systems. In electrical systems Fokker 27 aircraft see figure 1, one of the most important tools is the Alternator 115/208 Volt 400 Hz 12 KVA generating power.

Altenator is electricity supplier for avionics equipment or other equipment on the aircraft in large numbers. Because the alternator is vital quite in generating electrical power for the aircraft, care and maintenance is very important because the aircraft will not fly without a power supply. Due to financial constraints that exist today for financing and maintenance should be conducted as well as how to analyze the performance of the alternator to the other electronic devices that use the life or alternator in a long time.

Figure1. Fokker F-27 aircraft owned by the Air Force

## II. ELECTRICAL

### A. Electrical In Fokker -27

In order to know the alternator as a backup power source, it first has to be discussed on electricity on Fokker-27, as follows:

The Electrical power from the AC bus Foker-27 aircraft supplied by three different sources is:

- a. The twin engine driven were voltage 208 volts, 3 phase, variable frequency alternator that produces electrical power for heating main. The alternator is not used by parallel, but independently operated.
- b. The twin main inverters, which is controlled by a DC motor, with the supply of 115 volts, 3 phase, a static

inverter frequency of 400 Hz are essential for the operation of the battery installed aircraft.

- c. The Twin power converter is supplied electricity at 115 volts, 400 Hz, single phase AC power for lighting equipment.

Alternator is 208 Volt AC generator brushless type that has a voltage 120/208 volts and 3 phase, which produces 12 kVA, with a power factor of 0.9 lagging the speed range of 6700-10000 rpm (10000 - 15000 rpm engine). The frequency of the output voltage of 400 Hz at 8000 rpm (12000 rpm engine). Common voltage alternator output will be reduced on minimum speed, which amounted to 4020 rpm (6000 rpm engine).

The most high-efficiency fan was set at anti-drive or inlet end of the generator. Therefore, fan can operate more efficiently in the air more and more cold on inlet, than heated air from the engine.

Thermostat for overheat warning coupled with the objective of identifying a surplus generator winding temperature. The Usability of thermostat is normally open circuit, which closes when the winding temperature reaches a critical point, i.e.  $374 + 10^{\circ}$  Fah ( $190 \pm 6^{\circ}$  Cel). Contactors are used to operate THE OVERHEAT warning light on the top left panel.

Loads is not really a burden raktif, because it is not regulated supply frequency (unfegulated).

Supply is provided by twin alternators, which are designed to be used by the left hand and right hand. Each alternator is generated by the core control, control switches, assorted gauges and indicator lights as a warning if something goes wrong and the isolation transformer and circuit breaker 3 phase.

#### B. The electrical components and panels on Fokker27

The template is used to format your paper and style the text. All margins, column widths, line spaces, and text fonts are prescribed; please do not alter them. You may note peculiarities. For example, the head margin in this template measures proportionately more than is customary. This measurement and others are deliberate, using specifications that anticipate your paper as one part of the entire proceedings, and not as an independent document. Please do not revise any of the current designations.

##### A. Alternator.

The Alternators used on aircraft Foker-27 Squadron Air 2 is a generator with voltage AC 120/208 Volt, 3 phase, 12 KVA, brushless assembly (no brush), installed on additional gearbox connected to the machine. Alternator is relatively mild when compared with the alternator in general with the same capacity (the alternator is low weight about 158 kg). This unit basically consists of three parts, that is a permanent magnet generator (PMG), an exciter generator, and a main generator. PMG produces power for the control system. Generator exciter produces a regular supply excitation to the main generator, which produce 3 phase AC output for

equipment that uses voltage 208 volts. In addition the unit is produced with an overheat thermostat.

##### B. The unit control

Control units are equipped with a transistor placed in the cargo compartment ceiling front right. This unit produces alternators with Voltage 'regulation and overvoltage protection. Internal power supply for the control unit is obtained from the PMG. Switch OVERVOLTAGE placed on maintenance and comes with a test panel to examine circuit voltages (over voltage circuit).

##### C. The switch control.

The Switch ON / OFF was a single pole alternator that is provided on the panel above the head to the left. This switch controls the internal power supply of the control unit.

###### a. Circuit Breaker 3 phase

Channel charger alternator is protected with a current 50 amperes per phase, using 3 phase circuit breaker. Circuit breaker is organized into additional gearbox of the engine compartment connected.

###### b. Isolation Transformer.

The Isolation transformer was provided to protect the voltage levels of the control unit using circuits of the wave (surge) of the busbar voltage. The transformer is wye-to-wye, same by changing the ratio of assembly which consists of a series to release capacitance resistance earthed neutral point to where the alternator is connected. The transformer is placed near the control unit.

The danger indicators of Fokker-27, can be caused by several reasons, that is:

###### a. The Alternator couldn't be operated

The Blinker indicating that the alternator INOP (not working) is a red indicator "press to test" that is placed on a panel at the top left. The panel is controlled by a relay inoperative alternator which is positioned on the AC voltage of 208 Volt.

###### b. Overheat

The Alarm is indicated by a red light. HEAT "press to test" warning light (light hazard) is positioned on the upper left. The panel is operated by the alternator overheat thermostat.

###### c. Over voltages

The Warning of the danger is provided by the magnetic indicator, placed on test and maintenance panel, and is controlled by the control unit overvoltage circuit. Under normal conditions, the indicator will look black but with the condition that excessive voltage, red indicator will appear on the glass.

D. Gauges located on the instrument panel are :

- a. Voltmeter  
 The Rating alternator is 120 volts line-to-neutral (L-N) and 208 volt line-to-line (L-L), the alternator main terminal. In circumstances where the voltage drop on the line until the filler (feeder lines), this terminal generates a voltage of 115 Volt L-N and 200 Volt L-L to regulasi point. The Potential point 115 Volt L-L monitored by a voltmeter, one for each alternator. Twin Voltmeter is placed on the left side panel.
- b. Amperemeter (Ammeter)  
 Load current from the alternator is monitored by Ammeter which is positioned on the top left. They used to be connected to a double pole, twin position switch, arranged near by Ammeters. Position switches spiked TOTAL description, and POWER UNIT. In this position, TOTAL, Ammeter in series with the situation of the current transformer connected to phase A of the output circuit of the alternator. At the position of POWER UNIT, Ammeter connected in series with a current transformer input circuit de-icing of the power unit. TOTAL current transformer placed on the panel at 208 volts AC.
- c. Test Point  
 Test point prepared on the maintenance and test panel to monitor line-to neutral and phase-to-phase voltage output of the alternator.
- d. Alternator Load Distribution.  
 Each alternator was located separate load. Alternator was operated independently of one another and in the event of failure of one of the alternator, the alternator the other can not be used to supply the load fails (a faulty alternator load from / failure).

Figure 2. (A) Panel cabin without a pilot

(b) The Pilot position at Fokker-27

III. CALCULATION AND ANALYZING OF FOKKER 27 MACHINES POWER AND ENERGY CALCULATIONS

A. Power of single machine

Power = 1835 Hp; if 1 HP= 746 watt, so the power of machine is = 1835 x 746 watt = 1369 kW

B. Energy for a single machine

the formula :  $P = Q/T$  (1)  
 with : P = power (watt)  
 Q = energy (kWh)  
 T = time (hour)

The energy produced by the engine is :  
 $Q = P \times T = 1369 \text{ kW} \times 1 \text{ hour} = 1369 \text{ kWh}$

C. Fuel usage

Specification Fuel Consumption (SFC) = 0,728 lb/HP/h  
 The fuels for single engine = 1835 x 0,728 = 1335,88

The Assumptions distance Surabaya and Jakarta ± 900km. The time required is 2.5 hours. The fuels for twin machines per-hour is 666 x 2 = 1332 liters/hour, so for 2.5 hours is used as fuel:

Total Consumption = Fuel consumption per hour x time (2)  
 = 1332 x 2,5 = 3330 liters for distance 900 km.

So consumption per kilometer is:  
 Consumption = Total consumption / Distance  
 = 3330 / 900 = 3,7 liters/km

#### D. The mileage of aircraft

Tank capacity is owned 5000 liters. So Foker-27 aircraft to fly the farthest distance is :

$$\text{Distance} = \text{Tank Capacity} / \text{Consumption every kilometers.} \\ = 5000 / 3,7 = 1351 \text{ km} \quad (3)$$

With flying time :

$$\text{Flying Time} = \text{Tank Capacity} / \text{Consumption every kilometers.} \\ = 5000 / 1332 = 3,75 \text{ hours} \quad (4)$$

#### E. Alternator frequency calculation

$$\text{From formula: } f = p.n / 60 \quad (5)$$

With :  $f$  = frekwensi (Hz)  
 $p$  = the number of pairs of poles  
 $n$  = speed of rotation (rpm)

Because alternator has 6 poles and the machine is 8000 rpm, the frequency of the alternator generated :

$$f = 3 \times 8000 / 60 = 400 \text{ Hz}$$

#### F. Speed Alternator

a. The ratio of engine speed versus alternator are:

$$\text{Engine : Alternator} = 1 : 0,672 ; \text{ so, if the engine speed is } 12,000 \text{ rpm, then :} \\ \text{Rotation of Alternator} = 12000 \times 0,672 = 8064 \text{ rpm}$$

b. Torque than the engine alternator is

$$\text{Engine torque} = \text{power} / (2\pi \times \text{rotation} / 60) \quad (6) \\ = 1369 \text{ kW} / (2\pi \times 12000 / 60) \\ = 1089,4 \text{ N} \\ \text{Alternator torque} = (12 \text{ VA} / 0,9) / (2\pi \times 8064 / 60) \\ = 15,79 \text{ N} \\ \text{Engine alternator} = 1089,4 : 15,79$$

So which is used to drive alternator for:

$$= (15,79 / 1089,4) \times 100\% = 1,45\%$$

$$\text{Power used} = 1,45 \times 1369 \text{ kW} = 19,85 \text{ kW}$$

The above calculation in accordance with the installed generator capacity, to 12 kVA.

#### G. Battery

The batteries used are nickel-cadmium batteries with a capacity of 40 Ah. Charging required is 140% of capacity rating 5 hours so, the charging current is needed:

$$I_{\text{charge}} = \text{Capacity (Ah)} / \text{time} \quad (7) \\ = 40 \text{ Ah} / 5 \text{ hour} = 8 \text{ Ampere}$$

$$\text{So, to achieve 140 \%, than: } 140\% \text{ Capacity} = 140\% \times 40 \text{ Ah} \\ = 56 \text{ Ah}$$

The time required for charging is

$$T = 140\% \text{ Capacity} / I_{\text{charge}} \quad (8) \\ = 56 \text{ Ah} / 8 \text{ A} \\ = 7 \text{ h}$$

#### H. Power and efficiency inverter

a. Generated power inverter is:

$$P = V \times I \quad (9)$$

with :  $P$  = Power (VA)  
 $V$  = Tension (Volt)  
 $I$  = Flow (ampere)

For phase I, the power generated :

$$P_{\text{in}} = 27,5 \times 106 = 2915 \text{ VA} \\ P_{\text{out}} = 115 \times 13,1 = 1506,5 \text{ VA}$$

With an efficiency of :

$$\eta = P_{\text{out}} / P_{\text{in}} \times 100\% \quad (10) \\ = 1506,5 / 2915 \times 100\% \\ = 51,68\%$$

b. Power to 3 phase

Generated power: The current generated by phase 3 phase selector is 9.1 A, the current flows are:

$$I = \sqrt{3} \times I_{\text{phasa}} = 15,76$$

For the third phase, the power generated:

$$P_{\text{in}} = 27,5 \times 116 = 3190 \text{ VA} \\ P_{\text{out}} = 115 \times 15,76 = 1812,4 \text{ VA}$$

With an efficiency of:

$$\eta = P_{\text{out}} / P_{\text{in}} \times 100\% \\ = 1812,4 / 3190 \times 100\% = 56,8\%$$

#### I. Expense analysis

Alternator used on Foker-27 aircraft at the Air Squadron 2 was used for:

Heating equipment (heating), covering is:

- Extra Cockpit Heating = 5,5 Ampere
- Windshield De-Icing = 7,5 Ampere
- Power de-icing unit consisting of :
  - Air Intake Continuous = 3,5 Ampere
  - Air Intake Cycle = 19,7 Ampere
  - Propeller Blade dan Spinning Cycle = 24,2 Ampere

Load rating safety is used attached to the equipment. To load Air Intake Cycle and Propeller blade alternately stated, so for the calculation of the largest taken Propeller Blade.

a. Total current used is 40,7 A.

b. Maximum current is generated alternator

$$P = \sqrt{3} \cdot V \cdot I$$

$$I = 12000 / (\sqrt{3} \times 208) = 33,3 \text{ A}$$

In this analysis, it appears that the alternator is used is not sufficient when compared with the load attached. The difference is due to differences in the burden of manual list maintenance (Maintenance Manual) and manual repairs / maintenance (Overhaul Manual) because at the Air Squadron

2 used Foker-27 aircraft with the old type altenator (12 KVA), while the Handbook is used has been revised by the Vendor (the company that made the plane) concerned (15 KVA). In this case, should the Air Squadron 2 change or modify the aircraft used, However as the aircraft used are considered to meet the eligibility standards flying, then the modification is still not necessary see figure 3 about specification Fokker F-27 Indonesian Air Force.

Figure 3. Specifications of the Fokker 27

#### IV. CONCLUSION

From the calculation and analysis of the performance of Alternator 115/208 Volt, 400 Hz, 12 KVA aircraft Fokker-27 on Air Squadron 2, it can be summed up as follows :

1. Altenator used on Fokker-27 aircraft Air Squadron 2 is minimized with a large enough power (12 kVA). This can be achieved with a high frequency (400 Hz), in order to get a small physical size.
2. Altenator used should be 15 kVA (corresponding maintenance manual). Altenator used now 12 kVA at 0.9 lagging power factor is time modified in accordance with

the new load to improve the performance of the aircraft.

**Abstract** – Spiral resonator (SR) structure is used in many microstrip antenna design due to its unique properties, such as negative permeability value as an artificial magnetic inclusion. This paper present the formulation of the radiation pattern of the microstrip antenna with single patch SR shaped structure using linear array model of  $n$  nonisotropic similar point sources. The linear array is assumed by modeling of each stripline of the spiral with length  $l$  and width  $w$  as a nonisotropic point source. The result of this approach is compared to the simulation result through CST software and it shows the similarity between both results for the same  $N$ . Moreover, with both  $w$  and  $s$  are constant; the radiation level tends to increase with the increasement of  $N$ .

**Keywords** : *Spiral Resonator; Radiation Pattern; Linear Array Approach*

## I. INTRODUCTION

Mobile communication needs portable device with characteristics such as compact, light and small size. To achieve this requirement, many research on size reduction of microstrip antenna has been conducted such as [1]–[2]. Commonly, the dimensional miniaturization of the microstrip antenna has been done by using the high permittivity substrate. However, if the high permittivity substrate is used to design microstrip antenna, this will increase the surface wave which will impact to the reduction of gain, efficiency, and bandwidth parameters. To solve these problems, the negative permeability or Miu Negative (MNG) material is used to design the microstrip antenna. MNG material has unique properties, such as no wave absorption or transmission in this material, so that it is suitable used to miniaturize the microstrip antenna dimension. Generally, the MNG microstructure is shaped as split ring resonator (SRR) or spiral resonator (SR), both are the artificial magnetic inclusion [3]–[4]. The SR structure is better than the SRR due to dimensional reduction. Bilotti [5]–[6] has presented the lumped element model to calculate the  $R$ ,  $L$ ,  $C$  calculation of SRR and SR structures and give the  $L$ ,  $C$ , and resonance frequency values to the variation of the spiral turn number  $N$ . However, these model can not be used to calculate and predict the radiation pattern. Therefore, this paper discusses the formulation of the

radiation pattern of the microstrip antenna with single patch SR shaped structure as linear array approach.

## II. SR LOOP PLANAR STRUCTURE

To derive the radiation pattern formulation, consider the single patch SR structure with  $N$  loop as shown in Fig. 1(a). This structure is assumed as a planar loop that has a continuous path. The single patch SR structure is a square loop with the length of each stripline  $l_n$ , where  $n$  is the number of stripline as nonisotropic similar point sources,  $N$  is total amount of the spiral turn,  $w$  is the stripline width, and  $s$  is a gap between stripline. Therefore, using  $N$  variation and  $w$ ,  $s$ , and inner radius parameters that defined constant, the different length of each stripline due to inward turning of spiral can be calculated. For the linearly array model,  $s$  is assumed to be equally distant. For further analysis, the planar loop as shown in Fig. 1(a) can be assumed geometrically as linear arrays of  $n$  nonisotropic similar point sources at the  $X$ - $Z$  or  $Y$ - $Z$  plane and the vector addition of  $E$  field as shown in Fig. 1(b) and Fig. 1(c), respectively. The length of stripline at the  $X$ - $Z$  plane can be calculated as  $l_1 = 5(w + s)$ ,  $l_2 = 3(w + s)$ ,  $l_3 = (w + s)$ ,  $l_4 = l_3 + (w + s)$ ,  $l_5 = l_4 + 2(w + s)$ ,  $l_6 = l_5 + 2(w + s)$ ; while at the  $Y$ - $Z$  plane one is  $l_1 = 6(w + s)$ ,  $l_2 = 4(w + s)$ ,  $l_3 = 2(w + s)$ ,  $l_4 = l_3 + (w + s)$ ,  $l_5 = l_4 + 2(w + s)$ ,  $l_6 = l_5 + (w + s)$ .

Consider to substitute the slot line [7] with the stripline, the radiation pattern can be formulated as

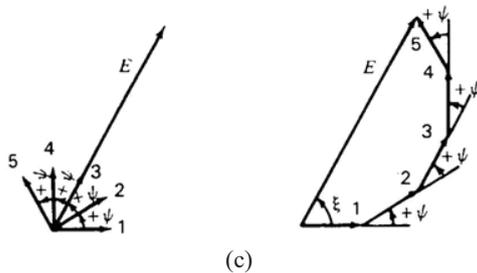

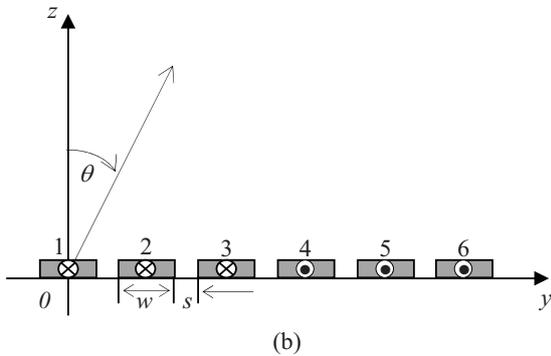

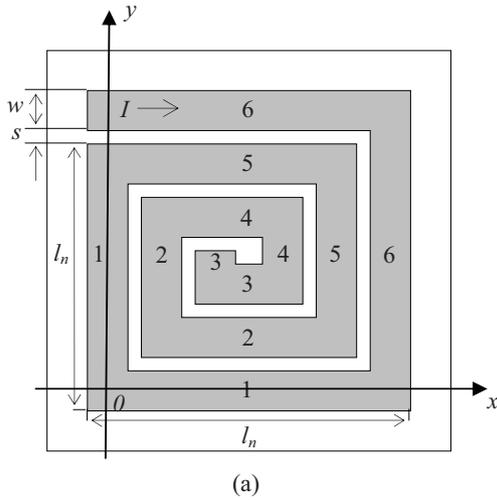

$$E_\theta = I_0 \frac{\sin\left[\left(\frac{2\pi l}{\lambda}\right)\cos(\theta)\right]}{\left(\frac{2\pi l_1}{\lambda}\right)\cos(\theta)} ; \quad (1)$$

$$E_\theta = I_0 \frac{\sin\left[\left(\frac{2\pi w}{\lambda}\right)\cos(\phi)\right]}{\left(\frac{2\pi w_1}{\lambda}\right)\cos(\phi)}$$

If the (1) is applied to Fig. 1, then the  $n^{\text{th}}$  stripline  $E$  is :

$$E_{\phi 0n} = I_0 \frac{\sin\left[\left(\frac{2\pi}{\lambda} \frac{l_n}{2}\right) \cos(\theta)\right]}{\left(\frac{2\pi}{\lambda} \frac{l_n}{2}\right) \cos(\theta)} ;$$

$$E_{\theta 0n} = I_0 \frac{\sin\left[\left(\frac{2\pi}{\lambda} \frac{w_n}{2}\right) \cos(\phi)\right]}{\left(\frac{2\pi}{\lambda} \frac{w_n}{2}\right) \cos(\phi)}$$

**Fig. 1** (a) Single Patch SR Structure as a Continuous Loop ( $N=3$ ,  $w=3$  mm,  $s=1$  mm, inner radius 1 mm); (b) Linear Array of Six Nonisotropic Similar Point Sources for X-Z or Y-Z Plane; (c) Vector Addition of  $E$  Field for  $n=5$  [8]

According to the electric current direction at each stripline, the electric current at the 1<sup>st</sup> up to 3<sup>rd</sup> striplines are opposite with the electric current at the 4<sup>th</sup> up to 6<sup>th</sup> striplines. If the electric current at the 4<sup>th</sup> up to 6<sup>th</sup> striplines are positive, then the electric current at the 1<sup>st</sup> up to 3<sup>rd</sup> striplines are negative.

(2) The radiation pattern of each nonisotropic point source can be formulated :

$$E_{\phi n} = -E_{\phi 0n} e^{j(n-1)\psi} ; 1 \leq n \leq N ;$$

$$E_{\phi n} = +E_{\phi 0n} e^{j(n-1)\psi} ; N < n \leq 2N$$

(3)

$$E_{\theta n} = -E_{\theta 0n} e^{j(n-1)\psi} ; 1 \leq n \leq N ;$$

$$E_{\theta n} = +E_{\theta 0n} e^{j(n-1)\psi} ; N < n \leq 2N$$

where :

$$\psi = \frac{2\pi d}{\lambda} \sin \theta ; d = s = 0.5 \text{ mm} ; N \geq 2$$

(4)

The radiation pattern of linear array of nonisotropic similar point sources is the product of the pattern of the individual source and the pattern of linear array of isotropic point sources, having the same locations, relative amplitudes and phases as the nonisotropic point sources. The individual nonisotropic source or antenna may be of finite size but can be considered as a point source situated at the point in the antenna to which phase is referred. Therefore, the total radiation pattern of the single patch SR structure can be formulated :

$$E_{\phi,SR} = -\sum_{n=1}^N E_{\phi n} + \sum_{n>N}^{2N} E_{\phi n} ;$$

(5)

$$E_{\theta,SR} = -\sum_{n=1}^N E_{\theta n} + \sum_{n>N}^{2N} E_{\theta n}$$

If the (2) to (4) are applied to the (5), and by splitting its real and imaginary parts, then the radiation pattern of  $E_{\phi,SR}$  and  $E_{\theta,SR}$  can be solved.

### III. RESULTS AND DISCUSSION

For the comparison of the radiation pattern between the simulation and the linear array approach, the microstrip antenna with single patch SR structure is designed at FR4 substrate with thickness 1.6 mm,  $\epsilon_r = 4.3$  and  $\mu_r = 1$ . The microstrip antenna is designed without the ground plane for both the simulation and linear array approach. The single patch SR characteristic due to the variation of  $w$  and  $s$  parameters through CST simulation is shown in Table 1 and Fig. 2. The parameter variation of  $w$  and  $s$  shows similar radiation pattern, with a slight difference of amplitude level of the  $E$  field.

TABLE I. SINGLE PATCH SR CHARACTERISTICS USING CST SIMULATOR WITH  $w$  AND  $s$  VARIATIONS

Parameters	Single Patch SR, $N = 3$							
	$w=3$	$s=1$	$w=3$	$s=2$	$w=2$	$s=3$	$w=2.5$	$s=2.5$
Freq (GHz)	2.325		2.175		2.400		2.290	
$S_{11}$ (dB)	-23		-25		-25		-25	
BW (MHz)	150		181		251		215	
$E$ (V/m)	4.3		4.1		4.5		3.8	
Pattern	Similar							

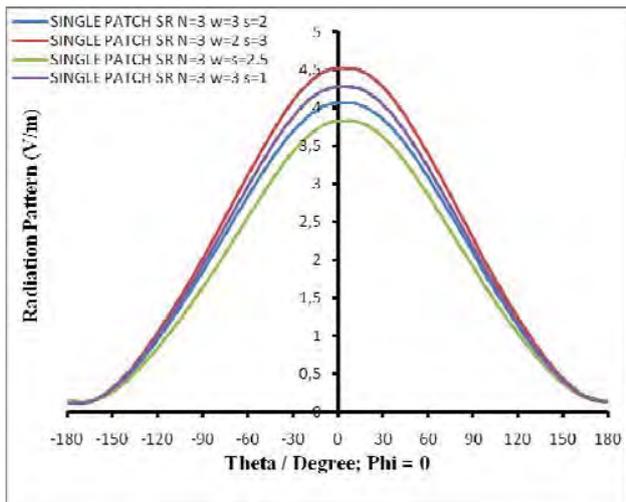

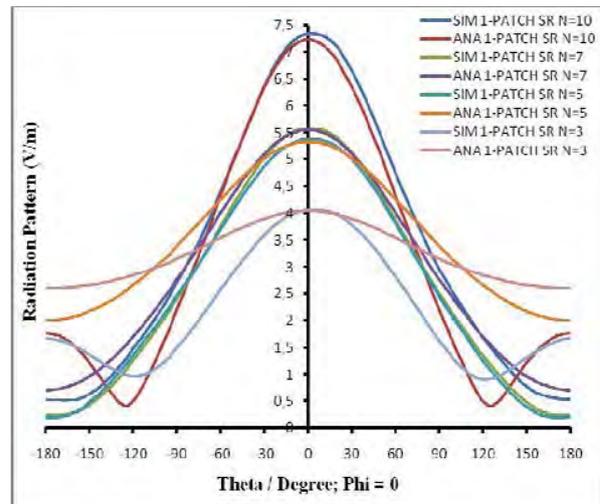

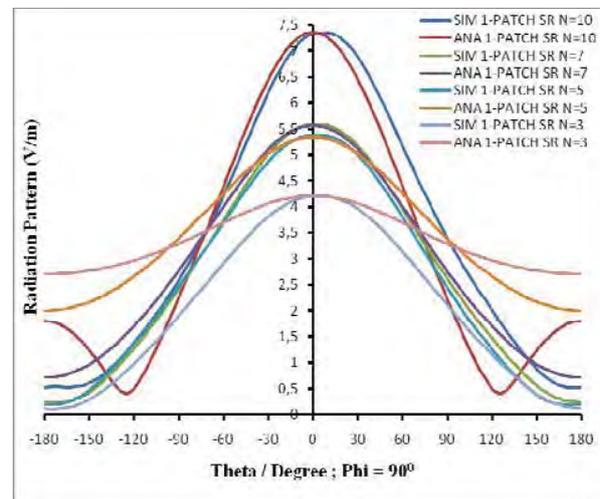

Fig. 2 Radiation Pattern of Single Patch SR with  $w$  and  $s$  Variation Using CST Simulation

Figure 3 shows the radiation pattern for  $w = 3$  mm and  $s = 1$  mm. The radiation pattern is obtained by using CST simulation and linear array approach from (5). The simulation results using CST software are compared to the achieved result of the absolute values from linear array approach as shown in Fig. 3 (a) for  $X$ - $Z$  plane and Fig. 3 (b) for  $Y$ - $Z$  plane. The radiation pattern using linear array approach has the similarity with the radiation pattern using the CST simulation for the same  $N$  at boresight direction. The radiation level tends to increase with the increment of  $N$  for both approaches. The difference at the sidelobes occur due to the different method between CST simulation and linear array approach. The radiation pattern simulated with CST Studio Suite uses the finite difference time domain (FDTD) with finite integration technique (FIT) algorithm and cartesian mesh but with much improved PBA (perfect boundary approximation), whereas the calculation of the radiation pattern proposed uses the linear array of point source method. Table 2 shows the difference value of the side lobe level between CST simulation and linear array approach from  $\pm 90^\circ$  to  $\pm 180^\circ$ . From Table 2, the minimum average value difference occurs for  $N = 7$ . Therefore with the increment of  $N$ , it does not show a more accurate sidelobe level of radiation pattern. Thus, the proposed linear array approach can be used as an alternative method to solve

the radiation pattern problem of the microstrip antenna with single patch spiral resonator structure.

$\pm 110$	1.8018	1.1685	0.3973	0.7611
$\pm 100$	1.6007	1.0473	0.3738	0.5562
$\pm 90$	1.3964	0.9305	0.3539	0.3377
Average Value Difference	2.1590	1.4551	0.4573	0.7306

#### IV. CONCLUSIONS

The radiation pattern characteristics of single patch SR structure have been studied using linear array approach synthesis. The computation results have been verified by simulation using CST Microwave Studio which shows good agreement. Therefore, this approach can be used as the alternative method to provide field pattern.

# Multiple Slots Technique for Bandwidth Enhancement of Microstrip Rectangular Patch Antenna

Achmad Munir, Guntur Petrus, Hardi Nusantara  
School of Electrical Engineering and Informatics  
Institut Teknologi Bandung  
Bandung, Indonesia  
munir@ieee.org

**Abstract**—This paper discusses the investigation of bandwidth enhancement for microstrip rectangular patch antenna by putting up multiple slots etched on the patch. The technique is proposed in overcoming the nature characteristic of microstrip patch antenna which has narrowband bandwidth response. Here, the antenna is designed to work at center frequency around 1.6GHz for GPS application. The patch of antenna is fed by using a microstrip transmission line feeding network extended from a center pin of 50Ohm SMA connector. The number of slots etched on the patch is set to be 13 which are separated 3mm each other. The 13 slots which have different length for each are arranged in parallel with the feeding line. To shows the feasibility of proposed technique, the characteristics of microstrip patch antenna with multiple slots are compared to the conventional microstrip patch antenna. Both antennas are implemented using FR-4 Epoxy dielectric substrates with the dimension of 55mm x 80mm and the thickness of 1.6mm. From the characterization, although there are some slight differences of simulation and measurement results, in general the microstrip patch antenna with multiple slots demonstrates bandwidth enhancement up to 98.3% and 70.8% for simulated result and measured result, respectively.

**Keywords**— *Bandwidth enhancement, rectangular patch antenna, microstrip, multiple slots technique*

## I. INTRODUCTION

In recent years, numerous applications developed from patch array which is deployed by employing printed circuit board (PCB) have been widely implemented in wireless communication devices [1]-[3]. Due to the planar structure of patch array which is deployable on some dielectric substrate, the use of patch element and its array are becoming popular for practitioners involved in the design of RF components [3]-[4]. The applications include the use of microstrip patch antenna in various shapes also referred as patch antenna, which is developed based on microstrip technology. In addition to have the portability aspect, this type of antenna has some advantages such as easy to be incorporated with other planar structure, low cost in realization, and robust for the implementation on rigid surfaces [5]-[6]. Furthermore, the antenna is also able to be easily produced both in linear and circular polarizations, and has the capability to provide dual-band, multiband, and wideband frequency responses [7]-[8].

Unfortunately, the transverse dimension of microstrip patch antenna cannot be made arbitrarily short, since a regular patch antenna will have resonant frequency when its linear transverse dimension is of the order of one-half wavelength. Moreover, the microstrip antenna has also some disadvantages such as low gain, low efficiency, high loss, narrow bandwidth. Some efforts to overcome those disadvantages have been investigated numerically and experimentally. In [9]-[10], microstrip patch antennas with parasitic patch substrate have been proposed to improve the overall gain and bandwidth response. Hence, the similar attempt to enhance the bandwidth response has been conducted by employing parallel feeds to the L-probe coupled single layer patch antenna and metamaterials [11]-[12].

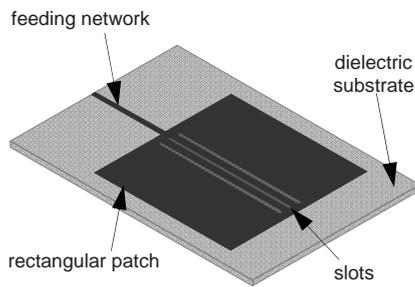

In connection with overcoming disadvantages of microstrip antenna especially for widening the bandwidth response, in this paper, the bandwidth enhancement is proposed by utilizing multiple slots technique over the patch of antenna. The antenna is designed to operate at frequency of 1.6GHz for GPS (Global Positioning System) application. Actually, the characteristic bandwidth of microstrip antenna which is naturally narrow is almost affected by the use of dielectric substrate with some relative permittivity. However, since the use of dielectric substrate for the deployment of patch antenna is unavoidable thing, therefore the possibility effort is by handling the patch through some treatments. Here, the rectangular type is used as the shape of patch as well as the shape of slot for investigation. Meanwhile, the permittivity of dielectric substrate used for the antenna deployment is 4.2 realized using an FR-4 Epoxy substrate. The antenna which has the dimension of 80mm length and 55mm width is fed by use of a microstrip transmission line feeding network which is extended from a center pin of 50Ohm SMA connector. Hence, the number of slots is set to be 13 which are separated 2mm each other. Before designing and characterizing the antenna, a theoretical background which explains the correlation between the slot and the bandwidth will be briefly introduced. Then the design of microstrip patch antennas with and without slots is described. Some basic parameters of antenna especially the bandwidth as the focus of investigation will be observed in which the design result will be compared and verified with the experimental measurement. Some discussion related to the characterization results will be presented consecutively.

## II. BRIEF THEORETICAL BACKGROUND

An approximation of equivalent circuit model for rectangular microstrip patch antenna with slots is illustrated in Fig. 1. The antenna is constructed of a ground plane at the bottom side of dielectric substrate and a radiating element, i.e. rectangular patch, connected to microstrip line feeding network at the top side. The feeding network uses a quarter-wavelength matching impedance to minimize the impedance mismatch between the impedance of connector and the impedance of rectangular patch contact point. The equivalent circuit model consists of  $L_p$  as the inductance of connector's probe and feeding network, and the  $RLC$  circuit as the approximately model of rectangular patch. Hence, each slot is approximately modeled by using a combination of  $L_{ss}C_{ss}$  series connected to another  $L_{sp}C_{sp}$  shunt which produces a characteristic of bandpass filter. The approximation model of slot is coupled to the rectangular patch through the patch inductor.

(a) rectangular microstrip patch antenna with slots

(b) approximation of equivalent circuit model

Fig. 1. Rectangular microstrip patch antenna with slots and its approximation of equivalent circuit model

From the equivalent circuit model, the resonant frequency of microstrip rectangular patch antenna without slots can be determined from the value of inductance ( $L$ ) and capacitance ( $C$ ) as expressed in (1). Hence the value of patch resistance ( $R$ ) influences to the quality factor and bandwidth of antenna. By providing a number of slots over the patch, as a consequence the resonant frequency is affected as the patch inductance changes. However, the effect can be elaborated to be synchronized by taking the shape of slot to be able resonates at the same resonant frequency.

$$f = \frac{1}{2\pi\sqrt{LC}} \quad (1)$$

The correlation of bandwidth (BW) and quality factor ( $Q$ ) of patch antenna are denoted in (2), where the bandwidth is defined for voltage standing wave ratio (VSWR) value  $< 2$ . By using the equivalent circuit model, the  $Q$  factor of patch antenna without slot can be determined as written in (3).

$$BW = \frac{1}{Q\sqrt{2}} \quad (2)$$

$$Q = \frac{R}{\omega_0 L} \quad (3)$$

In other term, the  $Q$  factor of patch antenna exists due to the conductor loss of patch ( $Q_c$ ) for the  $nm^{\text{th}}$  mode and the dielectric loss of substrate ( $Q_d$ ) as expressed in (4) [13].

$$Q = \frac{1}{\frac{1}{Q_c} + \frac{1}{Q_d}} = \frac{1}{\frac{2\beta_{nm}^2}{\omega\varepsilon_0\varepsilon_r h_d \sigma_c \delta_c (\beta_0 Z_0)^2} + \frac{\sigma_d}{\omega\varepsilon_0\varepsilon_r}} \quad (4)$$

where  $\varepsilon_r$ ,  $\sigma_d$  and  $h_d$  are parameters related to the dielectric substrate, i.e. relative permittivity, conductivity and thickness, respectively. Whilst,  $\sigma_c$  and  $\delta_c$  are patch conductivity and skin depth, respectively. Hence,  $\beta_0$ ,  $\beta_{nm}$ ,  $\omega$ , and  $Z_0$  are propagation constant at resonant frequency, propagation constant for  $nm^{\text{th}}$  mode, working radian frequency, and surface impedance of antenna, respectively.

Due to the presence of slots, the  $Q$  factor of patch antenna with slots in (3) decreases as the value of patch inductance increases. This can also be figured out that the existence of slots evokes the decrease of patch area which affect to the conductor loss of patch and the dielectric loss of substrate in (4), as a result the  $Q$  factor decreases. By the decrease of  $Q$  factor, therefore, the bandwidth (BW) of patch antenna in (2) increased accordingly.

## III. DESIGN AND CHARACTERIZATION

Figure 2 shows the illustration of rectangular microstrip patch antenna with and without slots which are designed on FR-4 Epoxy dielectric substrates with relative permittivity of 4.2 and thickness of 1.6mm. The antenna is designed to work around the resonant frequency of 1.6GHz for GPS application. Based on equations in [8], the patch dimension can be determined theoretically by including value of relative permittivity, fringing extension length and thickness of dielectric substrate in calculation. After some parametrical studies, the patch dimension takes the length of 44.5mm and the width of 45mm. The width of patch is slightly wider than the length to obtain the better bandwidth characteristic for some mode of resonance. Hence the total dimension of antenna including feeding network is 80mm length and 55mm width. The patch is then fed using microstrip transmission line as feeding network which is extended from a center pin of 50Ohm SMA connector. In addition to be a feeding network, microstrip transmission line also acts as matching impedance circuit between the impedance of connector and contact point of rectangular patch, therefore it takes a dimension of a quarter-wavelength with the width of 1.2mm.

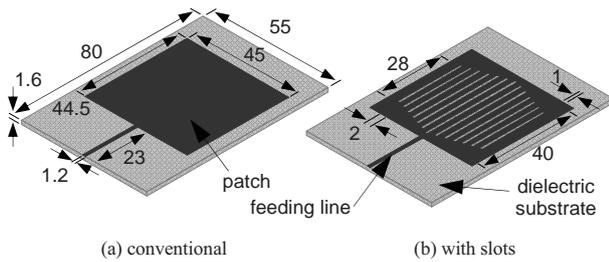

Fig. 2. Illustration of rectangular microstrip patch antennas (unit in mm)

For microstrip patch antenna with multiple slots, as shown in Fig. 2(b), the number of slots over the patch is set to be 13 which are separated 3mm each other from its center line. The 13 slots which are arranged in parallel with the feeding line have different length where the outer slot has 2mm shorter than each the inner consecutive slot. The longest and the shortest slots are 40mm and 28 mm, respectively. In the design, the patch of antenna, microstrip line feeding network and ground plane are made of copper metal with the thicknesses of 0.035mm. To obtain an accurate design, copper conductive loss with  $\sigma_c$  of  $5.8 \times 10^7$  S/m and the dielectric loss with  $\tan\delta$  of 0.02 are taken into account. Then, both designs of microstrip patch antenna are characterized numerically to obtain their characteristic responses.

The numerical characterization results of both antennas are depicted in Figs. 3-6 for reflection coefficient, VSWR, gain, and radiation pattern, respectively. From the coefficient reflection in Fig. 3, it shows that the center frequency of antenna with slots is shifted to higher frequency around 15MHz compared to the conventional antenna. Hence, the working bandwidth depicted in Fig. 4 for the antenna with slots at  $VSWR < 2$  is 692MHz which is wider 34.3MHz than the working bandwidth of conventional antenna, i.e. 34.9MHz. It could be noted that the working bandwidth of antenna with slots is almost 100% enhanced from the conventional one. Unfortunately the gain of antenna with slots is relatively lower for all frequency ranges. Whilst from Fig. 6, it is seen that the radiation pattern of both antennas is almost similar each other with slightly difference in the magnitude.

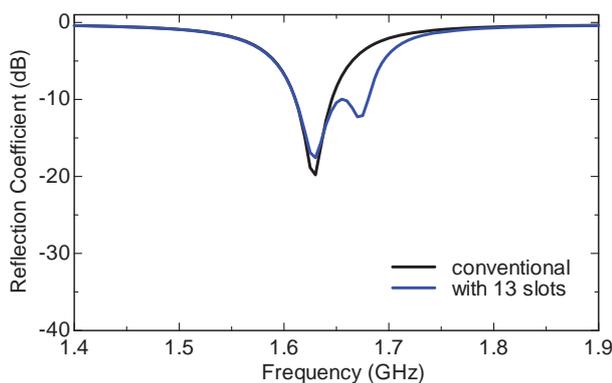

Fig. 3. Simulated results of reflection coefficient for both patch antennas

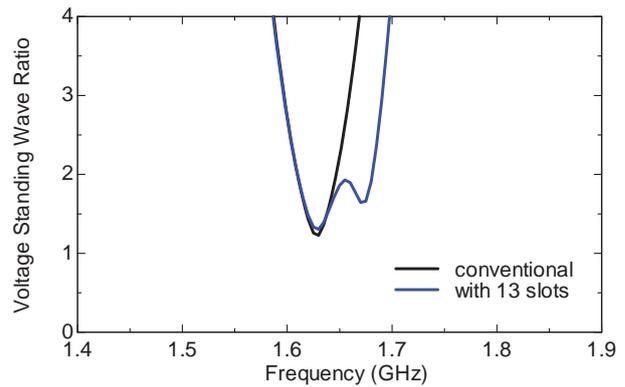

Fig. 4. Simulated results of VSWR for both patch antennas

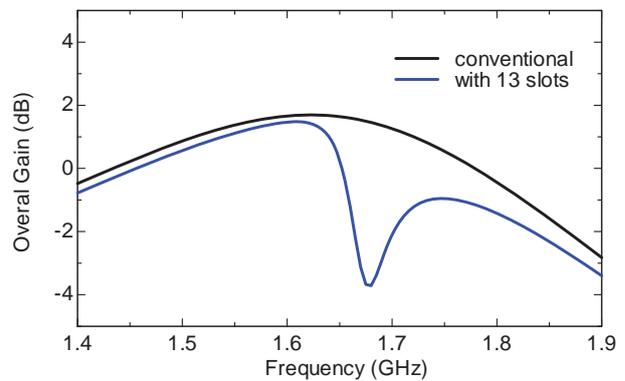

Fig. 5. Simulated results of gain for both patch antennas

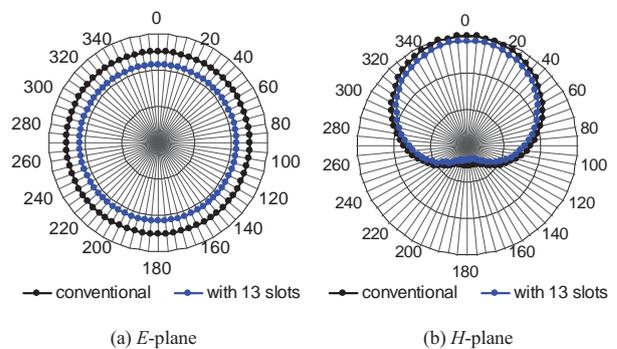

Fig. 6. Simulated results of radiation patterns for both patch antennas

#### IV. MEASUREMENT AND RESULTS COMPARISON

To verify the numerical characterization, hardware realizations of rectangular microstrip patch antennas without and with slots are carried out by fabricating the designed antennas on FR-4 Epoxy dielectric substrate through wet etching technique. Figure 7 shows a picture of fabricated patch antennas without slot (right) and with 13 slots (left) for experimental characterization.

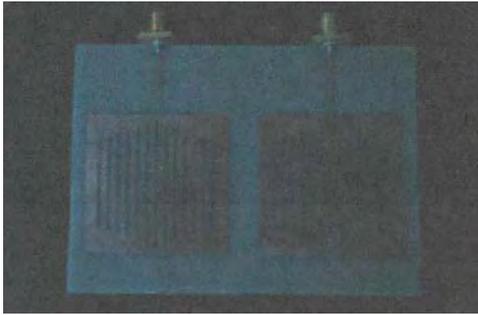

Fig. 7. Fabricated rectangular microstrip patch antennas for measurement; right is conventional patch antenna; left is patch antenna with 13 slots.

Figure 8 plots the measured reflection coefficient of both fabricated antennas with the numerical characterization results as comparison. It is seen that the both fabricated antennas have better characteristic responses than the design ones; however with the center frequencies are shifted less than 10MHz to the higher frequency. The difference is mostly evoked by the value of relative permittivity used in the numerical design which is slightly higher than the value in the measurement. The measured resonant frequency of patch antenna with slots is 1.642GHz which is higher 2MHz than the measured conventional patch antenna, i.e. 1.64GHz. The achievement of frequency shift is better than the numerical result of 15MHz. Nevertheless, the measured results of reflection coefficient have good agreements qualitatively with the simulation results for all frequency ranges.

Whilst from the measured VSWR results shown in Fig. 9, the measured working bandwidths also show the similar trend as the numerical results. The measured working bandwidth of patch antenna with slots for VSWR < 2 is 53.3MHz. This bandwidth is 22.1MHz wider than of the conventional patch antenna, i.e. 31.2MHz, so the bandwidth enhancement achieves 70.8%. In comparison with the numerical result, the measured bandwidth enhancement is smaller. This is probably affected by the inaccuracy of fabricated slots which have probably narrower dimension than the design one. As the narrower dimension of slot, the higher  $Q$  factor is produced; therefore the narrower bandwidth is obtained.

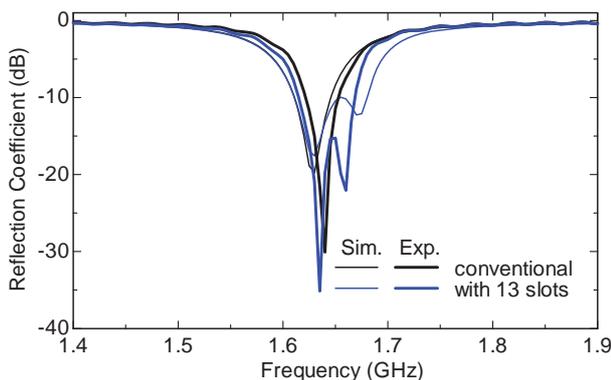

Fig. 8. Measured and simulated results of reflection coefficient for both patch antennas

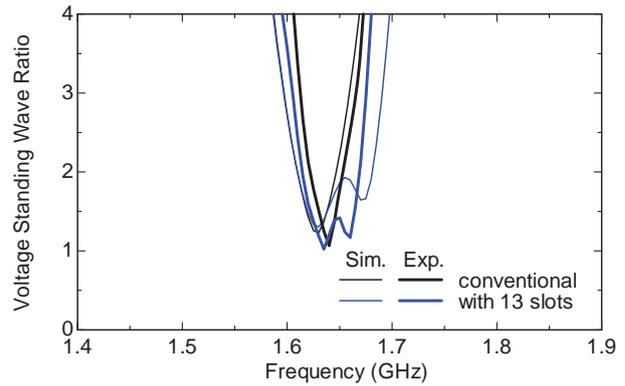

Fig. 9. Measured and simulated results of VSWR for both patch antennas

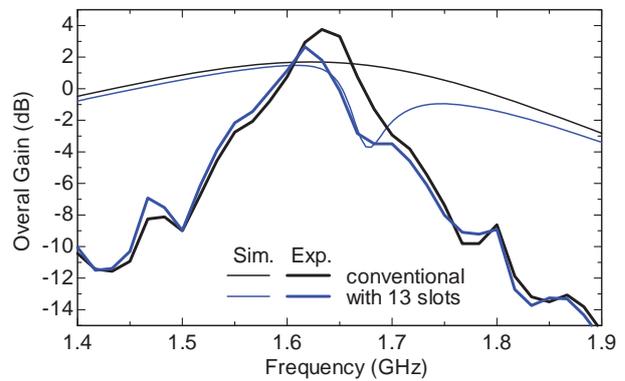

Fig. 10. Measured and simulated results of gain for both patch antennas

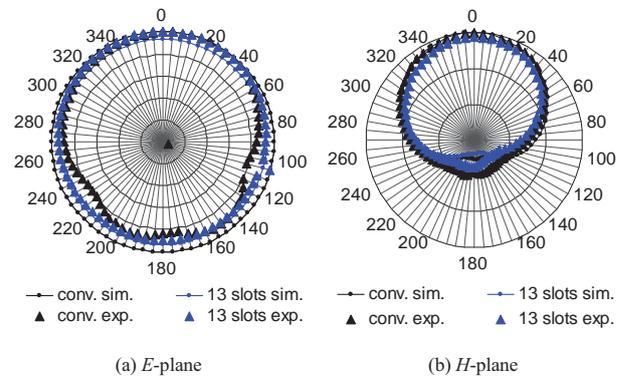

Fig. 11. Measured and simulated results of radiation patterns for both patch antennas

In the overall gain result as plotted in Fig. 10, it is seen that around resonant frequency, the measured gain for both antennas is higher than the numerical results, whereas in other frequency ranges are lower. Similar as the numerical result, the measured gain of patch antenna with slots is also lower, i.e. less than 2dB, around the resonant frequency and the higher frequency band compared to the conventional patch antenna, but at the lower frequency band the overall gain is higher.

Hence from Fig. 11, it can be understood that the utilization of slots over the patch of antenna has no effect significantly to the radiation pattern both for  $E$ -plane and  $H$ -plane. In spite of radiated power in some direction has distortion in the magnitude, however, both results for numerical and experimental characterizations show good agreements each other. This is an advantage of utilizing multiple slots technique which is usable to improve the working bandwidth of rectangular microstrip patch antenna.

#### V. CONCLUSIONS

The bandwidth enhancement of microstrip rectangular patch antenna by implementing multiple slots technique has been investigated numerically and experimentally. It has been successfully demonstrated by experimental characterization that the multiple slots, here was 13 slots, could improve the working bandwidth of conventional patch antenna up to 70.8% without affecting remarkably the resonant frequency, gain as well as the radiation pattern. Whilst from the numerical characterization, the bandwidth enhancement has achieved up to 98.3%. Although, there were some discrepancies in term of resonant frequency, bandwidth, gain, and radiation pattern between the numerical and the experimental characterizations, however, in general it could be concluded that the proposed technique has been successfully applied for bandwidth enhancement of rectangular microstrip patch antenna and should be implementable for other patch antenna shapes.

**Abstract**—The constructions of the novel and robust lungs antennas were examined. Several kinds of the lungs patch structure antennas were numerically computed, fabricated and tested. A number of the lungs antenna models were designed to be suitable for large varieties of modern wireless communication applications including mobile computing devices, GPS-SAR, LTE, detection and sensing networks, satellite communications, and other cellular mobile peripherals. In this paper, each designed antenna was evaluated through a certain corresponding resonant frequency, i.e. 1.2 GHz, 1.98 GHz and ISM band 2.4-2.5 GHz. The fabrication step was performed using a simple and straightforward method that commonly applied in printing a PCB. The most advantageous of the constructed antenna lied not only on its robust and unique electrical properties but it also has a compact and reconfigurable physical structure to meet the required technical specifications.

## I. INTRODUCTION

The high availability of such rapid data transfer provided through a microwave transmission media in the modern communication networks has boosted the popularity of wireless technologies access. This may also attract more consistent innovation and intensive development of antenna systems. The antenna has in fact emerged as a vital element on the wireless networking. Most wireless applications require miniaturization or improved performance. Thus, it is required an antenna that has excellent performance, easy installation and inexpensive costs. A patch antenna structure can meet such criteria. It has several advantages such as low profile and low cost of fabrication. Due to the compactness and resistance to extreme environments (ruggedness) its use in other fields such as in aerospace and satellite applications has received much attention. The radiator layer model of the patch antenna structure is commonly in the form of rectangles, squares, circles, ellipses and triangles [1-5].

In this study, the uncommon form of the radiating element, inspired from the actual life environment [4, 6-7], were constructed and examined. The new patch structure is so-called lungs antenna. The antenna models were constructed from the conventional patch forms including four elliptical and some rectangular patches. Benefits of this antenna

radiating layer includes capable of the compact construction and its easy way to be reconfigured to meet certain technical parameters such as return loss ( $S_{11}$ ), patterns, impedance bandwidth, VSWR and axial ratio. In addition, its electrical properties are very sensitive to change due to the alteration of various physical parameters such as the location of the RF input port, the length ( $L$ ) and the width ( $W$ ) of the RF-transmission line and the effective surface area of the radiator (see Figure 1). In construction, these parameters should be set appropriately and accurately in order to obtain the optimal performance.

This paper outlines several current researches and development of lungs antenna prototype intended to be deployed in various wireless communications. There are three areas of concern where the studies are focused. These include, for instance, the GPS-SAR antenna technology onboard an autonomous spacecraft, nanosatellite antenna system for the telemetry application, and LTE technology. However, not all the constructed lungs antennas of these applications will be fully presented and discussed in this paper, but only the designed antennas intended for GPS-SAR and LTE applications that will be extensively evaluated.

## II. ANTENNAS MODELING, TESTING AND EVALUATION

The radiating element of a typical lungs antenna model has been constructed through the addition and subtraction algorithms to the common patch radiating layer including some elliptical and rectangular forms during the numerical computing process using FEM-HFSS Version 13. Several models of lungs radiating element were created to meet a particular wireless application. The experimental evaluations were also performed to all antenna models. The descriptive discussions of the lungs antennas fundamental operation are presented in the following sub-sections.

As described in Figure 1, the lungs shape antenna consists of three layers, i.e. the top lungs shape conducting layer, the dielectric material, and the ground plane. The type of dielectric materials used to construct the antenna systems was the one has  $\epsilon_r$  4.4 (FR4-Epoxy) and the loss tangent 0.021 and the thickness  $h$  1.6 mm. In the construction of a single lungs structure, the ground plane and the dielectric substrate size were flexibly altered to meet a certain resonant frequency. For

exactly the same substrate material type and thickness, FR4-Epoxy (1.6 mm thickness) as for instance, the smaller the size of the ground plane and the dielectric layer tends to produce the higher resonant frequency. This, off course, directly relates to the intended wireless network application. However, the dimension of those lungs antenna elements will significantly increase while the array configuration is set-up. In order to design two lungs patch array from its initial single lungs patch structure the required size of the ground plane and dielectric, respectively, is almost double. The size comparison of the ground plane and dielectric substrate to configure the designed lungs array and its corresponding particular application is tabulated in Table I.

A single lungs patch antenna as depicted in Figures 1, 2 (a) and 2 (c) exploited the excellent advantages of the coaxial edge feeding technique to feed RF-power to the whole lungs alike radiating layer. As clearly visualized in the figures, a copper 50  $\Omega$  SMA connector was soldered exactly in the middle position at one edge side of a double layers PCB material. In the transmit mode, the RF-energy fed from this connector will be transported through the short transmission line of  $L$  length (see Figure 1). The wave power will be equally divided by the passive patch splitter structure [5] of  $W$  width before entering the two identical lungs conducting layers. These top conducting layers perform two functions i.e. transmitting and receiving of RF-wave. However, an opposite RF wave processing is performed as the antenna working in the receive mode.

TABLE I: DIMENSION COMPARISON OF THE GROUND PLANE AND DIELECTRIC LAYER CONSTRUCTED IN AN ARRAY CONFIGURATION.

Typical Applications	Ground Plane and Dielectric Layer Size	
	Length (mm)	Width (mm)
Antenna array of 2.5 GHz nanosatellite telemetry [4]	93.52	160
Two elements array LTE 1.96 GHz	300	480
Two elements array GPS-SAR 1.2 GHz	280	495

In order to develop the antenna array for a particular application such as for the deployment in GPS-SAR, LTE and nanosatellite systems [4] an extensive optimization procedure

must be performed on the constructed lungs antenna structure to meet certain technical specifications. For instance, to produce the excellent axial ratio ( $AR$ ) 2.3 and 2.29 dB as previously tabulated in Table 2, three methods were applied on constructing the more powerful lungs patch array. First technique is by inserting a passive phase shifter [5] to a feeding line of the lungs linear array (see Figures 2 (b) and 2 (d)). The feeding port was set-up in the parallel configuration [1, 8]. Second technique adopted to achieve the required  $AR$ , the little conducting patch layer of the circle or circular form should be generated during the HFSS optimization process and used to subtract the two identical lungs patch structures. In practical, the size of the circle (or circular) patch form will determine the value of  $AR$  generated. The last technique is to optimize RF-port position along one edge side of the lungs patch structure (see Figure 2 (b)). With having those two axial ratio values it is guaranteed that the lungs antenna may work in the circular polarization property.

The electrical properties as outlined in Table II including  $S_{11}$ , impedance bandwidth,  $VSWR$ , axial ratio ( $AR$ ), beamwidth, and pattern were recorded at the antenna resonant frequency for each particular application. The 3D-patterns of the single element and the two elements of the constructed lungs antennas, both for GPS-SAR and LTE applications are illustratively presented in Figure 3. Based on those figures, it is clearly shown that gain and directivity of the optimized lungs array outperformed the single lungs design.

The reflection coefficient ( $S_{11}$ ) profiles of the constructed GPS-SAR and LTE-BTS antennas, both the simulated and measured  $S_{11}$ , are depicted in Figures 4 (a-b). All the measured  $S_{11}$  were recorded using VNA E5071C. From these figures, it has been shown that the constructed lungs antennas have met the required technical specifications working at certain frequency operation, i.e. 1.2 and 1.98 GHz, respectively. As tabulated in Table II, all the designed lungs antennas whether a single element or two elements array, are capable to generate the impedance bandwidth approximately 40 MHz to more than 100 MHz. While, the impedance matching are quite good where the  $VSWR$  achieved is from 1.05 to 2.

The  $S_{11}$  parameters of the designed GPS-SAR antenna are depicted in Figure 4.(a). Both the simulated and measured  $S_{11}$ , whether single lungs element or two lungs elements array, exhibited very close agreement within the intended operation frequency 1.2 GHz. The simulated single element of the lungs patch structure produces the impedance bandwidth of approximately 50 MHz while the two elements (both simulated and measured ones) exceed 100 MHz. Even though, the designed antenna is classified as the narrowband antenna (less than 8% bandwidth) however to fulfill such practical sensing, recording and transmitting the earth surface image or other environmental parameters (e.g. temperature, humidity, rain intensity and so on) from an UAV (unmanned aerial vehicle) to a ground station this available bandwidth is sufficiently enough.

The broader bandwidth of the designed lungs antennas for LTE-BTS 1.98 GHz application was obtained by configuring the single element of lungs patch structure into two elements array. The improvement of bandwidth achieved is more than 200%. The  $S_{11}$  profiles of the LTE-BTS antenna design is visualized in Figure 4.(b). Conceptually, the constructed antennas, both single element and array, provide the impedance bandwidth of 50 MHz and larger than 220 MHz, respectively. The bandwidth according to the measured  $S_{11}$  is approximately 80 MHz. However, this bandwidth will increase to more than 220 MHz while the 1.8 GHz and 2.2 GHz frequency operations are also considered.

### III. CONCLUSION

Various models of lungs patch antennas have been computed, optimized, manufactured and tested to meet the particular wireless communication applications including GPS-SAR onboard an automobile aircraft, LTE BTS terminal and nanosatellite system. The designed antennas provide the good performance in terms of the electrical properties such as *pattern*, *gain*,  $S_{11}$  and *axial ratio* as the physical parameters of the radiating elements set-up properly to meet certain technical requirements in modern wireless networks. In average, the constructed lungs patch antennas whether it is a single element or two elements array could provide the operation bandwidth from 40 MHz to 100 MHz, approximately. The gain and directivity profiles of lungs antenna configured in the array form are better than the single elements of lungs patch structure.

### ACKNOWLEDGMENT

This research activity is partially funded through the Riset Terapan Grant awarded from Ministry of Research and Technology (MENRISTEK), the Republic of Indonesia under the project of the 2012-2013 financial year. This also partially supported through Mandiri Research Grant funded from DIPA Faculty of Engineering, UNHAS 2012 financial year. The

authors would like to deliver our sincere thank to Mr. Danang Santoso and Mr. Ade Chandra for the generous helps and discussions to develop the previous investigated lungs patch antenna models to meet the intended wireless applications.

**Abstract**—This paper considers the relative merits of nuclear to geothermal power, largely from an economic perspective, but also with references to environmental, social and political issues. Both nuclear and geothermal have the potential to produce large amounts of base electricity, necessitating well-developed grids. Both have very low operation and maintenance costs. But both have very high capital costs, and therefore interest rates have a major impact on their financial viability.

The current feed-in tariffs appear to suggest that investing in either is now attractive, but that the tariffs are so high they are likely to increase the cost of electricity (as they are significantly higher than domestic supply and most industrial tariffs). Although over the long term Indonesia may need to invest in both nuclear and geothermal, to meet its increasing demand for electricity, the model suggests that Indonesia should first focus on its geothermal resources.

Nevertheless, local opposition to nuclear probably means that geothermal will take precedence, for political rather than economic reasons. Long-term international investment in nuclear and geothermal will require the generous published feed-in tariffs to remain in force, as Indonesian public finances would be stretched to internally fund all of the necessary development.

The remoteness and limited electricity network development in much of eastern Indonesia means that despite generous feed-in tariffs, development of large scale generation schemes will be limited to those initiated by Government, curtailing the community and economic development of some of Indonesia's most deprived communities.

**Keywords**—Nuclear Energy, Geothermal Power; Indonesia; International Investors; Market Regulation

## I. INTRODUCTION

The National Electricity Development Plan [1] forecasts that by 2027 electricity demand will be 813,000GWh, with increases of 7-9% per annum. It also outlines plans for an additional 217GW of capacity; meaning that Indonesia needs to invest \$4-\$5bn per annum in generation plant and transmission infrastructure. Indonesia must diversify its energy sources [2] to avoid the ecological impact of investment in coal fired power stations and to avoid a trade debt crisis from imported oil and gas.

Indonesia has the largest geothermal energy capacity in the world (around 38% of the global resource), and therefore, this would appear to be an ideal option for Indonesia's diversification. 265 geothermal fields have been surveyed; although some are not close enough to electricity grids to be economical (nearly half of the capacity is located in remote areas of Sumatra). There is a plan to develop 19% of the

country's most suitable capacity, so that nearly 6GW will be available; and then to increase this to 9.5GW by 2025.

Pertamina, PLN and private sector investors have been identified for large scale development in Bali, Java, Sulawesi and Sumatra (Bali, and Java share a grid, which connects to the Sumatra grid). The Government and PLN will take a lead in other regions, where small scale development is planned [3]. However, even these plans look unambitious when compared with the Philippines where 27% of total energy is derived from geothermal [4].

\$12bn of investment is required to achieve the initial 6GW of geothermal generation, or \$30bn for the full 9.5GW, of which it is anticipated that 70%-80% will come from the private sector. The World Bank has pledged a \$300mn loan, with the potential for more from its Clean Technology Fund.

For private investors, the tender process is currently that the Government, or Local Government (as it is now their responsibility), conduct a preliminary survey and initial exploration activities to define the field. Private companies then conduct advanced exploration, a feasibility study, followed by exploitation and steam production activities. The private company that conducts the advanced exploration is expected to then supply the electricity. In the past, the company producing the steam and the company producing the electricity were different, creating commercial conflict and production co-ordination issues [5]. However, recent legislation makes it mandatory for them to be the same company. Nevertheless, the commercial reality is that exploration companies may not develop a field that others would wish to exploit, meaning that the exploration company and producer are not necessarily the same.

In 2012 the feed-in tariff for geothermal was increased to between \$0.10 and \$0.185 [6], depending on the voltage and location. These both reflect the difficulty in developing large scale infrastructure in eastern Indonesia and its shortages of electricity, especially low cost non-diesel generated electricity.

A possible alternative to geothermal would be to develop nuclear energy. Like geothermal it supplies base power, produces large quantities of electricity (far greater than the average geothermal field) and therefore requires high levels of capital investment. Both really require well-developed grid systems and are ill-suited to small scale development, meaning that Java, Sumatra and Bali are the most obvious areas for their development.

Indonesia began its nuclear activities in 1954 and had its first test reactor in 1965. It now has test reactors in Bandung,

Pasar Jumat and Serpong south of Jakarta, and Yogyakarta [7] Indonesia also has a cadre of nuclear professionals and technicians and well developed programmes for training nuclear professionals [8]. Although Permana [9] argues that these professionals may be poached by neighbouring countries such as Malaysia, Singapore, Thailand and Vietnam. Potential sites for civilian reactors to generate electricity include:

- Muria in Jawa Tengah;
- Kramatwatu-Bojonegara in Banten;
- Bangka in Bangka-Beitung;
- Banjarmasin in Kalimantan Barat (largely in response to a proposal to develop a reactor in neighboring Sarawak, Malaysia).

At this stage two 1,000MWe reactors are proposed for each site. Of these, the least contentious and therefore, the most likely to be built, is Bangka, although the entire program has been thrown into some doubt following the disaster in Fukushima, Japan. Feasibility studies will need to be finished on all sites, which are between 3 and 7 years before completion.

## II. METHODOLOGY

In order to compare the relative economic merits I have constructed a discounted internal rate of return model, similar to those that international investors would use when considering investing in large capital projects. For the model, cost and revenue data has been taken from a variety of sources. For nuclear these include:

- Energy Fair, [10];
- International Energy Agency, Nuclear Energy Agency and Organization for Economic Co-operation and Development, [11];
- World Nuclear Association, [12].

These have been used because they seem to be a little more independent than some sources. The costs of nuclear production is a highly contentious area, vendors claim exceptionally low costs and the vociferous anti-lobby claim much higher lifetime costs, when all issues are considered. The great variability in the costs identified in the various studies, is a part of the reason for this; with importance of the learning curve and economies of scale in nuclear energy developments.

The First of Kind (FOAKE) costs of developing and building a reactor are always high and known for substantive cost overruns [13]. In addition, early nuclear programs never run at anything like capacity with scheduling and transmission being constant problems for these programs. Nevertheless, China and Korea are showing that, the large scale development of a single reactor technology can dramatically reduce the levelized cost of electricity (LCOE).

For geothermal the cost data is less contested (although the learning curve and economies of scale are still important); sources include:

- Engineering and Consulting Firms Association, [14];
- Geotherm Ex Inc., [15];
- PT Castlerock Consulting, [16] [17];
- Sanyal, [18];
- Sanyal, et al. [19];
- SKM, [20];
- Smith, [21].

The main assumptions are analyzed in a spreadsheet model, these are:

TABLE I. COST ASSUMPTIONS USED IN SPREADSHEET MODEL (\$MN.)

<i>Nuclear</i>	<i>Costs Low</i>			<i>Costs High</i>		
	<i>1000e</i>	<i>1400e</i>	<i>2000e</i>	<i>1000e</i>	<i>1400e</i>	<i>2000e</i>
Capital Costs	1,000	1,400	2,000	4,000	5,600	8,000
Annual Operating Costs	29	40	57	40	56	80
Decommissioning Costs	52	73	104	400	560	800
<i>Geothermal</i>	<i>Costs Low</i>			<i>Costs High</i>		
	<i>20</i>	<i>50</i>	<i>100</i>	<i>20</i>	<i>50</i>	<i>100</i>
Capital Costs	43	61	111	74	102	146
Annual Operating Costs	0.4	1.0	2.0	0.6	1.5	3.0
Decommissioning Costs	0	0	0	0	0	0

Nuclear overnight costs (or capital costs) are generally expressed in \$/kWh (which is another source of cost variability as plants rarely run at full capacity), meaning that there is no apparent reduction for larger reactors. This is because the effects of the learning curve are more important than economies of scale. Although economies of scale do exist; lacking evidence of what this discount should be, I have had to apply a standard rate.

Geothermal fields and plant have a lifespan of around 25 to 30 years that I have applied to the high cost (25 years) and low cost model (30 years) respectively. Third plus generation nuclear plants are double these at 50 to 60 years. As this is a discounted internal rate of return model I have included discount rates of 12.5%. However, nuclear reactors often come with cheap or interest free loans from the vendor countries (as is the case for the Russia reactors proposed in Vietnam [22]). For income I have used the \$0.10 and \$0.185 per kWh, the current tariffs for geothermal, for both geothermal and nuclear development.

The low and high costs form the parameters for the model, along with low and high revenues. I then look at average costs, which of course over-simplifies the myriad of permutations which exist in the real world. The actual costs of developments will depend on many things, including the network availability and capacity, current energy mix and availability, the geography and geology of the site and the

profile of the demand. A detailed feasibility study is required to assess individual investments in either nuclear, or geothermal. This paper only attempts to provide a comparison of these two technologies for the purpose of supporting Indonesia's energy policy and decision making within the context of the policy.

### III. RESULTS

Given the \$/kWh standard costs for nuclear; it is difficult to directly compare costs and returns to geothermal plants of differing capacity. However, all permutations make a profit and therefore have a positive rate of internal return (see line labeled Discounted IRR in Table II). As this is a discounted model, the cost of capital has already been factored in, so any positive return represents a real profit. Nevertheless, my model suggests that geothermal appears to produce a higher rate of internal return than nuclear. Although of course, in some actual situations, a detailed feasibility may contradict this finding.

TABLE II. MODEL COSTS, REVENUE AND INTERNAL RATE OF RETURN (\$MN.)

Nuclear	Costs Low/Revenue High			Costs High/Revenue Low			
	MW	1000e	1400e	2000e	1000e	1400e	2000e
Capital		1,000	1,400	2,000	4,000	5,600	8,000
Interest		8,250	11,550	16,500	28,000	39,200	56,000
Operations and Maintenance		1,720	2,408	3,440	2,000	2,800	4,000
Decommissioning		52	73	104	400	560	800
Total Costs		10,022	14,031	20,044	30,400	42,560	60,800
Revenue		82,651	115,711	165,301	30,660	42,924	61,320
Discounted IRR		12.08	12.08	12.08	0.02	0.02	0.02
Geothermal	Costs Low/Revenue High			Costs High/Revenue Low			
	MW	20	50	100	20	50	100
Capital		43	61	111	74	102	146
Interest		188	266	485	278	383	548
Operations and Maintenance		12	30	60	15	38	75
Decommissioning		0	0	0	0	0	0
Total Costs		200	296	545	293	420	623
Revenue		788	1,969	3,938	355	887	1,971
Discounted IRR		9.82	18.82	20.75	0.85	4.45	8.67

Table II shows great variability in potential costs and revenues; therefore, we cannot be clear about much, in such a broad and simplified model. What is perhaps more important is the average costs and average revenue model in Table III.

The model shows that for all sizes of power plant geothermal produce a greater return than nuclear (see line

labeled Discounted IRR in Table III). In other words Indonesia should focus first on developing its geothermal resource before it's nuclear. Although over the long term it may need to invest in both (certainly in Java and Bali achieving a balance of sources is important in offsetting fluctuations in the relative costs of different generation technologies), but as much as possible, geothermal should be developed prior to nuclear.

The average cost model (in Table III) also makes clearer the likely attitude of international investors. It would appear to suggest that investors may be interested in building nuclear and geothermal plants in return for future revenues; although this may not really help to solve the electricity shortages in eastern Indonesia, where geothermal fields tend to be much smaller [23], offering lower returns (see line labeled Discounted IRR in Table III), populations are dispersed and grids are less developed.

TABLE III. MODEL COSTS, REVENUE AND INTERNAL RATE OF RETURN (\$MN.)

Average Costs and Revenue	Nuclear			Geothermal			
	MW	1000e	1400e	2000e	20	50	100
Capital		2,500	3,500	5,000	58	81	128
Interest		22,400	31,360	44,800	229	319	503
Operations and Maintenance		1,860	2,604	3,720	14	34	68
Decommissioning		226	316	452	0	0	0
Total Costs		24,486	34,280	48,972	243	353	571
Revenue		56,655	79,317	113,311	571	1,428	2,955
Discounted IRR		2.27	2.27	2.27	4.84	10.88	14.91

### IV. DISCUSSION

The model results show that both nuclear and geothermal have the potential to produce large amounts of base electricity. Both have very low operation and maintenance costs, largely because neither consumes large quantities of fuel (unlike for example coal, oil and gas fired power stations). Nevertheless, both have very high capital costs, and therefore the cost of capital, or appropriate discount rate, has a major impact on their financial viability.

Prices for uranium are forecast to increase due to limited supply and increasing demand, however, Indonesia's own resources are sufficient to supply all of its needs [24]. Even if it does need to import uranium and costs rise drastically, nuclear plants use so little that this would hardly place an impact on overall costs. The issue of energy security is probably more significant, which includes which countries' technology Indonesia will use and therefore which country it will be dependent on. This is true to a lesser extent for geothermal, with drilling and exploration being quite specialized and normally conducted by international oil and gas companies.

It could be argued that the most important economic consideration is that of the financial risk and who mitigates them? The massive variations in the internal rates of return between the low cost/high return and high costs/low return models point to the high level of risk of any endeavor for either the Indonesian Government, or international investors, in developing either nuclear, or geothermal, in Indonesia. There are a number of geological and technical factors which feed into this, but the model shows that discount rate (or capital cost) is the most important element of this (see line labeled interest in Tables II and III).

Chevron already has a program of geothermal development in Indonesia and Tata have expressed interest; this proves that international investors are prepared to invest in geothermal exploration and production. For nuclear, it is normal for the host country to bear a much higher proportion of the risk involved. Indeed, Indonesia, in common with many countries, wants to retain some control over its nuclear program. The escalating costs of nuclear mean that, even with access to cheap capital, Indonesia would be taking on a major financial risk, potentially impacting on future economic stability. Indeed a consortium of the German companies (E.ON and RWE) have recently pulled out of building three reactors in the UK [25], following escalating costs [26].

A major uncertainty for nuclear, is the cost of decommissioning [27]. In my model I have assumed fairly high costs for decommissioning (see line labeled decommissioning in Tables I, II and III), notwithstanding the fact that there still is no adequate technical solution for disposal of high level radioactive waste. It is likely that the countries supplying the technology will bear some of this risk, but it remains a major area of uncertainty [28]. For geothermal whilst there are some decommissioning costs, these are normally less than the scrap value of the plant.

There is the contested issue of safety, particularly in area with high seismic activity, which the recent disaster at Fukushima, in Japan, highlights. However, nuclear power has a strong safety record compared with many industries [29]. In addition, the third plus generation reactors, that are likely to be built in Indonesia, incorporate a number of safety features. Nevertheless, Alan Marshall [30], possibly xenophobically, casts doubt on Indonesia's ability to manage and maintain such potentially dangerous technology (contrary to the opinion of the International Atomic Energy Agency).

Both nuclear and geothermal are believed to have a small environmental impact (ignoring the issues of high grade radioactive waste), with their main environmental impact being in their construction and decommissioning. For large nuclear reactors the environmental impact of their construction and the transport of materials for their construction are huge. But then this is offset by the fact that nuclear reactors produce a large amount of clean electricity! Both nuclear and geothermal plants tend to be located in remote and often environmentally sensitive locations, requiring full AMDALs as a part of their feasibility stage. Again their construction and decommissioning is the main issue here, particularly in terms of disturbing the habitat of endangered plants and animals.

Within Indonesia there is a very vocal anti-nuclear lobby; which has not only protested against nuclear power, but also called for a resistance movement. For example, Nahdlatul Ulama declared a fatwa on nuclear power which they have found to be haram (Hindu groups in Bali have a similar objection to geothermal)! Undoubtedly, the powerful coal industry will support and possibly promote such dissent. Whilst this opposition may not derail Indonesia's nuclear program, it will certainly lead to further delays and favor geothermal development.

It could be argued that, there are too many uncertainties to reliably construct a comparison of nuclear to geothermal. Nevertheless, a simple comparison of the issues that I have identified (see Table IV) would appear to suggest that geothermal should be developed prior to the nuclear program. So whilst both are relatively cheap, my model suggests that geothermal is cheaper than nuclear, hence I have rated geothermal '++' and nuclear slightly less positively is rated at '+'. It is a similar position for energy security, with nuclear relying on overseas vendor technology and comes with greater financial risk, reflecting the greater uncertainties that come with it. In part, these uncertainties are due to the unknown decommissioning technologies and costs for nuclear (proving an assessment of '-'). Neither nuclear, nor geothermal have a major environmental impact, although by their nature do occupy a lot of land, often in environmentally sensitive areas. Perhaps, the most significant obstacle to nuclear is the anti-nuclear lobby in Indonesia, meaning that further geothermal development will occur long before any nuclear development.

TABLE IV. COMPARISON OF NUCLEAR TO GEOTHERMAL

	<i>Nuclear</i>	<i>Geothermal</i>
Cost per kWh	+	++
Energy Security	+	++
Reduced Financial Risk to Indonesia	+	++
Decommissioning and Safety	-	++
Environmental Impact	+	+
Internal Opposition	-	+

## V. CASE STUDIES

Neighboring France and Germany provide an interesting comparison in terms of their overall energy policies and commitments to nuclear power.

Concerned about energy security France has a long-standing commitment to nuclear power, indeed, France generates over three-quarters of its electricity from 58 nuclear reactors [31]. In addition, France is the world's largest net exporter of electricity due to the very low cost of generation (arising from the economies of scale and effects of the learning curve from investing in so many nuclear power plants). Whilst electricity is not as deregulated as in other EU countries, French consumers and industry do enjoy comparatively low prices. France also exports nuclear technology and fuel products. Geothermal heating systems and heat pumps are widely used in France and there are three geothermal fields in operation in France's overseas territories. However, geothermal development for electricity production has really not been exploited in France; given the strong policy steer towards nuclear and only recently have

exploration licenses been granted to exploit its significant potential.

Germany is home to a significant green lobby including a number of Alliance 90/Green Party politicians. Public sentiment was severely tested by the Fukushima disaster, resulting in a commitment to close all of Germany's nuclear power plants by 2020. Currently four-fifths of Germany's electricity comes from fossil fuels and nuclear, the Federal Government plans that within 40 years four-fifths will come from renewables [32]. Geothermal is being actively promoted within these renewables, but is currently very under-developed. Electricity prices are rising sharply to underpin this investment in new generation and transmission systems (smart grids) and consumption per capita is forecast to decline. The Federal Government believes that this will put Germany at the forefront of renewable technology, opening opportunities in major export markets and offsetting the decline of high energy consuming industries, such as chemicals. In addition, by reducing the reliance on imported fossil fuels, Germany will achieve greater energy security.

Despite very different strategies, both France and Germany show a high level of concern for energy security and are using energy policy to support industrial policy. As Indonesia matures, it will also need to consider energy much more strategically; with decisions over nuclear and geothermal taken on more than just cost.

## VI. CONCLUSION

International investment in nuclear and geothermal will require the generous published feed-in tariffs to remain in place, which almost certainly means increasing the price of electricity.

The main vendors that are likely to be considered for nuclear include those from Russia, Japan and Korea. Other potential vendor countries include the US and France, both of which are likely to charge far more for their technology than Russia, or Korea; although India may also enter the market with highly competitive reactors. Over the long term the learning curve and economies of scale would suggest that Indonesia should choose a particular reactor technology and stick with it, but which should it be?

The major vendors of geothermal drilling and production facilities are in the US, Australia and Germany; although Tata, of India, is also actively exploring opportunities in Indonesia. Whilst strong economies of scale exist, these are not really tied to the technology so it would be possible to use a number of vendors. Nevertheless, the issue on choice of vendor country for both nuclear and geothermal is as much an issue of international politics as it is economic! But perhaps the greatest issue Indonesia faces is internal opposition to nuclear; therefore, it is more likely that internal politics will dominate investment decisions, more so than the relative merits of the various technologies available for base electricity generation.

Finally, despite the generous feed-in tariffs, especially for eastern Indonesia, it is unlikely the much development will occur for domestic consumption, other than those initiated by Government, as a result of the difficulties and uncertainties

identified. This is an opportunity missed as I have previously argued [33] that providing electricity to the remote areas of eastern Indonesia would provide a significant boost to community and economic development.

**Abstract**— Indonesia located at  $94^{\circ}$  -  $141^{\circ}$ E and  $6^{\circ}$ N -  $11^{\circ}$ S is the largest archipelago in the equator on earth. As a tropical country, Indonesia is endowed with abundant solar energy potential. This study is focused on modeling the Global Solar Radiation using Artificial Neural Network to predict GSR in a location which is available with meteorological data but lack with radiation measurement data. A case study on 5 locations in South Western region of Sulawesi was used to develop the model. The ANN model used 4 location with 5 years monthly meteorological and radiation data for training, and one location for testing. The simulation shows that an ANN with 4 layers and 5 neurons is the most appropriate model with an MSE of 0.003 and  $r$  of 0.99937. The model provides an excellent performance of prediction of with an MPE of 0.1427% and  $r^2$  of 0.999967. The predicted radiation data is in reasonable agreement with the actual data at the testing location; this shows the ability of ANN technique in generalization of data unavailability and produces an accurate prediction

## I. Introduction

Sufficient sustainable energy supply is one of key ingredient for national economic growth. Indonesia is currently facing some major challenges in fulfilling its energy needs, including the limited number of conventional fossil fuel energy resources, and the international demand for lowering the energy related greenhouse gasses emission. In this concern, renewable energy utilization is becoming a strategic alternative for energy source, particularly solar energy as this is available almost everywhere in any part of the nation, and free from greenhouse gasses emission.

During the planning process of solar energy conversion system, accurate information regarding the energy availability is critical for a fine design of the system. Good and reliable global radiation data is essential for an appropriate design of various solar power system designs including for, PV module and energy storage sizing for stand-alone solar power, as well as estimating energy yield and PV system performance for solar PV on-grid type. Ideally, the global radiation data should be obtained by direct local measurement; however, in

Indonesia it is rare if not difficult to have extensive data of global solar radiation measurement. Estimating the global solar radiation using prediction techniques could help as an alternative to provide global solar radiation data.

Indonesia is located at the equator, and the largest archipelagic nation in the world. It has various energy resources, but as a tropical country Indonesia is blessed with abundant amount of solar energy potential. Provided with 4.5 kWh/m<sup>2</sup>/day of average solar energy potential, this energy resource is a strategic option for supplying energy not only for its abundance, and environmental friendly type of energy, but also for its flexibility for supplying electricity particularly for remote, and isolated area. This would significantly help the National Program of Electrification.

The solar energy potential in Indonesia is not distributed evenly around the country. This is shown in the following Fig.1. [1] which graphs a processed measurement data from 18 location in Sumatra, Java, Nusa Tenggara Timur, Nusa Tenggara Barat. Eastern part of Indonesia, represented by measurement in Sumatra and Java is shown with lower value compare to eastern part measurement represented by Nusa Tenggara area measurement. Eastern part of Indonesia has an average of 5.1 kWh/m<sup>2</sup>/day as to compare with 4.6 kWh/m<sup>2</sup>/day of western part solar energy potential.

There are various methods in estimating the global solar radiation, in which some empirical methods have been developed by some researchers. Prescott [2] estimates the global solar radiation based on the ration between earth surface and extraterrestrial solar radiation, while Glover and McCulloch [3] introduce the use of geographical position to refine the estimation. Gophinatan [4] developed estimation formula that also includes the elevation of a location. Hargreeves et.al [5] formulated a simple estimation of global solar radiation which includes the local temperature factor. A formulation that takes into account the cloud covering was developed by Supit and Van Kappel [6].

Despite its wide use, the empirical model has not met the desirable accuracy required from a reliable prediction model. It does not wholly capture nonlinear characteristics exhibited by weather parameter.

Based on this concern, several authors have attempted to develop solar radiation prediction model based on the Artificial Neural Network (ANN) technique. S.M. Al-Alawi et.al [7], and Mohandes et.al [8] used the ANN to predict monthly solar radiation based on geographic parameter and solar hour data. Other ANN based prediction model developed by Reddy et.al [9], and Krishnaiah et.al. [10] used more weather parameter in their model. The difference between the two models is in the number of data, and the ANN structure. From both model it is shown that the use of larger number of data, and more number of layer in the ANN structure, as exhibited in Krishnaiah work, would provide better result in prediction.

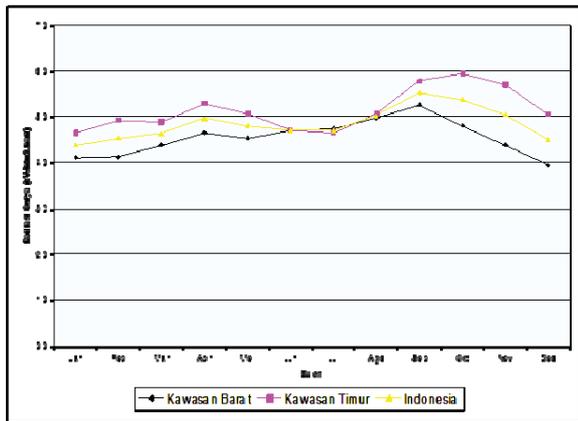

Fig. 1. Indonesia Global Solar Radiation

In this paper a study on the applicability of ANN technique in modeling a prediction tool of solar radiation is explored. Commonly available geographical and meteorological data is used as the model input basis: solar hours, latitude, longitude, elevation, maximum and minimum air temperature, humidity, and rainfall. To improve the model in capturing the seasonal period, the month of the respected data is also incorporated. Five locations are selected in Southern Region of Sulawesi Island as the study case. Data from four locations are used for developing the ANN model, while data set from one other location is used for validating the model.

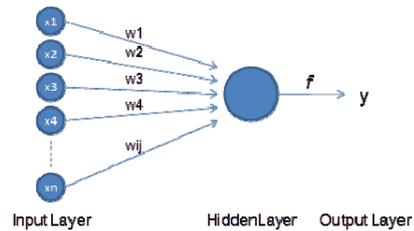

## II. Artificial Neural Network Model

An ANN model is an artificial intelligence technique, working by intensive data processing, learn and memorize them, and simulate the data structure. The advantage of ANN is that this able to capture and simulate data patterns within a multidimensional information domain [12]. It comprises of an integrated network with

A neural network typically is as shown in Fig. 2. comprises of input, hidden, and output layer. Each layer is connected through a transfer function or activation function in a connecting point called as node.

In mathematical form, the process in each neuron is represented by (1), where for a input vector X, and weight

factor W, then the product of input  $x_i$  and weight factor  $w_{ij}$ ,  $x_i w_{ij}$  is as the argument of the activation function  $f$ , where  $i$  is the number of input, and  $j$  is the number of nodes.

$$y = f\left(\sum_{i=1}^p x_i w_i\right) \quad (1)$$

The activation function  $f$  define the output of a neuron, may consist of simple linear transfer function, or more complex non-linear function. Sigmoid function is the most common transfer function used in the ANN due to its ability to provide smooth transition output from low to high value [12], represented as:

Fig. 2. Typical ANN Topology

$$f(y) = \frac{1}{1 + e^{-y}} \quad (2)$$

The most prominent characteristic of ANN is its ability to learn about the data pattern, so that enables the model to provide prediction of next data [Error! Reference source not found., Error! Reference source not found.]. The learning process of ANN is done through a training procedure. The most common training algorithm is the back propagation method. In this method, the network is fed with a group of input data, entering the activation function and produces the output. During the process, adjustment of the weigh is done through utilizing the error occurred between the produced and expected output. The back propagation method minimizes the error function which is defined as:

$$e_j^p = d_j^p - o_j^p \quad (3)$$

Where  $e$  is error,  $d$  is expected output,  $o$  is the ANN output,  $j$  is the number of output node, while  $p$  is the number of input-output pair data. Hence, the Mean Squared Error (MSE) is defined as:

$$E = \frac{1}{PJ} \sum_{p=1}^P \sum_{j=1}^J \frac{1}{2} (d_j^p - o_j^p)^2 \quad (4)$$

The learning rule is to minimize the MSE function, known also as *delta rule* atau *Widrow-Hoff rule* [Error! Reference source not found.]. According to this *delta rule*, in the training process the weigh factor  $w_{ij}$  is adjusted as the error exist, with an adjustment factor  $\Delta w_{ij}$ :

$$\Delta w_{ij}^p = \eta e_i^p x_i^p \quad (5)$$

Where  $\eta$  is a positive constant number as the *learning rate*. The adjustment factor is then used for computing a new weigh factor for the next iteration step of  $n+1$  from the previous weigh factor at iteration step  $n$ :

$$w_{ij}^p(n+1) = w_{ij}^p(n) + \Delta w_{ij}^p(n) \quad (6)$$

The iteration process continues until reaches a determined error level, or when the adjustment is not significantly affects the output anymore. When this condition is obtained then the ANN is ready for testing process. A linear regression of expected output and the ANN output is used to evaluate the correlation coefficient  $r$ , which should close to 1 for the best result

### III. Modeling Result

In this study, an ANN model is developed to predict Solar Energy Potential of Global Solar Radiation in a location in Indonesia with no solar radiation measurement data. A case study was conducted in southern part of Sulawesi Island, covering area about 200 by 700 km<sup>2</sup>, as shown in Figure 3. Data used in this study provided by a survey conducted during the Renewable Energy Project (REI) by BPPT in 1989 – 1995.

Fig. 3. Location of case study

There are five measurement sites in this area, which geographical data is presented in Table 1. below.

Data used in the ANN model development are longitude, latitude, elevation, month, and average monthly data of solar hours, maximum, and minimum air temperature, humidity, rainfall, and solar radiation.

Table 1. Site geographical data

No.	Site	Coordinate		Elevation, m
		latitude	longitude	
1	Majene	3.18 <sup>o</sup>	119.00 <sup>o</sup>	29
2	Masamba	2.37 <sup>o</sup>	120.17 <sup>o</sup>	50
3	Madai	5.04 <sup>o</sup>	119.33 <sup>o</sup>	14
4	Paotere	5.08 <sup>o</sup>	119.24 <sup>o</sup>	2
5	Panakukang	5.10 <sup>o</sup>	119.28 <sup>o</sup>	15

The model used the Multi-Layer Feed Forward (MLFF) ANN, with Back-Propagation training. Several configuration of number of nodes and layer are tested to get the best configuration, as this cannot be done deterministically. Five ANN with 1 to 5 hidden layers is each evaluated using 5, 10, 15, 20, 25, and 30 nodes.

Data from 5 sites, 4 sites are randomly selected for developing the ANN: Majene, Masamba, Maedi, dan Paotere. There are 288 data point in these 4 sites, where 50% as the training data, 25% for testing, dan 25% for validation. The 5th site, Panakukkang, is not included in the development process, and will be used as the prediction site target for testing the ANN.

Using the best network then a prediction is conducted for the target area, Panakukkang, and plotted the result as shown in Figure 5.

The running result of configuration evaluation shows in Table 2., which indicates the performance of each configuration. From the result, the 4 hidden layers with 5 Nodes is the best network, with MSE 0,003, r-value of 0,99958. The MSE (SIM) is the MSE value during ANN development, and the Case is when it was applied for the target site

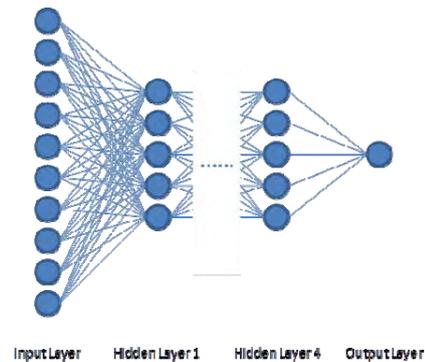

Fig. 4. ANN Structure for the Case Study

Table 2. Simulation Result in Developing the ANN

HIDDEN LAYER	NODES	MSE (SIM)	R (SIM)	MSE (Case)	R (Case)
1	5	0.003	0.99958		
2	5				
3	5				
4	5				
5	5				

1	10	0.0048	0.99934	0.0060	0.99941
2	5	0.0039	0.99945	0.1182	0.98790
3	5	0.0124	0.99830	0.0161	0.99841
4	5	<b>0.0030</b>	<b>0.99958</b>	<b>0.0098</b>	<b>0.99937</b>
5	5	0.0109	0.99863	0.0375	0.99652

The prediction result using this model is tested using the commonly used prediction performance measure as also used in previous works [8, 9, 10, 11]. Mean Percentage Error (MPE),  $r^2$  (coefficient of determination) defined by:

$$MPE = \frac{\sum_{k=1}^K \frac{d_k - o_k}{d_k}}{K} \times 100 \quad (7)$$

$$r^2 = 1 - \frac{\sum_{k=1}^K (d_k - o_k)^2}{\sum_{k=1}^K (d_k)^2} \quad (8)$$

The developed model was successfully used as prediction tools as its performance shows a satisfactory result. The MPE and  $r^2$  of the model is respectively 0,1472% and 0,999967, while similar research in other study such as Mohandes for Saudi Arabia area resulted with MPE 19,1% [8], Reddy for India area with MPE 12,5% [9], Sozen in Turkey dengan MPE 6,78% [10]. Best prediction showed in Krishnaiah work in 2007, yang improving Reddy's work, with MPE 4,61% and  $r^2$  0.999954 [11].

Mohandes and Sozen models both include the sun-hours and exclude the precipitation variable, but Sozen used more variable than Mohandes which includes only geographical data. Sozen model provide better performance than Mohandes. Reddy and Krishnaiah used more variable than Sozen. Their models include time of day, relative humidity, wind speed, rainfall, and ambient air quality in Krishnaiah, but exclude the sun-hour, in addition to the variable that was used by Sozen. Reddy Sozen's has better accuracy than Reddy although it employed fewer variables, this showed that the sun-hours, which was not used by Reddy, improved significantly Sozen's model. In contrary, although did not use sun-hour but ambient air quality instead, the Krishnaiah model provide better performance than Sozen. This shows that ambient air quality also may have strong correlation with solar irradiation.

In our study we utilized sun-hours, and all variable that is used in Krishnaiah except time, wind speed, and ambient air quality. It was revealed that sun-hour variable improved the model as our model has better accuracy.

#### iv. Summary

ANN technique has demonstrated its noble feature in providing prediction model for solar radiation. It shows that

the model has successfully captured the irregularity and stochastic nature of weather data for predicting the solar radiation value. This study exhibited that prediction modeling with ANN technique is possible to obtain solar radiation value using commonly available weather data with a satisfactory result.

The study also shows that the developed model has better performance compared to previous works in the similar field for sites at the other part of the world. Selection of variable has significant effect to the model quality, in this work, it is revealed that sun-hours is the most important variable.

# Voltage and Current Distortion Correlation Characteristics of Compact Fluorescent Lamp in Frequency Range of 2-150 kHz

Budi Sudiarto, Aji Nur Widyanto, Holger Hirsch  
Institute of Power Transmission and Storage  
Universität Duisburg-Essen  
Duisburg, Germany  
[sudiarto@ets.uni-due.de](mailto:sudiarto@ets.uni-due.de)

**Abstract**— Voltage and current distortions in the frequency range of 2-150 kHz are currently subject in research and standardization work. The reasons are that the appliances potentially generating such distortions are increasingly used and that the regulation and standardization are not completely covering and defining the limits and methods for that distortion. As consequence some interference problems have already been reported and it can be foreseen that more EMC problems will occur. Since many appliances potentially generating distortions and devices potentially susceptible to these distortions have been developed without any EMC requirements in that frequency band the discussions on suitable compatibility levels in the standardization will become critical.

This study investigates the characteristics of correlation between voltage and current distortion in the frequency range of 2-150 kHz for compact fluorescent lamp. The characteristics of correlation are important to analyze the current distortion generated by the load when specific voltage distortion is occurred. The level and frequency distortions of voltage input were set from 0-5 Volt and 2-65 kHz respectively. The Measurements of voltage and current were conducted in time domain and converted to frequency domain using Discrete Fourier Transform. The results show correlation characteristics and impedance properties for each specific frequency distortion. There are differences in the behavior depending on frequency.

**Keywords**— Frequency 2-150 kHz; Distortion; Compact Fluorescent Lamp; Impedance; Correlation.

## I. INTRODUCTION

International standards have firmly regulated the level of disturbance for the frequency range below 2 kHz (harmonics) and above 150 kHz (disturbance voltage, disturbance field strength), but the frequency range between 2 kHz and 150 kHz is not sufficiently covered. Some measurements were conducted and informed us that many equipment due to its operation characteristics produce distortion in frequency range of 2-150 kHz[1]. Since the lack of regulation for many devices and the adverse effects of the distortion in this frequency range are not significant yet even the risk of interference are possible[2], the efforts in managing the distortion for that frequency range are less. However, the increasing use of

appliances generated current distortion in frequency range of 2-150 kHz force us to observe the characteristics of the disturbance.

Compact fluorescent lamp is one of the devices producing current distortion for frequency range of 2-150 kHz. Since the widely use of appliances particularly in household installation, it is important to observe the characteristics of distortion in order to ensure their compatibility. Until recently, most of researcher focused on measuring the characteristics of distortion generated by appliances for the normal voltage input condition which is obtained from main network. There are several measurements have been conducted to observe the distortion characteristics of lighting in frequency range of 2-150 kHz including the current distortion emission characteristics[3][4] and the distortion characteristics of individual-simultaneous operation[5]. Refer to the measurement result, it can be noticed that the fluorescent lamp generated current distortion in frequency range of 2-150 kHz. The current distortion generated by the load obviously can influence the voltage quality by generating the distortion in the voltage. The study will focused on observing the characteristics of current distortion generated by compact fluorescent lamp when the voltage input contains distortion. The voltage distortions were adjusted both in frequency and level in order to get comprehensive results.

## II. MEASUREMENT SCHEME

This research activity is intended to find the characteristics of current distortion generated by the low watt compact fluorescent lamps when the voltage input contains distortion in frequency range of 5-70 kHz. In order to generate adjustable voltage input distortion, the testing circuit contained PC-Based function generator and power amplifier was designed and built as shown is figure 1.

Due to the limitation of PC sound card and Power Amplifier frequency range operation, the voltage input distortion was only generated from frequency range of 5-70 kHz. The measurement of Voltage-Current correlation was conducted in several testing group based on the frequency

distortion range of the voltage input. The grouping scheme can be seen in figure 2.

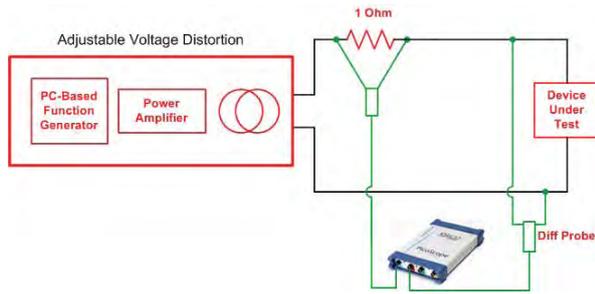

Fig. 1. Measurement Diagram

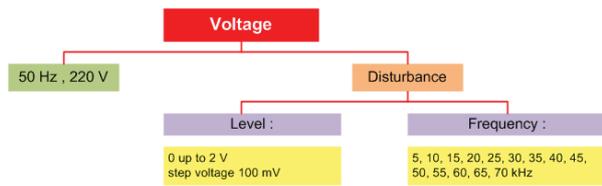

Fig. 2. Voltage Input Distortion Scheme

The measurement was conducted by Picoscope 3425 differential USB oscilloscope device. The frequency and time sampling of the current measurements were 2.5 MSa/sec and 20 ms respectively. Each measurement data contains 50.000 points of one full period current wave 50 Hz. Data was processed by Matlab software using DFT principle. From the current wave data, it can be obtained the current frequency spectrum for the range of 50 Hz up to 1.2 MHz (at 50 Hz interval), however in this paper only concern to the current distortions in the frequency range of 2-150 kHz.

### III. RESULT AND DISCUSSION

The devices under test used in this measurement were 2 brands of low watt power (7 Watt) CFL, that devices were chosen regarding to the limitation of voltage distortion source capacity. Based on the measurement result, we obtained the correlation characteristics between voltage and current distortion for compact fluorescent lamp which are shown in Table 1. and Fig. 3. According to the Table 1, it can be noticed that the correlation between voltage and current distortion is very strong since the correlation values are above 0.99 for both lamps. The high correlation value indicates that the current distortion generated by appliances is proportional with the input voltage distortion. It is mean that the current distortion generated by appliances will be higher when the voltage input distortion applied to the appliances is higher.

TABLE I. VI CORRELATION VALUE

freq (kHz)	V-I Correlation	
	Brand A	Brand B
5	0.995	0.991
10	0.996	0.992
15	0.995	0.992
20	0.993	0.993
25	0.992	0.994
30	0.993	0.995
35	0.995	0.995
40	0.994	0.993
45	0.994	0.989
50	0.993	1.000
55	0.994	0.993
60	0.991	0.992
65	0.997	0.992
70	0.995	0.989

The current produced by lamp for voltage distortion level 1-5 Volts in frequency range 5-65 kHz are shown in figure 3(a) and (b). Some properties of current distortion that can be noticed from the graph are current-voltage distortion values for each frequency is relatively linear and the gradient of linearity values between current and voltage is depending on the frequency. The gradient value between current and voltage is relatively high at frequency 5 kHz, then it will decrease when the frequency distortion increase up to 30 kHz. At frequency above 30 kHz up to 65 kHz the gradient is relatively constant. The graph in figure 3 shows the plot of current distortion produced for each voltage distortion level applied.

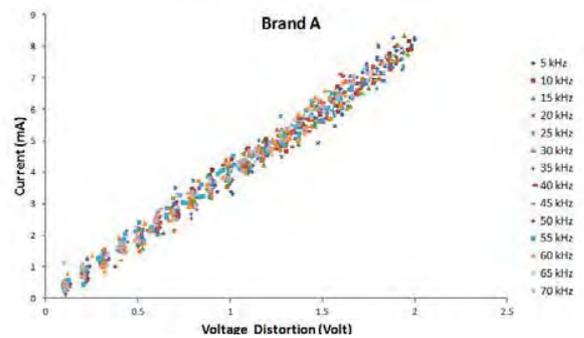

Fig. 3(a). Current and Voltage distortion value for Brand A

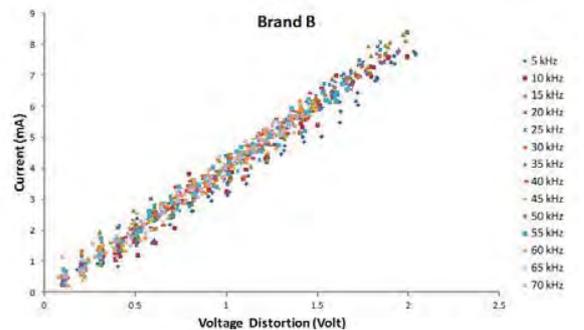

Fig. 3(b). Current and Voltage distortion value for Brand A

To simplify the current-voltage correlation for each frequency distortion, we calculate the average current distortion for specific voltage input distortion 0.5, 1, 1.5 and 2 V. The graph of current to frequency relation for specific voltage distortion can be seen in Fig 4(a) and 4(b). The graph show us clearly the current distortion produced by the lamps in specific range of voltage distortion for each frequency range from 5 to 65 kHz. The current distortion level decline at frequency 5-30 kHz then it is relatively constant at frequency range 30 to 65 kHz. We can also notice that there is a slight increase of current distortion at frequency 45 to 55 kHz. This similar trend occurred for all voltage distortion level.

The gradient between current and voltage is depended on the impedance characteristics of the device under test which is influenced by the frequency of distortion. The impedance values of both lamps for specific voltage distortion for all frequency range between 5-65 kHz are shown in figure 5(a) and (b).

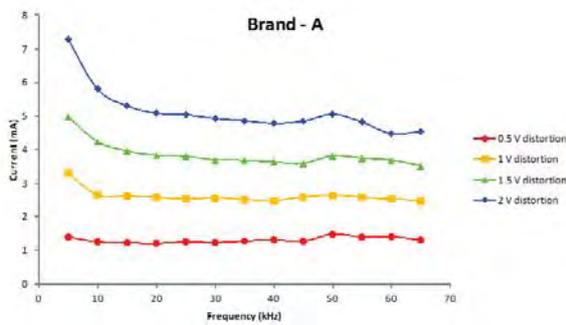

Fig. 4(a) Current value at each frequency distortion in specific voltage input level for Brand A

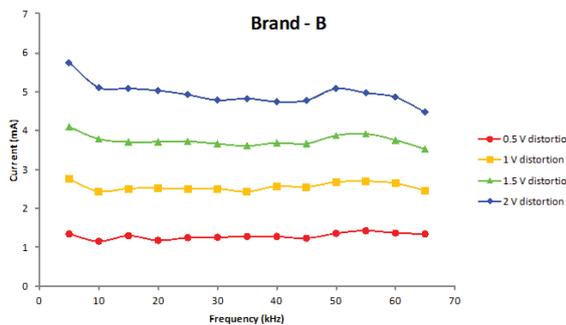

Fig. 4(b) Current value at each frequency distortion in specific voltage input level for Brand B

Fig.5. shows the impedance characteristics of the device under test. According to the graph, we can determine that the impedance of lamp is higher when the frequency distortion applied is higher. This condition occurred at frequency range 5 to 30 kHz, after that the impedance is relatively constant. We can also notice that the impedance is also depending on the voltage magnitude of disturbance, the higher voltage magnitude of disturbance the lower impedance of the lamp for

all frequency distortion range. Both of the lamps have relatively similar trend of impedance characteristics, the differences only in the magnitude value.

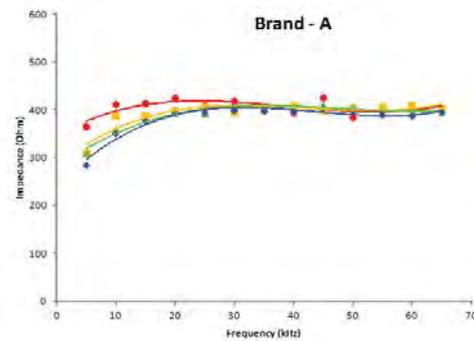

Fig. 5(a) Current value at each frequency distortion in specific voltage input level for Brand A

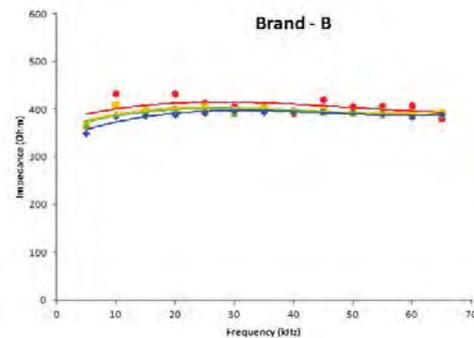

Fig. 5(a) Current value at each frequency distortion in specific voltage input level for Brand B

Refer to the all characteristics of current distortion and impedance of CFL lamps under test for frequency range of 5-65 kHz, we should pay attention more for the voltage distortion in frequency below 30 kHz since the current distortion produced by the lamp are relatively higher than the current in frequency above 30kHz. We can take one comparison for lamp Brand A as an example, when the voltage distortion applied was 2 volt at frequency 5 kHz the current distortion produced was 7.28 mA while for frequency 60 kHz the current produced was 4.47 mA for similar voltage applied. It is mean that the current distortion produced at frequency 5 kHz is around 60% higher than the current distortion at frequency 60 kHz.

#### IV. CONCLUSION

The measurement gives us two characteristics of current distortion for frequency range of 2-150 kHz. The first is that the correlation between voltage and current distortion is very strong since the correlation values are above 0.99. The high correlation value indicates that the current distortion generated by appliances is proportional with the input voltage distortion. The second characteristic is that the current-voltage distortion values for each frequency are relative linear and the gradient of

linearity value between current and voltage is different and depending on the frequency. Refer to this characteristics the attention of current distortion should be more given for specific range of frequency than the other range since the current produced by the lamp for the same voltage distortion value are not same and depending on the frequency. Particularly for the CFL under test, the higher current distortion produced for frequency range below 30 kHz. However, the characteristics of current distortion explained in this paper only were occurred for the compact fluorescent lamp under test, it is means that the characteristics of other device (different CFLs, computer, TV and etc) may has different characteristics and should be observed in further work.

E-mail: dany.perwitasari@gmail.com

**Abstract**—Climate change and energy crises nowadays become global issues in recent years which make alternative energy becomes more necessary than fossil fuels which limited availability. The use of wind generation in urban environments has increased in scale in recent years and provides significant potential. There has been an increasing interest in urban wind energy which using wind turbine in high rise building. The paper highlights to function wind turbine for high rise building, it is important to balance between BIWT (Building Integrated Wind Turbines) aerodynamic building shape design and geographic area and climate. In this paper study case in Tropical Climate, Java Island, Indonesia. Early research, designed some of numerous famous high rise building will be redesign and simulated using CFD (Computational Fluid Dynamics) analysis to find the most effective BIWT design in urban area and then validate using wind tunnel experiment. This BIWT design will adapt to chosen area in Indonesia. This paper, focus to the guidance that the results of wind power density around Java Island and combined with best design of BIWT. Main purpose of this research is helping Indonesian citizen, especially in Java Island to predict the wind energy for replace fossil fuel for their day life. The result shows that, West Java (Southern Hemisphere) has the best performance and potential for BIWT (turbine located in side of rounded shape building). Building energy can be optimized through aerodynamic building design, wind turbine position and best geographic area and climate to get maximum wind power for building energy consumption.

**Keywords**—climate change, building integrated wind turbines, wind power density, java island

## I. INTRODUCTION

Starting in the late 18<sup>th</sup> century with industrial Revolution, the global economy has increasingly relied on fossil fuels such as coal, petroleum, and natural gas [1]. Carbon dioxide and other gases are not dangerous. In fact, these gases naturally occur in the atmosphere and help moderate the global climate to support living organisms, including humans [2]. The problem is that the growing use of fossil fuels in increasingly the concentration of carbon dioxide and other gasses, which means increase the capacity of the atmosphere to absorb latent heat energy. Architects, as a designer, recognizing that the building sector is responsible for almost half of all greenhouse gas emissions annually [3]. Buildings are among the physical artifacts that society produces with the greatest longevity (50-

100 years). Consider the fact from US Department of Energy [4] that every year constructing and operating America's building generates 25% of the total municipal solid waste stream and 48% of all greenhouse gas emissions.

Recently the European Parliament [5], amending the 2002 Energy performance of Building Directive, has approved a recast of the Directive proposing that all new buildings built after 31 December 2018 will have to produce as much energy as they consume on-site. The UK Government has set some challenging targets, both the UK The Climate Change Act [6] and The Scotland Government Climate Change (Scotland) Act 2009 requires an 80% reduction by 2050.

Wind energy, one of alternative energy, therefore, is a catchall category of energy sources that can replace traditional fossil fuels in daily life, while causing less harm to the environment. The increasing population because of urbanization and fertility is difficult to control in urban area. Adaptation to the climate change is the best way to reduce the greenhouse effect. Now, it is the time to thinking how to build the high rise building in harmony with climate and using renewable energy resources. Building Integrated Wind Turbines (BIWT) nowadays becomes the new icon of Green Buildings. However to employ BIWT in urban area there are some limitation, wind energy operates effectively only in certain geographic area and climates. This paper is organized to place the best design BIWT in the best geographic area and climates in Tropical Climate (Java Island, Indonesia). It is interesting that Indonesian people, especially who lived in Java island exploit wind energy which cheap, environment friendly and renewable than fossil fuel.

## II. JAVA ISLAND WIND POWER DENSITY CALCULATION

Wind is a source of solar energy that does not rely on the condition of the sky. Wind energy creates very few greenhouse gases and will exist as long as the sun shines and wind blow. To maximize the performance of BIWT should combine with certain geographic area and climates. In this paper, Java Island is chose from all the available islands in Indonesia because the rapid growth population.

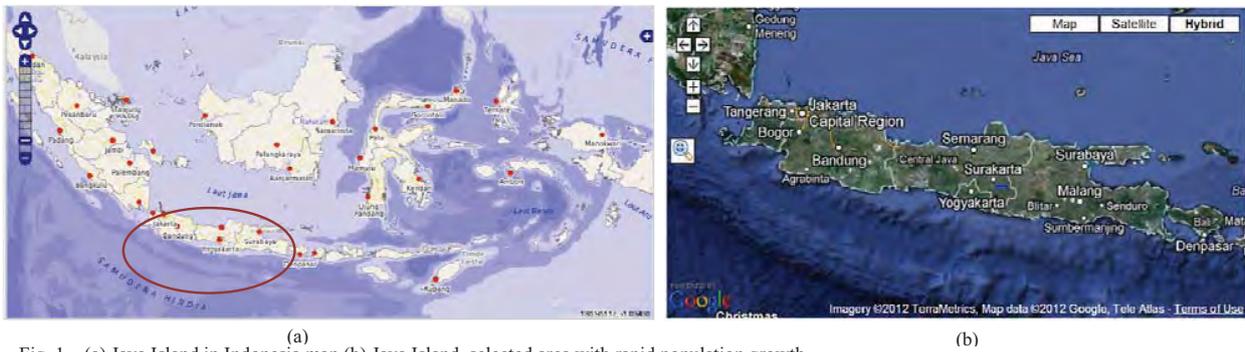

Fig. 1. (a) Java Island in Indonesia map (b) Java Island, selected area with rapid population growth  
 Source: <http://www.iccc-network.net/en/lib/map> [7], <https://maps.google.com/> [8]

The calculation of this wind power density of Java Island is adapted from Quanhua Liu, et al. research [1][9][10]. Firstly, calculation we find global power in Java Island, Indonesia which calculates around beach in Java Island (Figure 1) using Google map for looks for direction and geographic area. Wind turbine tower high calculated from 10, 25, 50, 100 and 200. We are putting wind turbine at higher altitude (minimum 10m) to capture more wind energy. Most wind energy is over the oceans, we calculated wind power around java island beach.

Wind power density as a tool to calculate annual electricity for BIWT. Firstly there are some assumptions for BIWT:

- BIWT is single building which use for office building
- BIWT consist of 16 floors, total area 4096m<sup>2</sup>
- Using 1 wind turbine in each BIWT
- Rotor diameter 20m

Wind power density result show in Figure 2. This graph also explain the higher the tower, the higher the wind power density. Southern hemisphere of Java island can produce wind energy higher than northern hemisphere because provide plenty of energy to atmospheric motions, and its roughness is generally smaller than northern which a lot of island.

### III. BIWT DESIGN WITH CFD AND WIND TUNNEL EXPERIMENT

The most important in BIWT is how much it can produce the power for energy consumption. Potential energy from the wind can be calculated using this equation [11]:

$$P_{\text{turbine}} = 0.5 \times \rho \times C_p \times A \times V^3 \quad (1)$$

Wind power (P) is depends on the wind velocity (V) raised to the third power (wind speed cubed). It can be seen that energy is dependent on the free wind velocity (1). If the wind velocity doubles, the power increases by a factor of eight (1). Wind velocity in addition to increases due to the height, can also be increased because of the shape of the building. The building architecture can be shaped to capture and tunnel wind through the turbines, which can in turn produce wind velocity through the turbines that are greater than the prevailing wind velocity. This study concentrates on looking for a BIWT that can increase the wind velocity in Java Island.

Wind created from differences in velocity on different earth surfaces [9]. Every country has wind load standards depending on their region. When wind hits the building structure, it will be deflected or stopped, thus converting the wind's kinetic energy into potential energy and pressure. This kinetic energy can make the blade from the wind turbine to start moving. Putting wind turbines on top of buildings, especially tall buildings, should allow them to take advantage of height without building an expensive, full size tower, especially in urban areas.

There are two kinds BIWT design are chose from earlier research [9] which simulated using CFD and validate using Wind Tunnel experiment. Computational Fluids Dynamics (CFD) is the science of predicting fluid flow, heat and mass transfer, chemical reactions, and related phenomena by solving numerically the set of governing mathematical equations.

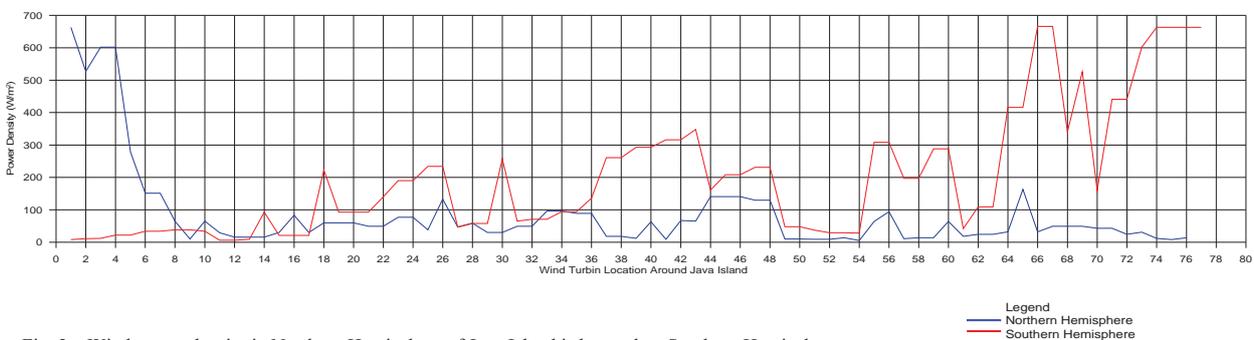

Fig. 2. Wind power density in Northern Hemisphere of Java Island is lower than Southern Hemisphere

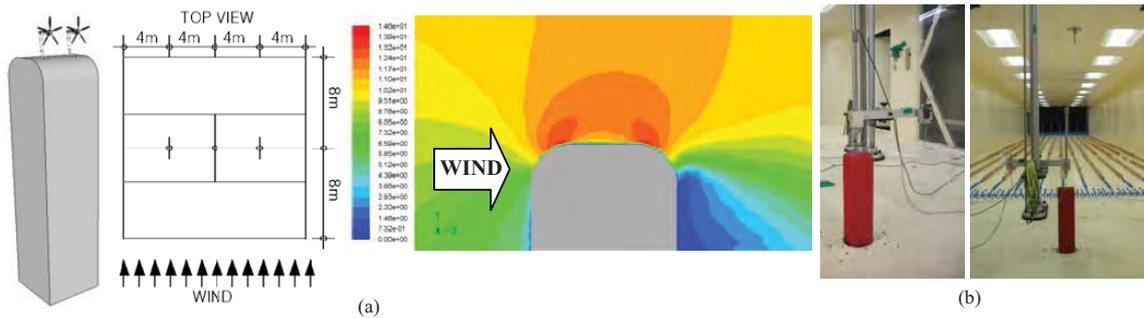

Fig. 3. Building A (a) CFD analysis (b) Wind Tunnel validate using Cobra Probes

CFD provides a cost-effective alternative to experimental fluid mechanics. A well developed and reliable computational code can be easily used to study flows in various geometries, boundary conditions, and flow parameters [12]. After analyze numerous design using CFD, BIWT best result make a prototype and validate the CFD result using wind tunnel experiment. Wind tunnel experiment is methods of analysis which can be used to predict the complicated flow of wind and its effect on the response of the building and its components have not been developed for routine office use. Wind tunnel experiment is generally accepted in the scientific and engineering community.

Some limitations imposed on the experiment are:

- BIWT is single building with The size of the building using high rise building scale depth:width:height = 1:1:4
- The basic form of model is rectangular in shape with the same ratio.
- Building design is redrawn using Sketchup 7 and Autocad 2009
- Building design with scale 1:150 to make similarities with wind tunnel model.
- BIWT is single building which use for office building
- These design buildings are only adaptations of the appearance of BIWT which currently exist and from literature.
- BIWT consist of 16 floors, total area 4096m<sup>2</sup>
- BIWT annually electricity consumption for office building in Indonesia 240 kWh/m<sup>2</sup>.year [13]

- For calculation electricity consumption, assume only using 1 wind turbine in each BIWT

A. Building A (Wind Turbine on The Top of Rounded Roof) CFD and Wind Tunnel Analysis Result

Building A is adapting from Near North Apartments, USA's building design. Contour (Figure 3;a) from Building A show that the wind velocity increases as it passes through a rounded shape. Highest wind velocity is near the rounded shape because the wind velocity increases because the rounded building restricts the passage of wind. Rounded shape restricts the passage of wind, causing the streamlines of the wind to coverage on the windward slope. The height of the building brings the gradient wind closer to surface, resulting in a reduction of the gradient of the rounded shape, which causes an increase in the wind velocity within the boundary layer. Wind velocity increase 39.29% from wind velocity approach. CFD and Wind Tunnel result (Cobra Probes and Pitot Tube) show that the result are almost similar (Figure 3;b). Building A is the best design for wind turbine which need high tower only in one side wind direction. For this kind building, HAWT (Horizontal Axis Wind Turbine) is the best solution.

B. Building B (Wind Turbine in The Side of Rounded Shape) CFD and Wind Tunnel Analysis Result

Some studies indicate that the position of the turbine on the side of buildings can increase wind speed. Several high rise buildings already use this method such as Kinetica Building, United Kingdom and Anti Smog Building, France Wind turbine of this building is located in the side of building and near with ground.

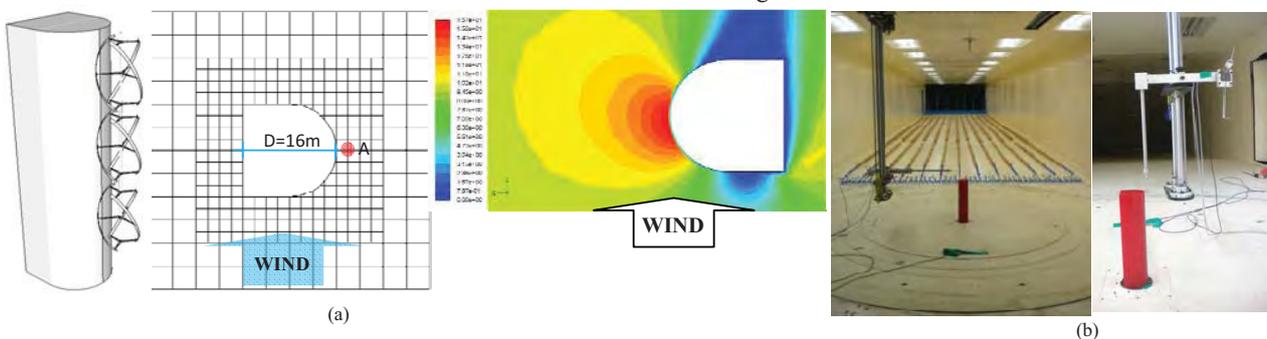

Fig. 4. Building B (a) CFD analysis (b) Wind Tunnel validate using Cobra Probes

Some high rise building will create wind flow around it which sometimes dangerous for low rise building and people which stays around it. Figure 4 shown wind turbine position to calculate wind velocity with height 1.5m up to 64m on the ground. In CFD analysis, writer also calculated wind velocity around the building. Wind velocity contour in Figure 4 show the high wind velocity is around the rounded shape. Highest velocity located  $1/8D$  or 2m (red dot A; Fig.4) in the side of rounded building and in the height 1.5 up to 8m from the ground. Rounded shape could increase wind velocity from 18.58% up to 182.02%. Wind velocity coefficient increase in the height of wind turbine 1.5m to 16m from the ground, stable in the height 16m to 56m, and decrease when almost in the rooftop.

### C. The Placement BIWT design (Building A and Building B) in Java Island

West Java (Southern Hemisphere) has the best performance and potential for BIWT because of its wind power density. In this area, we do not need high tower for wind turbine. The best design for BIWT is Building B which its wind turbine in the side of building (Figure 4). Those designs do not need high tower to harvesting maximum wind energy. From some assumption above, use one wind turbine, can supply almost 45% annual energy consumption every year. If there are 3 wind turbines, it means this BIWT office building does not need energy from fossil fuel anymore. Central Java and East Java in Southern Hemisphere does not have high wind energy performance like West Java. In this area another BIWT design is needed. Especially, BIWT design with higher wind turbine tower such as in Building A (Figure 3). Wind turbine in this kind building can support annual BIWT office building's electricity 15% every year.

## IV. CONCLUSION

Wind tunnel experiment and CFD analysis can be used as a tools to shown the increasing wind resources around the BIWT. Wind tunnel experiment and CFD analysis almost similar but have to be carefully when making the model for wind tunnel experiment especially in rounded shape Investing in urban renewable energy, pollution caused by the burning of fossil fuel will reduced allowing the quality of live in urban centers to increase. Building A and Building B could increase wind energy as the rounded shape.

Performed calculation and results show that single wind turbine for Building A is the best in Central Java and East Java and could reduce the electricity 15% every year. Building B could reduce 45% annual energy consumption every year in West Java (Southern Hemisphere), Java Island, Indonesia is easily accessible goals (Figure 11).

This research can be observed that Building Integrated Wind Turbines (BIWT) it is not harvesting wind energy only by Aerodynamics shape, at least in this case best geographic area and climate could increase the perform of wind turbines. We also hope that with the establishment of design is able to support the Government of Indonesia to reduce fossil fuel

consumption by 26% by the year 2020 [14]. The use of wind energy in Building Integrated Wind Turbines in urban area to generate electricity is especially advantages to developing countries, because of the new employment opportunities it will create, as well as the stimulation of local economies by attracting investment.

Generic conclusion cannot be drawn from one single case study, we do hope that this framework will inspire and enable other researchers and architect to perform similar studies in other rapid development area in Indonesia. Thus helping the adaptation in climate change and reduce the greenhouse gasses and global warming. We hope that our research could helping Indonesian citizen, especially in Java Island to predict the wind energy for reduce fossil fuel and solving land use problem because of rapid development area with BIWT.

## ACKNOWLEDGMENT

Our thanks to Indonesian Institute of Sciences (LIPI), Wonkwang University and CKP Wind Solutions for allowing this study to be undertaken and to the staff at each institute and university for taking the time to participate in the study.

# Cost Allocation of Transmission Usage Based on Current Magnitude

Hermagasantos Zein  
 Energy Conversion Departement  
 State Polytechnic of Bandung (Polban)  
 Bandung, Indonesia  
 e-mail: hermaga\_s@yahoo.co.id

**Abstract**—Transmission is one of the key utilities in the electricity market mechanism. Generally, it is managed by a provider that is monopoly but not in business. However, all costs that have been embedded in the transmission must be refunded by all transmission users, or generators. The paper proposes a method for determining the cost allocation of transmission usage with current magnitude as the basis for calculation. As a result, current flow contributions of each generator on the lines must be determined. Then it applies a method to decompose the actual current, of the load flow results, on every line. Mathematically, the proposed method has been illustrated clearly in this paper without approximations and assumptions. While the formulations have been tested with 5-bus system and the results have been compared to the published methods. The test results show that the proposed method gave slightly different results with the published methods. But it is in line with what were expected.

**Keywords**—Transmission; Cost Allocation; Generator; Current Magnitude; Contribution.

## I. INTRODUCTION

Cost allocation of transmission usage becomes an important issue when transmission is operated openly. It is always maintained under natural monopoly company. However, The transmission provider will be required to offer the basic transmission services in conjunction with a number of mandatory and/or voluntary ancillary services. This has been studied by A. Zobian and M.D. Ilic [1], about unbundling of transmission and L. Willis. et al [2], about unbundled service. Basic transmission service refers to the path provision function of the transmission grid while ancillary services, such as operating reserves, regulation, load following and voltage control, are the necessary for maintaining the reliability of the bulk system as well as undertaking commercial transactions across the grid.

A few references have published various methods to calculate cost allocation of transmission usage, such as generation shift distribution factors (GSDFs), line utilization factors (LUFs), Bialek and Kirschen algorithm. These methods have been reviewed by Jiuping P.. et al [3] through numerical examples that use 5 bus system and the results are enough different among one another, see Tables II and III, although they use the same active power flow as basic calculation.

This paper will propose a different basic calculation, current magnitude, through the decomposition method that has been studied by Hemagasantos Z. [4]. Decomposition

techniques here are done after results of load flow calculation are found, where these results are as a base case. Then the base case will be used to determine flowing current contribution from a generator to the lines. After the current contributions from generators are obtained, finally is continued to calculate the cost allocation of transmission usage for all of the generators.

To see the performance of the proposed method will be tested with the 5 bus system that was said above. the results will be compared with the results of the methods that have been published.

## II. PROBLEM FORMULATION

### A. Cost Allocation of Transmission Usage

Formulation for calculating cost allocation of transmission usage in this paper follow general equation from MW-Mile regulation, which is expressed by equation (1).

$$TC_i = \sum_{k \in K} C_k \frac{|F_{i,k}|}{\sum_{t \in T} |F_{t,k}|} \quad (1)$$

Where  $TC_i$  is total cost that is allocated to generator  $i$ ,  $C_k$  is the embedded cost of the facility  $k$  (included costs of wires, towers, connecting, arresters or others),  $|F_{t,k}|$  is power/current magnitude flowing on facilities  $k$  caused by generator  $t$ , and  $K$  &  $T$  are the number of transmission facilities and generators on the system. This equation (1) shows that direction of flow does not influence the responsibility of payment. This is analogous to the TOL (tax of line) usage for vehicles. The power magnitude used in the equation (1) can consist of active power (MW) or apparent power (MVA). So we have to choose one of the others (MW and MVA). Power usage in determining cost allocation of transmission usage will be influenced by losses, such as shown by Fig. 1 this below. This figure is a line of facility  $k$  with impedasi  $Z_{jk}$ . Furthermore it is assumed power from generator  $i$  to flow from left to right is equal to  $F_{i,k}^{LR}$  and the power was accepted on the right side bus is  $F_{i,k}^{RL}$ . There is line impedance will produce loss in the line, so that  $F_{i,k}^{RL}$  received on the right side of the bus will be reduced.

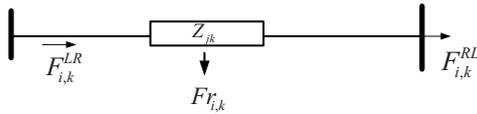

Fig. 1. Power flows in the line

Where  $Z_{jk}$  is line impedance. If generator i cause power losses,  $Fr_{i,k}$ , in the line (Fig. 1), power genertor i,  $F_{i,k}^{RL}$ , flows from right to left and received at right side is

$$F_{i,k}^{RL} = F_{i,k}^{LR} - Fr_{i,k} \quad (2)$$

While the power loss depends on the line impedance. For a fixed current flow, the power loss would be great if the line impedance is also getting bigger. In practice, the line impedance is not always zero. So  $F_{i,k}^{RL}$  is always less than  $F_{i,k}^{LR}$ .

Before equation (1) is applied, the direction of power flow on each line must be chosen first, from left to right or vice versa. Because of the power loss in the lines, the direction of power flows that have been chosen is definitely affect the calculation results. For example, the power flowing from generator i is from right to left. If direction of the power chosen is from left to right, the generator i will be getting profit.

In this paper will propose current flows as the basis for determining cost allocation of transmission usage. The idea is based on reality that current flows in transmission lines according to electrical laws, i.e. they did not changed (or no losses) after flowing across the transmission grid. So, using current as a basis calculation will more fortunate than using power in determining cost allocation of transmission usage. Then equation (1) in current variable is rewritten as this following equation.

$$TC_i = \sum_{k \in K} C_k \frac{|I_{i,k}|}{\sum_{t \in T} |I_{t,k}|} \quad (3)$$

Where  $I_{t,k}$  is the current from generator t that flows in the line k.

#### B. Current Contribution from a Generator to the Lines

General working equation of the electric network in the matrix can be expressed by following equation.

$$[I_{bus}] = [Y_{bus}] [V_{bus}] \quad (4)$$

Where  $[I_{bus}]$  is the bus injection current matix,  $[Y_{bus}]$  is the bus admittance matrix and  $[V_{bus}]$  is the bus voltage matrix.

Whereas the  $[I_{bus}]$  matrix consists of the bus injection current matrix of genertors,  $[I_{bus}^G]$ , and the bus injection current matrix of loads,  $[I_{bus}^L]$ . So equation (4) can be rewritten as this following equation.

$$[I_{bus}^G] - [I_{bus}^L] = [Y_{bus}] [V_{bus}] \quad (5)$$

Or.

$$[I_{bus}^G] = [Y_{bus}] [V_{bus}] + [I] [I_{bus}^L] \quad (6)$$

Where  $[I]$  is identity matrix. Based on study from Hermagasantos Z. [4], the current flow to the load at bus i can be expressed by

$$I_i^L = \left( \frac{S_i^L}{V_i} \right)^* = y_i^L V_i \quad (7)$$

Where,

$$\alpha + \beta = y_i^L = \frac{P_i^L (1) j Q_i^L (1)}{|V_i|^2} \quad (8)$$

Where  $V_i$ ,  $P_i^L$  and  $Q_i^L$  are the actual voltage, active power and rective power, repevively. In matrix form of equation (7) is substituted into equation (6) and yield

$$[I_{bus}^G] = [Y_{bus}] [V_{bus}] + [y_{bus}^L] [V_{bus}] \quad (9)$$

Where  $[y_{bus}^L]$  is diagonal matrix of load admittances expressed by equation (8). From the equation (9) is get bus voltage, that is

$$[V_{bus}^G] = [Z_{bus}^{\#}] [I_{bus}^G] \quad (10)$$

Where,

$$[Z_{bus}^{\#}] = ([Y_{bus}] + [y_{bus}^L])^{-1} \quad (11)$$

From the latest equation is applied superposition technique to calculate current contributions of each generator that flows in lines. For example, for generator at bus i, equation (11) can be rewritten to be the following expression.

$$\begin{bmatrix} V_1^{Gi} \\ V_2^{Gi} \\ \vdots \\ \alpha + \beta \\ \vdots \\ V_n^{Gi} \end{bmatrix} = \begin{bmatrix} Z_{11}^{\#} & Z_{12}^{\#} & \bullet & \bullet & \bullet & Z_{1n}^{\#} \\ Z_{21}^{\#} & Z_{22}^{\#} & \bullet & \bullet & \bullet & Z_{2n}^{\#} \\ \bullet & \bullet & \bullet & \bullet & \bullet & 0 \\ \bullet & \bullet & \bullet & \bullet & \bullet & 0 \\ \bullet & \bullet & \bullet & \bullet & \bullet & 0 \\ \bullet & \bullet & \bullet & \bullet & \bullet & 0 \\ Z_{n1}^{\#} & Z_{n2}^{\#} & \bullet & \bullet & \bullet & Z_{nm}^{\#} \end{bmatrix} \begin{bmatrix} 0 \\ 0 \\ 0 \\ I_i^G \\ 0 \\ 0 \\ 0 \end{bmatrix} \quad (12)$$

Where  $V_j^{Gi}$  is voltage at bus j caused by generator at bus i,

$Z_{ji}^{\#}$  is element of new bus impedance matrix on row j and column i and  $I_i^G$  is the injected current at bus i. From the equation (12) above is easily obtained voltage on each bus, that is

$$V_j^{Gi} = Z_{ji}^{\#} I_i^G \quad (13)$$

The following step, Fig. 2 will be used to calculate current flow contribution of a generator in the line. It is phi equivalent circuit of a line having admittance  $y_{jk}$  and half line charging susceptance  $y_{jk}^{sh}$ . The line connects bus j to bus k, where  $V_j^{Gi}$  and  $V_k^{Gi}$  are nodal voltage as consequence of the injected current at bus i.  $\alpha + \beta = \chi$ . (1) (1)

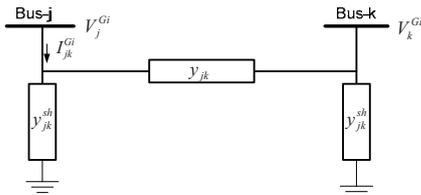

Fig. 2. Phi equivalent circuit of line j-k

From Fig. 1, the current flowing in the line j-k derived from generator at bus i is easily determined through a circuit theory, that is

$$I_{jk}^{Gi} = (V_j^{Gi} - V_k^{Gi})y_{jk} + V_j^{Gi}y_{jk}^{sh} \quad (14)$$

Or,

$$I_{jk}^{Gi} = F_{jk} I_i^G \quad (15)$$

Where,

$$F_{jk} = (Z_{ji}^{\#} - Z_{ki}^{\#})y_{jk} + Z_{ji}^{\#}y_{jk}^{sh} \quad (16)$$

### III. ALGORITHM

The proposed method explained in section II needs clearer procedure, so that it can be applied in computer calculations. These procedures are steps of algorithm to run a program from the proposed method. Then the procedure in this paper are realized by an algorithm as the following steps.

- Step-0: Start.
- Step-1: Input data of transmission, loads, generators, and embedded cost of each facilities.
- Step-2: Run program load flow with condition at step-1.
- Step-3: Form a new bus impedance matrix from the load flow results, by equation (11)
- Step-4: Determine a generator, for example  $G_i$ , that will be observed and calculate its current generated,.
- Step-5: Calculate voltage every bus that is caused by the  $G_i$ .
- Step-6: Calculate current that flows in each line base on bus voltages that are got from step-4.
- Step-7: Continue to step-5 for another generator until all generators have been observed.
- Step-8: Calculate cost allocation of transmission usage for all generators.
- Step-9: Write the results.
- Step-10: Stop.

Step-1 inputs all data, both data of line costs of every line and parameters of system. The data are used to obtain a base case by running load flow program in step-2. The base case is used to calculate bus admittance through equation (8) and then forming bus admittance matrix through equation (11) in step-3. Afterward, it is forming a bus impedance matrix from the bus admittance matrix in step-4. Choose a generator to be observed then uses equation (12) to determine bus voltages in step-5. After obtaining bus voltages, it is continued to calculate current flows in every line from the generator through equation (14) or (15) in step-6. In step-7 the process goes back to step-5 and choose again one of the other generators until all generators have been processed. Next step, it is continued to calculate cost allocation for every generator through equation (1) in the step-8. Finally, it is obtained cost allocations of transmission usage from each generator and

process is stopped.

### IV. NUMERICAL EXAMPLES

This section presents a illustrative example base on the 5-bus test system that was proposed by Jiuping P., et al [3]. It is aimed to see performance of the proposed method that was discussed above. The 5-bus test system is depicted in Fig. 3. This figure consist of two generators, three loads and seven facilities/lines. Total capacity of the loads of system is equal to 145 MW, which is distributed on bus 3, 4 and 5. The cost of each line in Tabel 1 is an annual cost which includes costs of wires, towers, connecting, arresters or others.

Table I gives the transmission data including the base case flows and the transmission revenue requirements. In the case, loads at bus 3, 4 and 5 are (45+j15 MVA), (40+j5 MVA) and (60+j10 MVA), respectively. The generator from bus 2 is fixed as 20 MW and bus 1 is the slack bus.

Cost (\$/MW)	1.9354	2.0147	2.1151	1.7381

Tables II and III consist of the test results of the published methods. These tables show generator-related active power flows for the base case determined by general generation distribution factors (GGDFs), line utilization factors (LUFs), Bialek and Kirschen tracing algorithm. They stated the generator-related MW flows and generator charges determined by GGDFs and LUFs are very close. From Table III for lines 1-2 and 1-3, Bialek and Kirschen algorithms resulted in zero charges for G2 and full responsibility of G1 to use them. However, the two algorithms have very different results for generator charges, i.e. 2.1151 \$/MW for Bialek and 1.7381 \$/MW for Kirschen.

While Table IV shows that the generator-related current flows for base case determined by the proposed method, where  $I_{G1}$  and  $I_{G2}$  are the generator-related current flows of  $G_1$  and  $G_2$ , respectively, in per-unit (pu). From the base case, G1 and G2 generate 131.27 MW and 20 MW, respectively. Power of G1 is so dominant so that  $I_{G1}$  is the very influential to every line. The next table consist of total cost, in unit \$/MW, of the five methods. The last row of the table contains the cost allocation for each generator. From the calculation results is obtained cost allocation for generator 1 is 2.5553 \$/MW and generator 2 is 2.1483 \$/MW. These results show that cost allocation from generator 1 is more than generator 2. The same is also indicated by the results of the published methods on Table II and III

TABLE IV.  
 TRANSMISSION USAGE AND CHARGES ( $G_1$  AND  $G_2$ )

Line #	$I_{G1}$ (pu)	$I_{G2}$ (pu)
1-2	0.9252	0.0304
1-3	0.3873	0.0304
2-3	0.2081	0.0506
2-4	0.2378	0.0525
2-5	0.4797	0.0871
3-4	0.1823	0.0128
4-5	0.0616	0.0043
Cost (\$/MW)	2.5553	2.1483

After the cost allocation of transmission usage was determined, then total revenues, or  $TR$ , of the methods can be calculated with the following equation.

$$TR = \sum_{i=1} C_{Gi} P_{Gi} \quad (16)$$

Where  $C_{Gi}$  is cost allocation of transmission usage for  $G_i$  and  $P_{Gi}$  is the injected power of  $G_i$ . Then equation (17) is used to calculate deviation:

$$\Delta = \frac{TR - EC}{EC} 100\% \quad (17)$$

Where  $\Delta$  is deviation and  $EC$  is total embedded cost of transmission. From Table I  $EC$  for the 5 bus system in the fig.3 is 3.3148 ( $10^6$  \$/year) or 378.4018 \$/hour.

Table V shows that there is slightly difference between  $TR$  and  $EC$  for the published methods. LUFs & Kirschen give negative deviation and GGDFs & Bialek give positive deviation. Which  $EC$  for ideal conditions is equal to  $TR$  (or zero deviation). This deviation occurs because it is influenced by losses when power is applied as a basis of calculation; It will become worse when losses increase. While the proposed method gives zero deviation. This is caused by the use of current magnitude as a basis of calculation. Current has advantages when compared to power, current magnitude flowing in both ends of each line is same. This has inspired writer to study current as basis of calculation in determining cost allocation of transmission usage. From the illustrative example, the proposed method gives very satisfying results.

TABLE V.  
 COST ALLOCATION OF TRANSMISSION USAGE FOR 5 METHODS

Method	Cost (\$/MW)		Total Revenue	$\Delta$
	$G_1 = 131.27\text{MW}$	$G_2 = 20\text{MW}$	$TR(\$)$	(%)
<b>Proposed</b>	<b>2.5553</b>	<b>2.1483</b>	<b>378.4018</b>	<b>0</b>
GSDFs	2.5880	1.9354	378.4348	0.0087
LUFs	2.5756	2.0147	378.3930	-0.0023
Bialek	2.5604	2.1151	378.4057	0.0010
Kirschen	2.6178	1.7381	378.4006	-0.0003

## V. CONCLUSION

A method for determining cost allocation of transmission usage has been proposed in this paper. Mathematically, the formulations have been illustrated clearly without assumptions and approximations. The method uses current magnitude as a basis of calculation so that the calculation results are not affected by the determination of the flow, either from left to right or from right to left. This is caused by current magnitude at two ends of line is same.

While the published methods use power magnitude as a basis of calculation so that the calculation results are influenced by losses. Determination of power flow will affect the calculation results due to the power flow from left to right be not equal to the power flow from right to left. The greater the losses in the line can make the calculation results that deviate further and further away.

Table IV shows that the proposed method can be applied with satisfactory results. From the table it can be shown that the current flow from each generator on each line can be determined properly. With the current flow can be separated perfectly well in each line are like well shown by the Tabel IV then this makes the key to the success of the proposed method. This is shown by Table V, the published methods gave a non-zero deviation whereas the proposed method gave a zero deviation. The smallest deviation is given by Kirschen algorithm, -0003%. It is very close to the proposed method.

From the test results, the published methods gave a small deviation. However, for large systems, they will give a large deviation. This is thier weakness when compared the proposed method, which the deviation is not influenced by the size of system.

**Abstract**—Magnetic flux resulting from geomagnetic anomaly is a natural energy source that never runs out, driven by tectonic settings or specific rock structures. Unfortunately, this natural resource has not been exploited at all; therefore frontier technological innovations in electromagnetic fields are required. Geomagnetic flux concentrator is a system designed to actively collect the Earth's magnetic fluxes and direct them in a catchment area, in order to increase the geomagnetic output flux densities to meet the required densities of common electrical generators. Earth's magnetic fields are of very low frequency or nearly static field that must be firstly manipulated to achieve a cut-off frequency, needed to be able to steer them through the waveguides. The designed magneto-static flux manipulator worked by periodically placing a round shielding sheet, which is continuously fast rotated across the constant magnetic fluxes flow. Hence the fluxes on the opposite side of the shielding sheet will turn into high frequency geomagnetic pulses (of some MHz), so that they will be just like a series of electromagnetic waves which are spatially separated, then they will be able to be further guided and concentrated. This paper report the initial results of performance tests of the magneto-static flux manipulator, tested with a Helmholtz coil in a calibrated semi-anechoic chamber. The manipulator was tested in the Lombok Island, which is located at the highest intensity of the geomagnetic anomaly of Indonesian region. Results show that the manipulator performed good frequency manipulations up to about 60 Hz for rotated shielding of 900 rpm, which will be possible to reach the higher frequencies.

**Keywords**—Geomagnetic anomalies; flux density; concentrator; waveguides

## I. INTRODUCTION

Geomagnetic studies over the Lombok Island regions have been conducted continuously since 2004 by a team of researchers from the Mataram University [1, 2, 3], where the results of a recent survey carried out in collaboration with the *Deutsches Geo-Forschungszentrum* (GFZ) Potsdam - Germany showed a difference in the intensity of the magnetic in the strongest dipolar structure up to 1000 nT [4, 5, 6]. The high Earth's magnetic fluxes density in the Lombok Island regions can become natural sources of inexhaustible energy, while their source comes from the tectonic settings of this region which is between two active subductions [6]. Unfortunately, these

natural resources have not been utilized at all, hence necessitating a frontier technological innovation in electromagnetic in order to practically utilize the geomagnetic field for electrical generators.

A multilevel concentrator system will be designed to collect and increase the geomagnetic flux density with a gain of 10, to finally get static magnetic intensity of 10,000 gauss from five levels concentrator. While Earth's magnetic fields are of very low frequency or nearly static field, so that they must be firstly manipulated to achieve a cut-off frequency, needed to be able to steer them through the waveguides. Therefore, what we need first to make the flux concentrator work is a magneto-static manipulator. This paper report the initial results of performance tests of the magneto-static flux manipulator, tested with a Helmholtz coil in a calibrated semi-anechoic chamber.

## II. DESIGN AND TESTING OF MANIPULATOR

The designed magneto-static flux manipulator worked by periodically placing a round shielding sheet, which is continuously fast rotated across the constant magnetic fluxes flow. Hence the fluxes on the opposite side of the shielding sheet will turn into high frequency geomagnetic pulses (of some MHz), so that they will be just like a series of electromagnetic waves which are spatially separated, then they will be able to be further guided and concentrated. The manipulator was tested in a semi-anechoic chamber 3 m x 3 m x 3 m equipped with a pair of 100 turns Helmholtz coils with a diameter of 2 m. We have previously demonstrated that our self arranged chamber can reduce external static magnetic fields from outside with shielding effectiveness of 87.5% [11], and refinement of the Helmholtz coils have been done in order to induce larger and more uniform static magnetic fields [12].

The manipulator basically consists of two round shape shielding sheets, each with diameter of 1 m. The sheets are of 3 mm thick of Mu-metal material, with nearly 70 % Nickel and the rest 30 % of mixed metals (i.e. Iron, Cadmium and Cobalt). The two sheets are sliced so as to make four identical holes as well as four shielded areas on each sheet, which their dimensions suitable with the planned waveguides (cut-off frequency around 1 MHz).

When the manipulator is in operation, the shielding sheets which placed in the rear will be kept static (no motion), while another sheet in the front will be turned around. The moving sheet is coupled to a 1500 rpm three phase induction motor via a fix rubber belt. While it runs with the moving shielding sheet as load, its maximum speed is reduced from 1500 rpm down to about 900 rpm. The motor speeds are controlled by a voltage regulator, which its output currents have been previously calibrated by using a photo tachometer to get the desired speed. During tests, all electrical parts including the magnetic fields measuring equipment (SPECTRAN NF-5035®) are controlled

from outside the chamber, and live monitored by two sets of CCTV cameras. Results of field measurements can be logged or live monitored using MCS computer program.

Fig. 1(a) shows the manipulator when it is placed between a pair of Helmholtz coils in a semi-anechoic chamber, while Fig. 1(b) shows the placement and setting of measuring equipment in front of the manipulator (behind the shielding sheet). Fig. 2 illustrates the electrical circuit used for the tests, while the sequences of tests as well as inputs and outputs parameters are given in Table 1.

TABLE I. TEST SEQUENCES AND PARAMETERS

Sequence	Parameters		Conditions
	Inputs	Outputs	
Shielding effectiveness	Fixed inducing current in the Helmholtz coil (2 A)	Magnetic fields intensities behind the shielding in x-, y- and z- directions	The shielding sheet is in no motion mode and the holes are in fully open condition
Frequency response	<ul style="list-style-type: none"> <li>Fixed inducing current in the Helmholtz coil (1 A)</li> <li>Velocity of rotated shielding (by regulating the voltage input of induction motor)</li> </ul>	<ul style="list-style-type: none"> <li>Magnetic fields intensities behind the shielding</li> <li>Frequency of magnetic fields behind the shielding</li> </ul>	The shielding sheet is in motions mode, with variations of speed (900 – 400 rpm).
Background frequency	Current in the Helmholtz coil	Magnetic fields intensities behind the shielding	The Helmholtz coil without and with fixed inducing current (1 A); while the shielding sheet is in three different states: <ol style="list-style-type: none"> <li>No motion mode and the holes are in fully open condition,</li> <li>No motion mode and the holes are in fully closed condition,</li> <li>Full speed of 900 rpm.</li> </ol>

### III. MANIPULATOR PERFORMANCE

#### A. Shielding Effectiveness Test

Shielding effectiveness test is performed in no motion mode and the four holes are in fully open condition. Fig. 3 shows the results of shielding effectiveness test, when a constant of 2 A inducing currents are given to the Helmholtz coils. Here we show that the shielding material is quite effective to stop the flux directed through the x-axis, evident by generated discrete pulses of very low frequency of some 2 Hz. In contrast, the fluxes on the other two axes will remain unchanged, because the shielding is placed orthogonally in front of x-axis.

#### B. Frequency Response Test

Frequency response test is performed in motion mode with various speeds, i.e. 900 – 400 rpm, in 100 rpm step. Twenty to twenty five data are collected and then averaged for each speed variations. Fig. 4 shows the results of frequency response test, when a constant of 1A inducing currents are given to the Helmholtz coils. Here again we show that the shielding is quite effective to stop the flux directed through the x-axis, evident by changes in magnetic intensity due to difference speed of shielding motions. In this case, the fluxes on other two axes will also be changed, because now the fields are no more static but have frequencies of some hertz. Magnetic intensities are linear to the velocity of shielding; due to how frequent the fluxes can pass the shielding through the holes. The frequency

(a)

(b)

Fig. 1. (a). The Magneto-Static Flux Manipulator, placed between a pair of Helmholtz coils in the semi-anechoic chamber. (b). Placement and setting of measuring equipment (SPECTRAN NF-5035®)

responses are quite good, nearly similar to the theoretical values.

### C. Background Frequency Test

Background frequency test is performed for two conditions, i.e. when the Helmholtz coils with and without induced current. For each condition, the manipulator is tested while the shielding is in three different states: a). no motion mode and the holes are in fully open condition, b). no motion mode and the holes are in fully closed condition, and c). in full speed of 900 rpm. Ten to fifteen data are collected and then averaged for each condition and state. Results for initial conditions, when no induced currents are applied on the coils, are listed in Table 1. They will be compared to the results when 1A inducing currents are applied as in Table 2. Fig. 5 shows the comparison of results under both conditions, while the shielding sheet is in three different states (fully open, fully closed, and 900 rpm). Frequency ranges are set from 15 Hz to 75 Hz in 15 Hz steps.

Here we show that for all cases of all frequency ranges, there are no changes in the magnetic intensities in the direction of y and z-axis as long as the shielding is in no motion mode. These are also valid in the case of no or with inducing currents applied on the coils, and whether the shielding holes are fully open or fully closed. It means that the inducing currents, when no motion of shielding, only induced static magnetic fields and affect only magnetic intensities in the direction of x-axis. In this direction, magnetic intensities will decrease for the higher frequency ranges. Besides, when inducing currents are applied, the intensities of fully open conditions are slightly higher than the fully closed ones. It means that by applying inducing currents, there should be low frequency magnetic pulses generated in the direction of x-axis.

Further, we should analyze the effects of shielding motions in the induced magnetic intensities. It is clear that by inducing currents in full speed motion state, the intensity in x-axis dramatically increase. On the other hand, the intensities slightly decrease in other two axes directions.

### IV. DISCUSSION

Testing of magneto-static flux manipulator shows that the manipulator performs good manipulations for various shielding velocities up to of 900 rpm, equal to the induced magnetic field frequency of about 60 Hz. However, comparing to the previous results when the manipulator has not been placed on the chamber, the static magnetic inductions (after correction factors applied) are 31,143.88 nT on the direction of x-axis [12]. It means that not all of the static magnetic flux (only about 0.16% of them) can be manipulated to frequency 60 Hz by placing the 900 rpm rotating manipulator in the chamber. Therefore, more detail calculation should be made before we decide how many levels of concentrators are needed to get the required flux densities and to be applicable for common electrical generators. Other alternative solutions, such as using parallel flux manipulators, probably more applicable to increase the intensity of output fluxes. However, economical costs investments should also be considered, since using valuable Mu-metals as shielding materials are clearly very expensive.

The manipulator was tested in the Lombok Island, which is located at the highest intensity of the geomagnetic anomaly of Indonesian region [5, 6]. The main objective of this research is therefore using natural anomalous phenomena of the Earth's magnetic field over the Lombok Island to supply electrical energy from renewable and environmentally friendly resources. Results of this research are expected to be applicable in other areas with high geomagnetic anomaly over the World. Some potential areas are in Indonesian region as mapped by the CHAMP satellite, which are along the northern island of Java, the island of Bali, the island of Sumbawa, and the north island of Sulawesi [7, 8, 9]. Moreover, [10] have marked several high potential geomagnetic anomalies in the first World Digital Magnetic Anomaly Map (WDMAM), which are in the Chicxulub crater in the North America, the Bangui anomaly in the Middle Africa, the Thromsberg anomaly in the South Africa, the Richat structure in the West Africa, the Bay of Biscay, along the Java Trench in Indonesia and the Paris Basin. These specific places are quite potential for locations of the geomagnetic flux concentrator applications.

### V. CONCLUSION

We have demonstrated the performance of magneto-static flux manipulator, and conclude that:

1. The shielding material with its holes is quite effective to stop the flux in the direction orthogonal to it, evident by generated discrete pulses of very low frequency of some 2 Hz.
2. The frequency responses of manipulator are quite good, nearly similar to the theoretical values. Magnetic intensities are linear to the velocity of shielding; due to how frequent the fluxes can pass the shielding through the holes.
3. When no motion of shielding, the coils induce static magnetic fields only. In the direction orthogonal to the shielding, magnetic intensities will decrease for the higher frequency ranges.
4. Not all of the static magnetic flux (only about 0.16% of them) can be manipulated to frequency 60 Hz by placing the 900 rpm rotating manipulator in the chamber.
5. More detail calculation should be made to decide how many levels of concentrators are needed to get the required flux densities for common electrical generators.

### ACKNOWLEDGMENT

This research is funded by the Indonesian Ministry of Research and Technology under SINas 2012 program entitled "Konsentrator Fluks Geomagnetik untuk Pembangkit Listrik Tenaga Magnet Bumi (RD-2012-481)". We gratefully thanks to the researchers of EMC Laboratory LIPI at the Puspiptek Serpong for their valuable assistances during preparation phases of our research. **Abstract**— The generator designed in this research is Axial Flux Wound Rotor (AFWR) and as two air gaps machine. It has a planar and somewhat adjustable air gap with slotted stator and rotor. This generator is small-scale capacity which has 380 V, 1 kW and 750 rpm. The windings are laid into slots made from laminated core. The generator has a single double-sided slotted wound stator sandwiched between twin rotor. The generator relates only to wound rotor machine with disc type rotor and stator. The axial flux machine generally uses permanent magnets mounted on the rotor. Replacing the permanent magnet with a winding in the rotor, makes it possible to control the flux by varying the current flowing into the field winding. The results of design computation reveal electric quantities suited with respect to performance of the generator. Varying the airgaps and excitation voltages of the axial flux generator, its performance might be controlled to meet the need of a load attached to its terminal. It has been found out that for the airgap of 1.0 mm and the excitation voltage of 11 V, the field current and the efficiency are 3.82 A and 85.30% respectively.

**Keywords**— Synchronous generator, axial flux, efficiency, air gap.

## I. Introduction

The axial flux permanent magnet (PM) machines have a number of distinct advantages over radial flux machines (RFM). They can be designed to have a higher power-to-weight ratio resulting in less core material. Moreover, they have planar and easily adjustable airgaps. The noise and vibration levels are less than the conventional machines. Also, the direction of the main air gap flux can be varied and many discrete topologies can be derived. These benefits present the AFMs with certain advantages over conventional RFMs in various applications [1].

Besides these benefits, the flux density is reduced due to the large airgap. However, one important advantage of this machine is that the structure transfers the heat from the stator frame very easily. Therefore, machine electrical loading can be relatively high. This is an important feature of axial flux machines because suitable shape and size to match the space limitation is crucial for some applications such as electric vehicle. From a construction point of view, brushless AFPM machines can be designed as single-sided or double-sided, with or without armature slots, with or without armature core,

with internal or external PM rotors, with surface mounted or interior PMs and as single stage or multi-stage machines. Stator and rotor positions can be interchanged, the number of stator and rotor can be multiplied and the air gap distance can easily be varied. Some configurations of axial flux permanent magnet machines as shown Fig. 1 [2].

This research will analyze the performance of three phase axial flux wound rotor synchronous generator. With the limited generator output power, it will be sought at what width of air gap, number of stator turns, diameter of stator conductor and excitation voltage will be obtained the highest efficiency. When the rotation of rotor is not constant caused by the prime mover rotation that is not constant, the output voltage generated by the generator will vary. To make a constant voltage, the flux should be controlled by varying the field current flowing through the rotor winding. Therefore the expected advantage of the result of this study is to obtain a precise distance measurement of the air gap, the number of stator turns, the diameter of stator conductor and the excitation voltage on the axial flux wound rotor (AFWR) synchronous machine having the capacity 1 kW with high efficiency. Since a large number of poles can be accommodated, these machines are ideal for low speed applications.

Electrical machine which has high power and high efficiency and also small dimensions while lower price is the

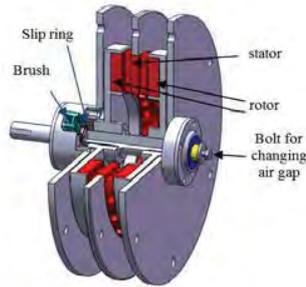

Fig. 2: AFWR synchronous generator

axial flux permanent magnet machine. However, the study has not been performed yet in three phase axial flux wound rotor synchronous generator which its air gap and voltage excitation can be varied. The air gap changes can affect machine parameters and the voltage excitation changes can affect the output voltage.

In the case of engine/generator sets most interest has focused on axial flux generator topologies that have two rotor discs and one stator disc. Such an axial flux generator can be usefully integrated with an engine as it is axially very short and so can be mounted directly on the engine output shaft, eliminating the need for separate bearings or couplings. The generator has, or can be designed to have, a moment of inertia that makes the flywheel redundant [3].

An axial flux machine with wound rotor is referred to as an axial flux wound rotor (AFWR). A cross sectional schematic of the AFWR machine is shown in Fig. 2. The AFWR generator consists of two wound rotor that two windings are connected in parallel. The stator of AFWR generator is located between two opposing wound rotors. The double-sided rotor simply called twin rotor with slots are located at sides of stator and rotor lamination core.

## II. DESIGN OF THE MACHINE

The design of axial flux synchronous generator is done by calculations based on the equations of the axial flux and the radial flux machines. Equations applied are related to electric circuits, magnetic circuits and mechanics on the stator and the rotor. The Matlab program is used for accuracy and precision calculations, while Solidworks software is used for drawing the machine and its parts.

The design of synchronous generator is started with determining the specifications of the machine, then selecting materials and assigning design parameters. Before processing the design of the electrical circuit, the magnetic circuit and the mechanics, it is first assumed the parameter optimizations associated with the specification of the machine. It is expected at the end of the design process, the performance of the machine is met the need. If the performance has not met yet, then the design process should be repeated by changing

optimization parameters. If the performance has been met, the design data sheet can be printed. Stages of the design are

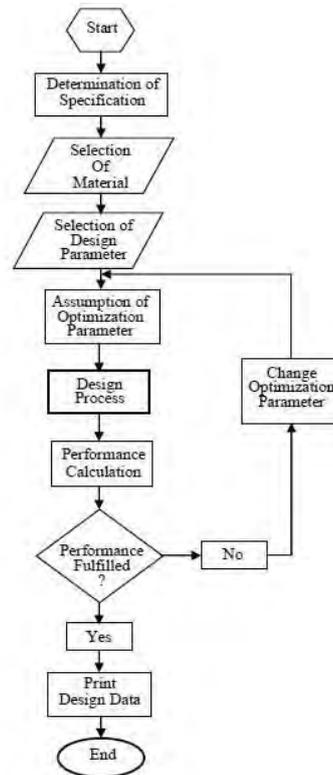

Fig. 3. The flowchart of design process

shown in the flowchart in Fig. 3. The process of optimization in the design of the machine aims to obtain higher efficiency with power output fixed previously.

Figure 4: The slotted stators and rotor, before and after winding

The machine designed is three phase axial flux wound rotor (AFWR) synchronous generator where magnetic flux lines cross the air gap in axial direction with the machine axis. The stator and rotors are disc shaped and located in parallel next to each other. The stator having two side slots are located between twin slotted rotors. Windings are then laid into slots carved in the rotor and stator face shown in Fig. 4.

In principle, the electromagnetic design of AFPM machines is similar to its radial flux PM (RFPM) counterparts with cylindrical rotors. However, the mechanical design, thermal analysis and assembly process are more complex [4]. Specifications of three phase AFWR synchronous generator designed is the nominal quantity (rated). Quantities include output power, terminal voltage (phase to phase), frequency, rotor rotation and power factor. The input power and the load torque are on the shaft of prime mover which rotates the generator rotor windings. The rotor winding is connected to a source of direct current so that the field current flows through the field winding. The field current produces a steady-state magnetic field in the rotor.

A synchronous generator can be operated as motor. The synchronous motor have several advantages in comparison with the induction motor such as controllable power factor and larger air gap. The drawbacks of induction motor are their small air gap, which are needed to create higher efficiency. However, the air gap of those of two machines can not be adjusted. In this case the nonmagnetic air gap is large and high energy magnet are required. The air gap magnetic flux density decreases as the air gap increases [5].

### III. MANUFACTURING OF THE MACHINE

This section contains the manufacturing of the generator based on the results of design calculations. The manufacturing is started from stator and then rotor parts. The stator and the rotor parts consist of core, slot, brush and slipring while mechanical parts consist of shaft and bearing. After calculations using Matlab software, the drawings either two-dimensional or three-dimensional can be done by using Solidworks software. Manufacturing of the generator is based on two-dimensional plot of Solidworks.

#### A. Manufacturing Of Stator

This AFWR generator is designed to produce frequency of 50 Hz, rotation of 750 rpm and has the number of 8 poles. Terminal voltage is 380 V and phase voltage is 220 V. Output power is 1.000 W. With  $\epsilon = 0.9607$ ,  $k_d = 0.5714$ ,  $n_s = 12,5$  rps,  $B_{mg} = 0,6305$  Wb/m<sup>2</sup>,  $A_m = 5.712$  A/m<sup>2</sup>,  $\cos\phi = 0,83$  and  $k_D = 0,1323$  obtained from the given equation, the disk outer and inner of stator and rotor are 0,28 m and 0.16 m respectively.

The stator and rotor core of the machine are made from CRGO (Cold-Rolled Grain Oriented) silicon electrical steel

with M-5 specification and thick of 0,3 mm. Rolled Silicon steel plate is shown in Figure 5. This generator has two rotors with single side slot and one stator with two slot sides. Each side either stator or rotor has the same number of slots. The

Fig. 5. Rolled silicon steel plate lamination

TABLE I. DIMENSION OF STATOR AND ROTOR

Parameter	Symbol	Stator	Rotor
Number		1	2
Side		2	1
Slot	S	24	16
Outer diameter	$D_{out}$	0,28 m	0,28 m
Inner diameter	$D_{in}$	0,16 m	0,16 m
Thickness	$d_s / d_r$	0,0405 m	0,0203 m
<b>Slot</b>			
- slot diameter	$d_{sc}$	0.0135 m	0.0135 m
- stator opening	$b_{14}$	0.003 m	0.003 m
- Cross section area	$A_s$	0.0143 m <sup>2</sup>	0.0143 m <sup>2</sup>

stator and rotor discs have 24 slots respectively. The dimensions of stator and rotor are listed at Table I. Rolled silicon steel plate lamination before slotting is shown in Fig. 5. The rated output current in a single side stator  $I_a = 1.0203$  A, so that the total output current from the generator will be 2.0406 A, where the three stator winding are Y-connected and the number of phase  $m_1 = 3$ , the number of armature turns of a single stator per phase  $N_1 = 440$  turns per phase.

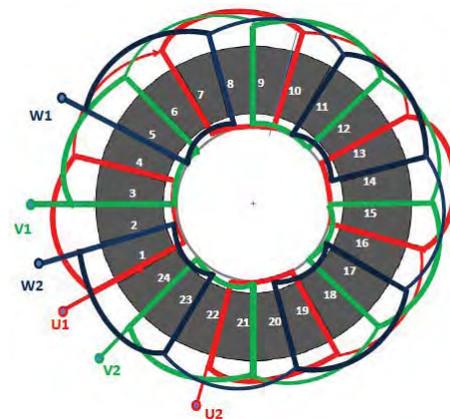

Fig. 6. A circle stator winding diagram which producing eight-magnetic poles

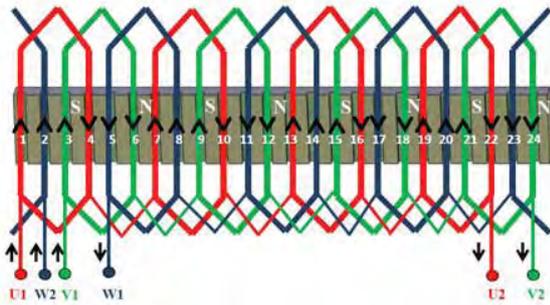

Fig. 7. A winding diagram of stator, showing how the stator currents produce north and south magnetic poles.

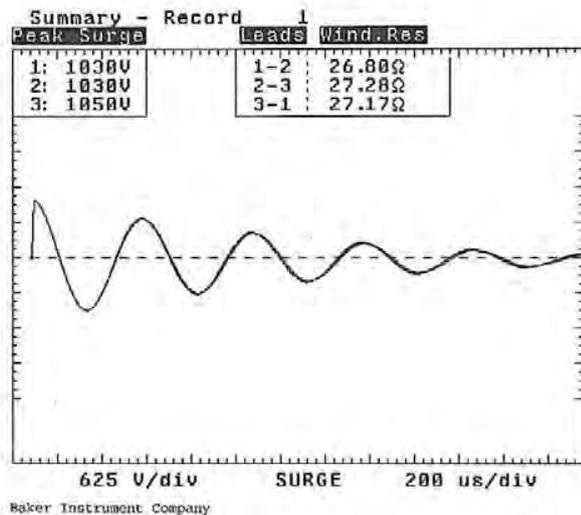

Figure 8: Voltage wave to know the balanced impedance of the three stator winding.

The stator is wound with coil pitch of 3 slots, so the coils must span 3 stator slots. It means for a conductor in slot 1 goes into slot 4 and for a conductor in slot 4 goes into slot 7 and so on. In order to get 8 poles in the stator, it might be wound as shown in Fig. 6 and 7. Copper wire conductors that are wound in the stator have cross section area  $s_a = 1.96 \times 10^{-7} \text{ m}^2$ , then its conductor diameter is 0.5 mm.

Using the class F (115 °C) enamel insulation of the armature conductors having thick ( $t_e$ ) of 0.024 mm, the diameter of the wire with insulation  $d_e$  is 0.548 mm. Hence, the total cross sectional area of all conductors in the stator slot  $A_{sc} = 5.3776 \times 10^{-5} \text{ m}^2$ , diameter and the cross section area of a single slot is approximately  $d_{sc} = 13.5 \text{ mm}$  and  $A_{scir} = 1.43 \times 10^{-4} \text{ m}^2$  respectively. The resulting slot fill factor  $k_{fs} = 0.3757$  showing the stator can be easily wound, since the

average slot fill factor for low voltage machines with round stator conductor is about 0.4. A circle and horizontal stator wiring diagram are shown in Fig. 6 and 7.

In order to know the balance of resistance among the three stator winding, test is done by giving an impuls voltage. From the test, it is obtained that the three voltage waves of phase winding are lines up with each other. It shows the balanced resistance of the three stator windings. The three balanced resistances are 26.80 Ω, 27.28 Ω dan 27.17 Ω respectively. The results of test records of balanced stator winding resistances are shown in Fig. 8. Each of phase winding in a stator side is connected in parallel with a phase winding in other stator side, the resistance of the three stator windings are divided by two then each resistance becomes 13.4 Ω, 13.64 Ω and 13.585 Ω.

#### B. MANUFACTURING OF ROTOR

This machine has 2 rotors (twin), each rotor consists of 24 slots. The slots will be filled with conductors of field coil flowed direct current fed by source voltage of 10 V. The rotor is wound with coil pitch of 2 slots, it means for a conductor in slot 1 will go to slot 3 and the conductor in slot 4 will go to slot 6 and so on. In order for the rotor to have 8 poles, it is wound as shown in Fig. 9. Conductor wound in the rotor has a diameter of 1,7 mm.

The rotor mmf  $AT_n = 314,06 \text{ AT}$ , resistivity of copper in the temperature of 20°C  $\rho = 2,1277 \times 10^{-8} \text{ } \Omega \text{ m}$ , the average of field coil turn  $I_{fav} = 0.4276 \text{ m}$  and the voltage of each field coil  $E_{fc} = 1,2 \text{ V}$ , the cross section area of field coil  $s_f = 2,18 \text{ mm}^2$

For the class F enamel insulation of the field conductors with thick of 0,024 mm, the diameter of wire  $d_{fc} = 1,748 \text{ mm}$ . The number of conductors in a rotor slot  $N_{fs} = 63$  conductors. To supply the dc power from an external dc source to the rotor winding, slip rings and brushes are used. The brush is made from graphite carbon material which has application limit for current density 8 to 12 A/cm<sup>2</sup> in continuous operation and maximum operation of 30 A/cm<sup>2</sup> with peripheral speed permitted until 25 m/s [6].

With dc current flowing through the field winding of 3.82 A, brushes are needed which have dimensions 10 mm x 16 mm EG367J (10x16x25 mm<sup>3</sup>). If the positive end of a dc voltage source is connected to one brush and the negative end is connected to the other, its total contact surface is 10 mm x 16 mm = 1,60 cm<sup>2</sup>. The current density is  $4,1260 \text{ A}/1,6 \text{ cm}^2 = 2,57875 \text{ A}/\text{cm}^2$ .

Because the rotor rotates and the brush is stationary, the machine needs slip ring as a media connecting rotor winding and brush. To connect external dc source with rotor winding which the ends of the two rotor wires are tied to slip rings on the rotor's shaft, it is required two brushes and two slip rings. The stationary brushes ride on each rotating slip ring. Slip rings are copper rings completely encircling the shaft of a machine but insulated from it. Each slip ring has a dimension of 12 mm x 2,5 mm = 30 mm<sup>2</sup>. This slip ring is capable carried the current more than 50 A [11]. Whereas the field

current flowing in this slip ring only 3.82 A with field voltage  $E_{fe} = 1,2$  V and field resistance  $R_f = 0,28 \Omega$ .

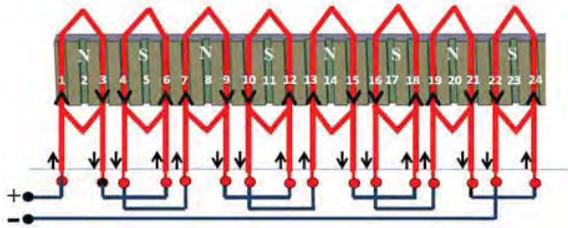

Fig. 9. A rotor winding diagram which producing eight-magnetic poles, showing how the rotor currents produce north and south magnetic poles.

#### IV. MACHINE PARAMETERS AND PERFORMANCE

The parameter values of this machine are obtained from calculations using MATLAB and it is used to analysis performance of the machine based on output power. The core losses are assumed 5% and the friction and windage losses are 7% of the output power [4, 7]. The principal problems are based on output power and efficiency of the machine. The magnitude output power has been fixed, while the efficiency is sought to the highest value. The output power and the efficiency will be changed by varying parameters.

An optimal efficiency value is sought in the fixed output power. The optimal efficiency is obtained by varying optimization parameters consist of airgap, excitation voltage, conductor diameter and number of stator turns. The specification of machine operation is shown in Table II.

The calculation results showing the output power of 1 kW and efficiency of 85.30% are shown in Table III. Varying optimization parameters, other machine parameters will also change. In the efficiency calculation, optimization parameter is spanned, while efficiency is spanned and output power is examined and selected. From the calculation, it is also obtained dimensions of stator and rotor slots.

From the calculation, it is obtained in the airgap of 1.0 mm, excitation voltage of 11 V, stator conductor diameter of 0,5 mm and number of stator turns per phase of 440 turns give the best solution. The effect of airgap, excitation voltage, number of turns and stator conductor diameter changes on efficiency of the machine are shown in Fig. 10, 11, 12 and 13.

Stator and rotor dimensions are kept constant in the calculation of optimization, so that the changes of number of turns and stator conductor diameter should be examined

TABLE II. MACHINE OPERATION SPECIFICATION

Quantity (unit)	Value
-----------------	-------

Output power (W)	1,000
Terminal voltage (V)	380
Number of poles	8
Frequency (Hz)	50
Power factor	0.83

TABLE III. OPTIMIZATION PARAMETERS IN THE EFFICIENCY OF 85.30 % AND OUTPUT POWER OF 1KW.

Quantity (unit)	Value
Airgap (mm)	1.0

Number of stator turns per phase	440
Diameter of conductor (mm)	0,5

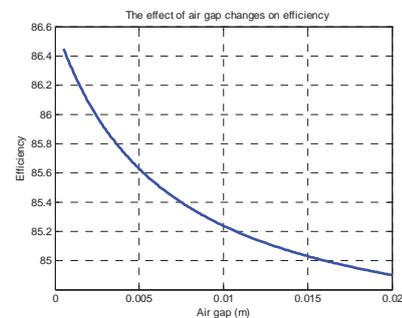

Fig. 10. The effect of air gap changes on efficiency

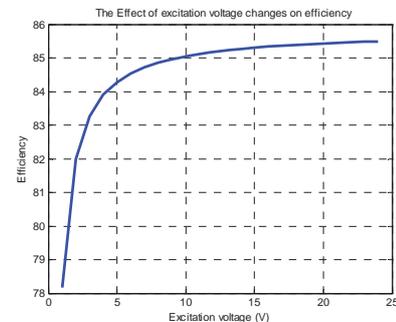

Fig. 11. The effect of excitation voltage changes on efficiency

wether they meet the requirements or not for the slot dimensions. The requirement examination is based on *slot fill factor*. For number of stator turns  $N_1 = 440$  turns, number of conductors per slot is 220 and conductor diameter  $d_a = 0,5$  mm, then according to the given equations, slot fill factor  $k_{fs}$  is 0,3629.

The slot fill factor for rectangular conductors and low voltage machines can be assumed to be 0.6. While the slot fill factor for circular conductors and low voltage machines can be assumed to be 0.4 [5]. In standard motors, copper occupies only half of the slot winding space, because the slot fill factor is about 0.5 [5].

From the calculation, the efficiency of three phase AFWR synchronous generator is higher than induction motor (copper rotor) [8], asynchronous motor (*single layer*), asynchronous motor (3 phase sinusoidal) [9] and TORUS

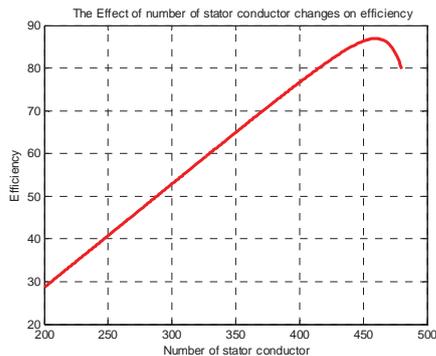

Fig. 12. The effect of number of turn changes on efficiency

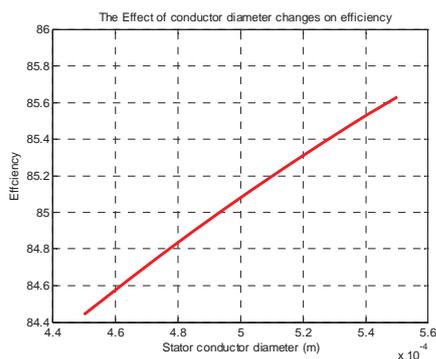

Fig. 13. The effect of conductor diameter changes on efficiency

generator [10] with nearly the same power output. The higher efficiency is obtained by utilizing the optimization parameters that have been previously calculated. The comparison of efficiencies in several machines is shown in Table IV.

TABLE IV. COMPARISON OF EFFICIENCIES IN SEVERAL ALTERNATING CURRENT MACHINES

Type of Machine	Rated Power (W)	Losses (W)	Efficiency (%)
Induction Motor (copper rotor)	1,100	229.2	82.8

Asynchronous Motor (sinusoidal 3 phase)	1,103	337	76.6

winding)			
Torus Generator	1,000	231.9	81.18
AFWR Synchronous Machine	1,000	184.6	85

## V. RESULT AND DISCUSSION

From the result of AFWR generator design calculated by Matlab software, it is possible to make the complete drawings by SolidWorks. If the calculation of stator, rotor, slot and tooth dimensions are not right, then it will be seen incorrectness at their drawings or occurred fault when they are drawn by SolidWorks.

The efficiency of 85.30% obtained in air gap of 1.0 mm, excitation voltage of 11 V, diameter of stator conductor of 0.5 mm and number of stator turns per phase of 440 turns are constrained by output power of 1 kW. If in the calculations, the efficiency is increased to more than 85.30%, parameters of the machine will occur changes include output and input power. The Conductor size obtained from the calculation results have not been adjusted to the size of the conductors in the market.

The efficiency of AFWR synchronous generator is higher than the efficiencies of alternating current machines because of total losses are lower especially copper losses. The total losses in the AFWR machine is 175.79 W, while in the TORUS AF machine is 231.9 W. Similarly, the total losses in the induction machine (copper rotor), the asynchronous machine (3 phase winding) are higher than AFWR machine 229.2 W and 402 W respectively.

For the number of stator turns per phase  $N_1 = 440$  turns, number of conductors per slot is 220 and the diameter of stator winding conductor  $d_a = 0.5$  mm, Slot fill factor is found to be  $k_{fs} = 0.3629$ . This value of fill factor still meets the requirement because of the value is less than 0.4 for circular conductors and low voltage machines.

Using the number of stator turns per phase  $N_1 = 440$  lilitan, this 3 phase generator will have total turns of 1320 turns. By using the number of conductors per slot and the number of turns per phase, it is possible to obtain the same total turns.

In the first experiment, the measurement of the output voltage result indicates 380 V at 750 rpm. The load connected to the terminal is tube lamp with voltage of 220 V (line to neutral voltage). For the other experiments such as no load test, short circuit test, on load test and the test of effect of air gap changes on the machine can be discussed for further work.

## VI. CONCLUSION

Calculations by using the given equations yield the air gap length is 1.0 mm, the excitation voltage is 11 V, the number of stator turns is 440 and diameter of stator winding conductor is 0,5 mm reveal the best solution at efficiency of 85.30%. With

the number of conductor per slot of 220 and diameter of stator conductor of 0,548 mm, the resulting slot fill factor is 0.3757 that still meets the requirement for rectangular conductors and low voltage machine. From the test of winding resistance, the three waves plot of phase winding voltages coincide with each other. Therefore, they reveal the balance resistance in the three phase stator winding and the resistances are 26.80  $\Omega$ , 27.28  $\Omega$  and 27.17  $\Omega$  respectively.

**Abstract** - Wind turbines are widely regarded as an alternative source for electrical power generation. Modern wind turbines are classified into horizontal axis wind turbine (HAWT) and vertical axis wind turbine (VAWT) categories. Vertical axis wind turbines (VAWTs) are attractive for applications in the built environment due to their ability to capture wind from different directions. One type of VAWTs is Darrieus turbine or H-type turbine. Experiments conducted in this paper aims to investigate the effect of number of blades in the performance of H-Darrieus type wind turbine. The experiments used 2,3 and 4 blades to show rotation, torque and TSR (tip speed ratio) of wind turbine. A simulation using ANSYS 13.0 software will show the coefficient of power of wind turbine. The results of experiments showed that the number of blades rotation and torque influence the performance of wind turbine.

**Keywords**—wind turbine, vertical axis, H-Darrieus type, blades, tip speed ratio, coefficient of power

## I. INTRODUCTION

Energy resources from earth's fossil energy are limited and the global production of oil, gas and coal will come beyond their peak in the next decades. In other side the need of the energy will rise and also the price of the fossil energy. At the same time there is strong political opposition against global climate change as a result of carbon-dioxide and sulphur-dioxide emission from the burning of fossil fuels. Effective mitigation of climate change will require deep reductions in that green house gas emission. The use of renewable energy as a cost-effective and reliable low-carbon energy sources is becoming an important objective of energy policy in the world. Renewable energy is a climate-friendly energy due to the absence of emissions detrimental to the environment. Some forms of renewable energy are solar thermal and photovoltaic, tidal wave, wind, hydro, geothermal, OTEC and bio-fuel.

Hydropower has been used in electrical power stations and pumped storage systems since many decades, but the use of wind power conversion in larger ratings has begun only in the 1980s. After that, wind energy has shown the fastest rate of growth of any form of electricity generation with its development stimulated by concerns of national policy makers over climate change, energy diversity and security of supply. Figure 1 shows the global cumulative wind power capacity worldwide based on the projection in the 2004 World Energy

Outlook report from the International Energy Agency (IEA) [1].

The wind as a fuel for producing electricity is inexhaustible, free and always available somewhere – and there is enough of it. Hence, wind energy offers a promising renewable energy source and wind turbines are the only way to extract energy from the wind. Wind turbines produce electricity by using the power of the wind to drive an electric generator. Classification according to their constructional design has two kinds of wind turbines, HAWT (horizontal axis wind turbines) and VAWT (vertical axis wind turbines). HAWT has a horizontal axis of rotation, but VAWT has a vertical axis of rotation. VAWT can catch the wind from all direction and at lower wind speed than horizontal axis one. There have been two distinct types of vertical axis wind turbines, the Darrieus and the Savonius types (figure 2). The first aerodynamic VAWT which look like a giant egg whisk was invented by Georges Darrieus and first patented in 1927 [2]. In the 80s, several wind farms with commercial Darrieus turbine was built with a rated power of 4 MW [3]. Peter Musgrove et.al. investigated the original Darrieus turbine with straight blades in the 80s and other researchers developed the straight-bladed Darrieus turbine called H-Darrieus [4]. Some of the most notable researches about H-Darrieus prototypes include a 500 kW version at Camarthen Bay [5].

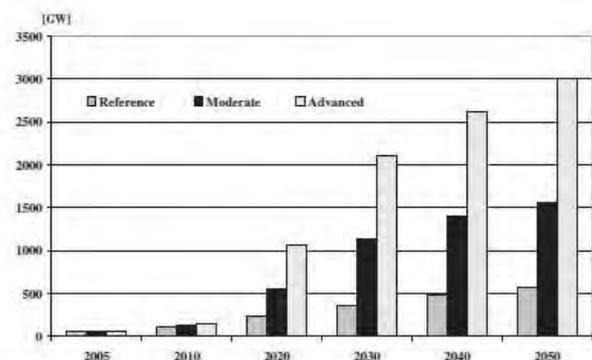

Figure 1. Global cumulative wind power capacity worldwide [1]

H-Darrieus turbine also called giromill and cyclo-turbine as shown in Figure 2c, have been built in recent years with different specifications. The performance of H-Darrieus turbine is related with some parameters such as turbine solidity, number of blades, airfoil selection, blade pitch angle and turbine aspect ratio (H/D).

Studies of small scale vertical-axis wind turbine have attracted a great deal of attention because of the possibility to use a wind tunnel. The advantage of using wind tunnels for research and development is that one can validate the design specification in a relatively short turn-around time. A case of providing the detailed comparison between wind tunnel tests and the full-scale field measurement was reported by Sheldahl [7]. This paper aims at studying the effect of number of blades on the performance of the H-Darrieus vertical axis wind turbine through wind tunnel test.

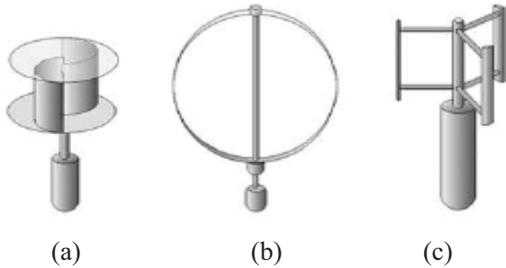

Figure 2. VAWT turbines: (a) Savonius rotor ; (b) Darrieus rotor ; (c) H-Darrieus rotor [6]

## II. WIND TURBINE THEORY

One of the important components of wind turbine is the blades which capture the kinetic energy of wind to generate thrust force as drag or lift force. The thrust force will be converted into mechanical energy or rotation of the shaft of turbine rotor and then converted into electrical energy by the generator. Wind turbine has rotational speed related with electric power as shown in figure 3. Cut in speed is the increasing of rotational speed and starting to generate the electrical energy. Cut out speed is the speed when the wind speed is over and wind turbine will reduce its strength. Rated wind speed is the speed when the wind turbine reaches the average of peak power from generator or rotor.

Coefficient of power or  $C_p$  is the ratio between  $P_k$  and  $P_a$  or

$$C_p = \frac{P_k}{P_a} \quad (1)$$

where  $P_k$  (W) is the power produced by the turbine and  $P_a$  (W) is the power supplied by the wind. The value of  $C_p$  will determine the performance of blades of a wind turbine.

The power of wind turbine is

$$P_k = T \frac{2\pi n}{60} \quad (2)$$

Where  $T$ (Nm) is the torque and  $n$  is the rotation of turbine shaft.

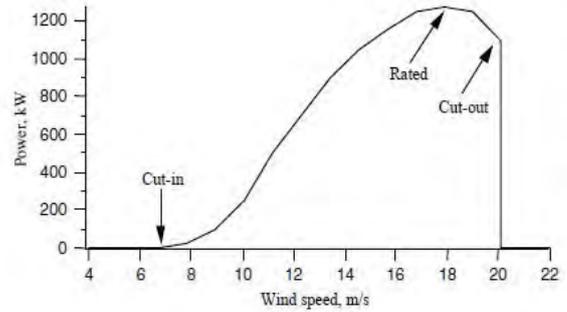

Figure 3. The curve of wind turbine power related with wind speed [8]

A parameter related with rated wind speed, rotation and rotor diameter defined as tip speed ratio (TSR). TSR as a ratio between the speed of tip blade and wind speed through it, can be determined as [9]

$$TSR = \frac{2\pi n}{60v} \quad (3)$$

where  $v$  is the wind speed (m/s).

TSR maximum or  $TSR_{max}$  can be determine related with number of blades as,

$$N_b = \frac{4\pi}{TSR_{max}} \quad (4)$$

where  $N_b$  is number of blades ( $N_b = 2, 3, \text{ or } 4$ ).

In recent research project one common number of blades is three, for various reason. The variation of 2, 3, and 4 number of blades was introduced to explore the effects of blade position againts upwind and downwind.

When the value of  $TSR > 1$  means more lift force in part of the blades, but if  $TSR < 1$  more drag in part of the baldes.

Number of blades will influence to the performance of the wind turbine, conforming with the solidity of the turbine. Solidity of wind turbines is the ratio between the area of blades and rotor sweeping, determined by [11],

$$\sigma = \frac{N_b C}{r} \quad (5)$$

where  $C$  is the length of blade chord (m) and  $r$  is radius of rotor (m).

Figure 4 shows the curve of power coefficient  $C_p$  and tip speed ratio TSR as an effect of solidity of turbine performance [8]. The curve shows that one blade has smaller solidity and the curve of  $C_p$  relatively flat which caused by higher drag force. Three blades gave optimal solidity with  $C_p$  maximum and they produced more energy.

## III. EXPERIMENTAL SET UP

Experiment used a model of H-Darrieus wind turbine were performed in a low speed open circuit wind tunnel, as in figure 4 (a). The model of H-Darrieus wind turbine consist of

one shaft, plank, connecting plate, and blades. Model has dimensions as in figure 4 (b) with rotor diameter is 40 cm, rotor height is 32 cm, table height is 103,2 cm, table width is 30 cm and table length is 40 cm. The blade of wind turbine model used airfoils as in figure 4 (c) with the length of chord (c) is 9 cm, the height of blade (h) is 32 cm and the maximum thickness of blade (t) is 1,6 cm.

Wind tunnel was started to produce wind and an anemometer measured the velocity of wind. When the wind from wind tunnel pushed the blades of wind turbine model, the rotor will rotate. The rotation of rotor was measured by tachometer and noted for three times of experiments. Each experiment with two, three and four blades respectively used the speed of wind from 1 to 15 m/s. The torque of wind turbine was also measured by a torque meter related with the speed of wind.

The specified speed of wind from 10 to 15 m/s were determined based on the assumption that small wind turbine in high speed wind will tend to split in angular motion. High speed of wind exerts high pressure on blade causes the rotation of rotor may exceed its design limit and become difficult to measure.

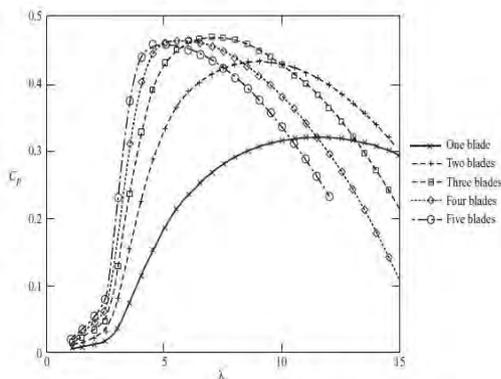

Figure 4. Curve of power coefficient  $C_p$  and tip speed ratio TSR of wind turbine [8]

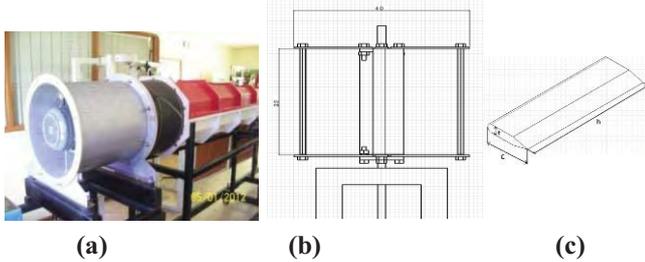

Figure 5. Wind tunnel (a) and model of H-Darrieus wind turbine (b) with airfoil (c)

#### IV. RESULTS AND DISCUSSION

Results of the experiment shows that wind turbine model with three blades has higher rotor rotation than that of two and four blades (figure 6). Wind turbine with three blades has attack angle more efficient than wind turbine with two and

four blades. As consequence is the wind turbine has rotation higher when the wind is also higher as shown in figure 6. Wind turbines with two and four blades have pressure coefficient in balance as a result of each blade has opposite pressure. Three blades wind turbine has three angles as  $0^\circ$ ,  $120^\circ$  and  $240^\circ$  that cause the wind turbine will rotate without obstacle from blade pressure.

Pressure distribution on wind turbine model with three blades (figure 12) is quite smoother than that of wind turbines with two and four blades (figure 11 and 13). It is caused by pressure coefficient on two and four blades adjust to balance with the result that more drags is produced and the rotor of wind turbine become difficult to rotate. Figures 11, 12 and 13 show pressure distribution for the model of H-Darrieus type wind turbine using simulation of contour of velocity from ANSYS 13.0 program. The simulation of contour velocity using constant wind speed at 15 m/s as in figure 11, 12 and 13. The results of simulation of contour velocity for many wind speeds is shown in table 1.

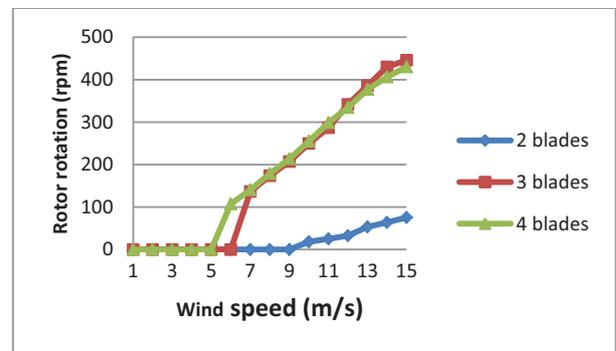

Figure 10. Rotation of wind turbine rotor (rpm) with wind speed (m/s) in wind tunnel

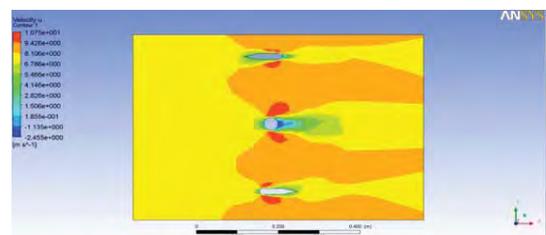

Figure 11. Contour of velocity for wind turbine model with two blades

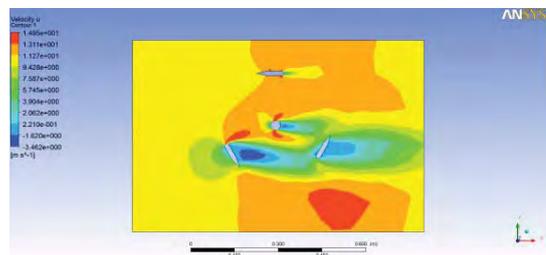

Figure 12. Contour of velocity for wind turbine model with three blades

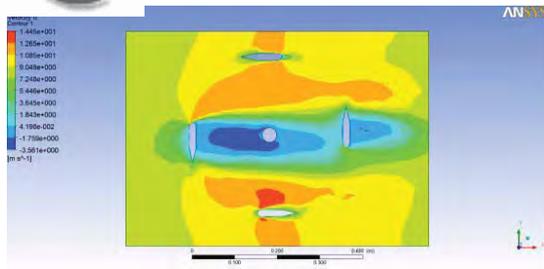

Figure 13. Contour of velocity for wind turbine model with four blades

Table 1. Pressure on two, three and four blades for wind speed (m/s)

Wind speed (m/s)	Pressure on the blades of airfoil (Pa)		
	2	3	4
1	0,407	1,348	1,765
5	14,08	33,62	43,86
10	55,56	134,6	174,4
15	128,8	303,6	392,6

The measurement of torque for two, three and four blades wind turbine model related with wind speed is shown in figure 14. The graphs in figure 14 shows that the torques of two blades wind turbine is smaller than torques of three or four blades wind turbine. Maximum torques at wind speed 15 m/s are 1,15 Nm for two blades ; 5,32 Nm for three blades and 5,53 Nm for four blades. Number of blades of H-Darrieus type wind turbine influence torque of rotor of wind turbine. If number of blades become increasing, then the wind turbine need more force and wind speed that torque produced is become higher.

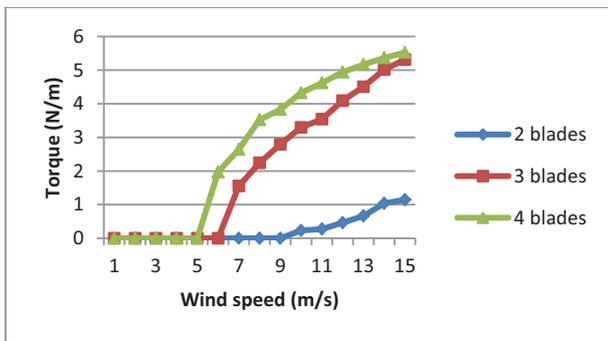

Figure 14. Torque of wind turbine rotor for different wind speeds

The relationship between tip speed ratio and coefficient of power for H-Darrieus type wind turbine model is shown in figure 15. Tip speed ratio for two blades wind turbine, 0 – 0,1 has low coefficient of power ( $C_p$ ), but the coefficient  $C_p$  for three and four blades wind turbines are higher. Three blades type wind turbine has cut in speed at 7 m/s related with TSR (tip speed ratio) = 0.409 and  $C_p$  = 0.828. Rated wind speed at 10 m/s has TSR = 0.522 and  $C_p$  = 1.098, and cut in speed at 15 m/s has TSR = 0.622 and  $C_p$  = 0.937. Four blades type wind turbine has cut in speed at 6 m/s related with TSR = 0,375 and  $C_p$  = 1.309. Rated wind speed at 8 m/s has TSR =

0.468 and the wind turbine produce  $C_p$  = 1.641. Cut out speed at wind speed = 15 m/s has TSR = 0.600 and  $C_p$  = 0.940.

Figure 15 shows that wind turbine model with two blades has slow performance and reduce more wind energy. Four blades wind turbine at wind speed of 6 to 11 m/s has higher rotation compared with three blades wind turbine. However, after the wind speed of 11 m/s the four blades wind turbine has low rotation and decreasing power when the wind speed between 9 m/s to 15 m/s. Three blades wind turbine has better performance than that four blades wind turbine. At wind speed 6 m/s to 15 m/s three blades wind turbine model has increasing power and the rotation produced can exceed the rotation of four blades wind turbine.

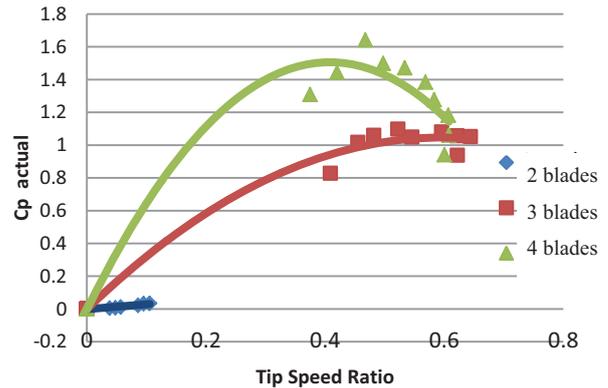

Figure 15. Power coefficient ( $C_p$ ) related with tip speed ratio

## 5. CONCLUSIONS

Some conclusions on the experimental study of H-Darrieus type wind turbine model in wind tunnel are,

- Number of blades will influence the rotor rotation of wind turbine. More number of blades used in wind turbine make easier the wind turbine to rotate with low wind speed.
- Data of torque, coefficient of power and tip speed ratio showed that more number of blades result in short performance and higher torque.
- Three blades rotor of wind turbine has performance more stabil than that two or four blades.

**Abstract**— In this paper, the data acquisition system is developed to monitor the wind speed, solar irradiation, and PV temperature based on a low-cost AVR microcontroller. Instead of using an expensive pyranometer, a low-cost PV module is used as the solar irradiation sensor. The integrated-circuit temperature sensor LM35 and a cup-type anemometer are used to measure the temperature and the wind speed respectively. To provide the flexibility of the data acquisition system, the Modbus protocol is adopted for communicating with other monitoring software or HMI. This feature enables the system to communicate with SCADA system. It provides useful information about the environment conditions for operating the hybrid power system effectively. The developed data acquisition system is tested in real environment and comparisons to the standard measurement instruments are conducted. The measurement errors of 4.46%, 3.45%, and 3.47% are obtained for the wind speed, solar irradiation, and PV temperature measurement respectively.

**Keywords**— *hybrid power system; data acquisition system; wind speed; solar irradiation; PV temperature; Modbus protocol.*

## I. INTRODUCTION

Recently, hybrid power system plays a significant role for providing electrical energy to the customer, especially in rural area. The hybrid power system combines several energy resources, usually the renewable energy such as wind power and solar power. The objective of hybrid system is to maximize the energy obtained from the resources, while maintaining the supply continuously. Naturally, the power generated by wind and solar power are affected by the weather or environment conditions, namely the wind speed for wind power, the solar irradiation and the temperature of solar panel for solar power. Therefore it needs to monitor those parameters in real-time for operating the hybrid power system effectively.

Many researchers have developed the data acquisition systems for monitoring the renewable energy plants [1] – [4]. The data acquisition system was developed to monitor the meteorological data such as wind speed, solar irradiation, humidity, temperature, and the operational parameters of the

renewable energy sources such as the voltage and current of photovoltaic and wind turbine generator [1]. The system was implemented using DAQ card installed on a PC. The LabVIEW software was employed to control the system. The LabVIEW was also employed in [2] to monitor hybrid wind-PV power systems. The data acquisition system based-on client/server architecture was developed to monitor and control the wind-PV power systems [3]. In the system, a data acquisition unit is connected to the data collection computer using a wireless system, while the internet was employed to communicate between the client measurement station and the server measurement station. In [4], they proposed a low cost data acquisition system for renewable energy plants using an USB interface. The system was developed for developing countries, thus the firmware and hardware is free and open source.

Instead of using PC for data collection, a microcontroller-based data acquisition system was developed in [5], [6]. A 8-bit microcontroller system with analog input was developed for solar irradiation monitoring [5]. A serial EEPROM was used to store the measurement data. In [6], a 10-bit microcontroller system was used in the wireless data acquisition system to collect solar irradiation, temperature, photovoltaic voltage and current of the PV water pumping station. The system was equipped with GSM module for data transmission over GSM network.

To monitor and control hybrid wind-PV-battery power system, a SCADA (Supervisory Control and Data Acquisition) was proposed in [7]. It performed the real-time measurement of the electrical parameters of hybrid power system.

In this paper, the data acquisition system is developed to monitor the wind speed, solar irradiation, and PV temperature based on a low-cost 8-bit AVR microcontroller. The main contribution of the work is on the Modbus protocol which is employed for communicating between the data acquisition module and the other devices or PC. By introducing the Modbus protocol, the data acquisition system offers an easy way for reading the measurement data.

The rest of paper is organized as follows. Section 2 presents the hybrid power system which is considered in this work. The proposed data acquisition system is presented in section 3. Experimental results are covered in section 4. Section 5 presents the conclusions of the paper.

## II. HYBRID POWER SYSTEM

Fig. 1 shows the architecture of hybrid power system [8]. It consists of solar power, wind power, battery, and load. The maximum power generated by solar power system is 300 watt (6 x 50 Watt PV modules). The wind power system is able to generate the maximum power of 200 Watt. Thus the hybrid power system is suitable for supplying 500 Watt electrical power to a small home. The supervisory controller is employed to supervise the hybrid power system in providing continuous supply regardless of the environmental conditions. The environmental parameters that affect the output power of hybrid power system are solar irradiation, ambient temperature of PV panel, and wind speed as discussed below.

The I-V characteristics of PV are shown in Fig. 2 and Fig. 3. Fig. 2 shows the I-V curves under varying solar irradiation. From the figure, it is clear that when solar irradiation changes, the I-V curve changes accordingly. For a fixed voltage, the current of PV increases when solar irradiation increases. It means that by increasing solar irradiation, the output power of PV will increase. Fig. 3 shows the I-V curves under varying PV temperature. The figure shows that for a fixed current, the PV voltage increases when temperature decreases. Thus increasing PV temperature affects in reducing the power output of PV.

Fig. 4 shows the wind turbine power curves under varying wind speed. In the figure,  $V_{Wx}$  is the wind speed, where  $V_{W3} > V_{W2} > V_{W1}$ . From the figure, it is shown that when wind speed increases, the output power of wind turbine increases.

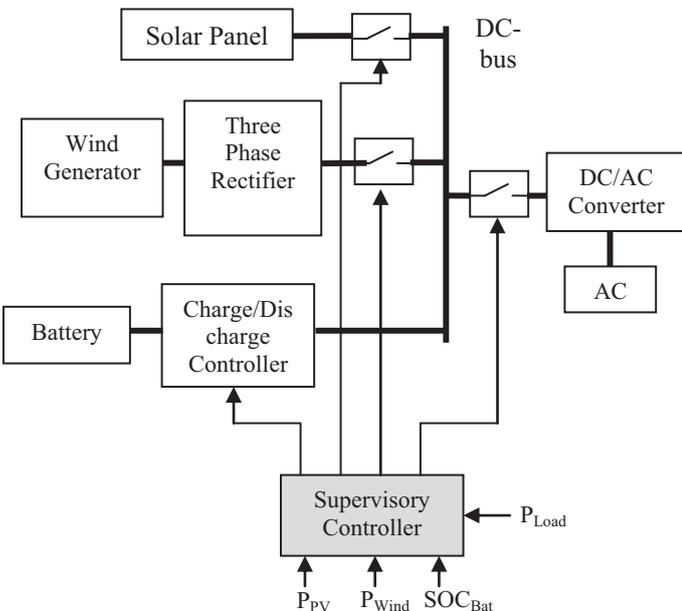

Fig. 1. Architecture of hybrid power system [8].

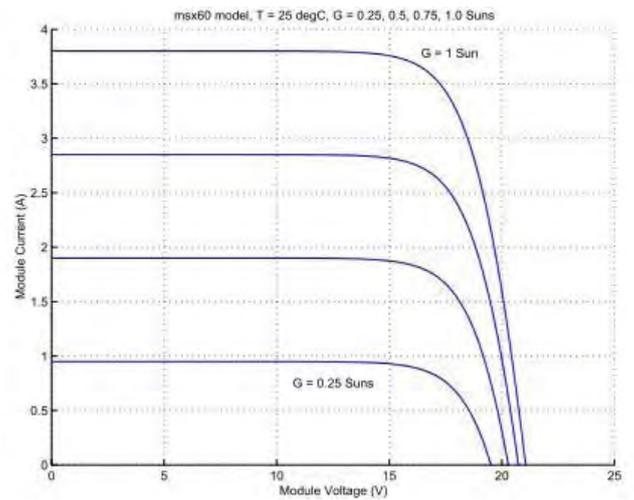

Fig. 2. I-V curves of PV under varying solar irradiation [9].

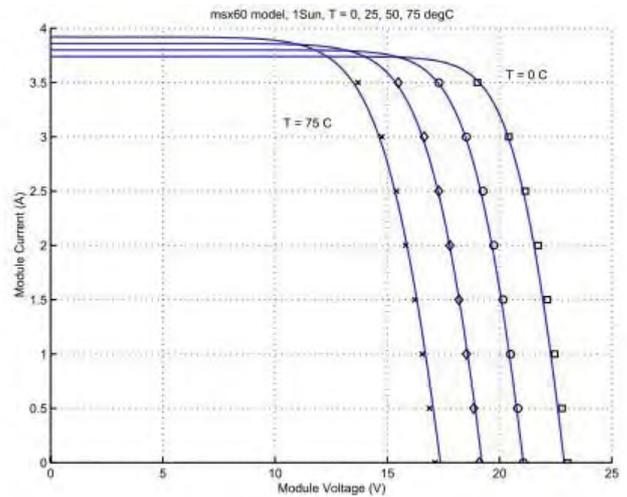

Fig. 3. I-V curves of PV under varying PV temperature [9].

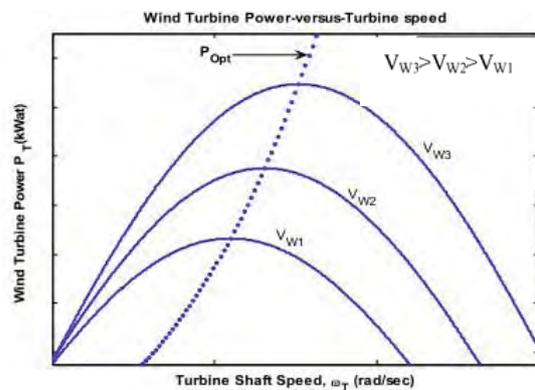

Fig. 4. Wind turbine curves under varying wind speed [9].

### III. PROPOSED DATA ACQUISITION SYSTEM

#### A. Hardware

The block diagram of proposed data acquisition system is shown in Fig. 5. It consists of a 8-bit AVR microcontroller system, a PV cell, an anemometer, LM35 temperature sensor, a Realtime clock (RTC), a LCD module, and a serial communication interface (RS232). A PV cell is used to measure the solar irradiation level. An anemometer is a sensor to measure the wind speed. LM35 is an integrated circuit (IC) used to measure temperature. A RTC (DS1307) is a serial I<sup>2</sup>C real-time clock module which is used as the clock/calendar. Using RTC, the measurement data could be recorded on time/calendar base. A LCD module is used to display the data measurement for local information or debugging the system. A serial RS232 is an interface for communicating between the microcontroller and a PC.

A small size PV cell (7 cm x 5.5 cm) is employed as the solar irradiation sensor. The output voltage and current of cell are 10 V and 30 mA respectively. In this work, the solar irradiation measurement is based-on the output voltage of PV cell. Since the maximum output voltage of the cell is 10 V, while the maximum input voltage of internal ADC of the microcontroller is 5 V, a simple voltage divider (divide by two) is employed.

A cup-type anemometer (from weather sensor assembly kit-Argent Data Systems) is employed to measure the wind speed. Fig. 6 shows the anemometer sensor. The anemometer has a contact switch which is closed when the cup rotates. The switch is close once per second if the measurement wind speed is 2.4 km/h. To interface with the microcontroller system, a pull-up resistor is put on the contact switch and connected to the external interrupt port of the AVR microcontroller.

LM35 is a precision integrated circuit temperature sensor. The output voltage is linearly proportional to the measured temperature (10 mV/°C). To interface this sensor to the microcontroller, a signal conditioner unit is added to gain the output of sensor by 5. Thus when measured temperature is 100 °C, the output of signal conditioner unit (input to ADC port of microcontroller) is 5 V.

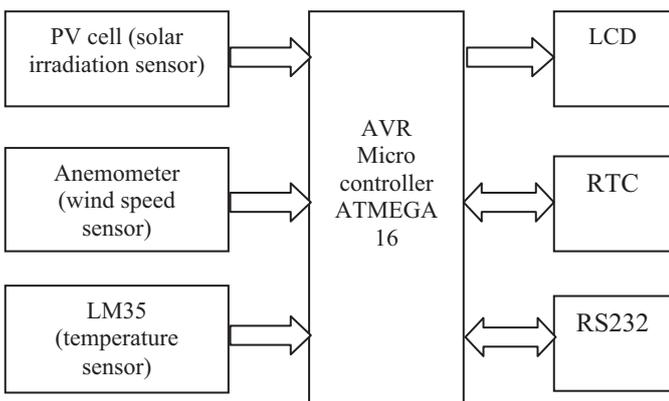

Fig. 5. Hardware architecture.

Fig. 6. Anemometer (Argent Data Systems).

#### B. Software

The program written for microcontroller system consists of the following parts : a) acquire data from sensor; b) display data to LCD module; c) transfer data to/from PC using Modbus protocol. To read data from solar irradiation and temperature sensors, the built-in 10 bit-ADC is used. The program reads the data from ADC buffer when the conversion is completed. While to measure the wind speed, it uses timer to generate five seconds interval for reading the number of pulses on the external interrupt port connected to the anemometer. Since the anemometer switch closes (i.e. triggers/interrupts the microcontroller) once per second if the wind speed is 2.4 km/h, then by counting the number of pulses in five seconds, the wind speed could be calculated.

The communication between data acquisition unit and PC is performed via serial communication using Modbus protocol. In this configuration, the client is PC and the server is the data acquisition unit. Therefore Modbus slave is implemented in the microcontroller. Modbus frame is shown in Fig. 7, where it consists of a protocol data unit (PDU) which is independent of underlying communications layer, and the application data unit (ADU) for mapping the protocol on network [11].

Additional address is the slave address (one byte). Function code denotes the action should be performed by the slave. In this work, only function code of 03 (read holding register) is used. The register address of the measurement data is described in Table 1. When packet data is sent by master device (received by slave device), data field contains of the starting register address and the number of data to be read. If there is no error, slave device will send data contains of the number of bytes and the register's value to be sent. Error check is CRC (cyclic redundancy check) value.

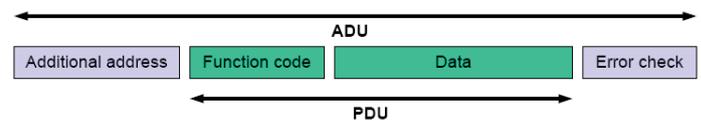

Fig. 7. Modbus frame [11].

TABLE I. REGISTER ADDRESS

Address	Content
16	Solar irradiation data
17	Solar temperature data
19	Wind speed data

#### IV. EXPERIMENTAL RESULTS

To test the functionality and performance of the developed data acquisition system, several experiments are conducted. In the experiments, the measurement data obtained by data acquisition unit are compared to the standard measurement instruments, i.e. solar power meter (TM-750, accuracy of +/- 5%), portable wind speed meter (Luxtron AM-4202, accuracy of +/- 2%), and room thermometer (accuracy of 1<sup>0</sup>C).

Table 2 shows the experimental results of the solar irradiation measurements. This measurement is conducted during sunny day from 10:00 AM to 04:00 PM. The measured data of the data acquisition unit are the data displayed on the LCD module. From the table, it is obtained that the average error is 3.45%. It is noted here that there are inconsistency in the measurements. In the measurements No. 11 and No. 26, the solar irradiation measured by solar power meter is the same, i.e. 960 Watt/m<sup>2</sup>, however the developed data acquisition system measures in the different values, i.e. 945 Watt/m<sup>2</sup> and 934 Watt/m<sup>2</sup> respectively. This phenomenon is caused by the non-linear I-V characteristic of PV under varying temperature as shown in Fig. 3. For a particular solar irradiation level, when PV temperature changes, the output voltage of PV will change. It results the different measurements of solar irradiation. Since the solar power meter does not use the PV cell for measuring the solar irradiation, the inconsistent measurement does not occur.

The experimental result of temperature measurement is shown in Table 3, where the average error is 3.47%. The experimental result of wind speed measurement is shown in Table 4. The wind speed measurement is conducted outdoor at the normal wind speed during two hours from 09:00 AM to 11:00 AM. From the experiments, the average error is 4.46%. The inconsistent measurements occur in the wind speed measurement are caused by the fact that the wind speed is not the steady value. The other factor affects the error is the non deterministic starting time of the timer used for counting pulse employed in the anemometer.

By considering the accuracy of the standard measurement instruments and average errors obtained from the experiments, it could be said that the developed data acquisition system is reliable for measuring solar radiation, temperature, and wind speed.

To test the Modbus communication, the microcontroller is connected to a PC using serial cable (RS232). Two SCADA software (Winlog SCADA and IntegraXor) are used for testing the Modbus protocol. In the SCADA software, the scanning interval for reading data from microcontroller is set to one second. From the experiment, it is shown that the measurement data could be read by SCADA software in real-time.

TABLE II. SOLAR IRRADIATION MEASUREMENT

No.	Solar irradiation (Watt/m <sup>2</sup> )		% error
	Measured by developed data acquisition system	Measured by solar power meter	
1	659	678	2.80
2	659	677	2.65
3	659	678	2.80
4	659	677	2.65
5	659	678	2.80
6	755	767	1.56
7	756	767	1.43

## V. CONCLUSIONS

A data acquisition system for measuring the environmental conditions in the hybrid wind-PV energy system is proposed. The proposed system employs the low cost sensors and microcontroller systems to measure the solar irradiation, PV temperature, and wind speed. Comparing to the standard measurement instruments, it is obtained that the proposed data acquisition system is reliable to monitor the environment conditions in the hybrid power plant. The simple and low cost PV cell shows a good accuracy in measuring solar irradiation. The Modbus protocol implemented on the microcontroller system allows the data acquisition unit to be interfaced to the wide range of data acquisition system software and the SCADA software.

In future, the measurement accuracy will be improved and additional environmental parameters as well as the electrical parameters of hybrid power system will be added. Further, the developed data acquisition system will be extended for operating with SCADA system.

**Abstract**— Stator fault of induction motor is one of the most common faults in industries. Fault detection in early stage of fault is importance to avoid catastrophic failure. This paper is concerned to analysis the behavior incipient stator fault that defined as high impedance and short time turn to turn short circuit. Mathematical model of induction motor with turn fault is developed to understanding the machine performance under fault operation. Moreover, detection system based on transient current during fault occurring is designed. Discrete wavelet transform is used to obtain the high frequency signal that used as detection parameter. The result shows that the proposed method can detect the temporary short circuit fault, even though the fault has high impedance and low current short circuit.

**Keywords**— High impedance fault, induction motor model, stator fault, wavelet transform.

## I. INTRODUCTION

Induction motors are one of the most important machines in industry. About 70% of utility in industry are uses this machine and it consume energy up to 60% of generated electricity energy in the industrialized nations [1-3]. In some application, motors are installed in harsh environment such as corrosive, high temperature and high humidity, which can lead motor deteriorated and failure. Based on industrial survey of induction motor fault, especially for medium voltage motor there are three component of motor that contribute high failure; bearing, stator and rotor. Stator related fault is give 26-66% of failure [4].

In order to avoid operating failure and sudden stop, monitoring system is needed to detect the fault in early stage of deterioration. This detection system is enable to fix the fault with well organized shutdown and will minimize the subsequence damage, outage time and repairing cost [5-7]. Several diagnostic techniques have been developed to detect incipient of fault such as an effective negative-sequence impedance detector [8, 9], line - neutral voltages monitoring [5], current frequency spectrum analysis [6], power decomposition technique [7], multiple reference frames theory for the diagnosis [10], adaptive observer [11], stator current envelopes [12], state observer [13], impedance identification approach [14], motor current signature analysis[15], also artificial intelligent techniques [16].

Moreover, mathematical and simulation model has been developed to understand fault characteristic. The fault signature and the effect on the motor performance can be analyzed using the simulation model [17]. Also, the model based analysis is give flexibility of modifying machine parameters, so that comprehensive and systematic analysis is easily to done. Some of proposed model are Finite element analysis based [18], winding function approach [6, 19], coupled circuit approach [20, 21], multiple coupled circuit [11, 22-24], a state-space model [10, 17, 25, 26], multi loop mathematical models [27], two orthogonal axis models [28, 29], bond graph model [30].

This paper is proposed mathematical model and simulation of induction motor under temporary and high impedance short circuit fault. Temporary short circuit is proposed to illustrate the early stage of short circuit fault that has the short time period and not permanently occurred. Moreover, high impedance fault is also considered as early stage of fault that produce low current short circuit fault. Stationary reference frame transformation is used in this model to investigate transient behavior of machine under fault [17, 28, 31]. The sensitive fault detection based on high frequency signal is proposed to detect low current fault. The proposed method is also not affected to unbalance operation.

## II. INDUCTION MOTOR MODEL UNDER HIGH IMPEDANCE TEMPORARY SHORT CIRCUIT

### A. Induction motor Model in Ideal operation

Electric and magnetic relation for induction motor model with ideal and balance winding is expressed as follows [28, 31].

$$\mathbf{v}_{abc}^s = \mathbf{r}_{abc}^s \mathbf{i}_{abc}^s + \frac{d\lambda_{abc}^s}{dt} \quad (1)$$

$$\mathbf{v}_{abc}^r = \mathbf{r}_{abc}^r \mathbf{i}_{abc}^r + \frac{d\lambda_{abc}^r}{dt} \quad (2)$$

$$\lambda_{abc}^s = \mathbf{L}_{abc}^{ss} \mathbf{i}_{abc}^s + \mathbf{L}_{abc}^{sr} \mathbf{i}_{abc}^r \quad (3)$$

$$\lambda_{abc}^r = \mathbf{L}_{abc}^{rs} \mathbf{i}_{abc}^s + \mathbf{L}_{abc}^{rr} \mathbf{i}_{abc}^r \quad (4)$$

The superscript  $s$  and  $r$  are represent the stator and rotor variable. Matrix for voltage, current resistance, flux linkage and inductance are expressed by  $\mathbf{v}$ ,  $\mathbf{i}$ ,  $\mathbf{r}$ ,  $\lambda$ , and  $\mathbf{L}$  respectively. Stator self mutual inductance  $\mathbf{L}_{abc}^{ss}$ , rotor self mutual

inductance  $\mathbf{L}_{abc}^{ss}$ , stator to rotor mutual inductance  $\mathbf{L}_{abc}^{sr}$ , and rotor to stator mutual inductance  $\mathbf{L}_{abc}^{rs}$ , are expressed as follow.

$$\mathbf{L}_{abc}^{ss} = \begin{bmatrix} L_{asas} & L_{asbs} & L_{ascs} \\ L_{bsas} & L_{bsbs} & L_{bscs} \\ L_{csas} & L_{csbs} & L_{cscs} \end{bmatrix}$$

$$\mathbf{L}_{abc}^{rr} = \begin{bmatrix} L_{arar} & L_{arbr} & L_{arcr} \\ L_{brar} & L_{brbr} & L_{brcr} \\ L_{crar} & L_{crbr} & L_{cr cr} \end{bmatrix}$$

$$\mathbf{L}_{abc}^{sr} = [\mathbf{L}_{abc}^{rs}]^T = \begin{bmatrix} L_{asar} \cos(\theta_r) & L_{asbr} \cos(\theta_r + \frac{2\pi}{3}) & L_{ascr} \cos(\theta_r - \frac{2\pi}{3}) \\ L_{bsar} \cos(\theta_r - \frac{2\pi}{3}) & L_{bsbr} \cos(\theta_r) & L_{bscr} \cos(\theta_r + \frac{2\pi}{3}) \\ L_{csar} \cos(\theta_r + \frac{2\pi}{3}) & L_{csbr} \cos(\theta_r - \frac{2\pi}{3}) & L_{cscr} \cos(\theta_r) \end{bmatrix} \quad (5)$$

Components of inductance matrix are calculated based on number of stator and rotor winding. The references of stator and rotor turn number are expressed by  $N_s$  and  $N_r$  respectively. Mutual and leakage inductance are expressed by  $L_m$  and  $L_{ls}$  respectively. Subscript *asbs* is used to express the relation between *phase-a* and *phase-b* stator windings.

$$L_{asbs} = L_{bsas} = \left(\frac{1}{2} N_a^s N_b^s\right) \left(\frac{2}{3} \frac{L_m}{N_s^2}\right)$$

$$L_{ascs} = L_{csas} = \left(\frac{1}{2} N_a^s N_c^s\right) \left(\frac{2}{3} \frac{L_m}{N_s^2}\right)$$

$$L_{bscs} = L_{csbs} = \left(\frac{1}{2} N_b^s N_c^s\right) \left(\frac{2}{3} \frac{L_m}{N_s^2}\right)$$

$$L_{asas} = \left(\frac{N_a^{s2}}{N_s^2}\right) \left(L_{ls} + \frac{2}{3} L_m\right)$$

$$L_{bsbs} = \left(\frac{N_b^{s2}}{N_s^2}\right) \left(L_{ls} + \frac{2}{3} L_m\right)$$

$$L_{cscs} = \left(\frac{N_c^{s2}}{N_s^2}\right) \left(L_{ls} + \frac{2}{3} L_m\right)$$

$$L_{arbr} = \left(-\frac{1}{2} N_a^r N_b^r\right) \left(\frac{2}{3} \frac{L_m}{N_s^2}\right) = \left(-\frac{1}{3} \frac{N_r^2 L_m}{N_s^2}\right)$$

$$L_{arcr} = L_{brar} = L_{brcr} = L_{crar} = L_{crbr} = L_{arbr}$$

$$L_{arar} = L_{lr} \left(\frac{2}{3} \frac{N_r^2 L_m}{N_s^2}\right)$$

$$L_{brbr} = L_{cr cr} = L_{arar}$$

$$L_{asar} = \frac{2}{3} \frac{N_a^s N_a^r}{N_s^2} L_m$$

$$L_{asbr} = L_{ascr} = L_{asar} = \frac{2}{3} \frac{N_a^s N_r}{N_s^2} L_m$$

$$L_{bsar} = L_{bsbr} = L_{bscr} = \frac{2}{3} \frac{N_b^s N_r}{N_s^2} L_m$$

$$L_{csar} = L_{csbr} = L_{cscr} = \frac{2}{3} \frac{N_c^s N_r}{N_s^2} L_m \quad (6)$$

The electromagnetic torque can be obtained using the following equation.

$$T_{em} = \frac{P}{2} [i_{abc}^s]^T \frac{d(\mathbf{L}_{abc}^{sr})}{d\theta_r} i_{abc}^r \quad (7)$$

In order to simplify equation model and simulation, the mathematical model of induction machine is transformed from *abc* to *dq0* stationary reference frame by matrix transformation.

$$\begin{bmatrix} f_q \\ f_d \\ f_0 \end{bmatrix} = [T_{qd0}^s] \begin{bmatrix} f_a \\ f_b \\ f_c \end{bmatrix}$$

$$[T_{qd0}(\theta)] = \frac{2}{3} \begin{bmatrix} 1 & -\frac{1}{2} & -\frac{1}{2} \\ 0 & -\frac{\sqrt{3}}{2} & \frac{\sqrt{3}}{2} \\ \frac{1}{2} & \frac{1}{2} & \frac{1}{2} \end{bmatrix} \quad (8)$$

The conversion of the equation in to *dq0* axis with stationary reference frame yields:

$$\mathbf{v}_{qd0}^s = \mathbf{r}_{qd0}^s \mathbf{i}_{qd0}^s + \frac{d\lambda_{qd0}^s}{dt} \quad (9)$$

$$\mathbf{v}_{qd0}^r = \mathbf{r}_{qd0}^r \mathbf{i}_{qd0}^r - \omega_r \begin{bmatrix} 0 & 1 & 0 \\ -1 & 0 & 0 \\ 0 & 0 & 0 \end{bmatrix} \lambda_{qd0}^r + \frac{d\lambda_{qd0}^r}{dt} \quad (10)$$

Where  $V_{qd0}^s$  is represent to stator voltage,  $V_{qd0}^r$  is represent to rotor voltage and will be zero for squirrel cage motor,  $i_{qd0}^s$  is stator current,  $r_{qd0}^s$  is stator resistance,  $\lambda_{qd0}^s$  is stator magnetic flux. Similar to stator side, rotor quantities is marked by superscript *r*, while  $\omega_r$  is representing rotor speed. Stator resistance matrix is calculated as follow.

$$\mathbf{r}_{qd0}^s = \begin{bmatrix} r_{11}^s & r_{12}^s & r_{13}^s \\ r_{21}^s & r_{22}^s & r_{23}^s \\ r_{31}^s & r_{32}^s & r_{33}^s \end{bmatrix} \quad (11)$$

Each component inside the matrix is calculated as follows

$$r_{11}^s = \frac{2}{3} \left( r_a^s + \frac{1}{4} r_b^s + \frac{1}{4} r_c^s \right)$$

$$r_{12}^s = \frac{\sqrt{3}}{6} (r_b^s - r_c^s)$$

$$r_{13}^s = \frac{1}{3} (2r_a^s - r_b^s - r_c^s)$$

$$r_{21}^s = r_{12}^s$$

$$r_{22}^s = \frac{1}{2} (r_b^s + r_c^s)$$

$$r_{23}^s = -\frac{1}{2} r_{12}^s$$

$$r_{31}^s = \frac{1}{2} r_{13}^s$$

$$r_{32}^s = -r_{12}^s$$

$$r_{33}^s = \frac{1}{3} (r_a^s + r_b^s + r_c^s)$$

$$r_a^s = \frac{N_a^s}{N_s} r_s; \quad r_b^s = \frac{N_b^s}{N_s} r_s; \quad r_c^s = \frac{N_c^s}{N_s} r_s$$

Flux linkage between stator and rotor can be written as follows:

$$\lambda_{qd0}^s = \mathbf{L}_{qd0}^{ss} \mathbf{i}_{qd0}^s + \mathbf{L}_{qd0}^{sr} \mathbf{i}_{qd0}^r \quad (12)$$

$$\lambda_{qd0}^r = \mathbf{L}_{qd0}^{rs} \mathbf{i}_{qd0}^s + \mathbf{L}_{qd0}^{rr} \mathbf{i}_{qd0}^r \quad (13)$$

$$\mathbf{L}_{qd0}^{ss} = \begin{bmatrix} L_{11}^{ss} & L_{12}^{ss} & L_{13}^{ss} \\ L_{21}^{ss} & L_{22}^{ss} & L_{23}^{ss} \\ L_{31}^{ss} & L_{32}^{ss} & L_{33}^{ss} \end{bmatrix} \quad (14)$$

Each matrix component in equation (14) is calculated as follows.

$$\begin{aligned}
 L_{11}^{ss} &= \frac{2}{3} (L_{asas} + 0.25L_{bsbs} + 0.25L_{cscs}) \\
 L_{12}^{ss} &= \frac{1}{2\sqrt{3}} (L_{bsbs} - L_{cscs} - L_{asbs} + L_{ascsc}) \\
 L_{13}^{ss} &= \frac{2}{3} (L_{asas} - 0.5L_{bsbs} - 0.5L_{cscs} + \\
 &\quad 0.5L_{asbs} + 0.5L_{ascsc} - L_{bscs}) \\
 L_{21}^{ss} &= \frac{1}{\sqrt{3}} (0.5L_{bsbs} - 0.5L_{cscs} - L_{asbs} + L_{ascsc}) \\
 L_{22}^{ss} &= \frac{1}{2} (L_{bsbs} + L_{cscs} - 2L_{bscs}) \\
 L_{23}^{ss} &= \frac{1}{\sqrt{3}} (-L_{bsbs} + L_{cscs} - L_{asbs} + L_{ascsc}) \\
 L_{31}^{ss} &= L_{13}^{ss} \\
 L_{32}^{ss} &= L_{23}^{ss} \\
 L_{33}^{ss} &= \frac{1}{3} (L_{asas} + L_{bsbs} + L_{cscs} + 2L_{asbs} + 2L_{ascsc} + 2L_{bscs})
 \end{aligned}$$

Stator and rotor mutual inductance is expressed as follow.

$$\mathbf{L}_{qd0}^{sr} = \begin{bmatrix} L_{11}^{sr} & L_{12}^{sr} & 0 \\ L_{21}^{sr} & L_{22}^{sr} & 0 \\ L_{31}^{sr} & L_{32}^{sr} & 0 \end{bmatrix} \quad (15)$$

If rotor is symmetric, stator-rotor mutual inductance coefficient can be simplified to

$$\begin{aligned}
 N_{asar} &= N_{asbr} = N_{ascr} = N_{asr} \\
 N_{bsar} &= N_{bsbr} = N_{bscr} = N_{bsr} \\
 N_{csar} &= N_{csbr} = N_{cscr} = N_{csr} \\
 L_{11}^{sr} &= L_{asr} + 0.25L_{bsr} + 0.25L_{csr} \\
 L_{12}^{sr} &= \frac{\sqrt{3}}{4} (L_{bsr} - L_{csr}) \\
 L_{21}^{sr} &= L_{12}^{sr} \\
 L_{31}^{sr} &= 0.5L_{asr} - 0.25L_{bsr} - 0.25L_{csr} \\
 L_{32}^{sr} &= -L_{12}^{sr}
 \end{aligned} \quad (16)$$

$$\mathbf{L}_{qd0}^{rr} = \begin{bmatrix} L_{11}^{rr} & L_{12}^{rr} & L_{13}^{rr} \\ L_{21}^{rr} & L_{22}^{rr} & L_{23}^{rr} \\ L_{31}^{rr} & L_{32}^{rr} & L_{33}^{rr} \end{bmatrix} \quad (17)$$

If rotor is symmetrical and balance, we can get

$$\begin{aligned}
 L_{11}^{rr} &= L_{11}^{rr} = L_{lr} + \frac{N_r^2}{N_s^2} L_m \\
 L_{33}^{rr} &= L_{lr} \\
 L_{12}^{rr} &= L_{13}^{rr} = L_{21}^{rr} = L_{23}^{rr} = L_{31}^{rr} = L_{32}^{rr} = 0
 \end{aligned} \quad (18)$$

$$T_{em} = \frac{3P}{2} (\lambda_d^s i_q^s - \lambda_q^s i_d^s) \quad (19)$$

$$\omega_r(t) = \frac{P}{2J} \int (T_{em} + T_{mech} - T_{damp}) dt \quad (20)$$

where superscript  $s$  is represent stator variable,  $P$  is number of poles,  $J$  motor inertia  $T_{mech}$  and  $T_{damp}$  are mechanical and damping torque respectively. Based on the normal and balance operation as the previous equation, model under short circuit is derived.

### B. Induction motor model under Short Circuit fault

The short circuit occurs in inter turn of *phase-a* winding as shown in Fig.1. [17, 28]. Because of the short circuit case, *phase-a* stator winding is divided into un-shorted turn,  $N_{a1}^s$ , and shorted turn,  $N_{a2}^s$ . The number of shorted turn is equal to  $\mu N_s$ , where  $N_s$  is the number of stator turn.

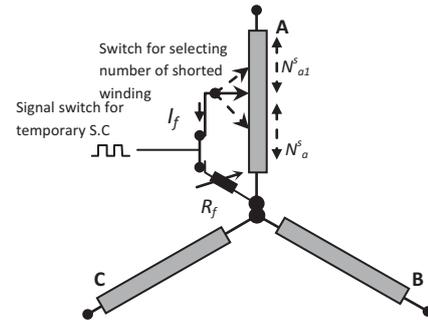

Figure 1 Temporary short circuit case.

Voltage and flux equation in *abc*-reference frame considering the short circuit fault case is expressed as follows.

$$v_{abc}^s = r_{abc}^s i_{abc}^s + \frac{d\lambda_{abc}^s}{dt} + \mu \begin{bmatrix} -r_s \\ 0 \\ 0 \end{bmatrix} i_f \quad (21)$$

$$v_{abc}^r = r_{abc}^r i_{abc}^r + \frac{d\lambda_{abc}^r}{dt} \quad (22)$$

$$\lambda_{abc}^s = L_{abc}^{ss} i_{abc}^s + L_{abc}^{sr} i_{abc}^r + \mu \begin{bmatrix} -r_s \\ 0 \\ 0 \end{bmatrix} i_f \quad (23)$$

$$\lambda_{abc}^r = L_{abc}^{rs} i_{abc}^s + L_{abc}^{rr} i_{abc}^r + \mu \left( -\frac{2}{3} L_m \right) \begin{bmatrix} \cos\theta \\ \cos\left(\theta + \frac{2\pi}{3}\right) \\ \cos\left(\theta - \frac{2\pi}{3}\right) \end{bmatrix} i_f \quad (24)$$

Voltage and flux expression for shorted winding part is shown as follows.

$$v_{a2}^s = r_s \mu (i_a^s - i_f) + \frac{d\lambda_{a2}^s}{dt} = r_f i_f \quad (25)$$

$$\begin{aligned}
 \lambda_{a2}^s &= \mu \begin{bmatrix} L_{asas} \\ L_{asbs} \\ L_{ascs} \end{bmatrix}^T i_{abc}^s + L_{sr} \begin{bmatrix} \cos\theta \\ \cos\left(\theta + \frac{2\pi}{3}\right) \\ \cos\left(\theta - \frac{2\pi}{3}\right) \end{bmatrix}^T i_{abc}^r - \\
 &\mu \left( L_{ls} + \mu \left( \frac{2}{3} L_m \right) \right) i_f
 \end{aligned} \quad (26)$$

Electromagnetic torque of the machine considering fault is obtained using following equation.

$$T_{em} = \frac{P}{2} [i_{abc}^s]^T \frac{d(L_{abc}^{sr})}{d\theta} i_{abc}^r - \mu \frac{P}{2} \left( \frac{2}{3} L_m \right) i_f \left\{ \frac{3}{2} i_a^r \sin\theta + \frac{\sqrt{3}}{2} (i_b^r - i_c^r) \cos\theta \right\} \quad (27)$$

In order to develop the simulation system, machine equation is converting into *qd0* stationary reference frame. Transformation for voltage equation is yields the following formula.

$$\begin{bmatrix} v_q^s \\ v_d^s \end{bmatrix} = \begin{bmatrix} r_{11}^s & r_{12}^s \\ r_{21}^s & r_{22}^s \end{bmatrix} \begin{bmatrix} i_q^s \\ i_d^s \end{bmatrix} + \frac{d}{dt} \begin{bmatrix} \lambda_q^s \\ \lambda_d^s \end{bmatrix} - \frac{2\mu}{3} \begin{bmatrix} r_s \\ 0 \end{bmatrix} i_f \quad (28)$$

$$v_0^s = -\frac{1}{3} \mu r_s i_f + \frac{d\lambda_0^s}{dt} \quad (29)$$

$$\begin{bmatrix} v_q^r \\ v_d^r \end{bmatrix} = \begin{bmatrix} r_{11}^r & r_{12}^r \\ r_{21}^r & r_{22}^r \end{bmatrix} \begin{bmatrix} i_q^r \\ i_d^r \end{bmatrix} + \frac{d}{dt} \begin{bmatrix} \lambda_q^r \\ \lambda_d^r \end{bmatrix} - \omega_r \begin{bmatrix} \lambda_d^r \\ -\lambda_q^r \end{bmatrix} \quad (30)$$

$$v_0^r = 0 \quad (31)$$

$$v_{a2}^s = r_f i_f = \mu r_s (i_q^s + i_0^s - i_f) + \frac{d\lambda_{a2}^s}{dt} \quad (32)$$

Flux linkage equation is transformed as follow.

$$\begin{bmatrix} \lambda_q^s \\ \lambda_d^s \end{bmatrix} = \begin{bmatrix} L_{11}^{ss} & L_{12}^{ss} \\ L_{21}^{ss} & L_{22}^{ss} \end{bmatrix} \begin{bmatrix} i_q^s \\ i_d^s \end{bmatrix} + \begin{bmatrix} L_{11}^{sr} & L_{12}^{sr} \\ L_{21}^{sr} & L_{22}^{sr} \end{bmatrix} \begin{bmatrix} i_q^r \\ i_d^r \end{bmatrix} - \frac{2\mu}{3} \begin{bmatrix} L_{11}^{ss} \\ 0 \end{bmatrix} i_f \quad (33)$$

$$\lambda_0^s = -\frac{1}{3} \mu L_{11}^{ss} i_f \quad (34)$$

$$\begin{bmatrix} \lambda_q^r \\ \lambda_d^r \end{bmatrix} = \begin{bmatrix} L_{11}^{sr} & L_{12}^{sr} \\ L_{21}^{sr} & L_{22}^{sr} \end{bmatrix} \begin{bmatrix} i_q^s \\ i_d^s \end{bmatrix} + \begin{bmatrix} L_{11}^{rr} & L_{12}^{rr} \\ L_{21}^{rr} & L_{22}^{rr} \end{bmatrix} \begin{bmatrix} i_q^r \\ i_d^r \end{bmatrix} - \frac{2\mu}{3} \begin{bmatrix} L_{11}^{sr} \\ 0 \end{bmatrix} i_f \quad (35)$$

$$\lambda_{a2}^s = \mu L_{ls} (i_q^s + i_0^s - i_f) + \mu L_{11}^{sr} (i_q^s + i_q^r - \frac{2\mu}{3} i_f) \quad (36)$$

$$\begin{bmatrix} \lambda_q^s \\ \lambda_d^s \\ \lambda_q^r \\ \lambda_d^r \\ \lambda_{a2}^s \end{bmatrix} = \begin{bmatrix} L_{11}^{ss} & 0 & L_{11}^{sr} & 0 & -\frac{2}{3} \mu L_{11}^{ss} \\ 0 & L_{22}^{ss} & 0 & L_{22}^{sr} & 0 \\ L_{11}^{sr} & 0 & L_{11}^{rr} & 0 & -\frac{2}{3} \mu L_{11}^{sr} \\ 0 & L_{22}^{sr} & 0 & L_{22}^{rr} & 0 \\ \mu L_{11}^{ss} & 0 & \mu L_{11}^{sr} & 0 & -\mu (L_{ls} + \frac{2}{3} \mu L_{11}^{sr}) \end{bmatrix} \begin{bmatrix} i_q^s \\ i_d^s \\ i_q^r \\ i_d^r \\ i_f \end{bmatrix} \quad (37)$$

Electromagnetic torque can be obtained using following equation.

$$T_{em} = \frac{3P}{2} (\lambda_d^s i_q^s - \lambda_q^s i_d^s) - \frac{P}{2} \mu L_{11}^{sr} i_f i_q^r \quad (38)$$

### C. Induction motor model under High Impedance and Temporary short circuit

External resistance is inserted in circuit equivalent, parallel to shorted inductance. The shunt voltage due to the fault resistance is expressed as  $v_q^{ext}$ , and calculated as follow.

$$v_q^{ext} = v_{a2}^s = i_f r_f \quad (39)$$

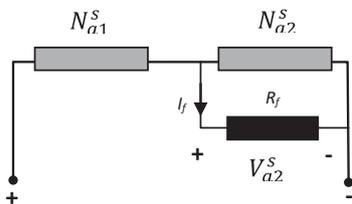

Figure 2 High impedance short circuit.

### III. SIMULATION AND ANALISYS

Based in the mathematical model that has developed above, simulation system is built in Matlab-Simulink system for 2hp, 3 phase and 460 Volt induction motor [28].

#### A. Current pattern under high impedance short circuit

Temporary short circuit is simulated after steady state operation after starting transient. Figure 3 shows the *phase-a* current signal during temporary short circuit in *phase-a*, with 20 turn of winding is shorted in 8 cycle. In this case, fault resistance,  $R_f$ , is to be set a zero or bolted short circuit. The current increase is not a slightly high because it only 8% of winding shorted.

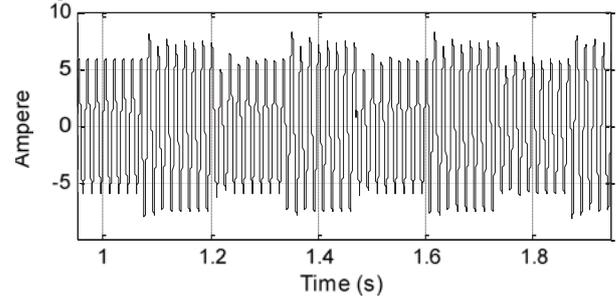

Figure 3 Simulation of temporary short circuit in *Phase-a* stator winding.

Figure 4 shows the transient current spectrum during high impedance fault. As shown in this figure, the magnitude current is decreasing when the resistance is increase. The short circuit cases are difficult to distinguish from normal operation when the current magnitude used as detection variable. However, the starting of short circuit can be noticed based on the transient current when the fault starting occurred. Moreover, short circuit case is produce high frequency that can be shown as low harmonics ripple in the current. Based on these phenomena, the detection system using high frequency signal current is proposed in this paper.

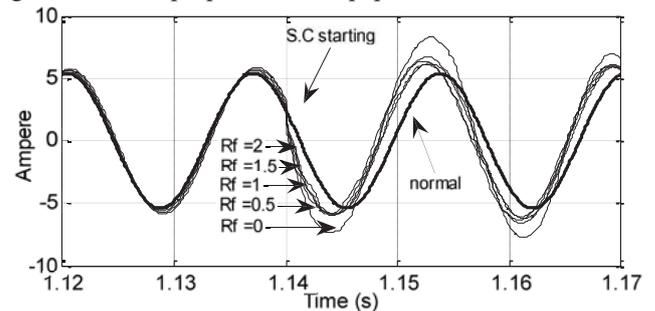

Figure 4 Simulation of temporary short circuit with high impedance fault.

#### B. Fault Detection

In this section, the proposed method of high impedance short circuit detection is discussed. The discrete wavelet transform is used to obtain high frequency signal of motor current. Haar wavelet is selected as wavelet filter because of

simplicity. From the current signal  $I(t)=[i_1 \ i_2 \ \dots \ i_n]$ , the Haar wavelet transformation for high frequency signal,  $HF$ , and low frequency signal,  $LF$ , can be calculated as follows

$$HF = [Wh] I(t) \tag{40}$$

$$LF = [Wl] I(t) \tag{41}$$

$$Wh = \begin{bmatrix} \ddots & \ddots & \ddots & & & & \\ & 0 & \frac{1}{2} & -\frac{1}{2} & 0 & 0 & \\ \dots & 0 & 0 & \frac{1}{2} & -\frac{1}{2} & 0 & \dots \\ & 0 & 0 & 0 & \frac{1}{2} & -\frac{1}{2} & \\ & 0 & 0 & 0 & 0 & \frac{1}{2} & \\ & & & & & & \ddots \end{bmatrix}$$

$$Wl = \begin{bmatrix} \ddots & \ddots & \ddots & & & & \\ & 0 & \frac{1}{2} & \frac{1}{2} & 0 & 0 & \\ \dots & 0 & 0 & \frac{1}{2} & \frac{1}{2} & 0 & \dots \\ & 0 & 0 & 0 & \frac{1}{2} & \frac{1}{2} & \\ & 0 & 0 & 0 & 0 & \frac{1}{2} & \\ & & & & & & \ddots \end{bmatrix}$$

In this method, three level transformation is used to obtain the appropriate signal that clearly to detecting the occurring of fault consist the starting and ending of short circuit. Low and high frequency signal is obtained at first step transformation as  $LF1$  and  $HF1$ , respectively. The next two transformation are used the high frequency signal to be transformed using wavelet filter as shown in Figure 5.

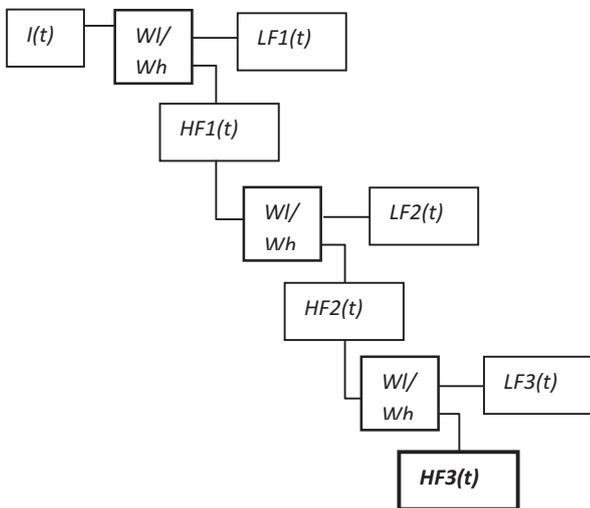

Figure 5 Calculation process of high frequency level-3 (HF3).

Figure 6 shows the current spectrum during temporary high impedance short circuit with 8% of stator winding is shorted and 2 Ohm resistance fault is inserted. In this case, normal

current has magnitude 5.4 Ampere, while a short circuit case is raising current to 6 Ampere or 0.6 Ampere differences. Because of small raising current, the short circuit case is difficult to detect. Figure 7 shows the high frequency current,  $HF3$ , of the current spectrum from Figure 6. The magnitude is very low during the normal operation. While short circuit is starting occur, the magnitude is increasing very high. Moreover, when the fault is cleared, the magnitude is decreasing back to the normal.

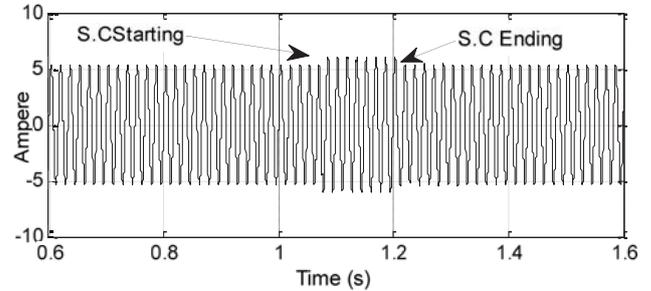

Figure 6 Current spectrum of temporary short circuit current with 20 turn shorted and 2 Ohm of resistance fault.

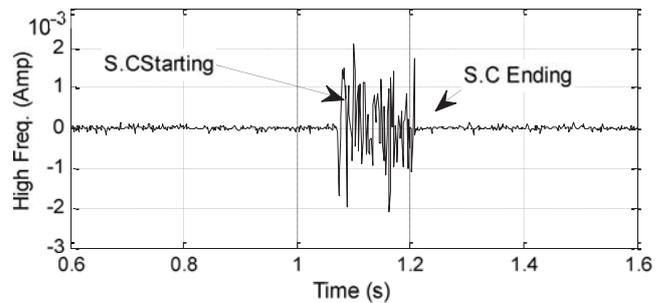

Figure 7 HF3-spectrum of temporary short circuit current with 20 turn shorted and 2 Ohm of resistance fault.

Based on this result, the short circuit fault is clear detecting using high frequency of 3<sup>rd</sup> level Haar transformation. The occurring of fault, including when the fault started and cleared, is easily detected even though the fault has small current magnitude.

#### IV. CONCLUSION

Mathematical model and simulation of induction motor under short circuit fault is presented. The short circuit is specified as temporary and high impedance fault to represent the early stage of winding deterioration. Sensitive short circuit detection is proposed based on the high frequency signal of motor current. High frequency signal is obtained using wavelet transform. Third level transformation of Haar wavelet result is the high frequency signal that suitable to detect high impedance short circuit. As the result, the proposed detection method can detect 8% of shorted turn winding with fault resistance 2 Ohm. This fault only has 11% of current fault magnitude comparing the nominal operating current.

## ACKNOWLEDGMENT

### ABSTRACT

Recently, aiming to the carry out the realization of advanced traffic systems, the optical communication system which is based on LED traffic lights is presently being studied. Devices used to find the area of signal light source, and receive the optical signal are strongly required. This paper investigates CMOS light pulse receiver (LPR) cell for car-to-car and road-to-car spatial optical communication. In present type of pixel, the LPR cell consists of a photodiode with a charge sensing node and charge overflow drain. If fringing field is created, the photodiode capacitance in depletion region is greatly reduced. Therefore the depleted diode implemented with pinned photodiode technology is of great help with regards to enhancing the time response while achieving high-sensitivity. In accordance with the analysis and calculation of SPECTRA simulation, the response to the received light pulse is optimized by considering charge sensing node capacitance of LPR cell in different structural parameters in order to select the most suitable ones.

**Abstract**— A novel design for ultra wideband microstrip antenna using T-shape stub fed by coplanar waveguide is proposed and experimentally studied. The multiband frequencies can be reached by controlling the length of a and b of the T shaped stub. The results shown that the proposed antenna can be achieved multiband frequencies with return loss -21.5 dB at frequency 2.65GHz, return loss -24.5dB at frequency 5GHz, and return loss -35dB at frequency 8.42GHz. Impedance bandwidth of the proposed antenna is 6570 MHz or about 200% (VSWR < 2) with broadside radiation patterns and the antenna gain is about 5.02 dBi.

**Keywords**— Coplanar waveguide, Multiband, T-shaped stub, Ultra Wideband

## I. INTRODUCTION

Recently, wireless communications have been developed widely and rapidly, which leads to a great demand in designing broadband antennas for mobile terminals. Among various forms of planar antennas, coplanar waveguide (CPW) fed printed slot antennas have the simplest structure of a single metallic layer. Because CPW fed wide slot antennas have the advantages of wide bandwidth and easy integration with monolithic microwave integrated circuit (MMIC). And the planar antennas fed by CPW have many advantages such as low profile, low cost, and suitable for integration with active device. The designs of the CPW fed wide slot antennas have recently received much attention [1-2].

A simple CPW fed square slot antenna, the impedance bandwidth can be reached about 30%[3-4]. As reported that CPW-fed slot antennas with strip-loaded [5] or with a widened tuning stub [6] can be reached the impedance bandwidth about 60%. Ultra Wide Band (UWB) technology is one of the most promising solutions for future communication systems due to its high-speed data rate and excellent immunity to multi-path interference. UWB is known as a Radio Frequency (RF) technology that transmits data in binary form, using extremely short duration impulses over a wide spectrum of frequencies. It has a marvelous quality of delivering data over 10 to 100 meters and did not require any kind of dedicated radio frequency, so it is also known as carrier-free, impulse or base-band radio and also transmits information over a large bandwidth (>500 MHz)[7].

It has been well known that the future communication technology pressingly demands integration of more than one

communication system into a limited equipment space. Thus, the future communication terminal antennas will not only be desired to be low profile, lightweight, flush mounted, and single-feed but also need to meet the requirements of multiband operation for sufficiently covering the possible operating bands.

This paper proposed a simple design of T-shaped stub microstrip antenna fed by coplanar waveguide to generate ultra wide band frequencies more than 60%. The proposed antenna design and the simulation results are presented.

## II. ANTENNA DESIGN

Fig. 1 shows the geometry of the proposed antenna. The antenna is excited by 50Ω microstrip line with T-shaped stub. The patch antenna is fabricated on FR4 substrate with the dielectric constant ( $\epsilon_r$ ) = 4.6 and the substrate thickness (h) = 1.6 mm. The coplanar waveguide, having a strip of thickness ( $w$ ) and gap ( $g$ ) between the strip and the coplanar ground plane, is used to excite the T-shape stub.

The structure and dimensions of the proposed antenna ultra wide band can be calculated by equation (1) and (2) for design a microstrip antenna shaped rectangular.

$$L_{eff} = \frac{c}{2f_{10}\sqrt{\epsilon_e}} \quad (1)$$

$$W = \frac{c}{2f_o \sqrt{\frac{(\epsilon_r + 1)}{2}}} \quad (2)$$

$$\epsilon_e = \frac{\epsilon_r + 1}{2} + \frac{\epsilon_r - 1}{2} \left( \frac{1}{\sqrt{1 + 12h/W}} \right) \quad (3)$$

The width of the 50Ω microstrip line ( $w$ ) is 3 mm, the gap of the coplanar waveguide line ( $g$ ) is 0.4 mm and the dimension of ground and T-shape stub  $a \times b$  is 12 mm x 6 mm.

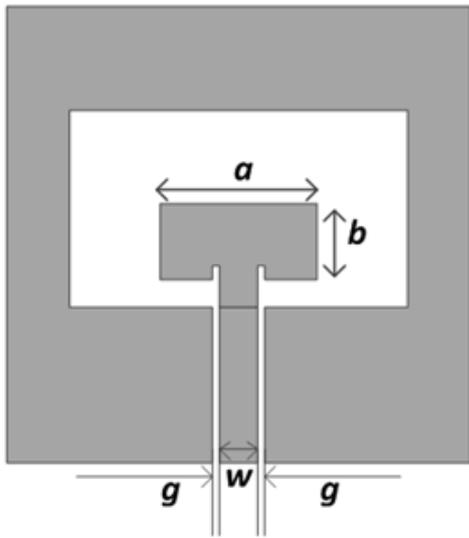

Fig.1. Geometry of the proposed T-shape stub antenna fed by coplanar waveguide

### III. EXPERIMENTAL RESULTS

The analysis and performance of the proposed antenna is explored to get the best impedance matching. The analysis of the antenna carried out by varying parameter. At the first iteration with parameter  $a = 6$  mm and  $b = 3$  mm. The simulation result is shown in Fig.2 with return loss less than -10 dB and the range frequency operation (5.51GHz – 6.68GHz) and (8.78GHz – 9.87GHz) can be generated bandwidth about 2260 MHz.

The second iteration with parameter  $a = 8$  mm and  $b = 4$  mm. From the simulation result, return loss value is shown in Fig.3 with the range frequency operation (3.78GHz – 6.8GHz) and (8.22GHz – 9.48GHz) bandwidth 4280 MHz can be achieved.

The third iteration with parameter  $a = 10$  mm and  $b = 5$  mm and the simulation result is shown in Fig.4. From Fig.4 shows that bandwidth about 5600 MHz can be reached in the range frequency operation of (2.81GHz – 6.94GHz) and (7.76GHz – 9.23GHz).

The fourth iteration with parameter  $a = 12$  mm and  $b = 6$  mm. Bandwidth 6570 MHz can be generated in the frequency operation (2.43GHz – 9GHz) as seen in Fig.5.

Figures (6a) shows the return loss -21.5 dB at frequency 2.65 GHz, return loss -24.5dB at frequency 5GHz, return loss -35dB at frequency 8.42GHz and impedance bandwidth of 6570 MHz or about 200% by adjusting the length of  $a$  and  $b$ . Table 1 shows the iteration parameters  $a$  and  $b$  to generate multiband frequencies. Figure (6b) shows that the proposed antenna using T-shape stub can be achieved wider bandwidth.

TABLE 1 PARAMETERS ITERATION

Iteration	$a$ (mm)	$b$ (mm)	Bandwidth
1	6	3	2260 MHz
2	8	4	4280 MHz
3	10	5	5600 MHz
4	12	6	6570 MHz

Fig. 6. Simulation results from the proposed antenna

Fig.7.Radiation patterns of the proposed antenna at frequency (a) 2.65 GHz, (b) 5 GHz, (c) 8.42 GHz

Figure (7a) until (7c) shows the radiation patterns in the H-plane and E-plane for the three frequencies of the proposed antenna at  $a = 12$  mm and  $b = 6$  mm. The result shows that the antenna has broadside radiation pattern. The antenna gain against frequency is presented in Fig.8 and the antenna gain is about 5.02dBi, with gain variations less than 3 dBi across the operating frequency from 2.42 GHz to 9.01 GHz.

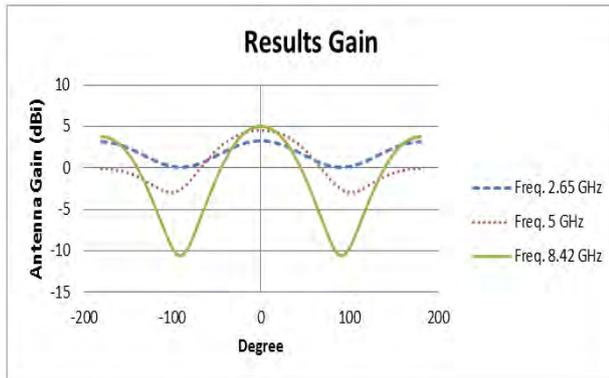

Fig.8. Antenna gain of the proposed antenna

#### IV. CONCLUSION

Rectangular T-shape stub microstrip antenna fed by coplanar waveguide for ultra wide band operation have been designed and experimentally studied. The maximum impedance bandwidth is 6570 MHz or about 200%. The antenna has broadside radiation pattern and gain of about 5.02 dBi is obtained.

## I. INTRODUCTION

**Abstract**—Previous studies suggested that seismo-electromagnetic signals were generated during earthquake preparation phase. While the anomalous signals in Japan, Russia, and Greece are rather clear; observational results in some regions including America and Indonesian have not conclusive yet, whether the signals are really exist or normal magnetic storm phenomena only. Some problems in measuring instrumentations might also result in anomalous signals. This paper reviews further possibilities by processing a nearly continuous geomagnetic data of INTERMAGNET observatories in three regions (Japan, America, and Indonesia) during the last twelve years (2000–2011). MATLAB ® with digital signal processing and statistical toolboxes is used for night-time data filtering, thereafter processing methods of differentiation and moving average are applied. To get relationship between these anomalous signals and natural processes, tectonic settings of the regions and global geomagnetic conditions are also considered in the analysis.

Fast decreasing of geomagnetic intensities signals are showed prior to earthquakes in Japanese regions, while some little increases of differentiation signals between two adjacent observatories were seen from their moving average values. The anomaly was 10.08 nT, during 8 days started from 32 days prior to the earthquake. Decreasing of geomagnetic intensities prior to earthquakes in American regions occurred rather longer and formerly (during 40 days started from 137 days prior to the earthquake), but the magnitudes are not so high. In Indonesian regions, fast decreasing of geomagnetic signals and increasing of differentiation signals are very clear, especially prior to the giant M9.1 Sumatra earthquake. The anomaly reached extreme magnitude of more than 200 nT during several days prior to the earthquakes. All observational results are back to the normal (base line) values after earthquake occurrences. The distances from the observatories to the epicenters and the magnitudes of earthquakes very affect the results. Elevations of observatories and the tectonic settings of regions may also affect the magnitude of anomalous signals. Some missing data during earthquake days are in fact very valuable to complete the analysis. After all, the geomagnetic signal processing is very valuable in searching appropriate precursors for successful earthquake predictions.

**Keywords**—Geomagnetic; earthquake; precursor; differentiation; INTERMAGNET

Earthquake occurrences are quite often reported to be preceded by some natural anomalous phenomena, among others are increasing or decreasing of regional electric and geomagnetic signals, especially Ultra Low Frequency (ULF) component. Researches on this topic, called as seismo-electromagnetic phenomena, have been conducted in various regions since early nineteenth century. However, [1] has underlined that much of the earliest work was recognized as spurious, because the transient signals were resulted from magnetic variometers (suspended magnets) and other instruments sensitive to ground displacement, acceleration, and rotation common in epicentral regions during the propagation of seismic waves. Only after the mid-1960s, these problems have been avoided through the use of absolute magnetometers installed in regions of low magnetic field gradient to reduce sensitivity to earthquake shaking and by the application of new noise reduction techniques. As a consequence, unambiguous observations of EM variations related to earthquakes and tectonic stress/strain loading, have now been obtained near active faults in many countries (Japan, China, Russia, Italy, Greece, America, and other locations).

Controversies around this crucial topic are still going on. The mostly cited seismo-electromagnetic report is of [2], who accidentally detected extreme ULF geomagnetic signals transient from a ground-based instrument installed at Corralitos, just close (7 km) to the epicentrum of 1989 M7.1 Loma Prieta earthquake in California. They observed increasing of ULF geomagnetic signal amplitudes (in the frequency range of 0.5–2.010 Hz) since one month prior to the earthquake, and detected strong enhancement of the 0.01–0.5 Hz signals from two days before until the occurrence of the earthquake. Conversely, [3] have re-examined all of the available Corralitos data (21 months from January 1989 to October 1990), have found that the reported anomalous geomagnetic signals transient identified by [2] is not related to the Loma Prieta earthquake but is an artifact of sensor-system malfunction.

Another minor opinion against seismo-electromagnetic signal analysis as earthquake precursors is of [4]. They have

concluded that useful prediction of damaging earthquakes seems unlikely using these electromagnetic data, based on the absence of electric and magnetic field precursors for the 2004 M6.0 Parkfield earthquake and other earthquakes with M5–7.3 elsewhere in the San Andreas fault system. Some other authors view the efforts of short term predictions of earthquakes using precursory anomalous signals with strong skepticism, while [5] even called such efforts as a magnetic fraud.

Contrarily, several authors believe that someday people will be able to predict the earthquake occurrences in only a short range of days. They argued that it is just like people being able to fly with airplanes today, which was still a dream before the 19<sup>th</sup> century. These optimistic researchers never give up to search and actively propose the appropriate methods that can be applied for middle-term and even short-term earthquake predictions, which are suitable for regional earthquake early warning system. Among this “optimistic” group members are [6] and [7, 8]. Some of important efforts in searching the methods have been collected by [9] and [10].

In fact, several seismo-electromagnetic satellite-based researches have reported anomalous signal evidences detected from the sky. Changes of ULF and VLF signals in the Ionosphere were detected by the Intercosmos-19 satellite, within 2° latitude and 60° longitude from the epicenter, since 8 hours prior to -until 3 hours after- the 1979 earthquake in Russia [11]. [12] reported that ULF/VLF signals below 450 Hz were detected by COSMOS-1809 satellite, within 6° latitude from the epicenter of the 1988 earthquake in Armenia. Finally, [13] have applied wavelet analysis to investigate if electromagnetic disturbances related to the 2004 M9.2 Sumatra great earthquake could be detected by satellite magnetometers. They have concluded that only a statistical study based on large earthquakes recorded during the CHAMP magnetic mission could bring an answer to such a crucial question.

Regarding all above achievements, searching appropriate methods for seismo-geomagnetic signal processing are still big challenges; because there is no single method appropriate to be applied for every case of earthquake occurrences in different regions over the entire globe. In other words, it is quite possible that each region needs a specific approach to find the most appropriate signal processing method, which depends on its geology and tectonic characteristics.

This paper reports seismo-geomagnetic signal processing by applying differentiation and moving average procedure in the Japanese, American, and Indonesian regions during the last twelve years (2000–2011). Three big earthquakes -two of them are giants- will be analyzed to know whether such earthquakes can generate anomalous geomagnetic signal fluctuations. When the anomalous signals appeared and how large the magnitude of earthquakes will affect the intensity of anomalous geomagnetic signals will also be analyzed. To get relationship between these anomalous signals and natural processes, tectonic settings of the regions and global

geomagnetic conditions are also considered in the analysis. Finally, a fundamental question will be answered, whether seismo-geomagnetic signal processing are really possible to be used as earthquake precursors and applicable for hazard mitigations.

## II. DATA COLLECTIONS AND METHOD

The geomagnetic data from the regions of Japan, USA, and Indonesian are obtained from the INTERMAGNET ([www.intermagnet.org](http://www.intermagnet.org)). The data are of one-minute total intensity (F), which have been initially measured every second, nearly continuously along twelve years during 2000–2011. The data of each region have to be collected from three different observatories, which surround the earthquake locations. To get the reliable data, we use only definitive one and of night time values (i.e. 00:00–06:00 of the local times). MATLAB ® with digital signal processing and statistical toolboxes is used for night-time data filtering, thereafter processing methods of differentiation and moving average are applied. The differentiation procedure was done to reduce signal fluctuations due to diurnal variation, ionospheric as well as magnetospheric disturbances, and to eliminate secular variations. Results will be only variations due to local lithospheric magnetizations, which might be in connection with tectonic activities. To determine how well localization of anomalous signals, observations on global geomagnetic indices were taken by evaluations of the summing of planetary index (Sigma Kp) obtained from ftp site of the *Deutsches GeoForschungsZentrum* (<ftp://ftp.gfz-potsdam.de/pub/home/obs/kp-ap/wdc/>).

The procedure of data processing has been used in [14], which can be shortly described as following: (i) The selected data from the three observatories on one region are daily averaged and plotted individually. (ii) The data are then subtracted each other, to get the differential signals between two observatories in the order of (Obs1-Obs2), (Obs1-Obs3), and (Obs2-Obs 3). (iii) The differential signals are moving averaged to get the low pass filtered (smoothed) signals, with time windows of 7 days (regarding 27 days time interval of the solar cycle). (iv) The signal trends are defined and evaluated over the elapsed times for each moving averaged results, with the focus on the time of earthquake occurrences.

## III. SEISMO-GEOMAGNETIC SIGNALS IN THREE REGIONS

### A. Japanese Region

Data from three INTERMAGNET observatories in Japanese region will be used, i.e. Memambetsu (MMB), Kakioka (KAK), and Kanoya (KNY). The geographical positions of the three observatories and their distances to the earthquake epicenter are listed in Table 1, while Fig. 1 depicts their locations and the epicenter location of studied giant Tohoku Earthquake. The earthquake occurrence is on March 11th 2011 at (38.3°N, 142.37°E) with M9.0 and 29 km depth.

Fig. 2 shows geomagnetic data during October 2010–September 2011 from MMB, KAK, and KNY. Fig. 2(a) shows daily averaged values of the geomagnetic total intensity data, while Fig. 2(b) shows the differentiations between two

observatories and their moving averages. We also show the sigma Kp values to be an indicator for global geomagnetic conditions, especially prior to the earthquake occurrence.

As seen on the parts marked with circles in Fig. 2, some anomalous signal clearly exist with their intensity values as calculated on Table 2. The highest anomalies are in the differentiation signals between KAK and KNY. There were four anomalous signals, with intensities of 9.06 nT on 33 days, 25.74 nT on 10 days, 6.51 nT on 4 days, and 16.8 nT on 1 day prior to the earthquake. Unfortunately, no data recorded on the day of earthquake and three days after, probably because of electrical power failure. Using moving average procedure, we see clear anomalous patterns with magnitude of 10.08 nT during 8 days (DOY 38–45), starting from 32 days prior to the earthquake (from DOY 70). In this case, sigma Kp values are low; means that no geomagnetic storms occurred during the anomalous days. We are, therefore, confident that the anomalous signals were local in the Japanese region and in close correlation to the earthquake occurrence.

### B. American Region

Data from three INTERMAGNET observatories in American region will be used, i.e. Boulder (BOU), Fresno (FRN), and Tucson (TUC). The geographical positions of the three observatories and their distances to the earthquake epicentre are listed in Table 1, while Fig. 3 depicts their locations and the location of studied Colima/Mexico Earthquake. The earthquake occurrence is on January 22<sup>nd</sup> 2003 at (18.77°N, -104.10°E) with M7.6 and 24 km depth.

Fig. 4 shows geomagnetic data during July 2002–June 2003 from BOU, FRN, and TUC. Fig. 4(a) shows daily averaged values of the geomagnetic total intensity data, while Fig. 4(b) shows the differentiations between two observatories and their moving averages

Fig. 1. Three geomagnetic observatories and the location of studied earthquake in Japanese region: MMB, KAK, and KNY with the giant M9.0 Tohoku Earthquake on March 11th 2011.

TABLE I. GEOMAGNETIC OBSERVATORIES IN JAPANESE, AMERICAN, AND CLOSE TO INDONESIAN REGION

Regional	IAGA code	Lat	Long	Elev. (m)	Dist. to EQ (km)
Japan	MMB	43.91°N	144.19°E	42	642
	KAK	36.23°N	140.18°E	36	301
	KNY	31.42°N	130.88°E	107	1295
America	BOU	40.14°N	-105.24°E	2682	2377
	FRN	37.09°N	-119.72°E	331	2541
	TUC	32.18°N	-110.73°E	946	1631
Indonesia	LRM	-22.22°N	144.10°E	4	3452
	KDU	-12.69°N	132.47°E	14	4402
	PHU	21.03°N	105.95°E	5	2246

TABLE II. INTENSITY OF ANOMALOUS GEOMAGNETIC SIGNALS ON MMB, KAK, AND KNY PRIOR TO THE TOHOKU EARTHQUAKE

Anomaly (nT)	Earthquake on 2011.03.11 (DOY 70)			
	DOY 37 (33 days before EQ)	DOY 60 (10 days before EQ)	DOY 66 (4 days before EQ)	DOY 69 (1 day before EQ)
MMB-KAK	9.62	3.38	10.62	1.62
MMB-KNY	10.00	14.00	-3.00	10.00
KAK-KNY	9.06	25.74	6.51	16.8
Sigma Kp	23	29.7	17.3	25.7

TABLE III. INTENSITY OF ANOMALOUS GEOMAGNETIC SIGNALS ON BOU, FRN, AND TUC PRIOR TO THE COLIMA/MEXICO EARTHQUAKE

Anomaly (nT)	Earthquake on 2003.01.22 (DOY 22)			
	DOY 206 (181 days before EQ)	DOY 250 (137 days before EQ)	DOY 277 (110 days before EQ)	DOY 12 (15 day before EQ)
BOU-FRN	7.26	33.86	33.56	30.0
BOU-TUC	-19.26	31.34	21.14	20.0
FRN-TUC	-26.58	-2.57	-12.43	-12.3
Sigma Kp	21.0	33.7	42.0	16.7

We also show the sigma Kp values to be an indicator for global geomagnetic conditions, especially prior to the earthquake occurrence. As seen on the parts marked with circles in Fig. 4, some anomalous signal clearly exist with their intensity values as calculated on Table 3. The highest anomalies are in the differentiation signals between FRN and TUC, but then between BOU and FRN. There were four anomalous signals, with intensities of -26.58 nT on 181 days, 33.86 nT on 137 days, 33.56 nT on 110 days, and 30.0 nT on 15 days prior to the earthquake. The minus signs mean that the signals are lower than normal values.

Unfortunately, no data recorded on some days prior to the earthquake, while anomalous signals were recognized. Nevertheless, by using moving average procedure, we still see the track of anomalous signals during 40 days (DOY 250–290), starting from 137 days prior to the earthquake. In this case, sigma Kp values fluctuate, with some high in between low values. It means that geomagnetic storms probably occurred during some of the anomalous days. Therefore, we considered that not all of the anomalous signals were local in the American region, but due global geomagnetic storms. On the other hand, we are also confident that some anomalous signals were really in close correlation to the earthquake occurrence.

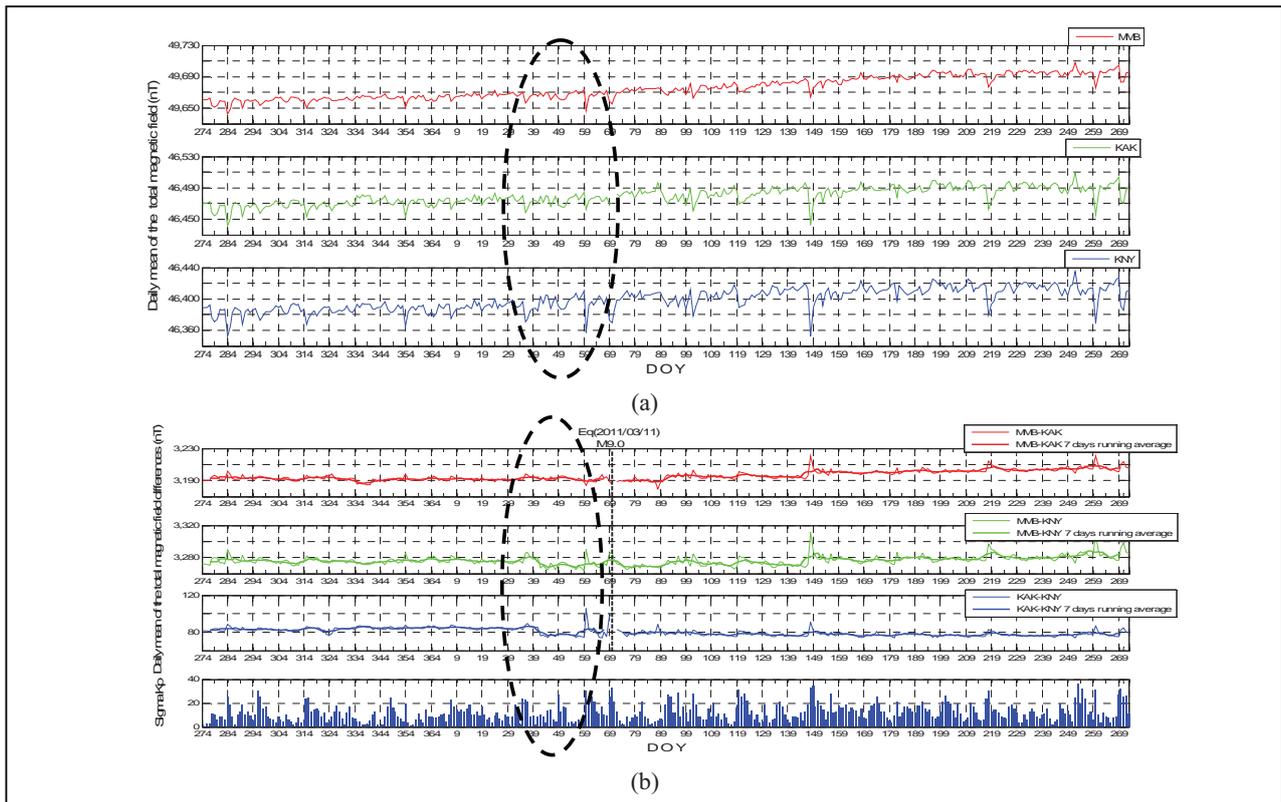

Fig. 2. Geomagnetic anomalous signal related to the M9.0 giant Tohoku Earthquake on March 11th 2011. (a) The daily mean of the total geomagnetic fields observed by three observatories in Japanese region (MMB, KAK, and KNY), and (b) The differentiations signals of two observatories and the moving averages, with sigma Kp values of corresponding days to evaluate the global geomagnetic conditions.

### C. Indonesian Region

Since no INTERMAGNET observatory in Indonesia, data from three INTERMAGNET observatories which are close to Indonesian region will be used, i.e. Learmonth (LRM) in Australia, Kakadu (KDU) in Australia, and Phuthuy (PHU) in Vietnam. The geographical positions of the three observatories and their distances to the earthquake epicenter are listed in Table 1, while Fig. 5 depicts their locations and the location of studied giant Sumatera Earthquake. The earthquake occurrence is on December 26th 2004 at (3.3°N, 95.98°E) with M9.1 and 30 km depth. Another M7.5 earthquake happened before on November 11th 2004 also in Indonesian region will be used as comparison.

Fig. 6 shows geomagnetic data during July 2004–December 2005 from LRM, KDU, and PHU. Fig. 6(a) shows daily averaged values of the geomagnetic total intensity data, while Fig. 6(b) shows the differentiations between two observatories and their moving averages. We also show the sigma Kp values to be an indicator for global geomagnetic conditions, especially prior to the earthquake occurrence.

As seen on the parts marked with circles in Fig. 6, some anomalous signal clearly exist with their intensity values as

calculated on Table 4. Unfortunately, many data were missing on some days prior to and after the earthquakes.

Fig. 3. Three geomagnetic observatories and the location of studied earthquake in American region: BOU, FRN, and TUC with the M7.6 Colima/Mexico Earthquake on January 22nd 2003.

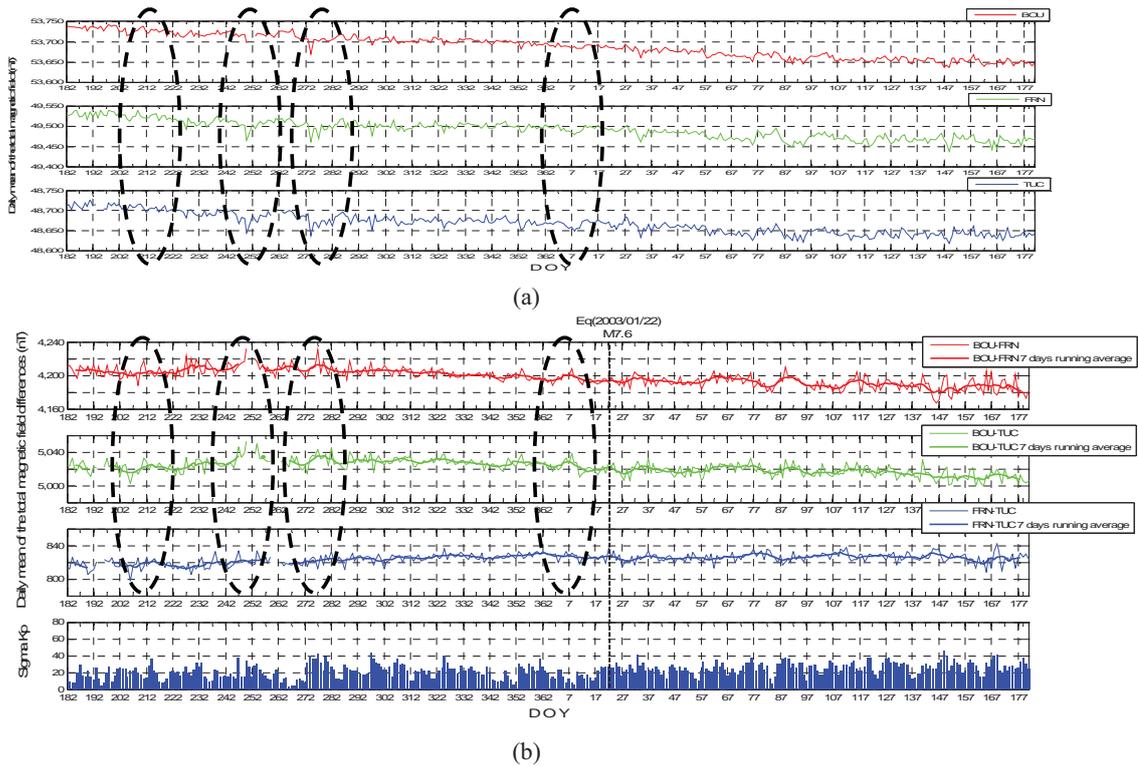

Fig. 4. Geomagnetic anomalous signal related to the M7.6 Colima/Mexico Earthquake on January 22nd 2003. (a) The daily mean of the total geomagnetic fields observed by three observatories in American region (BOU, FRN, and TUC), and (b) The differentiation signals of two observatories and the moving averages, with sigma Kp values of corresponding days to evaluate the global geomagnetic conditions.

Nevertheless, anomalies were clearly seen in the differentiation signal between LRM and PHU. There were four anomalous signals, with intensities of 46.04 nT on 21 (or 66) days, 61.64 nT on 12 (or 57) days, 253.24 nT on 3 (or 48) days, and 286.24 nT on 1 (or 45) days prior to the first (or the second) earthquake. Using moving average procedure, we also see clear anomalous patterns reaching extreme magnitude of more than 200 nT during several days prior to the earthquakes.

On these days, sigma Kp values were also extreme reaching abnormal values of more than 50 nT; but the background sigma Kp values were low. It means that some abnormalities were recorded globally, but we are not quite sure that whether geomagnetic storms occurred during the anomalous days. It is also possible that the anomalous signals were in close correlation to the earthquake occurrences, but they were not only locally detected over Indonesian region, moreover they spread globally due to the giant magnitude of the earthquake. Indeed the anomalies still persisted with approximately magnitude of 100 nT, then gradually decreased and until return to normal values in 112 days after the earthquake.

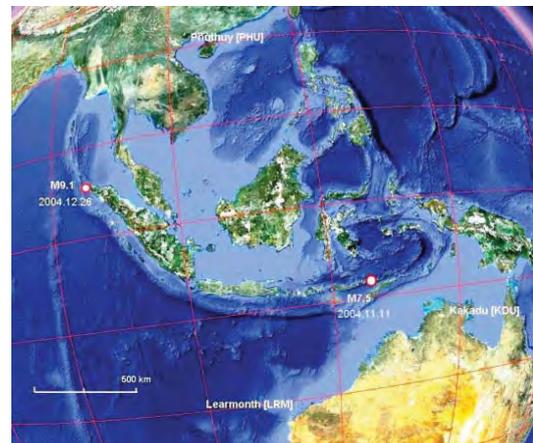

Fig. 5. Three geomagnetic observatories and the location of studied earthquake in Indonesian region: LRM, KDU, and PHU with the giant M9.1 Sumatera Earthquake on December 26th 2004 and of another M7.5 one happened before on November 11th 2004.

TABLE IV. INTENSITY OF ANOMALOUS GEOMAGNETIC SIGNALS ON LRM, KDU, AND PHU PRIOR TO THE SUMATERA EARTHQUAKE

Anomaly (nT)	Earthquake on 2004.11.11 (DOY 316) and 2004.12.26 (DOY 361)			
	DOY 295 (21/66 days before EQ)	DOY 304 (12/57 days before EQ)	DOY 313 (3/48 days before EQ)	DOY 315 (1/45 days before EQ)
LRM-KDU	Not Recorded	Not Recorded	Not Recorded	Not Recorded
LRM-PHU	46.04	61.64	253.24	286.24
KDU-PHU	Not Recorded	Not Recorded	Not Recorded	Not Recorded
Sigma Kp	14.3	25	50	56.3

#### IV. DISCUSSION

Results of study show that big earthquakes generate some anomalous geomagnetic signals prior to the day of occurrences, which can be recorded by the nearby observatories. The highest anomalies mainly in the differentiation signals between two observatories, which one of them located closest to-, and another one located most distant from-, the epicenter. It is possibly because the closest observatory recorded the highest intensity, while the most distant recorded the lowest intensity, so that the

differentiations are of greatest. However, in case of American region, TUC is the nearest to the epicenter and FRN is the farthest, therefore the differentiation signals of FRN-TUC should be the highest. Indeed those occurred more frequent in BOU-FRN signals, probably due to the location of FRN and TUC which are bounded to the epicenter by the same shoreline, while BOU is located on the high altitude (2682 m). Here BOU recorded is much less signals than other two observatories.

Anomalies in American region were less visible rather than ones in Japanese and Indonesian regions. We suggest that it was because larger distances between observatories to the epicenters, while the magnitude of earthquake is smaller. In contrast, the studied earthquake in Indonesian region is giant; therefore we observed anomalies even from rather remote observatories. The elevations of used observatories in Japanese and Indonesian regions are quite low, which one in Australia is only of 4 m above the sea level. We suggest further that observatories which are close to the sea level may more responsive to the earthquake.

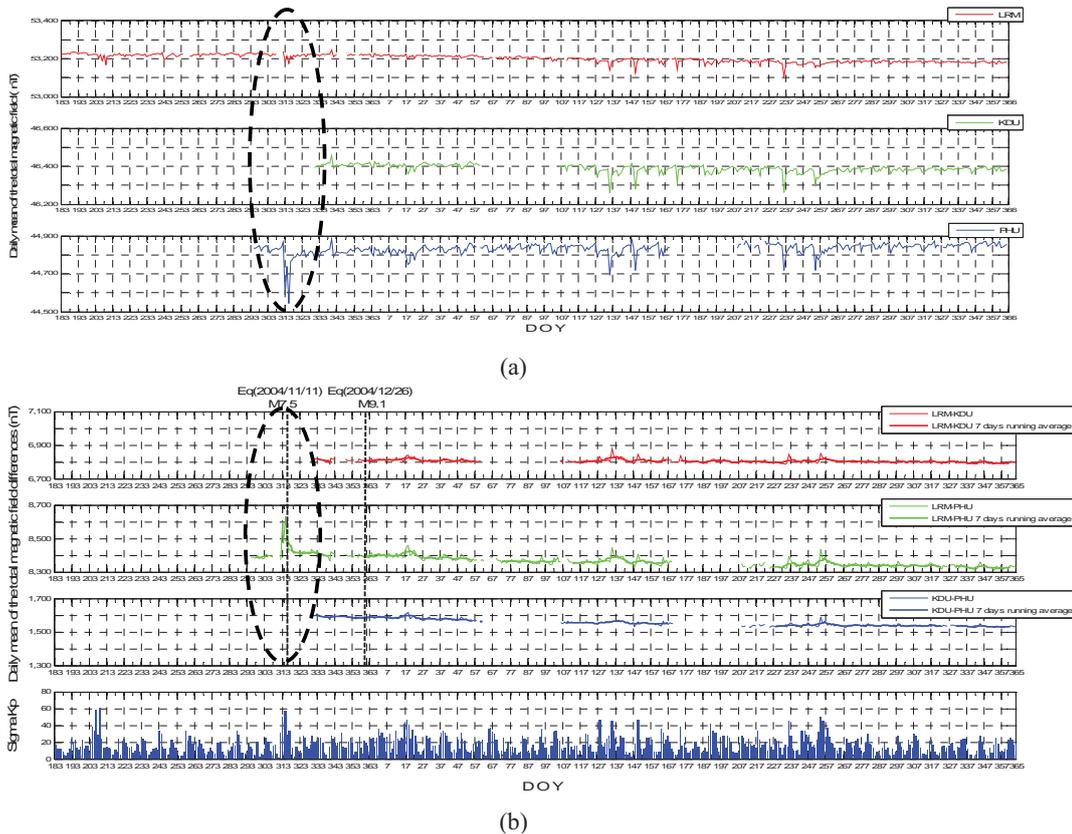

Fig. 6. Geomagnetic anomalous signal related to the M9.1 giant Sumatra Earthquake on December 26th 2004. (a) The daily mean of the total geomagnetic fields observed by three observatories which are the closest to Indonesian region (LRM, KDU, and PHU), and (b) The differentiations signals of two observatories and the moving averages, with sigma Kp values of corresponding days to evaluate the global geomagnetic conditions.

All studied regions have tectonic setting with normal fault mechanisms, which is caused by subduction of oceanic crust into continental crust. However, in American region the subducting Cocos plate is only a very small with a relatively low subduction speed of 44 mm/year, in comparison with the giant subducting Indian oceanic plate with a speed of 75 mm/year.

Further comparison to our previous study [15], we found that for other earthquakes with smaller magnitudes in Japanese region (on September 25<sup>th</sup> 2003 and September 5<sup>th</sup> 2004) anomalies were also clear. They were seen four to five times, from 99 days and 83 days prior to the earthquakes. These clear anomalies were generated due to closer distances from the epicentres to the observatories.

It is quite regret that we have no data of some important dates from the studied observatories in America and Australia, which probably have been filtered out by the national institutions who supplied the data to the INTERMAGNET, because they were quite extreme while no reasonable high sigma Kp values on the days. On the other hand, it is possible that the extreme (filtered out) data are quite valuable for seismo-geomagnetic analysis. There were many of these data losses from LRM and KDU after November 11<sup>th</sup> 2004 earthquake in Indonesia, therefore we could not analyze the most important days just before the giant Sumatera Earthquake on December 26<sup>th</sup> 2004. It will be useful to compare the recent results with data from other nearby observatories, even more to use data from Indonesian observatories for comprehensive analysis. In this case, we also found that for this giant earthquake, the sigma Kp were quite extreme. We therefore need more studies of 27 days of solar cycle, whether or not the anomalous days were on the maxima cycles (as normal geomagnetic storms phenomena, otherwise seismogenic ones). We further suggest studying the Kp cycle within quite longer time interval, e.g. 50–70 years maybe enough.

## V. CONCLUSION

We have processed geomagnetic signals and analyzed their correlations to three large magnitude earthquakes in Japanese, American, and Indonesian regions; and conclude that the geomagnetic signal processing is very valuable in searching appropriate precursors for successful earthquake predictions. Here we re-underline some important aspects:

1. Fast decreasing of geomagnetic intensities signals are showed prior to earthquakes in Japanese, American, and Indonesian regions. All observational results are back to the normal (base line) values after earthquake occurrences.
2. The highest anomalies mainly in the differentiation signals between two observatories, which one of them located closest to-, and another one located most distant from-, the epicentre.
3. The distances from the observatories to the epicentres and the magnitudes of earthquakes very affect the results,

while observatories which are close to the sea level may more responsive to the earthquake.

4. The regional tectonic setting, including size and velocity rate of subductions, may also affect the results.
5. Some missing data (which probably have been filtered out by the national institutions who supplied the data to the INTERMAGNET) during earthquake days are in fact very valuable to complete the analysis.
6. Further studies which will be very useful for Indonesian region are: (i) comparing the recent results with data from other nearby observatories even more to get data from Indonesian observatories, and (ii) studies of 27 days of solar cycle in quite longer time interval (e.g. 50–70 years) to determine whether the extreme sigma Kp values prior to the giant earthquakes are seismogenic phenomena, otherwise normal geomagnetic storms ones.

## ACKNOWLEDGMENT

This research is funded by the Indonesian Directorate of Higher Education under Hibah Penelitian Unggulan Perguruan Tinggi 2012 program entitled “Pengolahan Sinyal Seismo-Geomagnetik untuk Mitigasi Bencana Gempa Bumi Tektonik Regional di Wilayah Indonesia Timur (Seismo-Geomagnetic Signals Processing for Regional Tectonic Earthquake Hazard Mitigations of Eastern Indonesian Regions)”. The results presented in this paper rely on data collected at magnetic observatories. We thank the national institutes that support them and INTERMAGNET for promoting high standards of magnetic observatory practice ([www.intermagnet.org](http://www.intermagnet.org)). MATLAB® license number 863485 is used for data processing. TZ is alumni of Electrical Engineering Dept. of University of Indonesia (0493037152).

**Abstract**—Achievement multi-wideband with bandwidth 100 MHz of the passive antenna from a resonant frequency 4 GHz is proposed and investigated. Antenna design using two substrates. The upper layer used as an radiation element while the bottom layer is used for the feeding. The feeder of the microstrip line is connected to an electromagnetic proximity coupling with tuning stub technique and two elements of pi slot array so as to obtain multi wideband 3.25-3.35 GHz, 4.40-4.50 GHz, 4.82-4.94 GHz, 7.11-7.45 GHz (VSWR  $\leq 2$ )

**Keywords** — Ultrawideband, Bandwidth, Mikrostrip,

## I. Introduction

Today's in the world The development of telecommunications technology increasingly competitive and inovative, as an example the wireless telecommunications systems , which is in development the wireless technology requires a wide bandwidth. Of this phenomenon is very possible to created or researched antenna has a wide bandwidth with the concept of multi-frequency and wide bandwidth (multi-wideband).

The Researched of microstrip antenna has many uses slot elements type (MSA) and microstrip patch elements (MPA) with rectangles radiator especially for single elements to enhance bandwidths. Several researched has MPA technique to increase bandwidth by proximity coupling fed [1] [2]. In recent years a lot of focus design microstrip antenna to obtain multi-wideband characteristics [3] [4]. But as far as I know is still little research on MPA and MSA array configuration fed by proximity coupling using tuning stub to generate multi-wideband characteristics.

In accordance with the trend and the needed of wide bandwidth, in this research we design *Pi Slot Array Two Elements Multi Wide-band Microstrip Antenna Fed by Tuning Stub*. This study describes the incorporation of proximity coupling techniques and tuning stub techniques. The expectation from this experiments conducted to obtain a prototype microstrip antenna with multi-band characteristics, it is above two operating bandwidth of each

bandwidth >100MHz. More over from this study will support future communication systems with a terabyte capacity.

## II. Antenna Structure and Mechanism

In the process of designing pi slot microstrip patch antenna, we realized that the main parameters are important to determine in a microstrip line is the characteristic impedance ( $Z_0$ ). So that in this researched we did the simulation using impedance characteristic of  $50\Omega$  because  $50\Omega$  is the standart of microwave input impedance.

The initial stage in the design process is to find the value of the approach channel *width* of microstrip antenna ( $w$ ) with corresponding to the characteristic impedance of  $50\Omega$ . We use PCAAD software version 3.0 to do that as shown in the figure below:

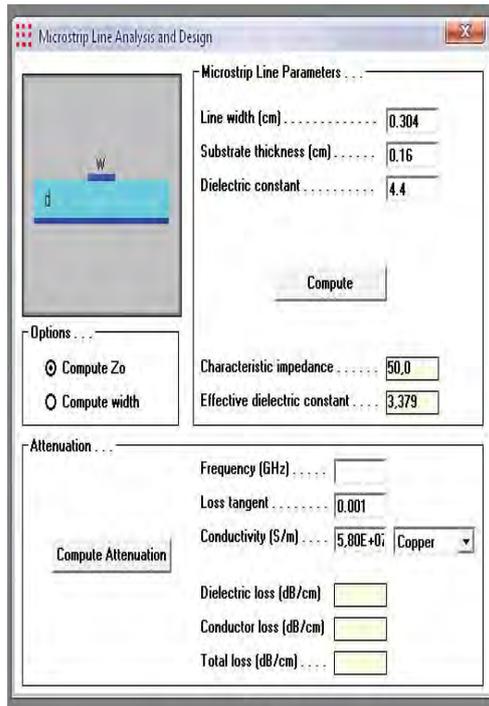

Figure 1. Simulation of line width

From the simulation results obtained PCAAD fed size using width channel (w) corresponding to the characteristic impedance of  $50 \Omega$  is equal to 0.304cm. After getting the value of (w), we look for approaches to obtain value of fed line length (l). In search of value (l) we uses a mathematical approach by first looking for value of  $\lambda_0$ ,  $\epsilon_{eff}$ , and  $\lambda_m$  according to mathematical formulas found in reference [5] that the result is obtained as follows:

$$\epsilon_{r\,eff} = 3,144825833$$

$$fc = 4GHz$$

$$\lambda_0 = 0,00125m$$

$$\lambda_m = \frac{\lambda_0}{\sqrt{\epsilon_{r\,eff}}} = 0,0070487436 \quad cm$$

$$l = \frac{\lambda_m \sqrt{\epsilon_{r\,eff}}}{2}$$

$$0,0070487436$$

After getting the numbers from these approaches as well as the length and width of the fed line channel, then the numbers are included as a reference in the next step of antenna design using the simulator. In the design process we use a simulator HFSS version 10 (High Frequency Simulator Sigh) the materials used FR4 substrate with a thickness of 0.16 mm and dielectric constant values  $\epsilon_r = 4.4$ , and copper (cu) for fed line and patch pi slot.

But in the simulation phase, the length and width numbers of fed line that have been sought was not exactly produce bandwidths that match to the resonance frequency of 4 GHz. Thus, in the simulation process the numbers from PCAAD and

mathematical formulas is altered to get the size of antenna according to the resonance frequency of 4 GHz. After the size of antenna is changed, eventually we get the appropriate size for the antenna to the resonant frequency 4 GHz with multi wide bandwidth (5 MHz) and the value of reflection coefficient is  $\leq -10$  dB and transmission coefficient is  $\leq 2$  that the design fix in the figure below :

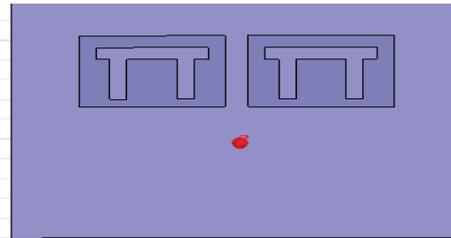

Figure 2. Antenna Dimension

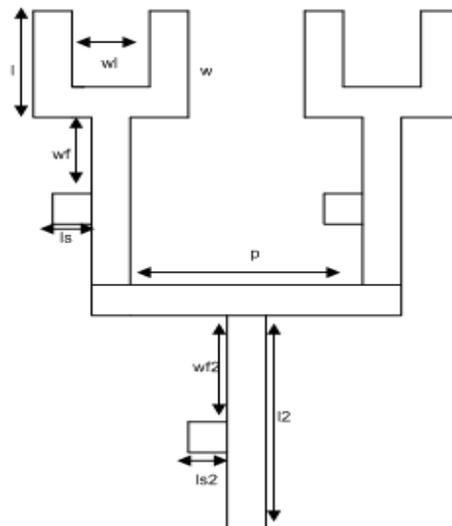

Figure 3. Feeder Antenna Microstrip with tuning stub (wl= 0,9cm. l=1cm. wf= 0,6cm. ls=0,5cm, wf2=1,9 cm. l2=2.5cm. ls2=0,5cm. p=3,3cm)

### III. Simulation Results and Analysis

From the simulation results using the antenna size as shown in figure 2 and (3) we found that the antenna has four operating bandwidths are at 3.25GHz - 3.35 GHz(100 MHz Bandwidth ), 4.40 GHz - 4.50 GHz(100 MHz Bandwidth ), 4.82GHz - 4.94 GHz(120 MHz Bandwidth ) , 7.11GHz - 7.45 GHz(340 MHz Bandwidth ) then  $VSWR \leq 2$  with a resonance frequency of 4 GHz. This report can be seen in figure 4 which intersected at -10dB return loss. From this simulation we show that the best wide bandwidth is obtained at the intersection of at most 340 MHz starting from frequency 7.11GHz - 7.45GHz. From the graph results of these simulations we can be

seen that the best return loss for frequency 7.11 GHz have a return loss value of -44.11 dB.

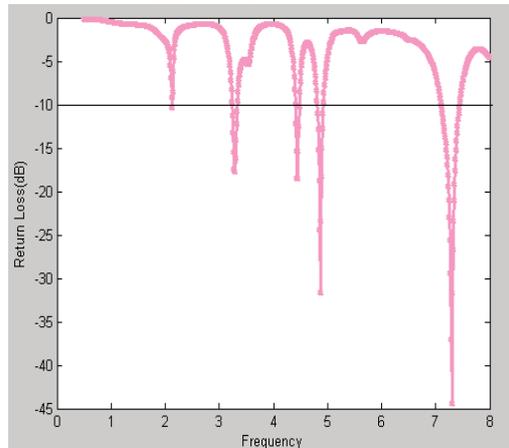

Figure 4. Return loss

In addition to the comparison of bandwidth and return loss, in the simulation we can also see the comparisons between frequencies with VSWR as shown in figure 5 where the value of VSWR  $\leq 2$  is starting from frequency 3.25GHz- 3.35GHz, 4.40GHz – 4.50 GHz, 4.82GHz - 4.94GHz, 7.11GHz – 7.45 GHz with the best VSWR value is 1.3 at a frequency of 7.16GHz.

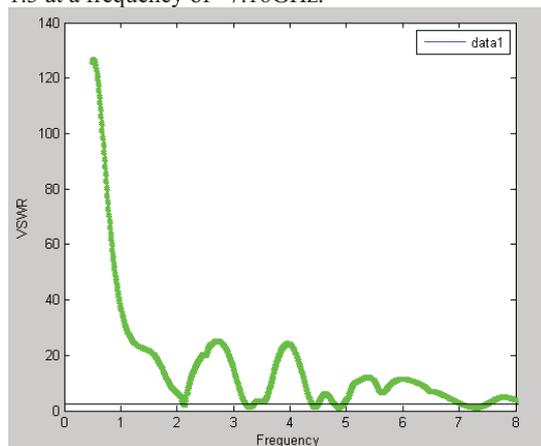

Figure 5. VSWR

Table1. sample of input impedance 50Ω with the frequency operation

No	Frequency	Z <sub>in</sub> Real(Ω)	Z <sub>in</sub> Imaginer(Ω)
1	3.230000	50.910372	42.209039
2	4.440000	50.678324	11.999867
3	7.270000	50.774246	-5.266951
4	7.280000	50.496741	-3.345230
5	7.290000	50.266414	-1.392474
6	7.300000	50.086306	0.592970
7	7.350000	50.0516	13.291308

Input impedance of this experiment is expected to get 50 Ω. From the simulation results in the frequency range from 3.25 GHz – 3.35 GHz, 4.40 GHz – 4.50 GHz, 4.82 GHz - 4.94 GHz, 7.11GHz – 7.45 GHz input impedance obtained were close to the -5 and +5 from the value of 50 Ω. The sample of frequency with 50 Ω input impedance is show in table 1.

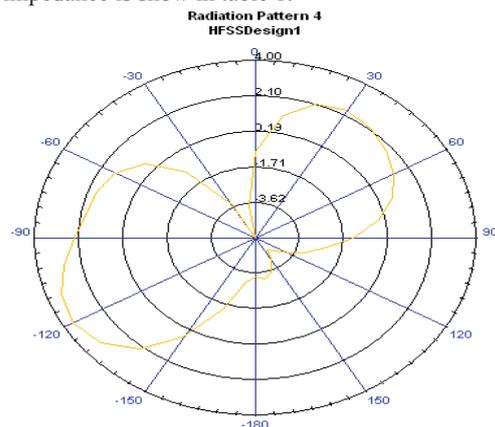

Figure 6. Radiation Patern

The resulting radiation pattern of the antenna design is lead to angle 0°-120° and -30°(-150°). The result of radiation is show in figure 6.

#### IV. Conclusion

Microstrip patch pi slot two element array antenna has been designed with 4 GHz resonance frequency using proximity coupling techniques and multi-tuning stub. The antenna has designed until simulation have frequency operation at 3.25GHz – 3.35GHz , 4.40GHz – 4.50 GHz, 4.82GHz - 4.94GHz, 7.11GHz - 7.45GHz. The antenna have a multi- wide bandwidth with the reflection coefficient  $\leq -10$  and VSWR  $\leq 2$ . This antenna have four bandwidth  $\geq 100$  MHz so that the antenna have multi-wideband characteristics.

**Abstract**— This paper presents three-dimensional (3D) fluid structure interaction (FSI) technique; using Mesh based Parallel Code Coupling Interface (MpCCI), for the visualization of wire sweep during encapsulation. The effects of number of mold cavity outlet vents on the melt flow behavior, wire sweep, and von Mises stress distributions, are mainly studied. 3D model of mold and wire were designed using GAMBIT, simulated fluid flow and structural using FLUENT and ABAQUS. Three types of mold cavity simple model namely Type D1, Type D2 and Type D3 with different outlet vents were studied to analyze wire sweep deformation. Polymer rheology model with curing effect (Castro-Macosko model) have been used in the fluid flow modeling and Volume of Fluid (VOF) technique was applied for melt front tracking for the Epoxy Molding Compound (EMC). In the present study, Type D3 with minimum outlet vent area of mold cavity shows the highest deformation of wire and highest stress distributions. The numerical results of wire deformation pattern were compared with the analytical method and found in good conformity. The strength of MpCCI software in handling FSI problems is proved to be excellent. This present work is expected to be the reference and guideline for microelectronics industry.

**Keywords**— Fluid Structure Interaction, Wire Sweep, MpCCI, Castro-Macosko model, Epoxy Molding Compound (EMC), Volume of Fluid (VOF).

## I. INTRODUCTION

Nowadays, the electronics industry could offer their product in a compact size but also give more functionality, better performance and lower cost. It is widely used in applications including computing, communications, biomedical, automotive, military, and aerospace. They must operate in varying temperature and humidity environments, exposure to moisture and mechanical stresses can be highly detrimental to electronic devices and may lead to device failures [1]. Therefore, it is essential that the electronic devices be packaged for protection from their intended environment. The design, fabrication and encapsulation of the package has become increasingly complex and challenging owing to increased number of components and the need for miniaturization [2]. The major objectives of electronics devices encapsulation are to protect of the device from mechanical and chemical hazards, and thermal path for heat dissipation [1].

Wire bonding is the one principal ways of connecting the silicon device to the lead frame in molded plastic packaging of

encapsulation process [3]. Typical wire bonding process uses gold or aluminum wire to connect the die pads with the leadframe [4]. New packages methods, such as Flip Chip, use Lead-Tin solder bump as interconnection between die and substrates [1]. The purpose of this process is to establish electrical interconnections for signal and power transfer.

During the encapsulation of microelectronic chips by the transfer molding process, the fragile gold wire bonds, which provide electrical connection from the chip to the leadframe, are subjected to flow stresses from the molding compound [5]. The flow stress can cause the leadframe and the wire bond to permanently deform from their original geometry [6]. If the displacement of a bonding wire is too large, it can result in a package failure; either short circuits due to contact between adjacent wires or open circuit due to a broken wire [7]. Even if the displacement is not so severe, wire deformation can result in deteriorated electrical and mechanical performance of the device, which will shorten its lifetime [8]. Hence, it's important to minimize the wire-sweep deformation during encapsulation.

The technique time-dependence and the two-phase aspects of the flow, especially the propagation of the resin front in the mold, and the effect of its impact with the wires, and by introducing the time-dependent material, geometric, and loading variations that exist in the actual phenomenon along wires was introduced [9].

In fact, the wire deflection during encapsulation is a typical fluid-structure interaction (FSI) problem. The drag force resulted from the fluid flow caused the wire sweep or normally known as the wire deformation. The use of finite volume method (FVM) for the flow analysis and the finite-element method (FEM) for the structure analysis, coupled with MpCCI was reported in various works [10-12]. However, as far as the authors are conscious, the use of FSI has not been reported so far in the wire sweep problems.

In the present study, 3D computational analysis is used to predict the wire sweep problems in the simple model of encapsulation process. The FVM-based (FLUENT) and FEM-based (ABAQUS) software with MpCCI coupling software are utilized as tools to perform the FSI for the virtual model of the package. The Castro-Macosko model is used to describe the polymer rheology with curing effect in the viscosity behavior of the epoxy molding compound (EMC). The program is

written in C language has been employed in UDF to calculate the curing kinetics of EMC. The volume of fluid (VOF) technique is also applied to track the flow front of the EMC. Wire sweep profiles are analyzed and presented by ABAQUS. The EMC flow field and wire sweep phenomena can be visualized simultaneously through this FSI simulation. The simulation results are also compared with the analytical results available in literature and found in good agreement.

## II. MATHEMATICAL MODEL

### A. Fluid Flow Analysis

In the simulation model, the encapsulation process material and air are assumed incompressible and the governing equations describing the fluid flow are conservation of mass, conservation of momentum, and conservation of energy [13]. FLUENT normally solves the governing equations using Cartesian spatial coordinates and velocity components.

The conservation of mass or continuity equation is:

$$\frac{\partial \rho}{\partial t} + \frac{\partial}{\partial x_i}(\rho u_i) = 0 \quad (1)$$

Eq. (1) is the general form of the mass conservation equation and is valid for incompressible and compressible flows. Conservation of momentum in  $i^{\text{th}}$  direction in an inertial (non accelerating) reference frame is described by:

$$\frac{\partial}{\partial t}(\rho u_i) + \frac{\partial}{\partial x_i}(\rho u_i u_j) = -\frac{\partial P}{\partial x_i} + \frac{\partial \tau_{ij}}{\partial x_j} + \rho g_i + F_i \quad (2)$$

where,  $P$  is the static pressure,  $\tau_{ij}$  is the viscous stress tensor and  $g_i$  and  $F_i$  are the gravitational acceleration and external body force in the  $i$  direction, respectively.

The energy equation cast in terms of  $h$  (static enthalpy) can be written as,

$$\frac{\partial}{\partial t}(\rho h) + \frac{\partial}{\partial x_i}(\rho u_i h) = \frac{\partial}{\partial x_j} \left( k \frac{\partial T}{\partial x_j} \right) + \eta \dot{\gamma} \quad (3)$$

where  $T$  is the temperature,  $k$  is the thermal conductivity,  $\eta$  is the viscosity and  $\dot{\gamma}$  is the shear rate. The molding compound was assumed to be a generalized Newtonian fluid (GNF).

Several models have been used to predict the relationship between viscosity and the degree of polymerization. The Castro–Macosko model has been applied in encapsulation process [14] and is selected to use in this simulation. It can be described as follows:

$$\mu(T, \dot{\gamma}) = \frac{\mu_0(T)}{1 + \left(\frac{\mu_0(T)\dot{\gamma}}{\tau^*}\right)^{1-n}} \left(\frac{\alpha_g}{\alpha_g - \alpha}\right)^{C_1 + C_2 \alpha} \quad (4)$$

where  $n$  is the power law index,  $\mu_0$  the zero shear rate viscosity,  $\tau^*$  is the parameter that describes the transition region between zero shear rates and the power law region of the viscosity curve,  $\dot{\gamma}$  is the shear rate,  $\alpha$  is the conversion,  $\alpha_g$

is the conversion at the gel point and  $C_1$  and  $C_2$  are fitting constants.

$$\mu_o(T) = B \exp\left(\frac{T_b}{T}\right) \quad (5)$$

$B$  is an exponential-fitted constant and  $T_b$  is a temperature fitted-constant. In addition, Kamal curing kinetics is coupled together with Castro–Macosko model. This model predicts the rate of chemical conversion of the compound as follows:

$$\frac{d\alpha}{dt} = (k_1 + k_2 \alpha^{m_1})(1 - \alpha)^{m_2} \quad (6)$$

$$k_1 = A_1 \exp\left(-\frac{E_1}{T}\right) \quad (7)$$

and

$$k_2 = A_2 \exp\left(-\frac{E_2}{T}\right) \quad (8)$$

where  $\alpha$  is the conversion,  $A_1$  and  $A_2$  are the Arrhenius pre-exponential factors,  $E_1$  and  $E_2$  are the activation energies,  $m_1$  and  $m_2$  are the reaction orders and  $T$  is the absolute temperature. TABLE I summarized the material properties of the EMC considered in the current study.

TABLE I. EMC MATERIAL PROPERTIES [14].

	Parameter	Value	Unit
Castro Macosko Model	$\alpha_g$	0.17	-
	$B$	0.000381	Kg/m/s
	$T_b$	5230	K
	$n$	0.7773	-
	$\tau$	0.0001	N/m <sup>2</sup>
	$C_1$	1.03	-
	$C_2$	1.50	-
	Curing Kinetics	$m_1$	1.21
$m_2$		1.57	-
$A_1$		33530	1/s
$A_2$		30540000	1/s
$E_1$		7161	K
$E_2$		8589	K
$\alpha$		0.05	-
Density		$\rho$	2000
Specific Heat	$C_p$	1079	J/Kg-K
Thermal Conductivity	-	0.97	W/m-K
Reference Temperature	$T$	298	K

The basic idea of the VOF scheme is to locate and evolve the distribution of, say, the liquid phase by assigning for each cell in the computational grid a scalar,  $f$ , which specifies the fraction of the cell's volume occupied by liquid. Thus,  $f$  takes the value of 1 ( $f = 1$ ) in cell which contains only resin, the value 0 ( $f = 0$ ) in cells which are void of resin, and a value between 0 and 1 ( $0 < f < 1$ ) in “interface” cells or referred as the resin melt front. The equation of melt front over time is governed by the following transport equation:

$$\frac{\partial u}{\partial t} = \frac{\partial f}{\partial t} + \nabla \cdot (uf) = 0 \quad (9)$$

### B. Wire Sweep Analysis

To calculate the drag force exerted on the wires by the resin flow, the value of velocities and viscosities have to be determined from the mold filling simulation. The effect of wire density on the resin flow is considered according to their occupied volume in the three dimensional filling simulation. Then, the Lamb's model is utilized to calculate the drag force as follows [5]:

$$D = \frac{C_D \rho U^2 d}{2} \quad (10)$$

where  $D$  is the drag force per unit length,  $\rho$  is the fluid density,  $U$  is the undistributed upstream velocity,  $d$  is the wire diameter and  $C_D$  is the drag coefficient, which can be written as:

$$C_D = \frac{8\pi}{Re[2.002 - \ln(Re)]} \quad (11)$$

where  $Re$  is the Reynold number, which can be defined as:

$$Re = \frac{\rho u d}{\eta} \quad (12)$$

where  $\eta$  is the fluid viscosity.

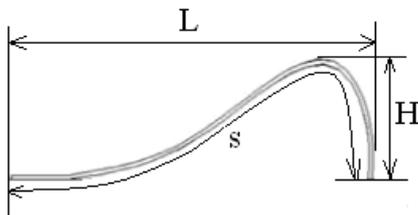

Fig.1: Curved profile of wire.

Wire sweep deflection  $\delta$  can be written as [8]:

$$\delta_{max} = S * D \left( f_B \left( \frac{H}{L} \right) \frac{H^3}{EI} + f_T \left( \frac{H}{L} \right) \frac{L^3}{GI_p} \right) \quad (13)$$

where  $S$  is the length of the wire bond,  $f_B$  is the bending geometry factor for the bending moment,  $f_T$  is the twisting geometry factor for the twisting moment,  $H$  is the height of wire,  $L$  is the length of wire span,  $G$  is the shear modulus of wire,  $E$  is the elastic modulus of wire,  $I$  is the momentum of inertia of the wire,  $I_p$  is the polar momentum of inertia of the wire.

The wire profile is shown in Fig. 1, where  $H$  has a length  $7.3 \times 10^{-4}$  m, the span of wire has a length  $L = 2.2 \times 10^{-3}$  m, and a square cross section of wire is 1 mil x 1 mil (i.e.,  $2.5 \times 10^{-5}$  m x  $2.5 \times 10^{-5}$  m). A square cross section was chosen for this case to simplify the derivation of the analytical solution.

## III. NUMERICAL SIMULATION

### A. Simulation Model and Boundary Conditions in FLUENT

The volume of fluid (VOF) model in FLUENT 6.3.26 is utilized to simulate the process [15]. Outlet vent types are set at different parameters, as shown in TABLE II. In the VOF model, a single set of momentum equations is shared by the fluids, and the volume fraction of each of the fluids in each computational cell is tracked throughout the domain [15]. Air and EMC (EME 6300HN Dynamic Modes) are defined as the phases in the analysis [15]. Implicit solution and time dependent formulation are applied for the volume fraction in every time step. The volume fraction of the encapsulation material is defined as one and zero for air phase.

Besides, viscosity Castro Macosko model and VOF techniques are applied to track the melt front. The mold chip boundary condition and its package model used in the present study are shown in Fig. 2 and 3 respectively. The dimension of mold is  $2.75 \times 1.5 \times 1$  mm. The model is created by using GAMBIT software and average 3500 tetrahedral elements are generated for simulation (Fig 4). Three types of the outlet vent namely Type D1, Type D2, and Type D3 as illustrated in Fig. 3 are considered for simulation. The boundary and initial conditions are used in the calculation are as follows [15]:

- (a) On wall :  $u = v = w = 0; T = T_w, \frac{\partial p}{\partial n} = 0$
- (b) On centre line :  $\frac{\partial u}{\partial z} = \frac{\partial v}{\partial z} = \frac{\partial w}{\partial z} = \frac{\partial T}{\partial z} = 0$
- (c) On melt front :  $p = 0$
- (d) At inlet :  $u = u_{in}(x,y,z); T = T_{in}$

Fig. 3. Models of package.

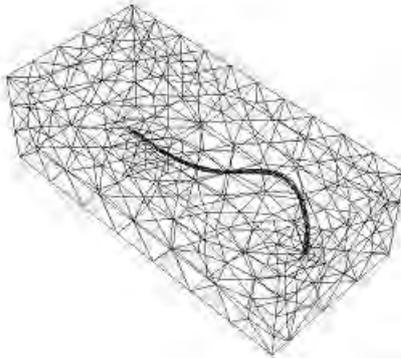

Fig. 4. Meshed model for FLUENT analysis of two outlet vents.

TABLE II. SPESIFICATION OF OUTLET VENT

Type of Mold	Number of outlet vent	Area of outlet vent [mm <sup>2</sup> ]
D1	2	0.04
D2	1	0.02
D3	1	0.01

This research introduce of a new three-dimensional computational technique for prediction of wire sweep in encapsulation process. Wire sweep is the deflection and deformation of wire loop during the encapsulant flow.

#### B. The computational domain and boundary conditions in ABAQUS

Commercial FEM based software; ABAQUS is use in this study to calculate the wire deformation. The structures of the wires are imported from GAMBIT in ACIS '.sat' format. The flow direction is normal to the un-deformed wire axis, and the properties are approximately the same as those used in [11]. The elastic modulus of wire is  $E = 17.73$  GPa; density,  $\rho = 19300$  kg/m<sup>3</sup>; Poisson's ratio,  $\nu = 0.42$ ; and reference temperature,  $T = 175^\circ\text{C}$ . The wire bond is divided into 291 elements as shown in Fig. 5. The shape of the wire also classified as typical J loop wire bond [10]. The ball bond boundary conditions of wire are set as fixed in ABAQUS as shown in Fig. 5.

#### C. Mesh based Parallel Coupling Code Interface (MpCCI)

MpCCI is a software library which enables the exchange of data defined on meshes of two or more simulation codes in the coupling region. Since the meshes need not match point by point, MpCCI performs an interpolation and, in case of parallel codes, keeps track of the distribution of the domains

onto different processes [16]. In this way, the intricate details of the data exchange are hidden behind the concise interface of MpCCI. As a consequence, the simulation codes themselves are changed only moderately when they are prepared for coupling via MpCCI (Fig. 6).

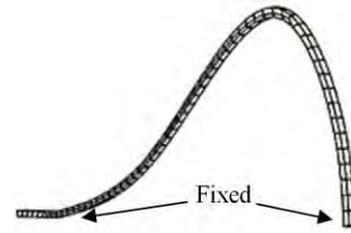

Fig. 5. Boundary condition for ABAQUS analysis

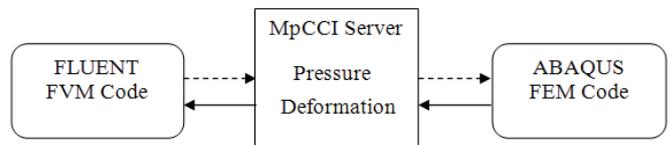

Fig. 6. FLUENT and ABAQUS coupling simulation process [16].

#### IV. RESULT AND DISCUSSION

The wire deformation pattern and the EMC volume is shown in Fig. 7, whereas Fig. 8 to describe of von Misses and displacement of wire in ABAQUS for all types.

The amounts of drag force and wire displacement of each type are shown in Fig. 9. Type D3 shows highest displacement of wire at highest drag force and minimum size of outlet vent.

The comparison of wire displacement of simulation and analytical results of Type D1, D2 and D3 are shown in Fig. 10. The wire deflection is validated with the analytical result that is calculated by using Eq. (13) as proposed by [8]. In the analytical calculation, the values of  $f_B$  and  $f_T$  used are 0.135 and 0.00215 respectively for  $H/L = 0.332$  [8].

Displacement error of analytical and simulation results at 3 s filling time of Type D1, Type D2 and Type D3 are 3.7%, 9.8% and 5.4 % respectively.

#### V. CONGCLUTION

The analysis of wire deformation of encapsulation process with the specific purpose of studying the effects of outlet vent type arrangement is presented. The parameter such as viscosity and curing effect that control the mould quality are also incorporated. Three different arrangements of outlet vent of mould have been investigated. Size, position and type of outlet vent were found affected the encapsulation result in electronics packaging process.

The IC simple packages encapsulation process was investigated numerically using Gambit and FLUENT of FVM

based simulation study. The three dimensional simple IC package was simulated to study the flow visualization and wire sweep in different number of outlet vent of the process.

Three types outlet vent of mold were examined to distinguish the wire sweep of wire bonding and compare with the analytical results and demonstrated that the methodology works very well. From simulation results, the Type D3 of outlet vent showed a highest wire sweep deformation in smaller outlet vent than the Type D1 and D2 of outlet vent. Thus, the strength of MpCCI software in handling wire sweep in encapsulation process is proved to be excellent.

**Abstract**—This study aimed to determine the effects of Gauss doping profile on electric potential of p-n diode. This effect is studied by simulating PN diodes at equilibrium condition with differences in doping fall-off constant ( $dfc$ ) using MATLAB and COMSOL software. According to the simulation results, it concluded that p-n diode with different Gaussian doping profile, will produce similar built-in voltage ( $V_{Gbi}$ ). But, each p-n diode with different Gaussian doping profile, has different maximum junction voltage ( $V_{jmax}$ ) and minimum junction voltage ( $V_{jmin}$ ). These junction voltages have strong correlation with  $dfc$ . We propose an equation of built-in voltage for Gauss Doping Profile, and also equations of  $V_{jmax}$  and  $V_{jmin}$ .

**Keywords**— Gauss Doping Profile, p-n Diode, Electric Potential.

## I. INTRODUCTION

The study about Gauss doping profile has been done by several researchers. In 1991, K. Suzuki investigated base doping profile, i.e., box, Gaussian, and exponential, which gives the minimum base transit time [1]. He stated that the exponential profile always gives the minimum base transit time at any base width.

J.A. Croon, *et al.* examined the influence of the doping profile on threshold voltage mismatch in 2002 [2]. They compared the calculated threshold voltage mismatch contributions for the case of the Gaussian and uniform profiles. They stated that by using the Gaussian profile, the predicted threshold voltage mismatch due to doping fluctuations is 20-35% smaller and the threshold voltage mismatch due to oxide capacitance fluctuations is 10-25% smaller. The other researchers, G. Zhang, Z. Shao, and K. Zhou proposed a novel surface potential function perpendicular to the channel for an FD SOI MOSFET with vertical Gauss doping profile in 2008 [3].

In 2009, J. Li *et al.* examined A model of Gauss-doped base 4H-SiC bipolar junction transistor (BJT) is simulated by two dimensional device simulator ISE [4]. The result shows Gaussian-doped base can effectively improve the current gain from 16.65 to 44.49, and decrease the output resistance. The

Base with Gaussian-doped SiC BJT also enhance the small signal AC performance.

Sarvesh Dubey, Pramod Kumar Tiwari, and S. Jit in 2010 proposed a two-dimensional 2D model for the threshold voltage of the short-channel double-gate (DG) metal-oxide-semiconductor field-effect transistors MOSFETs with a vertical Gaussian-like doping profile [5]. It is shown that the threshold voltage of a DG MOSFET can be well controlled by controlling only the profile parameters maintaining other device parameters unchanged. The model has been validated by comparing our results with the simulation data obtained from the ATLAS™ simulation software.

This research aims to study the effect of Gauss Doping Profile (GDP) on built-in voltage ( $V_{Gbi}$ ) and also at p-n junction under equilibrium condition with different doping fall-off constant. Here we simulate five GDP of p-n diodes, i.e., GDP 1 with  $dfc = 0.46599 \mu\text{m}$ ; GDP 2 with  $dfc = 0.37279 \mu\text{m}$ ; GDP 3 with  $dfc = 0.27959 \mu\text{m}$ ; GDP 4 with  $dfc = 0.18640 \mu\text{m}$ ; GDP 5 with  $dfc = 0.046599 \mu\text{m}$ .

## II. THEORY

A p-n diode is a two-terminal device. When the impurity concentration in a semiconductor changes abruptly from acceptor impurities  $N_A$  to donor impurities  $N_D$ , one obtains an abrupt junction. In particular, if  $N_A \gg N_D$  (or vice versa), one obtains a one-sided abrupt p<sup>+</sup>-n (or n<sup>+</sup>-p) junction [6]. The built-in potential  $V_{Abi}$ , and diffusion potential for non degenerate semiconductor, are equal to

$$V_{Abi} \approx \frac{kT}{q} \ln \left( \frac{N_D N_A}{n_i^2} \right), \quad (1)$$

$$V(x) = -\frac{q N_A (x + W_{Dp})^2}{2\epsilon_s}, \quad \text{for } W_{Dp} \leq x \leq 0 \quad (2)$$

$$V(x) = V(0) + \frac{q N_D}{\epsilon_s} \left( W_{Dn} - \frac{x}{2} \right) x, \quad \text{for } 0 \leq x \leq W_{Dn} \quad (3)$$

where

$$W_{Dp} = \sqrt{\frac{2\epsilon_s V_{bi} N_D}{q N_A (N_A + N_D)}} \quad (4)$$

$$W_{Dn} = \sqrt{\frac{2\epsilon_s V_{bi} N_A}{q N_D (N_A + N_D)}} \quad (5)$$

The p-type doping of the diode can be accomplished by implantation or diffusion of acceptor atoms. The resulting profile from these two steps is often approximated with a Gauss function. In addition, the transition between the n-type doped substrate and the lower doped n-type epitaxial layer can also be approximated with a Gauss function, because the dopants diffuse from the highly doped substrate during the high temperature step of the epitaxial growth [7]. The Gauss function defined by

$$G_f(x, y, x_1, y_1) = \begin{cases} \exp\left(-\frac{(x-x_1)^2}{dfc}\right) \exp\left(-\frac{(y-y_1)^2}{dfc}\right) & x > x_1, y > y_1 \\ \exp\left(-\frac{(x-x_1)^2}{dfc}\right) & x > x_1, y \leq y_1 \\ \exp\left(-\frac{(y-y_1)^2}{dfc}\right) & x \leq x_1, y > y_1 \\ 1 & x \leq x_1, y \leq y_1 \end{cases} \quad (6)$$

### III. SIMULATION PROCEDURE

We simulate the doping concentration of five GDP of p-n diodes, i.e., GDP 1 with  $dfc = 0.46599 \mu\text{m}$ ; GDP 2 with  $dfc = 0.37279 \mu\text{m}$ ; GDP 3 with  $dfc = 0.27959 \mu\text{m}$ ; GDP 4 with  $dfc = 0.18640 \mu\text{m}$ ; GDP 5 with  $dfc = 0.046599 \mu\text{m}$  using equations (7), (8) and (9). In this study, the p-n diodes have p-type doping  $N_A$  ( $1 \times 10^{18}$ ;  $1 \times 10^{17}$ ;  $1 \times 10^{16}$ ;  $1 \times 10^{15}$ )  $\text{cm}^{-3}$  and n-type doping  $N_D$  ( $1 \times 10^{16}$ ;  $1 \times 10^{15}$ ;  $1 \times 10^{14}$ ;  $1 \times 10^{13}$ )  $\text{cm}^{-3}$ . Here, we set  $N_A$  is 100 times of  $N_D$ . The diodes have different doping fall-off constant ( $dfc$ ) in accordance with Gauss function. The involved parameters are listed in Table I. The relationship between GDP,  $N_A$  and built-in voltage of p-n diode is determined by MATLAB.

Subsequently, we analyzed the result to find the relationship between  $dfc$  with built-in potential ( $V_{Gbi}$ ), and also with maximum junction voltage ( $V_{jmax}$ ) and minimum junction voltage ( $V_{jmin}$ ). The research conducted by means of

simulation of p-n diodes with Gauss doping profile (GDP) using COMSOL. The last step was to determine conclusions obtained from the analysis.

TABLE I. DEFINITIONS AND DESCRIPTIONS OF PARAMETERS

Parameter	Description
$N$	Concentration of free electron ( $\text{cm}^{-3}$ )
$P$	Concentration of free hole ( $\text{cm}^{-3}$ )
$N_A$	Maximum p-type doping ( $\text{cm}^{-3}$ )
$N_D$	Maximum n-type doping ( $\text{cm}^{-3}$ )
$n_i$	Intrinsic concentration for Si = $1.46 \times 10^{10} \text{ cm}^{-3}$
$N$	Doping concentration
$W_p$	Maximum p-type doping thickness ( $\mu\text{m}$ )
$V_{Abi}, V_{Gbi}$	Abrupt built-in potential (V), Gauss built-in potential (V)
$W_{Dp}$	Depletion width in n-type material (cm)
$W_{Dn}$	Depletion width in p-type material (cm)
$V(x)$	Electric Potential (V) at depth $x$
$\epsilon_s$	Relative permittivity for Si = 11.8
$ju$	Junction depth = $-2 \mu\text{m}$
$y_1$	Diode dimension = $7 \mu\text{m}$
$x_1$	Diode dimension = $5 \mu\text{m}$
$ac$	Anode dimension = $2 \mu\text{m}$
$dfc$	Doping fall-off constant ( $\mu\text{m}$ )
$k$	Boltzmann's constant = $1.3 \times 10^{-23} \text{ J/K}$
$T$	Room temperature = $300 \text{ K}$
$q$	Elementary charge = $1.602 \times 10^{-19} \text{ C}$
$V_{jmax}$	Maximum junction voltage (V)
$V_{jmin}$	Minimum junction voltage (V)
$G_f$	Gauss function

### IV. RESULT AND DISCUSSION

Based on (6), the Gauss function is depicted in Fig. 1 using (7) and (8).

$$dfc = -(ju-wp) / \text{sqrt}(-\log(N_D/N_A)) \quad (7)$$

$$y = \exp(-((x-wp)/dfc)^2) \times (x < wp) + 1 \times (x \geq wp) \quad (8)$$

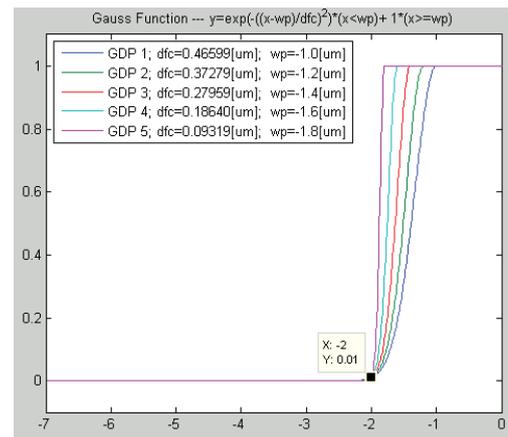

Fig. 1. Gauss Function.

As illustrated in Fig. 1, the junction is set at  $2 \mu\text{m}$  due to  $N$  must be zero here. Equation (9) is used to simulate the GDP in 3-D as shown in Fig. 2 - 6.

$$\begin{aligned}
 N = & ((N_D - N_A \times \exp(-((y-wp)/dfc)^2)) \times (y < wp) \\
 & + (-N_A \times (y \geq wp))) \times (x < ac) \\
 & + ((N_D - N_A \times \exp(-((y-wp)/dfc)^2)) \\
 & \times \exp(-((x-ac)/dfc)^2)) \times (y < wp) \\
 & + (N_D - N_A \times \exp(-((x-ac)/dfc)^2)) \\
 & \times (y \geq wp) \times (x \geq ac)
 \end{aligned}
 \tag{9}$$

The electric potential at thermal equilibrium for GDP 1 of p-n Diodes are depicted in Fig. 7 - 10. The simulation shows that p- region has lower voltage than n-region. In Table II we tabulated built-in voltage ( $V_{Gbi}$ ) of p-n diode using GDP 1, GDP 2, GDP 3, GDP 4, and GDP 5.

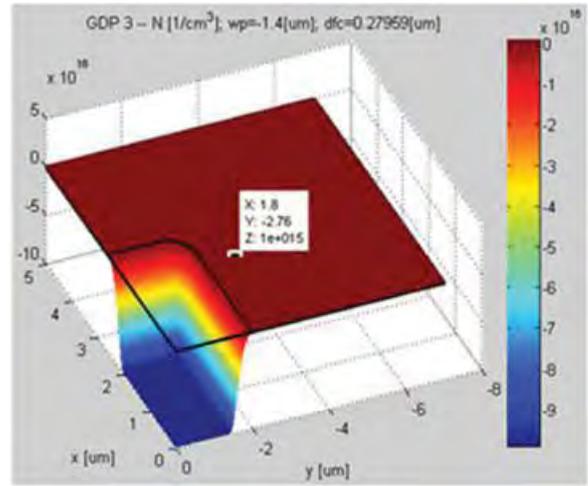

Fig. 4. p-n Diode doping concentration with  $N_A = 1 \times 10^{17} \text{ cm}^{-3}$  and  $N_D = 1 \times 10^{15} \text{ cm}^{-3}$  using GDP 3

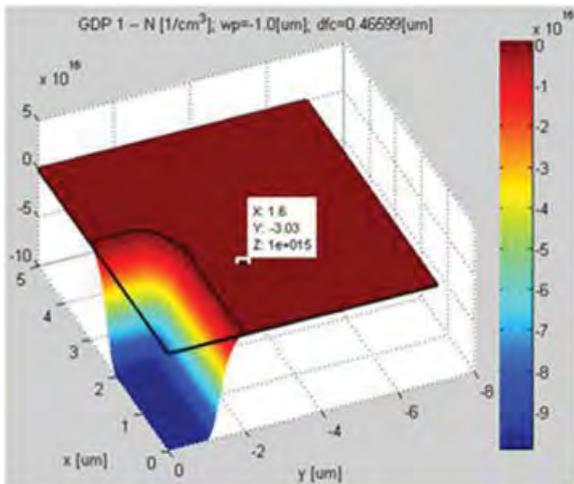

Fig. 2. p-n Diode doping concentration with  $N_A = 1 \times 10^{17} \text{ cm}^{-3}$  and  $N_D = 1 \times 10^{15} \text{ cm}^{-3}$  using GDP 1

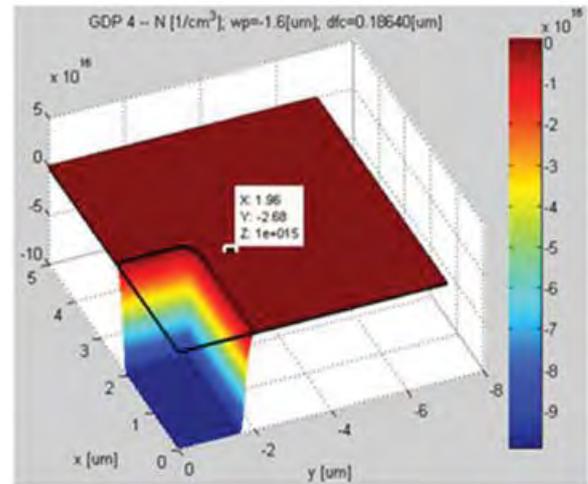

Fig. 5. p-n Diode doping concentration with  $N_A = 1 \times 10^{17} \text{ cm}^{-3}$  and  $N_D = 1 \times 10^{15} \text{ cm}^{-3}$  using GDP 4

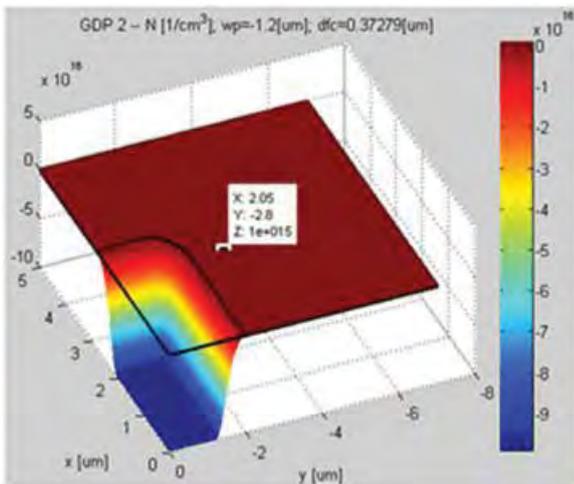

Fig. 3. p-n Diode doping concentration with  $N_A = 1 \times 10^{17} \text{ cm}^{-3}$  and  $N_D = 1 \times 10^{15} \text{ cm}^{-3}$  using GDP 2

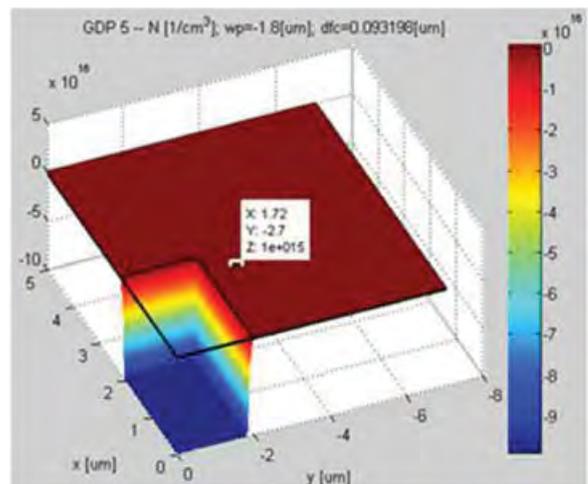

Fig. 6. p-n Diode doping concentration with  $N_A = 1 \times 10^{17} \text{ cm}^{-3}$  and  $N_D = 1 \times 10^{15} \text{ cm}^{-3}$  using GDP 5

TABLE II. GAUSS DOPING PROFILE BUILT-IN VOLTAGE ( $V_{Gbi}$ )

GDP	$dfc$	$N_1$	$N_2$	$N_3$	$N_4$
GDP 1	0.465990	0.813 V	0.695 V	0.575 V	0.456 V
GDP 2	0.372790	0.813 V	0.695 V	0.575 V	0.456 V
GDP 3	0.279590	0.813 V	0.695 V	0.575 V	0.456 V
GDP 4	0.186400	0.813 V	0.695 V	0.575 V	0.456 V
GDP 5	0.093198	0.813 V	0.695 V	0.575 V	0.456 V

where

$$\begin{aligned}
 N_1 : N_A &= 1 \times 10^{18} \text{ cm}^{-3}; N_D = 1 \times 10^{16} \text{ cm}^{-3} \\
 N_2 : N_A &= 1 \times 10^{17} \text{ cm}^{-3}; N_D = 1 \times 10^{15} \text{ cm}^{-3} \\
 N_3 : N_A &= 1 \times 10^{16} \text{ cm}^{-3}; N_D = 1 \times 10^{14} \text{ cm}^{-3} \\
 N_4 : N_A &= 1 \times 10^{15} \text{ cm}^{-3}; N_D = 1 \times 10^{13} \text{ cm}^{-3}
 \end{aligned}$$

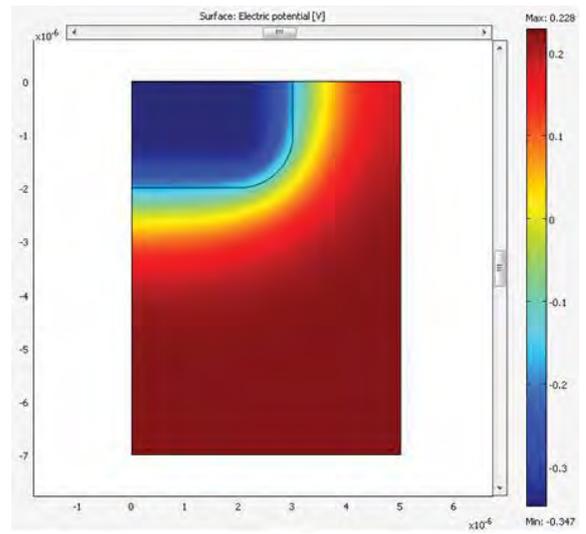

Fig. 9. Electric Potential of GDP 1 with  $N_A = 1 \times 10^{16} \text{ cm}^{-3}; N_D = 1 \times 10^{14} \text{ cm}^{-3}$

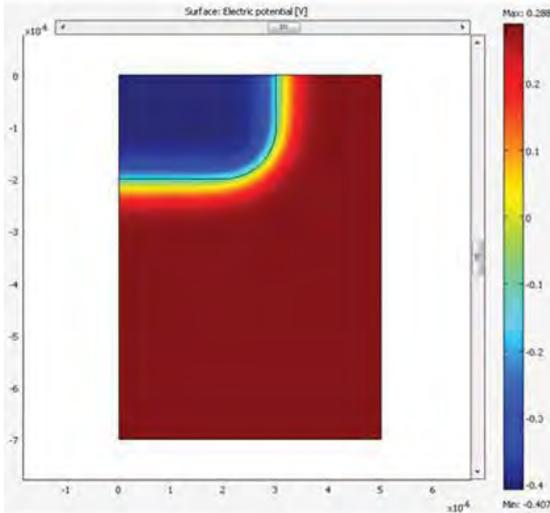

Fig. 7. Electric Potential of GDP 1 with  $N_A = 1 \times 10^{18} \text{ cm}^{-3}; N_D = 1 \times 10^{16} \text{ cm}^{-3}$

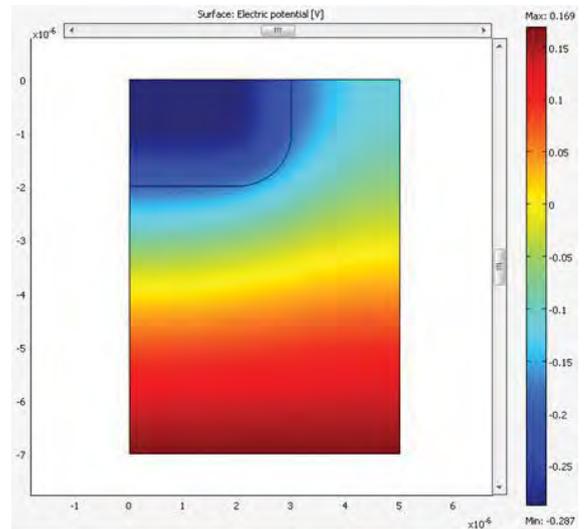

Fig. 10. Electric Potential of GDP 1 with  $N_A = 1 \times 10^{15} \text{ cm}^{-3}; N_D = 1 \times 10^{13} \text{ cm}^{-3}$

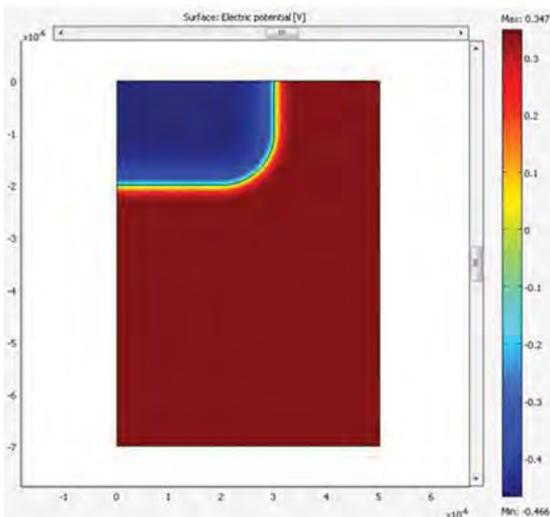

Fig. 8. Electric Potential of GDP 1 with  $N_A = 1 \times 10^{17} \text{ cm}^{-3}; N_D = 1 \times 10^{15} \text{ cm}^{-3}$

According to Table 2, we achieve the relationship between  $dfc$ ,  $N_A$ , and  $V_{Gbi}$  by simulations as shown in Fig. 11. In particular concentration composition  $N_1, N_2, N_3, N_4$  with different doping profiles ( $dfc$ ), we find similar  $V_{Gbi}$ . The built-in voltage of Gauss Doping Profile using pattern as shown in Fig. 1 at thermal equilibrium is determined by  $N_A$ . The higher  $N_A$  will get higher  $V_{Gbi}$ .

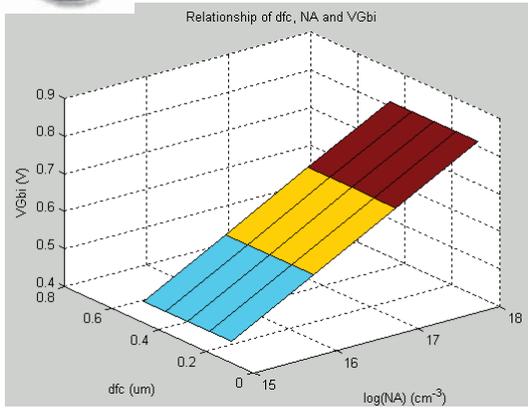

Fig. 11. Relationship of  $dfc$ ,  $N_A$  and  $V_{Gbi}$ .

We propose an equation of built-in voltage for Gauss Doping Profile as a function of  $\log(N_A)$ ,

$$V_{Gbi} \approx 0.1191 \log(N_A) - 1.3304 \text{ V} \quad (10)$$

Equation (10) shows a linear relationship between the  $N_A$  and  $V_{Gbi}$  with gradient of  $0.1191 \text{ V.cm}^3$  and constant term of  $-1.3304 \text{ V}$ . Referring to the built-in voltage equation for abrupt junction (1), we determined the percentage difference of built-in voltage for abrupt junction with built-in voltage for Gauss doping profile as shown in Table III.

TABLE III. BUILT-IN VOLTAGE COMPARISON

$N_A$	$N_D$	$V_{A_{bi}}$	$V_{G_{bi}}$	% diff
$1 \times 10^{18}$	$1 \times 10^{16}$	0.8135	0.8130	0.06
$1 \times 10^{17}$	$1 \times 10^{15}$	0.6945	0.6950	0.07
$1 \times 10^{16}$	$1 \times 10^{14}$	0.5747	0.5750	0.08
$1 \times 10^{15}$	$1 \times 10^{13}$	0.4565	0.4560	0.11

We also investigate the electric potential at p-n junction, especially the maximum junction voltage ( $V_{jmax}$ ) and the minimum junction voltage ( $V_{jmin}$ ). The junction voltage parameters are plotted in Fig. 12.

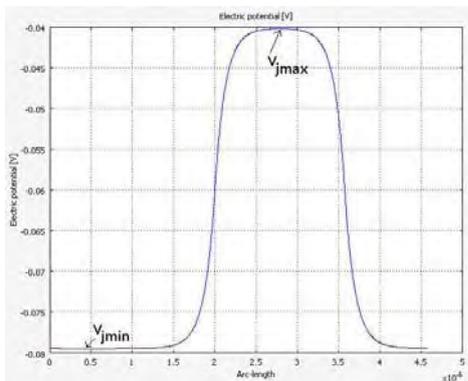

Fig.12. Junction voltage of GDP 1 using  $N_A = 1 \times 10^{18} \text{ cm}^{-3}$ ;  $N_D = 1 \times 10^{16} \text{ cm}^{-3}$

In Table IV we tabulated junction voltage of p-n diode using GDP 1, GDP 2, GDP 3, GDP 4, and GDP 5. The maximum junction value ( $V_{jmax}$ ) and the minimum junction value ( $V_{jmin}$ ) as stated in Table 4. Under thermal equilibrium condition and doping profile according to Fig. 2- 6, we acquire that  $V_{jmax}$  and  $V_{jmin}$  are the function of  $dfc$  and  $\log(N_A)$ . The higher  $dfc$  will produce higher  $V_{jmax}$  and also higher  $V_{jmin}$ . Similarly, the higher the  $N_A$  will produce higher  $V_{jmax}$  and also higher  $V_{jmin}$  as shown in Fig. 13-14.

TABLE IV. JUNCTION VOLTAGE  $V_{jmax}$  AND  $V_{jmin}$

GDP	dfc	$N_1$		$N_2$	
		$V_{jmax}$	$V_{jmin}$	$V_{jmax}$	$V_{jmin}$
GDP 1	0.465990	-0.0402 V	-0.0794 V	-0.0709 V	-0.1344 V
GDP 2	0.372790	-0.0468 V	-0.0925 V	-0.0813 V	-0.1516 V
GDP 3	0.279590	-0.0565 V	-0.1122 V	-0.0955 V	-0.175 V
GDP 4	0.186400	-0.0734 V	-0.1445 V	-0.1185 V	-0.2078 V
GDP 5	0.093198	-0.1109 V	-0.2082 V	-0.1615 V	-0.2590 V
GDP	dfc	$N_3$		$N_4$	
		$V_{jmax}$	$V_{jmin}$	$V_{jmax}$	$V_{jmin}$
GDP 1	0.465990	-0.1095 V	-0.1778 V	-0.1541 V	-0.1946 V
GDP 2	0.372790	-0.1207 V	-0.1924 V	-0.1606 V	-0.2034 V
GDP 3	0.279590	-0.1360 V	-0.2102 V	-0.1686 V	-0.2134 V

GDP 5	0.093198	-0.1885 V	-0.2641 V	-0.1909 V	-0.2419 V

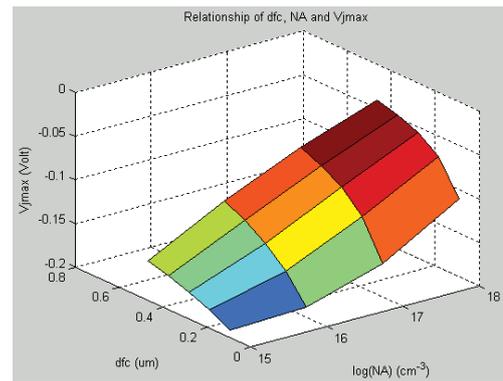

Fig. 13. Relationship of  $dfc$ ,  $N_A$ ,  $V_{jmax}$

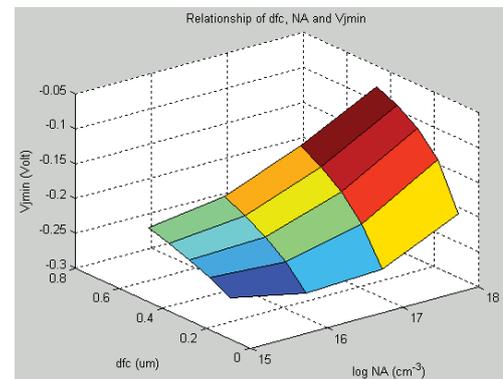

Fig. 14. Relationship of  $dfc$ ,  $N_A$ ,  $V_{jmin}$

We propose equations for  $V_{jmax}$  and  $V_{jmin}$  as a function of  $dfc$  and  $\log(N_A)$ , as stated in equation (11) and (12).

$$V_{jmax} \approx A \times dfc^3 + B \times dfc^2 + C \times dfc + D \quad (11)$$

where

$$A = -0.22470 \log(N_A)^3 + 11.0231 \log(N_A)^2 - 179.1617 \log(N_A) + 965.70$$

$$B = 0.22670 \log(N_A)^3 - 11.0645 \log(N_A)^2 + 178.7741 \log(N_A) - 957.70$$

$$C = -0.06670 \log(N_A)^3 + 3.1952 \log(N_A)^2 - 50.6149 \log(N_A) + 265.50$$

$$D = 0.00420 \log(N_A)^3 - 0.1899 \log(N_A)^2 + 2.7964 \log(N_A) - 13.77$$

$$V_{jmin} \approx A \times dfc^3 + B \times dfc^2 + C \times dfc + D \quad (12)$$

where

$$A = 0.01710 \log(N_A)^3 - 0.5772 \log(N_A)^2 + 5.8160 \log(N_A) - 14.80$$

$$B = 0.01490 \log(N_A)^3 - 0.9966 \log(N_A)^2 + 19.7647 \log(N_A) - 122.88$$

$$C = -0.02795 \log(N_A)^3 + 1.4316 \log(N_A)^2 + 23.9822 \log(N_A) + 132.22$$

$$D = 0.00555 \log(N_A)^3 - 0.2589 \log(N_A)^2 + 3.9822 \log(N_A) - 20.47$$

## V. CONCLUSION

We achieve the relationship between  $dfc$ ,  $N_A$ , and  $V_{Gbi}$  of p-n Diode with Gauss Doping Profile in which  $N_A$  is 100 times of  $N_D$  as stated in (10) using MATLAB and COMSOL software. We also propose equations for  $V_{jmax}$  and  $V_{jmin}$  as a function of  $dfc$  and  $\log(N_A)$ , as stated in (11) and (12).

## ACKNOWLEDGMENT

We would like to thank to *Pusat Komputer FT UI* for their permission to use MATLAB software version R2012 and also to the reviewers for their suggestions and improvements.

**Abstract-** The automotive manufactures company has Packing Vanning Division, which acts to process components or parts needed for assembly of four-wheeled vehicle products. To ensure components are delivered in accordance with customer demand, we check in accordance with standard components. However, there are some problems, complaint of the customer, such as errors of color according to customer demand. The problem was due to a predetermined color samples have almost the same color so it is difficult to be distinguished by the operator. In this research, we designed the color detector that will be used to facilitate the work of an operator. The detector uses photo diode as a sensor which is controlled by the microcontroller PIC16F877A. Error color checking manually for Component Knock Down in automotive manufacturing companies can be overcome by using color detection as a tool for checking. The result of the use of color detector is the operator job can be simplified and reduce operator eye fatigue. The problem of complaint miss-color part can be reduced from an average of 30 pieces to 0 piece.

**Keywords** -color detecto;, photodiode; Component Knock Dow; Microcontroller PIC16F877A.

## I. INTRODUCTION

The automotive manufactures company has Packing Vanning Division, which acts to process components or parts needed for assembly of four-wheeled vehicle products. To ensure components (especially Component Knock Down) are delivered in accordance with customer demand, we check in accordance with standard components. However, there are some problems, for instance complaint of the customer, such as errors of color according to customer demand. The problem was due to a predetermined color samples has almost the same color so it is difficult to be distinguished by the operator. It occurs because the color samples that have been determined are the same color.

To facilitate the operator in distinguishing colors, hence made tools for color detection. This tool uses a photo diode (photo diode) as sensors and controlled using PIC16F877A microcontroller. Color detector can facilitate operators in CKD colored checks so as to reduce problems complaints (claim) of the customer. In this paper, we will discuss about how to cope the problems with error checking manually for component

CKD and how to design and create a color detector control system CKD. Previously, we have researched about the application of Microcontroller PIC 16F877A that related with this research [1, 2, and 3].

## II. METHODOLOGY

In 2011 there were a reported claim by the importer country to Quality Control Engineering. Claims data were obtained from Quality Control Engineering in August to October 2011. Figure 1 shows the data and the external party claim pareto diagrams claim average August-October 2011. Problems that occur are sortage, eg parts, and quality. Explanation of the three types of problems are as follow:

- Sortage is the claim due to lack of quantity or number of components of demand.
- Mis part is the claim due to improper component passes to the customer.
- Quality is the claim due to the quality standard does not pass to the customer.

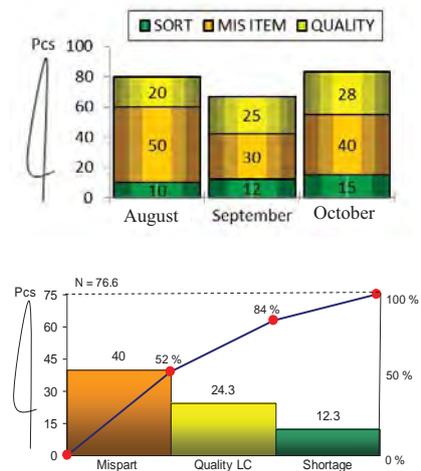

Figure 1. External claim and Pareto average data from August-October 2011

To find the most dominant type of claim, then from the above data was made pareto diagram. From the

analysis of Pareto diagram, it can be seen that the most dominant type of claim is a claim mis part. Mis part happens there are two types of mis color and mis item. Figure 2 shows the data of parts between March to May 2011. Mis part most is mis color or color errors, as many as 30 cases.

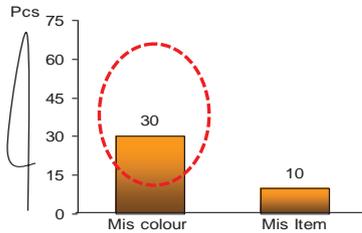

Figure 2. Mis part data from March-May 2011

### A. Problem Analysis

Based on existing problems, in general it can be concluded that the problem of frequent claim is mis color. Then be analyzed to determine the problems and get the solutions to problems that occur to reduce mis color.

Based on the process flow Vanning Packing Division, which is tasked to check the color quality is a process of receiving and auditing case. In the process, the operator checked limit sample components and Key Point Part Inspection. Figure 3 shows the process of checking the components based on color samples and Key Point Part Inspection.

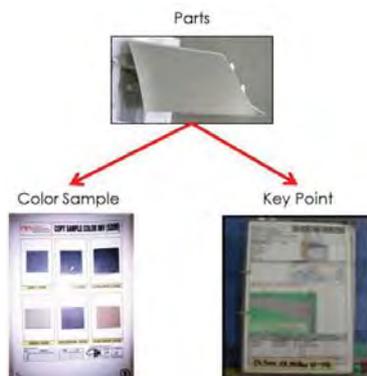

Figure 3. Checking components based on color samples and Key Point Part Inspection

In the process of checking, analysis is performed to determine the cause of the frequent occurrence of mis color. Based on the analysis it can be concluded that the cause is that the operator is difficult to distinguish the color sample limit is almost the same (similar). It is caused by the ability of the eyes of the operator is not able to check the colors similar to many times. From the analysis above, it is a necessary tool for color checking. A tool that can be color-checking tool to distinguish colors is nearly the same components.

### B. The Concept of Color Detector

The concept is that the tools needed to help the operator to distinguish the component colors easily. Figure 4 shows an example of CKD components are checked. These components include: garnish pillar lwr, cover seat track, box assy console, shield fr seat cushion, panel assy quarter, and cover rr seat.

Figure 4. Examples of CKD components are checked

The colors those distinguished are Grey, Mid Grey, Dark Grey, Grege, Ash Brown, Sand Beige, and Light Grey. The colors of these components if at first glance will look the same or similar, but each color will reflect light at different intensities. Figure 5 shows the concept of the color detection.

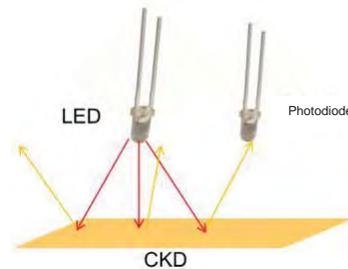

Figure 5. The concept of the color detection

From Figure 5 can be explained that the LED light serves to illuminate the CKD components. The reflection of CKD components will reflect the intensity of light according to the color components of CKD. To detect the color of CKD components are used photodiode. Photodiode has a working principle can stream analog signal voltage be comparable to the value of the intensity of light received. Furthermore, the voltage signal must be converted into digital data. To convert analog signals into digital data, then use a microcontroller which has a facility analog to digital conversion (Analog-to-Digital Converter (A / D)). The working principle is that each ADC input voltage change; it will change the value of output in the form of digital numbers. Voltage changes that can be distinguished by an ADC (Analog Digital Converter), depending on the resolution of the ADC. In this research, we used a 16F877A PIC microcontroller with 10-bit ADC, the input voltage range of 0 to 5 volts.

### III. DESIGN

Based on the concept of the tool in the section above, it was made the workings of the desired device. Figure 6 shows the color detector CKD components. The ways of the device works are as follow:

- First there is the selection of the operating mode, i.e. the mode checking and detection modes. Mode checking is intended to check the mode of a single color, which has been pre-selected by the operator. Mode detection is a menu aimed to find out the name of the color of CKD components is checked.
- If you select the operation mode checks, then it will go to the color selection menu. In this menu, it has to be checked to choose the color components. There are seven colors available, i.e. Grey, Mid Grey, Dark Grey, Grege, Ash Brown, Sand Beige, and Light Grey.
- After selecting the color, it will go into the checking mode.
- The operator will put a sensor on the component to be checked.
- When the button is pressed to detect, the microcontroller will read the input from the sensors and compare with the data that has been programmed.
- If the appropriate comparisons, shows the words "RIGHT" on the LCD. But if the results do not match, it will display "WRONG" and turn rotary lamp.
- If the main menu selects the detection mode, it will go into the detection mode.
- The operator will put a sensor on the component to be checked.
- When it had gone into the detection mode and presses the button to detect pressed, the microcontroller will read the input from the sensors and compare with the data that has been programmed.
- After comparing the data, the LCD will display the name of the color component detected.

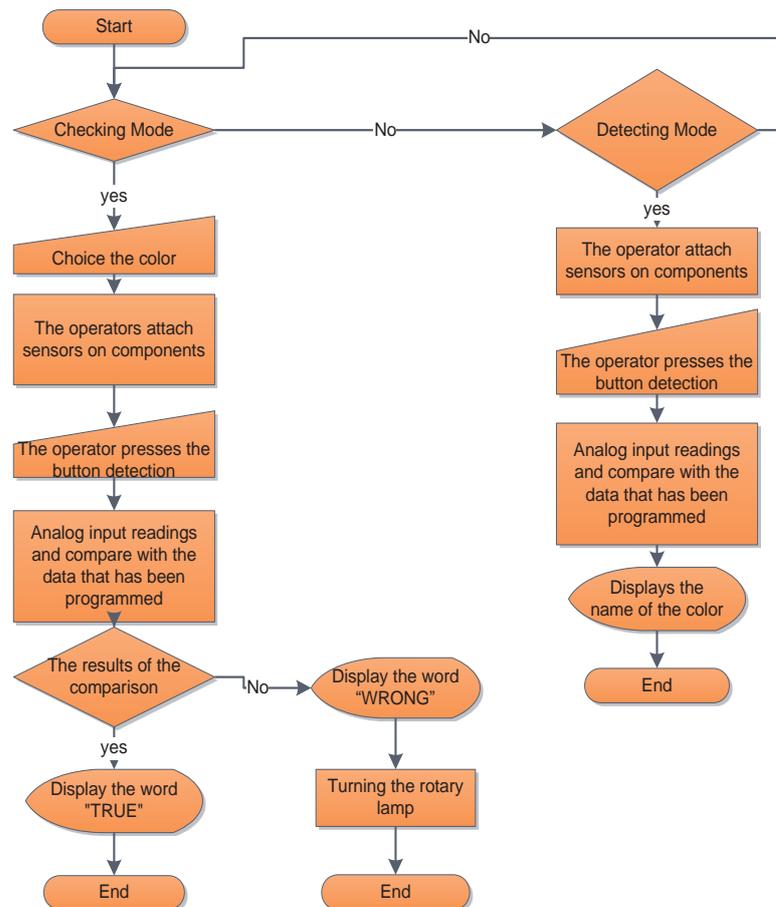

Figure 6. The working principle of the color detector

Based on the concept of the overall device, then be made to the design of the control system components of the color detector CKD. Figure 7 shows a block diagram of the control system components of the color detector CKD.

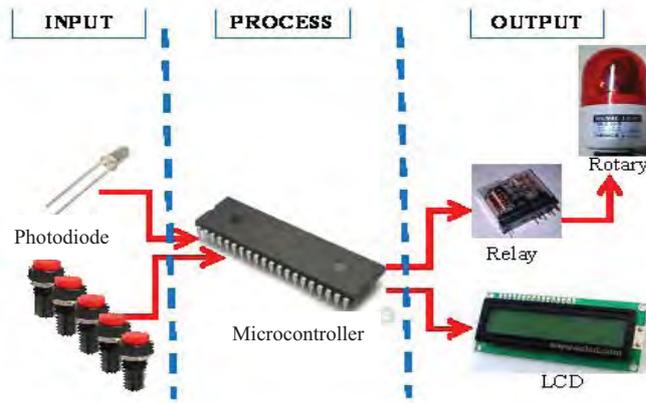

Figure 7. Block diagram of the control system components of the color detector CKD.

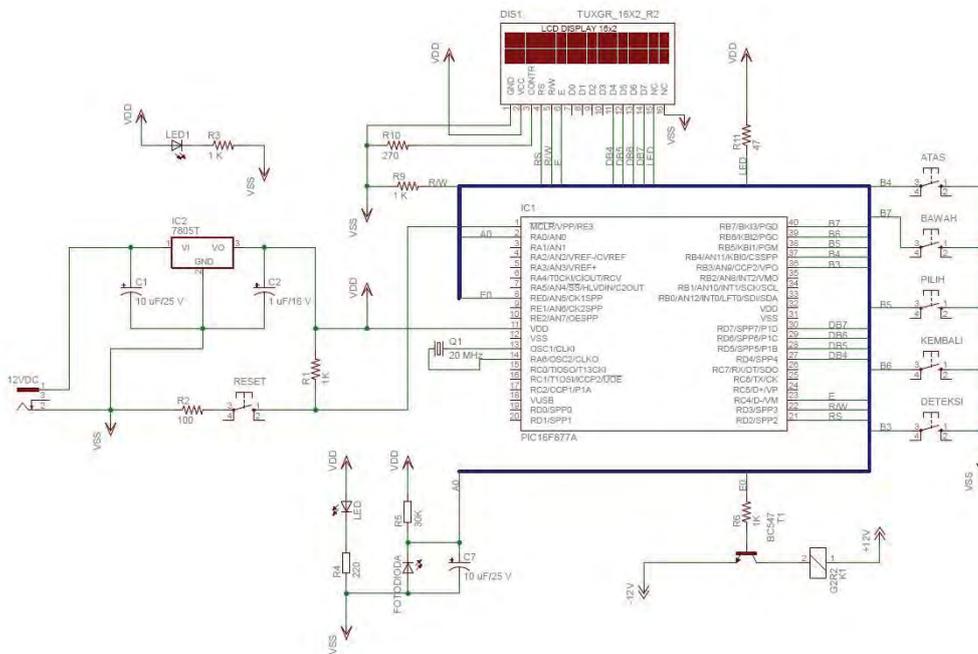

Figure 8. Electric circuit schematic of color detector

The workings of each block of the circuit are as follow:

- Photodiode, serves as analog input to the microcontroller
- Button, functioning as a digital input to the microcontroller. Keys are used there are five that have functions such as shown in the following table.
- Microcontroller, serves as a central data processor, change the analog input into digital output mengandalkan LCD and relays.
- 16x2 LCD, serves to display the program and the results of the detection.
- Relay, Rotary works to turn on the lamp.
- Rotary lamp, serves as a check mark if the component is wrong.

#### A. Realization of the Electric Design

Figure 8 shows the schematic of electric circuit color detector that fulfills the concept and support to the design. From this figure, we divide the circuit into five circuits. It because of this equipment can be inserted into the casing. Those circuits are microcontroller circuit, relay circuit, LCD circuit, push button, and sensor circuit.

#### B. Realization of Creation

To realize a design that has been made, then the design is divided into two types: the realization of the electrical design and realization of the program design. Sensor and the detection circuit incorporated into a flashlight casing. It aims to be easy to use by operators. Distance from the photodiode to the end of the hole is 1 cm flashlight. Figure 9 shows the overall physical color detector.

Figure 9. The overall physical color detector.

### C. Realization of The Programming

Microcontroller will be able to work after downloading the program. Before making a program, the first step is to create a flowchart as a reference for the manufacture of program listings. To make the program a PIC microcontroller 16F877A, the authors use Microcode Studio Plus software as a compiler. The

programming language used in the software is the Basic language.

## IV. THE TESTING AND ANALYSIS

### A. Input and Output Testing

At this stage the microcontroller which has been programmed, the input and output tested. This test is intended to ensure that the input and output of the microcontroller to function properly. This test includes testing the buttons, LCD, photodiode sensors, and relay.

### B. Testing of Input Sensor Photodiode

Photodiode sensor connected to port A0 on the microcontroller. To pass the test, firstly, it must provide a program to send a digital value via serial communication on mikrokontrolernya. After that, by using the Serial Communicator Microcode Studio Plus software, can be seen the value of the photodiode sensor readings. The value will change if the sensor is held to the body with different colors as well.

Tests performed are using the color sample. From these test results obtained digital value of each color. Table 1 shows the results of the tested sensor readings into color samples available are Grey, Mid Grey, Dark Grey, Grege, Ash Brown, Sand Beige, and Light Grey, that performed ten times.

TABLE I. Results of the tested sensor readings into colour samples

Testing	Grey	Mid Grey	Dark Grey	Grege	Ash Brown	Sand Beige	Light Grey
1st	608	780	865	366	765	483	281
2nd	603	776	860	361	760	476	276
3th	609	780	863	364	764	485	281
4th	605	779	864	369	764	483	279
5th	608	780	861	366	761	484	281
6th	611	783	865	364	764	482	281
7th	607	780	868	366	762	479	281
8th	608	780	870	366	764	484	285
9th	613	785	870	371	769	488	286
10th	608	777	865	368	764	483	281

From the above values, it was made the upper and lower limits of each color, as shown in Table 2. These values are used for programming the microcontroller programming realization.

TABLE II. Value of each color

No.	Color	Decimal Value
1	Grey	603-613
2	Mid Grey	775-780
3	Dark Grey	860-870
4	Grege	361-371
5	Ash Brown	759-769
6	Sand Beige	478-488
7	Light Grey	279-286

### C. Testing of LCD Output

LCD is controlled by the microcontroller through the Port C4, D2 Port-Port D7. To pass the test, the first giving the program the microcontroller. Figure 10 shows the LCD that has managed to display text.

Figure 10. LCD display the text

### D. Testing of input Pushbutton

The buttons those located on the tool are: up, down, select, back, and detection. The buttons are connected to a port on the microcontroller B3-B7. To pass the test, the first giving the program the microcontroller. When the button is pressed it will change the display on the LCD or in writing in accordance with the program. Table 3 shows the function of the input. Figure 11 shows the control buttons on the color detector.

TABLE III. The function of the input

No	Button	Functions
1	Up	Shifting to the next menu option

2	Down	Shifting to the previous menu option
3	Choice	Selecting a menu option displayed
4	Back	Return to the previous menu
5	Detection	Displays sensor readings

Figure 11. The buttons on the color detector

#### 4.5 Testing of Relay

To control relay, used E0 port on the microcontroller. To Perform testing, use mode sensor placed on the checks and the wrong color. If the detection button is pressed, the rotary light lamp is lit as a sign that the relay has been triggered. Figure 12 shows that the relay is functioning properly. Table 4 shows the results of the test input and output.

Based on the input-output microcontroller testing shows that LCD, keypad, photodiode sensors, and relays are functioning properly in accordance with the indicators shown each input and output.

Figure 12. Relay turn on the rotary lamp

TABLE IV. The Results of input-output testing

No	Testing	Result	Indicator
1	LCD	Ok	Showing the text
2	Buttons	Ok	Change the display on the LCD when pressed
3	Photodiode Sensor	Ok	Sending color values detection
4	Relay	Ok	Rotary Lamp on

#### V. DISCUSSION

Comparison before and after the use of tools, can be viewed from four factors. These factors are safety, quality, cost, and productivity.

- In terms of the safety factor, the previous operator got eye fatigue because they had to check it manually. After using the tool, operator can reduce eye fatigue because it has been aided by

the color detector. Figure 13 shows the checks before and after using the tool.

- In terms of the quality factor, the wrong color break-out part of the suppliers can be reduced from an average of 30 pieces to 0 piece. Figure 14 shows the decline in break-part color chart. From Figure 13 can be explained that after the discovery of the problem, then do temporary action in the form of additional man power to check the color of CKD and investigation to address the problem. After a color detector is completed and implemented, it can reduce the man power.
- In terms of cost factors, companies can reduce expenses for claims caused by mis part financing of Rp 650.000 per month.
- In terms of factor productivity, the operator can check faster. Before, it has taken an average of 32 seconds to do the checking. After using the tool, a check can be reduced to an average of 18 seconds. So the total time reduction obtained an average of 15 seconds per component.

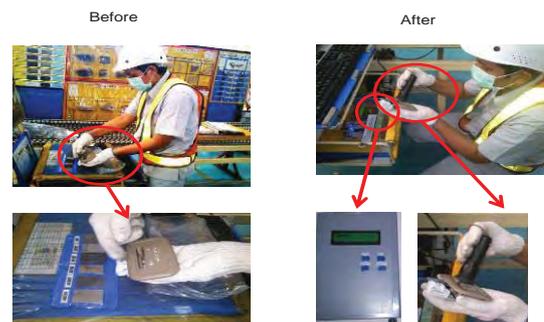

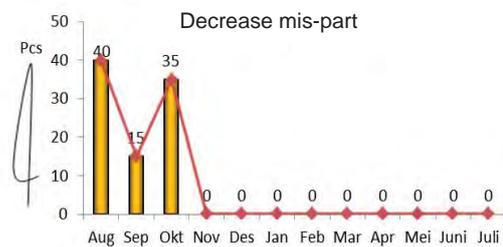

Figure 13. Comparison of the process of checking the color components of CKD

- adding manpower to check the color components of CKD
- implementation detector component colors CKD
- reducing the manpower to check the color components of CKD

Figure 14. Graph reduction claim mis part color.

## VI. CONCLUSION

In this paper, we have discussed the design and testing of the detector component colors CKD automobile. The control system detector CKD component colors are using PIC 16F877A microcontroller, which has facilities ADC (Analog-to-Digital Converter). The facility can alter the form of analog input voltage signal from the photodiode circuit to digital. While the output relay to power the LCD and rotary lamp. From this study, it was found that the error checking manually for the component colors that CKD can be overcome by using color detection as a tool for checking. Mis color part can be reduced from an average of 30 pieces to 0 piece, and checking time can be reduced from an average of 32 seconds to an average of 18 seconds.

**Abstract**— ZnO thin films have been deposited on Si (111) substrate by ultrasonic spray pyrolysis (USP) with various growth temperatures. The polycrystalline of ZnO thin films have preferred plane (002) and relatively low donor concentrations comparing with GaN. Optically, photoluminescence (PL) spectra show the UV emission increased with increasing growth temperature. Nevertheless, green emission does not increase monotonically with increasing temperature. We believed that the ZnO thin films quality improved by increasing growth temperature.

**Keywords**— ZnO thin films, Growth temperature, XRD, Hall measurement, PL

## I. INTRODUCTION

Recently, ZnO has been received much attention for optoelectronics application due to its superior advantages over GaN.[1] Instead of wide band gap energy (3.36 eV) and large exciton binding energy of 60 meV, the quality of ZnO thin film also believed to be improved optoelectronic devices such as UV LEDs and light diodes (LDs) at room temperature.[2] The ZnO thin film quality generally depends on crystallinity, degree of preferred orientation, grain size, morphology, and surface roughness.[3] Some substrates with different lattice constants also used to improve crystalline film quality.[4] However, ZnO suffers from the doping-asymmetry problem, in that the n-type conductivity can be obtained rather easily, but p-type doping proved to be formidable challenge.[5] This doping-asymmetry problem of the wide band gap semiconductors is still the main challenge at the present research. In order to realize applications in optoelectronics technology, a lot of efforts to growth ZnO films on top of a variety of substrates as p-type, such as GaN, Si, SiC, SrCu<sub>2</sub>O<sub>2</sub> and CuGaS<sub>2</sub>. [Error! Bookmark not defined.] Among these

attempts, ZnO thin film on top of Si have stirred-up considerable interest for integrating ZnO onto Si technology.

In this paper, the ZnO thin films grown on Si (111) substrate using ultrasonic spray pyrolysis (USP) technique by various growth temperatures. USP is chosen, due to low cost for fabricating thin films comparing with other technique. X-ray diffraction (XRD), Hall effect, and photoluminescence (PL) measurements were employed to investigate structure, electrical, and optical properties of ZnO thin films.

## II. EXPERIMENTAL METHODS

Undoped ZnO was deposited on p-type silicon (111) substrate using USP. The Zinc acetate dehydrate (Zn(CH<sub>3</sub>COO)<sub>2</sub>·2H<sub>2</sub>O) was chosen as precursors for undoped ZnO. The Zinc acetate 0.02 mol/ml diluted in de-ionized water. The aerosol of precursor's solution was generated by commercial ultrasonic spray pyrolysis (USP). Then it was transported to the heated Si substrate. Each substrate heated at various growth temperature 400 °C, 450 °C, up to 500°C. Heated substrate is intended to increase the density of atom on film deposition, minimize the oxidation, govern the preferred growth orientation, and generally improve the mechanical properties of film.[6] After deposition the ZnO thin film thickness of about 200 nm were characterized by XRD, Hall measurement, and photoluminescence (PL) spectrometer.

## III. RESULTS AND DISCUSSION

X-ray diffraction (XRD) was performed to characterize crystal structure of the ZnO thin films.

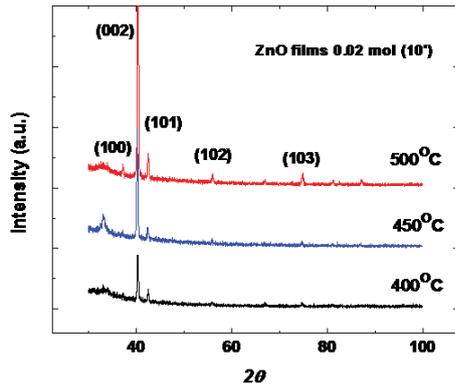

Fig. 1. XRD pattern of ZnO thin films at various growth temperatures

Fig. 1. XRD pattern of ZnO thin films at various growth temperatures

Fig. 1 shows the typical XRD patterns of as grown ZnO films at various different temperatures which ranging from 400°C to 500°C with the increment of 50°C. There is no shifting peak of 2θ angles when growth temperature increases. Nevertheless, the peak (002) of 2θ angles increases by increasing growth temperature.

By using Scherrer's formula, the grain size for crystallographic plane at (002) can be estimated.[7]

$$D = \frac{0.9\lambda}{B\cos\theta} \quad (1)$$

Where  $D$ ,  $B$ ,  $\lambda$ , and  $\theta$  are the average grain size, the full width at half maximum (FWHM), wavelength, and Bragg diffraction angle, respectively. Furthermore, the grain size estimation for crystallographic plane (002) can be seen in the table 1. The grain size increased monotonically with temperature. Nevertheless, other reported that the grain size does not increase monotonically with temperature.[7]

Table I. The ZnO thin films grain size estimation for crystallographic plane (002) at various growth temperatures

Growth Temperature (°C)	Grain size (nm) in Crystallographic plane (002)
400	10.57
450	13.63
500	15.49

In general the electrical properties of bulk ZnO are excellent. Figure 2 show the room temperature Hall measurement of ZnO thin films. Hall measurement predicted that the conduction type is  $n$ .

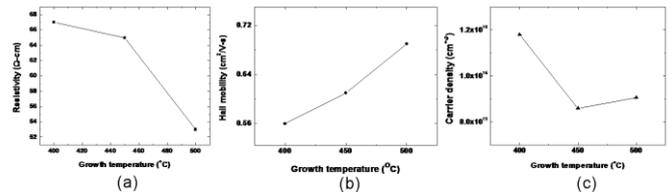

Fig. 2. The room temperature Hall measurement of ZnO thin films (a) resistivity, (b) Hall mobility, (c) Carrier density

As can be seen from the fig. 2 (a), the resistivity of the films decreased with increasing temperatures. It indicates that ZnO thin films relatively have high resistivity which is predicted due to the presence of higher concentration of O vacancies.[8] On the other hand, figure 2 (b) shows that Hall mobility increased with increasing growth temperatures. The Hall mobility of ZnO thin films generally are influenced by scattering from the ionized impurities ( $\mu_i$ ) and grain boundaries ( $\mu_g$ ). Therefore, linearly Hall mobility increased with growth temperatures, mainly due to the grain boundary scattering.[9] Meanwhile, figure 2 (c) shows that the carrier density values are  $1.18E+16$ ,  $8.59E+15$ , and  $9.06E+15$  at temperatures 400°C, 450°C, and 500°C, respectively. It is proper with other reports that the ZnO films have relatively low donor concentrations comparing with GaN.[10] Normally, the dominant donor in ZnO is usually assigned to oxygen ( $O^{-2}$ ) vacancy or zinc (Zn) interstitial atoms.[10]

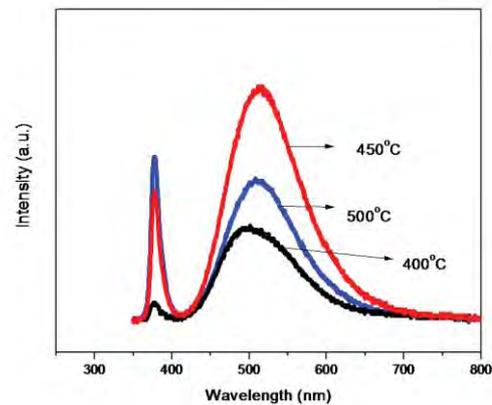

Fig. 3. PL spectrum of ZnO thin films at various growth temperatures

Fig. 3 shows the room-temperature photoluminescence (PL) spectrum of ZnO thin films deposited on to Si (111) substrat. In undoped ZnO thin film the ultraviolet (UV) emission peak which is ascribed to the free exciton emission observed around 375 nm. Then, the strong green band due to the presence defect which originates from deep level emission (DLE) observed as broad peak at 530 nm. The intensity of UV emission increased distinctly with the increasing the growth temperatures (400-500°C). Nevertheless, the others claimed that the UV emission of ZnO thin films which was grown by laser ablation increased by increasing substrate temperature. While, the green band emission are not be uniform and the

estimated value of the intensities may not be linear with increasing temperature.[11]

#### IV. CONCLUSIONS

In conclusions, we have deposited ZnO thin films on Si (111) substrate by ultrasonic spray pyrolysis (USP) with various growth temperatures ranging from 400 °C, 450 °C, and 500°C. The polycrystalline of ZnO thin films have preferred plane (002) and relatively low donor concentrations comparing with GaN. The UV emission increased with increasing growth temperature. Nevertheless, green emission does not increase monotonically with increasing temperature.

### ABSTRACT

We developed a pocket gamma-ray radiation recorder with CdTe sensor. This radiation recorder has an energy-compensated CdTe gamma-ray sensor but also GPS position sensor, three-axis geomagnetism sensor, three-axis acceleration sensor, and temperature and pressure sensor with SD-memory. Therefore, we can know the accurate dose rate with absolute position and direction of the recorder. We can estimate Radioisotope(RI) direction because the CdTe sensor has directivity. However, the directivity is not so sharp, therefore it is difficult to detect an accurate position of RI. In this research, we used 8-CdTe radiation recorders for detection of RI direction. Moreover, we used the changing of the gamma-ray energy spectra of Compton scattering in CdTe sensor for assistance of estimation calculation because the CdTe radiation recorder can obtain gamma-ray energy spectrum. In this research, we will like to apply this system to measure at Fukushima areas, Cs137 single RI was used for the estimation.

**Abstract--** Current trends and future sharing of communication that needs to be done in a mobile communication device. On the other hand, the creation of a mobile communication device multi-function communication will encourage the creation of such devices will become cheaper and mass production is compared to one with a single communication function of mobile devices. One of the components to support a dream antenna is characterized by compact and lightweight. Microstrip antenna is an antenna types is possible to support mobile communication devices. In this paper is propose a design of microstrip antenna that can receive and send information from several different communications systems operating frequency allocation (multiband) and large information capacity (wideband). The design of the antenna is made using a new technique which combines multi tuning fork-shaped to fed the patch for produce a wideband characteristic and narrow slot technique a modified form of E at 6 patch element in the array to produce multiband characteristics. The configuration of an antenna design in this study is proximity coupling technique by using two layers of epoxy substrate FR-4 with a thickness of 1.6 mm and a dielectric constant of 4.4. From simulation acquired three operating in the frequency band of 1.05 - 7.96 GHz (return loss <-10 and VSWR <2). These frequency band are; 1.05 to 1.96 GHz, 2.65 - 2.80 GHz, and 7.76 to 7.96 GHz.

**Keywords:** multi-wideband, tuning, stub, E-slot, proximity coupled

### I. INTRODUCTION

The development of communication technology in the modern world is getting faster and variety, so many of the new emerging technology standards and increasingly sophisticated. Antenna was instrumental in the development of telecommunications, particularly

telecommunications with radio waves. In its recommendation that have enlightened bandwidth's requirement to wideband case goes to in a few frequency allocation which is [Akhavan, 1995] Manatu Ohanga, 2005] ; bandwidth 10 MHz to frequency distance of 30 MHz until 1 GHz, 50 MHz to 1 GHz until 3 GHz, 100 Mhz to 3 GHz until 10 GHz, 250 MHz to 10 GHz until 15 GHz, and 500 MHz to frequency distance upon 15 GHz. At plays favorites state [Nakano et. al., 2002] there are some frequency allocation alternative for ultrawideband's application as American As and European allocates for radar system with a brass band frequency under 900 MHz, 1.9 – 10.6 GHz and 3.1 – 10.6 GHz. Both of for vehicular is system's radar on 22 – 29 GHz, 24 – 24.25 GHz and 23.6 – 24 GHz. Third for application on communication system without cable which operating on 3.1 – 10.6 GHz. Multiband characteristics appear in many communication systems that can be applied. Wideband characteristics seen in the width of each frequency band communication systems. For example, the mobile phone functions can be used two operators / two cellular systems such as GSM or CDMA-GSM-GSM is also coupled with the function of wireless fidelity (WIFI / Wi-MAX), Global Positioning System, bluetooth all of which are integrated in a single device communication moves.

The purpose of this research is microstrip antenna patch E - slot six elements made with the technique of multituning stub to Enlarge the bandwidth can be applied to a multi-service wireless communication device that works on a frequency of 1-10 GHz. the benefit of double-layer microstrip antenna design is expected to anticipate the

needs of the technology in large capacity and fast, and economical and practical for its users.

## II. DESIGN AND SIMULATION MICROSTRIP ANTENNA

In the design of microstrip antenna substrate materials used have the following specifications:

- Material Dielectric: FR-4 epoxy Konstanta dielektrik ( $\epsilon_r$ ) = 4,4
- dielectric layer thickness ( $h$ ) = 0,0016 m = 1,6 mm
- Loss tangent = 0,02
- upholstery material substrate (conductor) conductivity copper copper ( $\sigma$ ) =  $5.80 \times 10^7$  mho m-1
- 1-10 GHz Frequency Range
- line characteristic impedance = 50  $\Omega$

### 2.1 Planning Feeding Channel

Feeding channels are used in the design is expected to have or at least close to the input impedance of 50  $\Omega$ . To get the value of the impedance is done setting the width of the channel by using the software pncatu PCAAD. For value  $Z_0 = 50 \Omega$ ,  $r = 4.4$  (FR-4 Epoxy) and  $h = 0.16$  cm, the width feeding is obtained 0.3 cm, as shown in figure 6

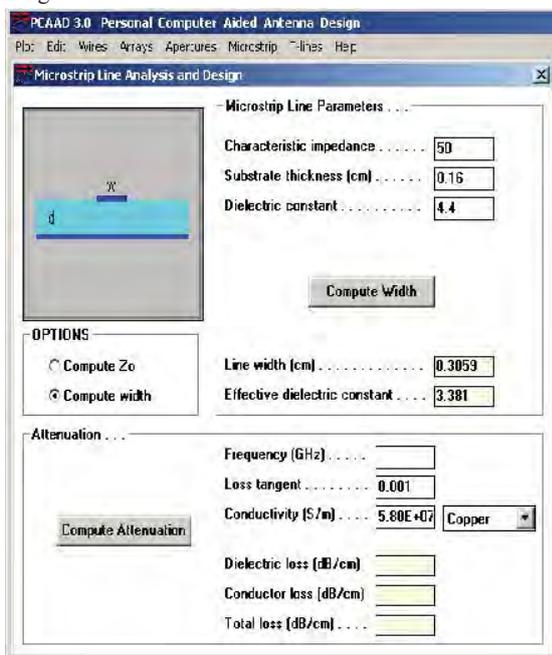

Figure 1. Fed width calculations

Finding width and length patch antenna Rectangle (Rectangular) can use a mathematical method to Determine equation Patch width (W):

$$W = \frac{c}{2f_0 \sqrt{\frac{\epsilon_r + 1}{2}}}$$

The length L is defined as follows:

$$\Delta L = 0.412h \frac{(\epsilon_{reff} + 0.3) \left( \frac{W}{h} + 0.264 \right)}{(\epsilon_{reff} - 0.258) \left( \frac{W}{h} + 0.8 \right)}$$

For the resonance frequency  $f_0$  indicated the effective length is given as:

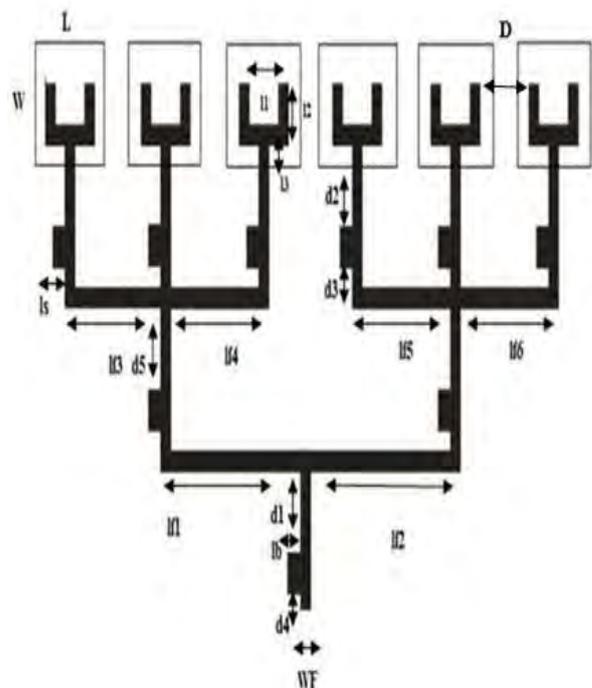

$$L_{eff} = \frac{c}{2f_0 \sqrt{\epsilon_{reff}}}$$

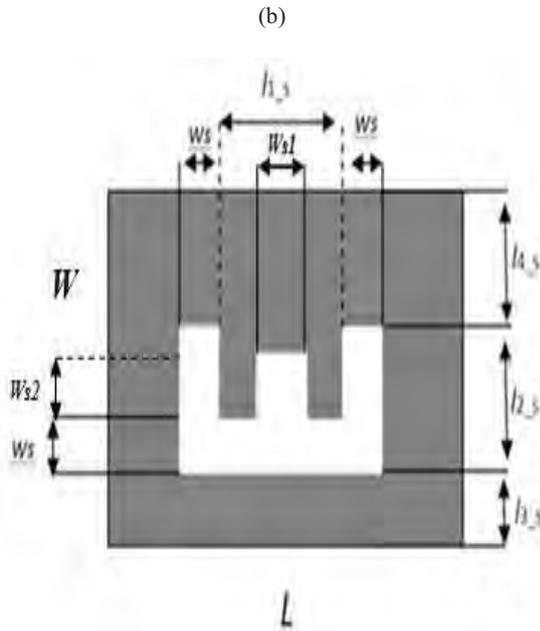

So the length of the field L is:

$$L = L_{eff} - 2 \Delta L$$

From the calculation of the dimensions of the antenna is obtained as follows.

(a)

**Figure 2.** Dimension slot microstrip antenna array element 6 (a) Dimensions designing feeding (b) dimensions of the patch radiator design with E slot

Table 1. The size of the antenna radiator element E-slot double layer

No	Dimension Radiator and E-Slot Patch	Design (cm)
1	$W$	1.6
2	$L$	2.3
3	$W_s$	0.3
4	$W_{s1}$	0.2
5	$W_{s2}$	0.5
6	$l1\_s$	0.6
7	$l2\_s$	0.9
8	$l3\_s$	0
9	$l4\_s$	1.4

Table 2. Size feeding the antenna E-slot double layer

No	Dimension Feeding	Size (cm)
1	$W_f$	0,3
2	$L_{f1}$	4.43
3	$L_{f2}$	4.575
4	$L_{f3}$	3
5	$L_{f4}$	3
6	$L_{f5}$	3
7	$L_{f6}$	3
8	$l_b$	0.4
9	$D$	1.5

18	$l3$	0.3

### III. SIMULATION RESULTS

#### A. Return Loss Dan VSWR

The results of the simulation design antenna E-6 slot double layer can be analyzed with graph element Return Loss and VSWR values resulting from the simulation design and presented through the charts to be declared as a result of good design is where the value of return loss  $< -10$  dB and VSWR  $< 2$ . Representation of the simulation results can be seen through the following graph:

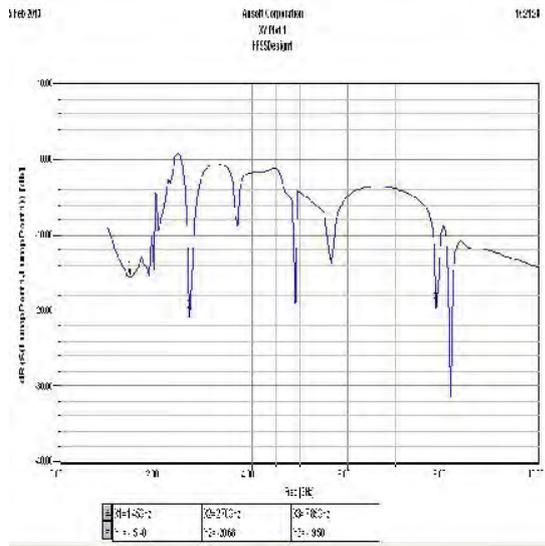

Figure 3. Graph the results of the simulation return loss

value-10dB return loss over the frequency range obtained at 1.05 - 1.96 GHz, 2.65 - 2.80 GHz and 7.76 - 7.96 GHz. Resulting in a wide bandwidth of the return loss for microstrip slot array antenna for 910 MHz, 150 MHz and 200 MHz. From the results I observed in the resonance frequency range on the graph above produces multi bandwidth because it has three resonance frequency and wide bandwidth wideband meet the criteria for having a wide bandwidth of over 100 MHz.

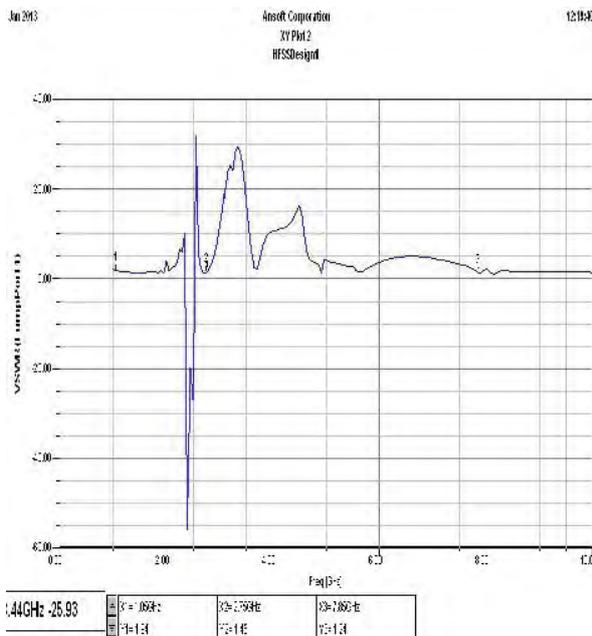

Figure 4. results Graphics simulation VSWR

From the results shown in the chart above, that the value of the frequency tolerance  $VSWR < 2$  During the simulation, the above-10dB VSWR values obtained at 1:05 frequency 1.64 GHz VSWR values obtained, the frequency of 2.75 GHz VSWR values obtained frequency of 7.85 GHz 1:45 and VSWR values obtained 1:24 .

### B. Radiation Pattern

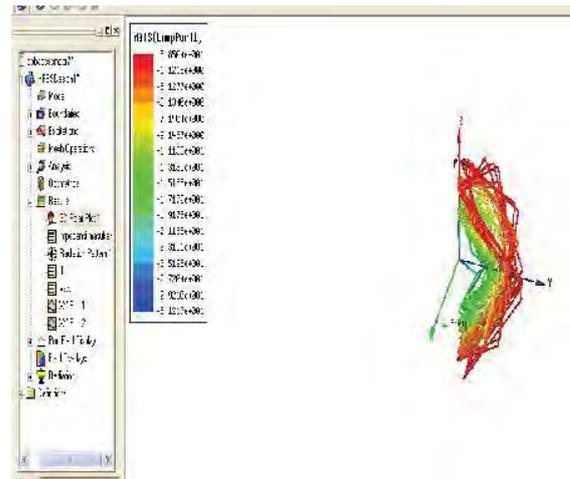

Figure 5. 3D Radiation Pattern Polar Plot

Can in clay of the radiation pattern of the image 8. that red is the radiation pattern of the most powerful and the most blue the weakest radiation pattern. can be inferred from the radiation pattern of microstrip antenna radiation pattern is circular.

### CONCLUSION

Several theories microstrip antenna design techniques in literature by previous researchers as evidenced in the design of microstrip patch antenna wake phi-slot 2 uses proximity coupled elements are; the more slots on the radiation pattern of the antenna on an antenna also will not even become good radiation pattern. Stub connected in shunt at feeding system to affect a wide bandwidth. Position stub on microstripline be able to produce a wide tuning for optimal bandwidth. Forms patch, slot shape, and position of the slots on the patch can affect the amount of the resulting band operation. Slot on the patch, in this case E-slot, capable of producing multiple operating bands (multiband characteristic).

### ABSTRACT

Red-emitting SrTiO<sub>3</sub>:Pr<sup>3+</sup>,Al phosphors were synthesized by sol-gel method. In this study, dependence of luminescent properties of SrTiO<sub>3</sub>:Pr<sup>3+</sup> phosphor on Pr<sup>3+</sup> concentration has been investigated. Moreover, the influence of Al addition for the luminescent and structural properties of the phosphor has also been investigated. It was found that the effective concentration of Pr<sup>3+</sup> for luminescence intensity of SrTiO<sub>3</sub>:Pr<sup>3+</sup> under low-energy electron and UV light excitation is around 0.2 mol%. It was shown that both luminescence intensity and crystallinity of the phosphors were deteriorated by Al addition up to 15 mol%. This result is different from that synthesized by solid phase reaction. It is suggested that the SrTiO<sub>3</sub>:Pr<sup>3+</sup> phosphor can be synthesized by sol-gel method without Al. The high luminance of 1840 cd/m<sup>2</sup> from SrTiO<sub>3</sub>:Pr<sup>3+</sup> phosphor without Al was obtained under excitation with anode voltage of 10 kV and current density of 60 μA/cm<sup>2</sup>.

cantika.felita@ui.ac.id<sup>1</sup>, m.suryanegara@ui.ac.id<sup>2</sup>

**Abstract**—The “not yet officially defined” 5G standard leads to the consequence that its relevant technological innovation is still widely open. For identifying innovations opportunity, we should discover the specific technical area to contribute to the technological development of 5G. This paper discusses a framework answering the main question: In which technological area one may contribute to the innovation? The answer shall benefit countries, firms, universities and research institute which intends to contribute to the formulation of official 5G standard.

First, we reviewed the key technologies of 5<sup>th</sup> generation mobile communication technology (5G). Ubiquitous and interoperability of the network are main technical focus. A flat IP-based network concept was reviewed, as well as cognitive radio technology to reach the terminal which have artificial intelligence. BDMA technology was proposed to help achieving system efficiency in terms of multiple access system. Second, we identified technological challenges, focusing on the issues related to security and problems to deal with limited frequency spectrum resources. Subsequently, we mapped the innovation opportunity based on technical area which is recently published in research article. We concluded that innovation opportunities lies on the research regarding security, network, technological implementation and applications issues.

**Keywords**—5G; innovation; standard

## I. INTRODUCTION

Today, changes in the realm of telecommunication technology have occurred and will remain happening. Mobile telecommunication grows from first generation, known as 1G, to 2G, 3G, and now to the fourth generation that still in implementation stage in several countries, 4G. Every generation of technology have several differences and innovations.

5G is a terminology that is used for the 5th generation mobile technology. Telecommunication companies or standardization bodies of telecommunication such as 3GPP, WiMax Forum, or ITU-R haven't issued the official standard for 5G [1]. The absence of official standard makes the 5G have limitless possibilities. However several expectations have been raised about how 5G should and will be.

The 5G technology is expected to complete the 4G technology and provide solutions to the shortage arising from 4G technology. This technology will be a new technology that makes users able to access different Radio Access Technologies (RATs) using one mobile [2]. 5G has been proposed to assemble the existing wireless and wired communication techniques into an all IP (Internet Protocol) high performance world wide network [3]. 5G technology will help perfecting World Wide Wireless Web (WWWW) [4]. WWW itself is an attempt to create a circumstance where subscriber can savor the great quality and quick access of internet, dynamic movement, favorable Bit Error Ratio (BER) and great security as on wired communications in their wireless communication devices. Limitations of frequency resources making 5G shall have a technical development, which uses other resources than frequency/time resources in order to increase a capacity of the system [1].

In this paper, we try to identify innovation opportunity of the 5G technological development. It explored the fundamental literature framework to answer a question: in which technological area one may contribute to the innovation? The answer shall benefit countries, firms, universities and research institute which intends to contribute to the formulation of official 5G standard.

The second section of this paper provides the review of the key technologies of 5th generation mobile communication technology (5G). The third section presents our identification of technological challenges, focusing on the issues related to security and problems to deal with limited frequency spectrum resources. In the fourth section, we mapped the innovation opportunity based on technological area which is recently published in research article.

## II. REVIEW OF 5G KEY TECHNOLOGIES

There are several key technologies which are expected to help fulfilling the need of improvement for 5G. Those are Flat IP Based Network and Cognitive Radio (CR).

### A. Flat IP Based Network

Previous works by Toni Janevski from University Sv Kiril I Metodij define the basic concept of 5G mobile network which

is seen as user-centric concept instead of operator-centric as in 3G or service-centric concept as seen for 4G. The 5G mobile phone is designed as an open platform on different layers, from physical layer up to the application [5].

The network layer at 5G networks will be divided into several sub-layers to provide all-IP connectivity anywhere and anytime. The use of the Internet Protocol (IP) in the network layer is inevitable, given the IP system is the best and most used system to support and expand the network layer nowadays. All IP Network (AIPN) system has started well since the development of LTE.

All IP Network (AIPN) system has started well since the development of LTE as an evolution of the 3GPP system. Flat IP Network is a key concept that is expected to make 5G acceptable to all kinds of technology [1]. Flat IP architecture provides a way to identify each device using symbolic names, unlike the hierarchical architecture commonly used in the usual IP address [1]. With the shift to flat IP architectures, mobile operators will be able to [1]:

- Reduce the number of network elements in the data path, thereby reducing operations costs and capital expenditure.
- Splitting the cost of service delivery from the amount of data that is sent to equate infrastructure capabilities to the requirements of emerging applications
- Minimize system latency and enable applications with a lower tolerance for delay; upcoming latency enhancements on the radio link can also be fully realized.
- Evolve radio access and packet core networks independently of each other to achieve greater development and make better flexibility in network planning and deployment.
- Develop a flexible core network that can be the basis of innovative services for mobile and generic IP access network.

Create a platform that will enable mobile broadband operators to be competitive with wired networks in terms of price and performance.

IPv6 is the best possible system that can support a flat IP network for technology implementation 5G later. IPv6 is the latest revision of the IP system is expected to overcome the shortcomings of the predecessor version of IPv4. Each device will then have a fixed IPv6 address, and multiple addresses Care of Address (CoA). The number of CoA for the device is according to the number of access networks where device is connected. There are 3 sub-layers of the network layer, the lower network layer, middleware layer and the upper network layer. Lower network layer use CoA, middleware network layer translates CoA into IPv6 so the upper network layer using IPv6 addresses.

Device is expected to be provided by a variety of options in order to get the best wireless connection in accordance with the type of device and current network conditions. QoS parameters such as delay time, jitter, bandwidth, reliability and so on will

be stored in a database that can be used for training intelligent algorithms in a mobile terminal, thus the 5G technology can choose the best connections for the device at the given time and condition.

### B. Cognitive Radio

For mobile and wireless communications technologies, since the 4G, interoperability was an important thing, as it is also applied for 5G. Interoperability system means any system with different technologies can work together and communicate with each other. The network architecture for 5G mobile system consists of a user terminal and a number of independent, autonomous radio access technologies [6]. Within each of the terminals, each of the radio access technologies is seen as the IP link to the outside Internet world [6]. With the use of cognitive radio terminal, 5G can achieve interoperability and still have a good quality of service. In the cognition system, the system recognizes the location, position and condition to determine the best option for network. With this system, users can choose a suitable network for communication and different wireless networks will be able to integrate and communicate with each other via cognitive radio devices.

Cognitive radio is an intelligent communication system that is aware of its surrounding environment (i.e., outside world), and uses the methodology of understanding-by-building to learn from the environment and adapt its internal states to statistical variations in the incoming RF stimuli by making corresponding changes in certain operating parameters (e.g., transmit-power, carrier-frequency, and modulation strategy) in real-time, with two primary objectives in mind: highly reliable communication whenever and wherever needed; efficient utilization of the radio spectrum [7].

By that definition, the cognitive terminal is a smart terminal with intelligence to choose the proper network from all the existing wireless networks [5]. The choice is based on some information such as time, demand, and resource. The 5G technology proposes a universal terminal, which should include all of the radio predecessors features into a single device [5]. This terminal convergence is strongly sustained by the users' needs and demands; therefore, cognitive radio becomes the ideal 5G terminal candidate [5].

## III. TECHNOLOGICAL CHALLENGES

By understanding the key technologies of 5G, we identified the technological challenges which mainly lie on the problems concerning security as well as limited frequency resources.

### A. Security

Being able to scan the available spectrum, select from a wide range of operating frequencies, adjust modulation waveforms, and perform adaptive resource allocation— all of these in real-time— these new Cognitive Radio technology will be able to adapt to a wide variety of radio interference conditions and adaptively select the most efficient communication mechanisms [8]. However, in addition to the advantages and potential of the cognitive radio technology, there are a number of challenges related to security, especially in cognitive radio terminals. The paradigm of cognitive radio

systems poses a new threat on security, such as selfish misbehaviors, harmful interference, licensed user emulation, competition between licensed users and eavesdropping [9].

There is an opportunity and need to develop a system that able to prevent the misuse in the highly open and granular control which is provided to the radio interface. One of them was proposed by [8] with a framework known as TRIESTE which is short term for Trusted Radio Infrastructure for Enforcing SpecTrum Etiquettes. TRIESTE will be able to ensure that radio devices are only able to access and use the spectrum in a manner that conforms to their privileges [8].

### B. Limited Frequency Spectrum Resources

Limited spectrum resources yielded a major challenge for mobile and wireless technologies. Those limited frequency and time are divided to be used among multiple users. Due to this condition, it is expected to improve efficiency in order to enhance the capacity and quality of the system. To achieve this, several multiple access techniques used today, for example, Time Division Multiple Access (TDMA), Frequency Division Multiple Access (FDMA), Code Division Multiple Access (CDMA), Orthogonal Frequency Division Multiple Access (OFDMA), etc. However, in all of multiple access system that are used nowadays, the capacity of a mobile communication system depends on time and frequency. This generates a challenge to develop a multiple access system which is able to resolve the dependencies of capacity to the limited frequency spectrum. Korean research and development has suggested BDMA as a radio interface for 5G, which is not depended on frequency/time resources [1].

The BDMA technique of the present invention divides an antenna beam according to locations of the mobile stations to allow the mobile stations to give multiple accesses, thereby significantly increasing the capacity of the system [1]. In such a concept, mobile stations and a base station are in a Line of Sight (LOS) state, so they exactly know each other's positions. In this condition they will be able to transmit beams which direct to each other's position to communicate without interfering with mobile stations at cell edge [1].

For adapting the BDMA system into 5G, the development of the phase array antenna is required. The smart antenna with the ability to switch its beam is needed. Switched beam antennas support radio positioning via Angle of Arrival (AOA) information collected from base and mobile stations. The use of adaptive antenna arrays is one area that shows opportunity for improving the capabilities.

## IV. INNOVATION OPPORTUNITIES

Opening up innovations opportunity means to discover the technical area as the guidance to conduct research work on such particular technological agenda. We monitored the spread of technical issues related to 5G in various scientific and engineering journals. There are 18 research articles which have stated 5G as the main corresponding topic in their research work. Those publications include 7 conference papers, 7 journal papers, 3 conference reviews and 1 document review.

Subsequently, we map the technical area based on 40 keywords mentioned in those 18 research articles. Table 1 lists the keywords and the corresponding number of research articles. In general, it mainly indicates that technical area is not yet heavily concentrated on certain technological agenda. However, more researches were conducted concerning topics of relay selection, mobile ad hoc network and one hop cooperative MAC, while other topics are equally distributed.

We identified that the keywords are likely relevant to three technological agenda, i.e. security, network, and technological implementation and applications issues.

TABLE I. KEYWORDS ON 5G RESEARCH PUBLICATIONS

Keyword on the research articles	Number of research publications
Relay selection	4
Mobile Adhoc Networks (MANETS)	3
One-hop cooperative MAC	3
Ad hoc On-Demand Distance Vector (AODV)	2
Architecture for humanity	2
Blacklisting	2
Dynamic Source Routing (DSR)	2
Error Vector Magnitude (EVM)	2
GNU Radio	2
Multihop wireless network	2
Orthogonal space time codes	2
Prognoses	2
Remote monitoring	2
Two-hop cooperative communication	2
Universal Software Radio Peripheral (USRP)	2
Wireless optics	2
All IP networks	1
Collision avoidance	1
Constellation sizes	1
Cooperative protocols	1
Core networks	1
Denial of Service (Dos)	1
Dense network	1
Heterogeneous networking	1
Linear complexity	1
MIMO channels	1
Modulation technique	1
Multi-hops	1
Network achitecture	1
OFDM systems	1
Packet delivery ratio	1
Parallel transmission	1
Piraeus	1
Service oriented architecture	1
Space diversity	1
Space time code	1
Spatial diversity	1
Spectrum efficiency	1
Throughput improvement	1
Ubiquitous and pervasive computing	1

Security technological agenda spreads over collision avoidance, Denial of Service (DoS), blacklisting, etc. Meanwhile, network technological agenda consists of protocol, all IP network, ad hoc network, etc. Some other technological agenda that remain being the most researched topic are frequency hopping topic, MIMO system, space time codes, relay selection techniques, multi hop systems, etc. There are also a few of topics other those main topics, which are covering about implementation of the proposed 5G applications, such as implanted medical devices, remote monitoring and telemedicine.

Based on those findings, we may formulate the concept to exploit opportunity on certain technological agenda. Researchers may work on those specific areas, which can lead to new innovation on 5G. Such a concept is mainly benefit the developing country which intends to increase their innovation and technological competitiveness. For example, since relay selection has been frequently researched, a new researcher may establish the cooperative work with other researchers working on that field. As in the future, wireless network is forecasted will able to support the relay-based communication, where the relay node is well-placed to receive messages from the source node, process it, and then forward it to the node of its intended destination [10]. Alternatively, developing country can put more concentration on another topic such as spatial diversity, AODV, or technique to improve collision avoidance, since the works on those fields are relatively less conducted.

As the continuous upgrading of wireless technologies, the basic concept of 5G is to open up all the doors of possible methods, technologies and techniques used to leverage telecommunication for human life. Combining with the perspective of 5G key technologies, in particular about flat-based IP and cognitive radio, any researchers may contribute to the development of relevant standard. Such research activities are not only to improve faster data access, but also to create innovation on many technical areas as shown in Table 1.

Finally, it is commonly known that technological development of preceding standards (1G, 2G and 3G) were dominantly controlled by developed countries such as USA, Japan and some European countries. Therefore, in current and future time, developing countries should contribute to 5G technological development by utilizing innovation opportunities. Results of research works on 5G can be made into technical submission to the international standardization bodies, such as ITU. Meanwhile, developing countries can also push their national industries to develop patents and to create innovation on relevant 5G technical areas. It is believed that those schemes may influence the global standards development and increase the country's competitiveness.

## V. CONCLUSIONS

Key technologies in the seam of 5G has been reviewed, i.e. Flat IP Based Network and Cognitive Radio. The key technologies help us to spot the 5G technological challenges. The challenges mainly exist in the security area and the limited frequency resources problem.

We have identified innovation opportunity regarding the technological development of 5G standards from understanding technological challenges and exploring fundamental literature framework. There is an opportunity and demand to develop a system that will be able to prevent the misuse of control, maintain the security and enhance the capacity of system. As the result of exploring literature framework, we conclude three technological agenda in which one may contribute to, i.e. security, network, and technological implementation and applications issues. Accordingly, researchers can make new research focusing on those technical area and make new innovation for the 5G technological development. It is expected that research works may result a relevant submission to the international standardization bodies. On the other hand, innovation can be also made by pushing national industries to develop patents and to create innovation on such relevant 5G technical areas.

# Vulnerability and Economic Considerations in Designing Network Topology

Antonius Suhartomo

Study Program of Electrical Engineering, Faculty of Engineering,  
 President Univeristy Kota Jababeka, Bekasi 17550, Indonesia  
 Email: [asuharto@president.ac.id](mailto:asuharto@president.ac.id) , [asuharto77@yahoo.com](mailto:asuharto77@yahoo.com)

**Abstract**—Technological developments change the way of life of all people in interacting with each other, regardless of distance and time. One such interaction is the activity of the exchange of information through communication networks, which are either one-way or two-way with a variety of information, such as voices, images, and data, with the desire to have a fast and reliable delivery. If  $G(V,E)$  represents a graph or a network with a number of nodes,  $V = n$ , and the number of links,  $E = e$ , then assume the nodes are reliable and the links can fail. We investigate new parameter of connectivity called “k-component order edge-connectivity” or “component order edge-connectivity”, denoted by  $\lambda_c^{(k)}$ , in which within each type of topology is then compared such as in the topology of path, cycle, star, complete, and wheel networks, then choose the best selection in vulnerability and economic point of views.

**Keywords**— edge-connectivity, component order edge-connectivity, component edge- failure set, component edge-failure state, minimum degree.component;

## I. INTRODUCTION

If there is a communication from one station to another station the communication network can be represented by a graph  $G(V, E)$  where  $V$  is a station node and link  $E$  is a bidirectional link between these two stations. This link is not limited between the two stations and within a limited distance, but it can be in the form of a complex network and an unlimited distance. Thus a communications network topology form that is built will determine the level of vulnerability and the cost of construction of the communication network.

A communications network that forms a particular network topology with the same number of stations will have level of vulnerability and cost of construction cost that is different from one topology to another topology. Both of these considerations will be the focus of further discussion.

In the discussion that will be conveyed in writing this paper is that the consideration of the reliability of a network topology is one of them will be determined by its level of vulnerability. The mentioned vulnerability in a topology is an edge connectivity,  $\lambda(G)$  or  $\lambda$ , assuming that the node is reliable and links can be disconnected, such as the amount of links that should be removed so the remaining network becomes disconnected [1]. The author examines the new edge connectivity within his dissertation [3] that is called component order edge - connectivity,  $\lambda_c^{(k)}(G)$  or  $\lambda_c^{(k)}$ , which

is when a network is removed as much as  $k$  link so the remaining network will be disconnected if all remaining components of subnetwork have a number of nodes as  $\leq k - 1$ . Value of  $k$  is deterministic value with the amount of  $2 \leq k \leq n$ , where  $n$  is the number of nodes of a particular network topology.

However, the economy aspect will be seen from how many links it takes to establish a communications network topology and then compared from several possibility topologies with the same number of nodes, including network topology path, circle, complete, star and wheel. In calculating the economic aspects to form a network topology is assumed that every link that connects two nodes needs funds one unit cost. Thus, the more links required to form a communication network, the greater the economic value or the cost of investment.

## II. CONNECTIVITY MODEL OF A COMMUNICATION NETWORK

Graph theoretic techniques provide a convenient tool for the investigation of the vulnerability of a communication network to damage from natural or enemy – induced damage. Thus, a network communication system can often be represented as interconnection of stations and links. The assumption is that the system is subject to natural failure or enemy attack aimed at isolating stations from each other. The problems of determining the vulnerability and designing communication network which are invulnerability to enemy attack are of paramount importance. As yet, neither the analysis nor synthesis problems have been completed proved, although a number of practical results have been discovered. One difficulty immediately encountered in vulnerability studies is lack of a completely appropriate vulnerability criterion.

## III. RESULTS

In 1966, Chartrand [1] has defined that the vulnerability of a communication network represented by a graph  $G(V, E)$  if the node is assumed to be reliable and link can fail, which is called edge connectivity,  $\lambda(G)$  or  $\lambda$ . In this classical model, a network is considered to be operating when every station can communicate with every other station via some path of stations and operating links. If the failure of some links results in some pair of stations no longer able to communicate, then the network has failed. When this occurs, we say that the network

has become disconnected. The traditional vulnerability parameter for this model is the minimum number of links required to be removed so that the surviving graph is disconnected [1,3,4]. Clearly, if all the links emanating from a particular station fail, then that station is unable to communicate with any other station, and the network has become disconnected. It is easily seen that the value of the traditional vulnerability parameter is at most the minimum number of links to any station. However, it may be possible that a network may become disconnected when fewer links have failed. Chartrand [1] proved that if each station has a link to at least half of the other stations, then the network could not be disconnected if fewer than minimum number of links to any station fail, i.e., the network is invulnerable to failure if fewer than the minimum number of links to any station fail. Since that time considerable attention has been given to the study of this traditional vulnerability parameter.

In the traditional edge-failure model it is assumed that nodes are perfectly reliable but edges may fail. When a set of edges  $F$  fail we refer to  $F$  as an edge-failure set and the surviving subgraph  $G - F$  as an edge-failure state if  $G - F$  is disconnected.

**Definition 3.1**[3]. The edge connectivity of  $G$ , denoted by  $\lambda(G)$  or simply  $\lambda$ , is defined to be  $\lambda(G) = \min\{|F|: F \subseteq E, F \text{ is an edge-failure set}\}$ , i.e.,  $G - F$  disconnected.

Before you begin to format your paper, first write and save the content as a separate text file. Keep your text and graphic files separate until after the text has been formatted and styled. Do not use hard tabs, and limit use of hard returns to only one return at the end of a paragraph. Do not add any kind of pagination anywhere in the paper. Do not number text heads- the template will do that for you.

Back to the traditional model of edge failure is that the graph  $G - F$  is said to be edge - failure state if the graph is disconnected and no consideration is given whether or not a subnetwork have a lot number of stations connected one to another that can still communicate properly. So in this discussion paper will be introduced edge - failure new model called the component order edge connectivity failure model.

Frank Boesch made significant contributions to this body of knowledge. Then, in 2006, Boesch et al. [2] considered a new network model in which a network is considered operating as long as there is a predetermined number of stations, say  $k$ , that can still communicate, regardless of whether the network

Finally, complete content and organizational editing before formatting. Please take note of the following items when proofreading spelling and grammar:

#### A. New Edge Connectivity Model [2,3,5]

Classical link connectivity models above have limitations that if there are  $N$  nodes and only one node apart from the original network nodes and form two sub-networks, but the network is said to be disconnected already. Even as many as  $N - 1$  nodes can still communicate to each other well.

Conventionally the parameters connectivity and edge connectivity have been used to measure a network's vulnerability to disconnection due to failure of nodes or edges, respectively. One deficiency of these measures of vulnerability is that they do not take into account the orders of the resulting components, such that no distinction in a case where of links results in two components of equal order and the case where one of the component is an isolated node [2,3].

For the entirely network communication system, it may be enough that a certain number of stations can maintain communication after link failure for the network to be considered operational, even if the network is disconnected.

Under the supervision of Frank Boesch as a leader among others: Charles Suffel, Daniel Gross, John Saccoman, and L.W. Kazmierczak, I have the opportunity to study a new network parameter model of vulnerability, called component order edge - connectivity, denoted by  $\lambda_c^{(k)}(G)$  or  $\lambda_c^{(k)}$ , to address this notion. In this model, says that a network is considered operating as long as there is a predetermined number of a station, say  $k$  that could still communicate regardless of whether the entirely network is disconnected.

In the occasion that has given the author has defined new edge connectivity model [3].

It is reasonable to consider a model in which it is not necessary that the surviving edges form a connected subgraph as long as they form a subgraph with a component of some predetermined order. Thus we introduce a new edge-failure model, the  $k$ -component order edge-failure model, which is called component order edge connectivity. In this model, when a set of edges  $F$  fail we refer to  $F$  as a  $k$ -component edge-failure set and the surviving subgraph  $G - F$  as a  $k$ -component edge-failure state, if  $G - F$  contains no component of order at least  $k$ , where  $k$  is a predetermined threshold value. So the component of each separate communications subnetwork could still be said operational because each subnetwork can do his internal relation with minimum  $k$  orders.

**Definition 3.2.** Let  $2 \leq k \leq n$  be a predetermined threshold value. The component order edge connectivity of  $G$ , denoted by  $\lambda_c^{(k)}(G)$  or simply  $\lambda_c^{(k)}$ , is defined to be  $\lambda_c^{(k)}(G) = \min\{|F|: F \subseteq E, F \text{ is } k\text{-component edge-failure set}\}$ , i.e., all component of  $G - F$  have order  $\leq k - 1$ .

**Definition 3.3.** A set of edges  $F$  of graph  $G$  is  $\lambda_c^{(k)}$ -edge set if and only if it is a  $k$ -component order edge-failure set and  $|F| = \lambda_c^{(k)}$ .

Next we compute  $\lambda_c^{(k)}(G)$  for specific type of graphs.

The first type of graph we consider is the **star**,  $K_{1,n-1}$ . To build communications network of star-shaped with the number of nodes  $n$ , it requires an investment cost of links construction, which is different from the cost of the nodes, for the number of links that allow all the nodes can be connected either directly or through intermediaries of other nodes in the network star. If the assumed cost of each link that connects the two nodes is a unit

cost, then the star to form a star communications network needs  $n-1$  unit cost.

In terms of any vulnerability, deletion of any set of  $m$  edges results in a subgraph consisting of  $m+1$  components, one isomorphic to  $K_{1, n-m-1}$  and the remaining components isolated nodes. Therefore a  $k$ -component edge-failure state exists if the component  $K_{1, n-m-1}$  contains at most  $k-1$  nodes. Thus  $n-m \leq k-1$  or  $n-k+1 \leq m$ . Since component order edge connectivity is the minimum number of edges whose removal results in a  $k$ -component edge-failure state we obtain the following result:

**Theorem 3.1:** Given  $2 \leq k \leq n$ ,  $\lambda_c^{(k)}(K_{1, n-1}) = n - k + 1$

The next type of graph we consider is the **path** on  $n$  nodes,  $P_n$ . In addition, the investment cost of the links construction of the path model network is the same as the form of star network, which is equal to  $n-1$  unit cost.

As for the analysis vulnerability, starting at a pendant edge label the edges consecutively from 1 to  $n-1$ . Let  $F$  be the set of edges whose label is divisible by  $k-1$ . The deletion of the edges in  $F$  creates  $|F|+1$  components, the first  $|F|$  having order exactly  $k-1$  and the last order at most  $k-1$  (but at least 1). We also note that if fewer edges are removed then there will be fewer components and thus by the Pigeonhole Principle, there must be at least one component of order at least  $k$ . Since  $|F| = \left\lfloor \frac{n-1}{k-1} \right\rfloor$  we have:

**Theorem 3.2:** Given  $2 \leq k \leq n$ ,  $\lambda_c^{(k)}(P_n) = \left\lfloor \frac{n-1}{k-1} \right\rfloor$ .

The next type of graph considered is the **cycle** on  $n$  nodes,  $C_n$ . For the cycle network model with the number of nodes  $n$ , it requires an investment cost of link construction as  $n$  unit cost. Thus the formula for  $\lambda_c^{(k)}(C_n)$  can be derived in a similar manner to that of  $\lambda_c^{(k)}(P_n)$ . When one edge of the cycle is removed, it becomes the path with  $n$  nodes,  $P_n$ . Thus  $\lambda_c^{(k)}(C_n) = \lambda_c^{(k)}(P_n) + 1$ , and since  $\left\lfloor \frac{n-1}{k-1} \right\rfloor + 1 = \left\lfloor \frac{n}{k-1} \right\rfloor$  we have the following result:

**Theorem 3.3 [3]:** Given  $2 \leq k \leq n$ ,  $\lambda_c^{(k)}(C_n) = \left\lfloor \frac{n}{k-1} \right\rfloor$ .

The next type of graph considered is the **complete graph** on  $n$  nodes,  $K_n$ . The complete network model is an ideal network that requires an expensive investment cost link construction, because each node must be connected to all existing nodes in the network. So the cost of link construction requires an investment as much as  $n(n-1)/2$  unit cost. The mentioned ideal shape is hardly found in the field because of the complexity and expensive construction, so it is considered less economical.

For vulnerability analysis this network, let  $F \subseteq E(K_n)$  be a  $\lambda_c^{(k)}$ -edge set. We can compute  $|F|$  by calculating the maximum number of edges that can remain in the  $k$ -component edge-failure state  $K_n - F$ . It is easy to see that any edge in  $F$  must have its endpoints in two different components of  $K_n - F$ ; thus each component of  $K_n - F$  must itself be complete.

**Lemma 3.4.** Given  $2 \leq k \leq n$ , let  $n = \left\lfloor \frac{n}{k-1} \right\rfloor (k-1) + r$

where  $0 \leq r < k-1$ . Let  $H$  be a graph on  $n$  nodes consisting of  $\left\lfloor \frac{n}{k-1} \right\rfloor$  copies of  $K_{k-1}$  and if  $r > 0$ , one copy of  $K_r$ . Then  $H$  has the maximal number of edges among all  $k$ -component edge-failure states of order  $n$ .

**Proof:** Consider the class  $F$  of all  $n$  node  $k$ -component edge-failure states and let  $H \in F$  be such that  $e(H)$ , the number of edges in  $H$ , is maximum over all graphs in  $F$ . Let  $C_1, C_2, \dots, C_m$  be the components of  $H$ ,  $1 \leq m \leq n$ , and let  $n_i$  be the order of  $C_i$ . It follows that  $\sum_{i=1}^m n_i = n$  and, since  $H$  is a failure state,  $n_i \leq k-1, \forall i$ . In addition, since  $H$  has the maximal number of edges, each component  $C_i$  is complete, i.e.  $C_i = K_{n_i}$ . We claim that there is at most one component of order  $< k-1$ . If not then there exists components  $C_i$  and  $C_j$ , with  $1 \leq n_i \leq n_j \leq k-2$ . Let  $H'$  be the failure state obtained by deleting the components  $C_i$  and  $C_j$  from  $H$  and replacing them with  $C'_i = K_{n_i-1}$  and  $C'_j = K_{n_j+1}$  (In the case that  $n_i = 1$  we only add the component  $C'_j$ ). Then

$$2[e(H') - e(H)] = [(n_i - 1)(n_i - 2) + (n_j + 1)n_j] - [n_i(n_i - 1) + n_j(n_j - 1)] = 2(n_j - n_i + 1) > 0$$

Hence  $e(H') > e(H)$ , which contradicts that  $e(H)$  is maximum over all graphs in  $F$ . Thus we can have at most one  $n_i < k-1$ . Thus if we write  $n = \left\lfloor \frac{n}{k-1} \right\rfloor (k-1) + r$  where  $0 \leq r < k-1$ ,  $H$  has the prescribed form. ■

From this it immediately follows that a maximum size  $k$ -component edge-failure state of  $K_n$  consists of  $\left\lfloor \frac{n}{k-1} \right\rfloor$  complete components each of order  $k-1$  and possible one additional component of order less than  $k-1$ . Thus we have the following:

**Theorem 3.5.** Given

$$2 \leq k \leq n, \lambda_c^{(k)}(K_n) = \binom{n}{2} - \left\lfloor \frac{n}{k-1} \right\rfloor \binom{k-1}{2} - \binom{r}{2},$$

where  $n = \left\lfloor \frac{n}{k-1} \right\rfloor (k-1) + r, 0 \leq r \leq k-2$ .

The final type of graph considered in this section is the **wheel graph** on  $n$  nodes,  $W_n$ . This network is likely suitable for use metropolitan area network (MAN). The investment cost of the link construction is  $2(n-1)$  unit cost.

In order to find vulnerability for wheel graph we will draw back some investigations that have been discussed in [3] to consider many steps.

Since we do not have a formula or an algorithm that computes  $\lambda_c^{(k)}(G)$  of an arbitrary graph  $G$ . Therefore we want to find bounds (both lower and upper) that may be applied to establish a range of possible values of  $\lambda_c^{(k)}(G)$ . Before we introduce a set of bounds we need to establish some notation and terminology.

First we consider the value of  $\lambda_c^{(k)}(H)$ , where  $H$  is a subgraph of  $G$  but  $H$  is not spanning or not connected. If  $H$  is a graph on  $m$  nodes, and  $m < k$ , then every component of  $H$  has order  $\leq k-1$ , so it follows that  $\lambda_c^{(k)}(H) = 0$ . If  $H$  is disconnected and  $H_1, H_2, \dots, H_p$  are the components of  $H$ , then  $\lambda_c^{(k)}(H) = \sum_{i=1}^p \lambda_c^{(k)}(H_i)$ .

**Definition 3.4. [3.5]** If  $F \subseteq E$  is a set of edges,  $G[F]$  denotes the subgraph of  $G$  with node set  $V$  and edge set  $F$ , i.e.  $G[F] = G - (E - F)$ .

**Definition 3.5. [3.5]** If  $U, W \subseteq V$  with  $U \cap W = \emptyset$ ,  $[U, W]$  denotes the set of all edges with one endpoint in  $U$  and the other endpoint in  $W$ .

Now we start with the basis theorem of our lower bound.

**Theorem 3.6. [3.5]** If  $E_1 \cup E_2$  is a partition of  $E$ , then  $\lambda_c^{(k)}(G[E_1]) + \lambda_c^{(k)}(G[E_2]) \leq \lambda_c^{(k)}(G)$ .

**Proof:** Let  $D \subseteq E$  be a  $\lambda_c^{(k)}$ -edge set and let  $D_i = E_i \cap D, i=1,2$ . Since  $E_i - D_i \subseteq E - D$ , each component of  $G[E_i] - D_i$  is contained in a component of  $G - D$  and thus is of order  $\leq k-1$ . It follows that  $\lambda_c^{(k)}(G[E_i]) \leq |D_i|$ . Therefore

$$\lambda_c^{(k)}(G[E_1]) + \lambda_c^{(k)}(G[E_2]) \leq |D_1| + |D_2| = |D| = \lambda_c^{(k)}(G).$$

Therefore we obtain the following lower bound:

$$\lambda_c^{(k)}(G[E_1]) + \lambda_c^{(k)}(G[E_2]) \leq \lambda_c^{(k)}(G), \text{ where } E_1 \cup E_2 \text{ is a partition of } E.$$

In particular if  $u$  is a node of full degree, then  $(n-k+1) + \lambda_c^{(k)}(G-u) \leq \lambda_c^{(k)}(G)$ .

Now let  $U \subseteq V$  be a set of nodes with  $|U| = k-1$ . We construct a  $k$ -component edge-failure set as follows: Delete all edges that connect  $U$  to the rest of the graph, and then delete edges from  $\langle V-U \rangle$  until all components have order  $\leq k-1$ . Thus we obtain the following upper bound:

$$\lambda_c^{(k)}(G) \leq |[U, V-U] + \lambda_c^{(k)}(\langle V-U \rangle), \text{ where } U \subseteq V \text{ with } |U| = k-1.$$

We will apply these bounds to compute  $\lambda_c^{(k)}(G)$ , when  $G$  is  $W_n$ , the wheel of order  $n$ .

**Definition 3.6. [3.5]** The wheel of order  $n$ ,  $W_n$ , is the graph formed by connecting a single vertex to all the vertices of a  $C_{n-1}$ .

The picture below is an example of a network wheel,  $W_n$ , with  $n$  nodes.

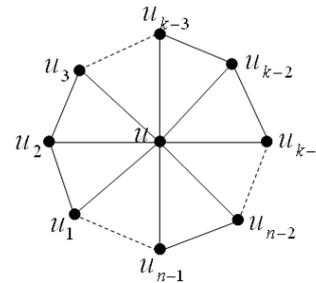

Figure 3.1 A wheel network,  $W_n$ , with  $n$  nodes

Let  $G = W_n$  and let  $u$  be the full degree node. Then  $G - u = C_{n-1}$  and the **lower bound** implies

$$\lambda_c^{(k)}(W_n) = \lambda_c^{(k)}(G) \geq (n-k+1) + \lambda_c^{(k)}(C_{n-1}) = (n-k+1) + \left\lfloor \frac{n-1}{k-1} \right\rfloor \quad (3.1)$$

Now if  $U = \{u, u_1, \dots, u_{k-2}\}$ ,  $V - U = \{u_{k-1}, \dots, u_{n-1}\}$ , then  $|[U, V-U]| = (n-1) - (k-2) + 2 = n-k+3$  and  $\langle V-U \rangle = P_{n-k+1}$ .

Thus the **upper bound** implies

$$\lambda_c^{(k)}(W_n) \leq (n-k+3) + \lambda_c^{(k)}(P_{n-k+1}) \leq (n-k+3) + \left\lfloor \frac{n-k}{k-1} \right\rfloor \quad (3.2)$$

Inequalities (3.1) and (3.2) together yield the following bounds on  $\lambda_c^{(k)}(W_n)$ :

$$(n-k+1) + \left\lceil \frac{n-1}{k-1} \right\rceil \leq \lambda_c^{(k)}(W_n) \leq (n-k+3) + \left\lceil \frac{n-k}{k-1} \right\rceil \quad (3.3)$$

We will find a formula for  $\lambda_c^{(k)}(W_n)$  by comparing the lower and upper bounds.

$$(n-k+1) + \left\lceil \frac{n-1}{k-1} \right\rceil \leq (n-k+3) + \left\lceil \frac{n-k}{k-1} \right\rceil. \text{ Subtracting } (n-k+1) \text{ from each side gives}$$

$$\left\lceil \frac{n-1}{k-1} \right\rceil \leq 2 + \left\lceil \frac{n-k}{k-1} \right\rceil \quad (3.4)$$

Applying the division algorithm write  $n-k = \alpha(k-1) + r$  where  $0 \leq r \leq k-2$ , thus  $\alpha = \left\lfloor \frac{n-k}{k-1} \right\rfloor$ .

Hence  $n-1 = (n-k) + (k-1) = \alpha(k-1) + (k-1) + r = (\alpha+1)(k-1) + r$ . If  $r \geq 1$ , i.e.,  $(k-1)$

does not divide  $(n-1)$ , then  $\left\lceil \frac{n-1}{k-1} \right\rceil = \alpha + 2 = \left\lfloor \frac{n-k}{k-1} \right\rfloor + 2$ . If

$r = 0$ , i.e.,  $(k-1)$  divides  $(n-1)$ , then  $\left\lceil \frac{n-1}{k-1} \right\rceil = \alpha + 1 =$

$$\left\lfloor \frac{n-k}{k-1} \right\rfloor + 1.$$

**Theorem 5.2.** Let  $G = W_n$  be wheel on  $n$ -nodes then

$$\lambda_c^{(k)}(W_n) = \begin{cases} (n-k+1) + \left\lceil \frac{n-1}{k-1} \right\rceil & \text{if } (k-1) \text{ does't divide } (n-1) \quad (1) \\ (n-k+2) + \left\lceil \frac{n-1}{k-1} \right\rceil & \text{if } (k-1) \text{ does divide } (n-1) \quad (2) \end{cases}$$

#### IV. CONCLUSION

Edge connectivity failure model provides opportunities that if new model component subnetworks that are separated by the removal of some links, the resulting subnetworks can still in operate if every subnetwork has node of order greater than  $k-1$ . This provides advantages over conventional forms of edge connectivity failure model, which does not give an opportunity to operate subnetwork if overall network is not connected. Although such communication networks are disconnected with only one node that is not connected while the other  $n-1$  subnetwork that has a numbered node, it can still communicate well with each other.

From the description of the amount of investment cost of link construction, if the purpose of the construction of a communications network is intended for the construction of a fiber optic network that spans the width of the country, the total investment cost of the construction of the link must be considered to determine the economic network model, given the cost is expensive enough. But it also needs to consider choosing a network model that has a low level of vulnerability

to the threat of dissolution all personal communication network. So the level of vulnerability to edge connectivity new models discussed above can be considered to select the appropriate network. For the number of  $n = 30$  and by taking a value  $k = 5, 10, 15$ , both of large investment costs and the level of development link vulnerability are compared. Star and Path networks need the same investment cost, 29 units cost, but Star network is less vulnerable than Path network. Cycle network needs 30 units cost of investment, with degree of vulnerability less than Path but higher than Star networks. Complete and Wheel networks need investment cost of 435 and 58 units cost, respectively, with Complete less vulnerable than Wheel. However, Complete network has never been implemented in the real communication network. Wheel network is the most expensive but has less vulnerability compared with others. The highest vulnerability is the Path network.

**Abstract**— At the firstly, single element of the singly fed pentagonal patch antenna using air gap is proposed. The results show that the bandwidth of impedance, axial ratio, and gain at the resonant frequency 2.4925 GHz are 15.67 %, 4.11 % and 52.16 %, respectively. Moreover, the value of S-parameter, axial ratio and gain at 2.4925 GHz are -15.03 dB, 0.06 dB and 8.74 dBic, respectively.

Furthermore in this research, it is also investigated circularly polarized array pentagonal microstrip antenna for mobile satellite communications especially to enhance the bandwidth axial ratio that are examined both of simulation and measurement. The results of array pentagonal patch antenna is similar with its single, especially the value of S-parameter, axial ratio and gain as the mentioned above.

The other results related the simulation show that the cutting of beam angle between of them is the same. In case of measurement results, owing to loss during measuring, the gain decreasing and affect the cutting of beam angle between gain and axial ratio that is not satisfied yet.

## I. INTRODUCTION

Multimedia communications through geostationary satellites will be an essential part of future information infrastructure since the satellite-based communication provides "simultaneous" and "flexible" information network without large facilities. The future satellite networks will be tightly integrated with the terrestrial networks as an integral part of our future global information infrastructure. Space-based network which has survivability against disasters and flexibility will complementally work with mobile and fixed ground-based system in order to realize a reliable and mobile "ubiquitous" information society.

As geostationary satellites are remotely located (about 36,000 km) from the earth, the incoming wave is very weak. Consequently, it is required that the antenna for mobile satellite communications has a high gain in the case

multimedia communications performing large-capacity data communication is aimed. Furthermore, when thinking of the integration to cars, from the point of view of the car design, it is recommended the overall system to be light and compact.

Inside a view of the car that the antenna located above it need a feeding. The singly fed circularly polarized (CP) antennas have inherent limitation in gain, impedance and axial ratio bandwidths. This is mainly owing to the resonant nature of the patch antenna which has a high unloaded Q-factor and the frequency-dependent excitation of two degenerative modes ( $TM_{01}$  and  $TM_{10}$ ) when using a single feed. In order to achieve enhanced gain, impedance and CP bandwidth, several single-feed single element patch antenna designs using an air-layer or foam substrate for minimizing the unloaded Q-factor [1],[2]. Another way to increase the bandwidth of antenna by using the stacked patches and electromagnetically coupled patch configurations have been presented [3],[4].

Here, it will be designed pentagonal antenna using thick substrate (with air gap) for enhancing bandwidth of antenna with a simple configuration (see Figure 1) and also for designed the array pentagonal antenna configuration both of simulation (by the method of moments using Ensemble version 8 software) and measurement to prove that the cutting of beam angle between gain and axial ratio is the same. The other shape of pentagonal like a kite has been proposed by Weinschel [5] which the characteristic of antenna parameter similarly with pentagonal antenna. The purpose of this research is to yield the enhanced bandwidth of antenna for mobile satellite and radar applications.

One of the most common techniques for calculating the unknown current is the Method of Moments. This discretizes the integral into a matrix equation which can then be solved. This discretization can be considered as dividing the antenna surface into a number of small elements. From the current distribution, the S-parameters, radiation pattern and any other parameters of interest can be obtained.

## II. CONFIGURATION OF ANTENNA

Figure 1 and Figure 2 show the configuration of antenna design, for single and array pentagonal antenna, respectively. Both of antennas are using a conventional substrate (relative permittivity 2.17 and loss tangent 0.0009) and fed by a coaxial probe to avoid the degradation of elliptic by unwanted radiation from the feed network.

Figure 1 show the single model designed of pentagonal antenna using air-gap whose angle  $\angle\theta$  is  $45^\circ$ . The shape of such a pentagonal can be prescribed completely by two parameters  $c/a$  and  $b/a$ . The pentagon becomes a rectangle when  $c/a = 0$ , an isosceles triangle when  $c/a = 1$ . It is considerable for enhanced the bandwidth, its position of  $c/a$  is  $0 < c/a < 1$  or in the others word the patch shape should combine two or more shapes in becoming one (pentagon = triangle + rectangle). In this case, only combining two shapes for getting wide bandwidth of antenna is not enough, for matching impedance  $50 \Omega$  and smoothly axial ratio and gain are added the dimensions of antenna, air gap and feed location which must be chosen correctly (see Figure 1). They are used to excite more than one mode where each of mode degenerates two frequencies closed, hence much of the magnitude currents paths around this area move to  $y$  direction and  $x$  direction which perpendicular with each others, hence increasing the bandwidth of axial ratio.

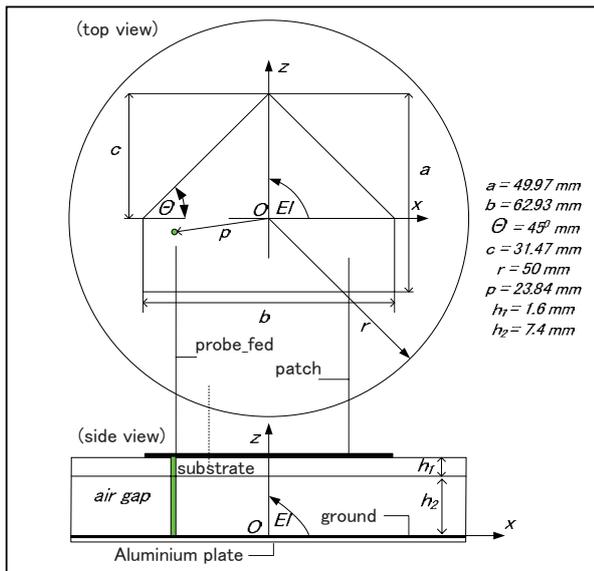

Figure 1. Configuration of single pentagonal antenna

For LHCP (Left Hand Circular Polarization), the feeding is located on the left side from null potential. This is happened 3 modes at the frequency operation 2.4925, 4.5 and 6.8 GHz, but only a good radiation characteristic is happened in the first mode at 2.4925 GHz. This is dominant modes ( $TM_{01}$  and  $TM_{10}$ ) owing to by the shape perturbation (pentagonal) using air-gap, the effective excited patch surface current path in the  $y$  direction is slightly shorter than that in the  $x$  direction, which gives the  $y$ -directed resonant mode a resonant frequency slightly larger than that of the  $x$ -directed resonant modes of

equal amplitudes and  $90^\circ$  phase difference at the left side of pentagonal for LHCP operation.

In this paper, the method of moment (Ensemble version 8 software) is employed to simulate the model with an infinite ground plane. Consideration of the efficient thickness of the antenna (see Figure 1) allowed either the substrate thickness for pentagonal patch to be defined with the single substrate or single layer using air-gap ( $h_1 = 1.6 \text{ mm}$  and  $h_2 = 7.4 \text{ mm}$ ).

Figure 2 depicts design of simulated array pentagonal antenna is composed of three pentagonal patch antennas which fed directly from the switching circuit on the beneath of the construction. Figure 3 shows geometry of array the fabricated antenna is made by microstrip material ( $\epsilon_r = 2.17$ , loss tangent 0.0009) which instead of three pentagonal patch antennas and the same fed with simulated antenna, but this antenna without used the parasitic elements. With this geometry the antenna becomes simple, compact and low loss, because no need a power divider to distribute power signal to the antenna element. The dimension of the construction is 190 mm and 7.2 mm in diameter and height, respectively.

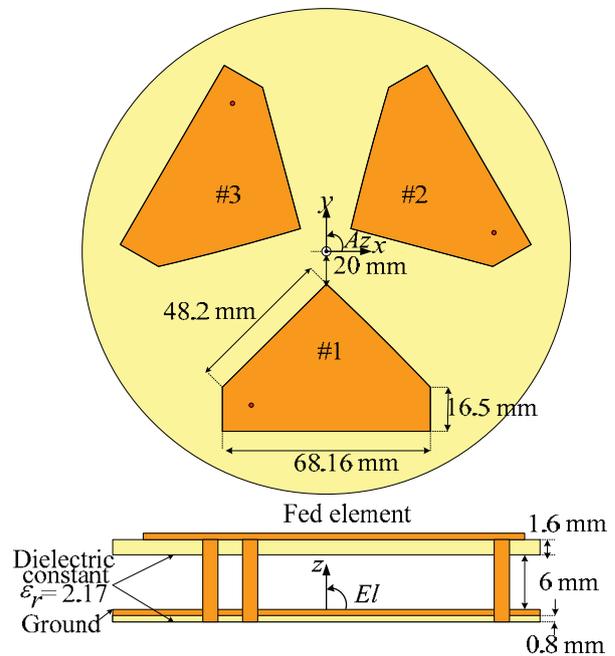

Figure 2. Design of simulated array pentagonal antenna

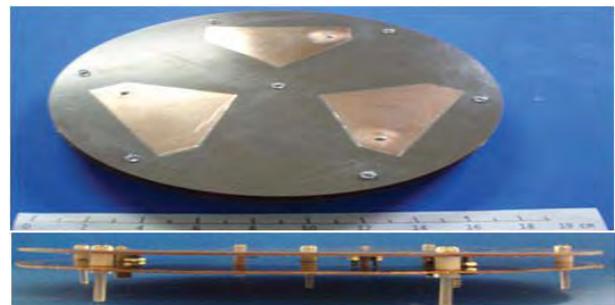

Figure 3. Geometry of array fabricated antenna

### III. DISCUSSION

Figure 4 to Figure 6 shows the result for simulation both single element and array pentagonal antenna, in the case of frequency characteristic,  $S$ -parameter, and input impedance. Figure 4 shows that the value of gain and axial ratio ( $Ar$ ) for simulated at the resonant frequency 2.4925 GHz i.e. about 8.74 dBic and 0.06 dB, respectively. In addition, the bandwidth of axial ratio antenna is about 4.11%.

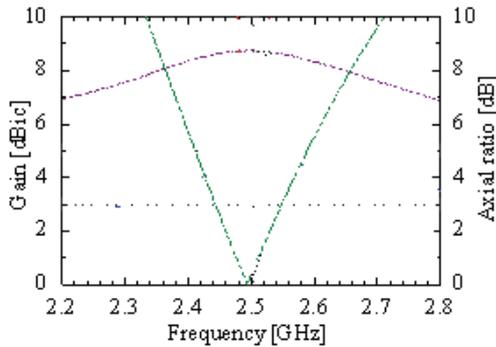

Figure 4. Gain and axial ratio vs frequency

Figure 5 shows the relationship between the reflection coefficient ( $S$ -parameter) and frequency for the simulation antenna. From this figure, it can be seen that the bandwidth of  $S$ -parameter enough width i.e. about 15.67%. It is caused by the new shape of perturbation antenna likely a pentagonal where the area square is large about 2154.3 mm<sup>2</sup>. In addition, it is also caused the effect of air-gap and location of feeding that matched with the configuration of antenna to yield the targets satisfied. Moreover, the value of  $S$ -parameter at the resonant frequency is good around -15.03 dB.

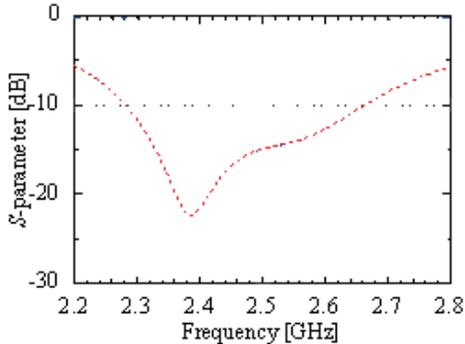

Figure 5.  $S$ -parameter

Figure 6 depicts the input impedance characteristic that the real and reactance part are satisfied where for real and reactance impedance by closed 50  $\Omega$  and by closed 0  $\Omega$ , respectively.

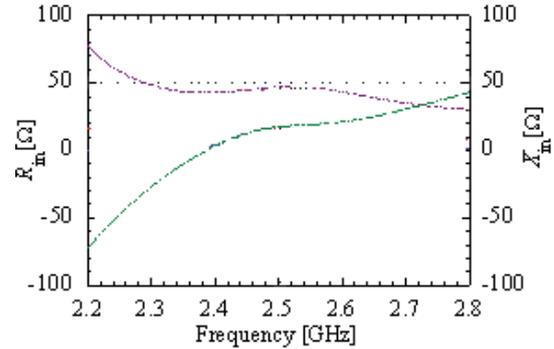

Figure 6. Input impedance

For coaxial-fed antennas, it can slightly effect toward the resonant frequency, axial ratio,  $S$ -parameter and input impedance which is dependent on the feed position. By choosing the feed position properly, an effective match between the antenna and the transmission line can be obtained.

Figure 7 shows the frequency characteristics for the simulation and measurement of array antenna results are difference between them, usually the measurement antenna shifted to higher frequency, but in this case shifted to lower frequency. This is probably owing to error during fabricated and measurement. The resonant frequency for simulation located at 2.48 GHz, but measurement is located at 2.43 GHz [8]. In this case, the phenomenon of antenna is still investigated for knowing the reason of this anomaly. Furthermore, to analyze radiation pattern, this antenna allocated at 2.5 GHz.

It is necessary to have a traveling wave current distribution which has constant amplitude and a linearly changing phase for a pentagonal antenna to radiate a circularly polarized wave. In the generally theoretically of antenna, a circularly polarized wave can be radiated by means of loading a reactance of an appropriate value. Instead of loading an appropriate reactance, a very simple method is to use air gap. By introducing such air gap with a certain size of pentagonal antenna and feeding the antenna with a coaxial probe, a traveling-wave current distribution could be excited, and as a result, a circular polarization can be achieved.

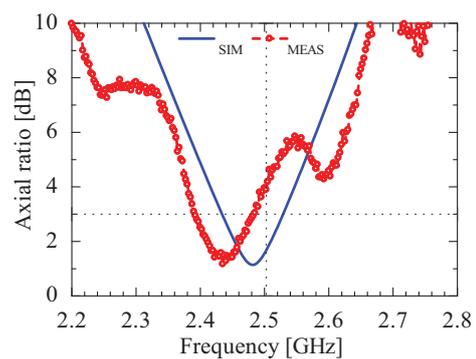

Figure 7. Frequency characteristics at  $El = 48^\circ$

Figure 8 describes the elevation cut-plane with performance of the antenna at the elevation angle  $El = 38^\circ$ .

58°. In this results, generally are the same between simulated and measured array antenna results, especially of gain, but axial ratio in measured is considerably effected by the shape of ground (considering that simulation used infinite ground and measurement used finite ground with a circle-shape) and also effected by conductivity ( $\sigma$ ) and permittivity ( $\epsilon_r$ ) of ground. Hence, the axial ratio at the elevation direction from 38° - 58° is not satisfied the targets yet. Moreover, it owing to error during fabricated, especially when soldering a feed on the ground is still not optimized.

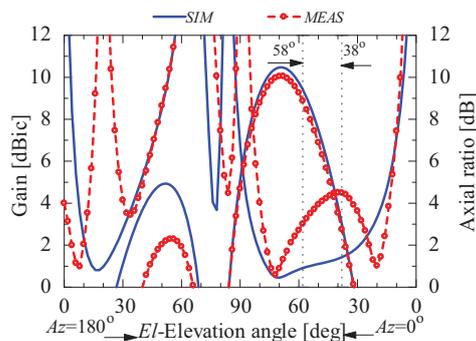

Figure 8. Elevation cut-plane at  $f = 2.5$  GHz

Figure 9 depicts conical cut plane for  $El=48^\circ$  at the frequency  $f = 2.5$  GHz for measurement. This is meant to evaluate the antenna system without circuit switching as far as how the good performances could be occurred with a new shape of antenna and also the effected of using a ground antenna [9].

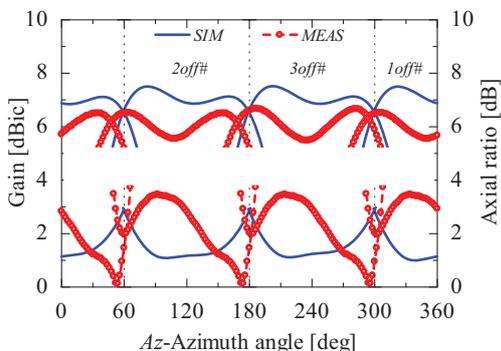

Figure 9. Conical cut-plane at  $f = 2.5$  GHz

In this figure, it is seen that the cutting of beam angle between the axial ratio and gain in simulated is the same. This happened probably owing to the phase of modes both of gain and axial ratio in simulation are the same. Contrary, in measurement that is not occurred yet in one beam angle for that case. This is owing to performed of ground is not optimized, especially its conductivity ( $\sigma$ ) and permittivity ( $\epsilon_r$ ) is not matched with the radiating antenna. The strongly effect of a ground could be seen in gain measurement, it decreases significantly compared with the gain simulation, so the cutting of beam angle in measurement is difference between axial ratio and gain [10]. The other reason is probably in fabricated

antenna, whereas a soldering between feed and ground also not good, hence the current distribution on the patch radiating of antenna could not flowed normally. In addition, owing the effected of power divider and semi-rigid is not optimized, especially a phase of semi-rigid circuit to connected two of three feed on beneath of the construction antenna is not same, hence the axial ratio could not obtained satisfy, because of the axial ratio is very sensitive with difference of phase.

#### IV. CONCLUSION

- A configuration of circularly polarized single and array pentagonal microstrip antenna for mobile satellite applications is proposed.
- A circular polarization can be simply obtained by properly adjusting the element parameters and using air gap.
- The results show that the bandwidth of impedance, axial ratio, and gain at the resonant frequency 2.4925 GHz are 15.67 %, 4.11 % and 52.16 %, respectively.
- Moreover, the value of S-parameter, axial ratio and gain at 2.4925 GHz are -15.03 dB, 0.06 dB and 8.74 dBic, respectively.
- The results of characteristic performance, especially bandwidth of axial ratio of the pentagonal antenna is good, caused by a new shape of pentagonal antenna using air-gap and good choosing of a feed position.
- The problem in cutting of beam angle between gain and axial ratio owing to phase of modes both of gain and axial ratio in simulation and measurement.

**Abstract**— Halim Perdanakusuma an alternative airport for domestic flights and overseas, lack of human resources and the amount of electronic equipment at the airport does not allow technicians to always be on station transmitter 'DVOR' (VHF Doppler Omny Range). 'DVOR' is an air navigation system that emits electromagnetic waves all these directions and provide information bearing on the station as well as the data plane bearing, beacon transmitter also transmits data to the three-letter code identity or the identity of the sound to be received by the recipient on the plane. This resulted if DVOR 'off', the technician cannot know the condition early this highly disturbing aviation safety. We need a draft monitoring status on the desk DVOR tower. One is to use 'sms' DVOR order status can always be monitored.

This research was designed a system of observers. In the design of the system output RCSE DVOR will affect the output of the logic gate, if it is operating normally at the logic gate output = 0 so that the relay is not switched on, the green LED will be on the line desk Tower will produce a voltage of 3 Volts DC in addition to the microcontroller does not work. In DVOR, RJ11 stated, if the output on RJ 11 = 0 Volt DC and if DVOR 'off' at the transmitter is on one or both transmitter off the output at the logic gate = 5 Volt DC so that the relay will be active so that line the red LED on the desk tower will generate a voltage of 3 Volts DC and output on an RJ 11 = 0.5 Volts DC so that the modem will be activated and sends a message to the technician in charge DVOR.

**Keywords**— DVOR, re-engineering, wireless communication

## I. INTRODUCTION

DVOR (Doppler VHF Omny Range) is an air navigation system that emits electromagnetic waves all these directions and provide information bearing aircraft of the station DVOR equipment is working at a frequency of 108-118 MHz, in addition to bearing the data, beacon transmitter also transmits data to the identity of the three-letter code or the identity of the sound to be received by the recipient on the plane. By looking at the function of the equipment were very influential to aviation safety, the required equipment is always in a condition ready for use. However, there are many things that cause the equipment off, both internal factors such as the condition of older equipment and the condition of the components are not functioning properly, as well as external

factors such as lightning. Given such conditions, should be in charge of electronics technicians constantly monitor the status DVOR. However DVOR, the lack of adequate manpower, while the amount of equipment that is under the responsibility of electronics so much that it is not possible to always be on the equipment that is located very DVOR far as non workshops electronics technician. All this to determine whether or not an operating DVOR pilot to report through the ATC (Air Traffic Control). Thus, the flight safety can be compromised. In addition, the presence of complaints - complaints that often occurs can lead to decrease in the company's image as the manager of airport services in the eyes of the domestic flights, and airport image in the eyes of the international flight. From the description above, one solution to determine if it is operating normally DVOR or not, is to create a design DVOR status monitoring.

## II. BASIC THEORY

### A. DVOR (Doppler VHF Omnidirectional Range)

DVOR is an air navigation aid that can provide directional information to aircraft on the airport to provide information bearing aircraft of the marionette DVOR. This equipment works at a frequency of 108- 118 MHz, in addition to bearing the data, beacon transmitter also transmits data to the identity of the three-letter code or voice identification that will be accepted by the recipient on the plane. Besides, it is a function of DVOR Indicates the position of the aircraft station transmitter so as to know the area in its path, and shows the radial direction so as to Run Way. Run Way towards specified. Reference signal is 30 Hz AM signal emitted by the instantaneous phase uniformly in all directions resulting from the RF carrier signal ( $f_c$ ) are modulated AM signal with 30 Hz. The resulting signal is then emitted by the antenna carrier see figure 1(a).

The variable signal is a signal generated from the modulation frequency from the simulation of movement or rotation of non directional RF signal source ( $f_c \pm 9960$  Hz) around the circle with a speed of 1800 rpm which cause modulation frequency of 30 Hz, this is done by connecting the electronic switching sequentially at each sideband antenna located on the antenna around the carrier signal variable pattern formation is shown in figure 1(b).

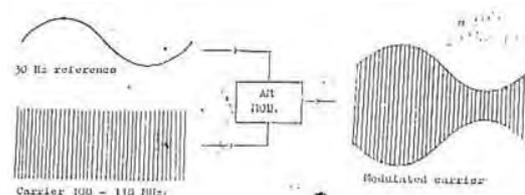

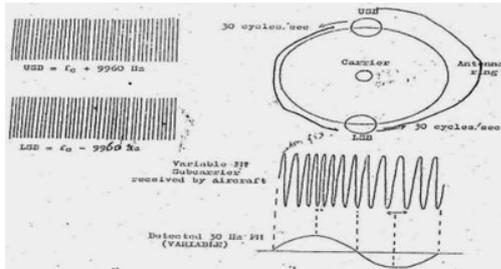

Figure 1 (a) AM Modulation between reference 30 Hz and carrier signal

(b) Pattern formation variable signal

Mixing between the reference signal and the variable signal occurs in the air, a combination of variable reference signal and the signal power radiated into the air will produce a carrier frequency modulated by a 9960 Hz AM (Subcarrier). Further 9960 Hz subcarrier FM modulated with 30 Hz, because of the Doppler effect see Figure 2. Reference signal and the signal is generally used as a pattern variable instantaneous phase, the phase difference between the signal and reference signal to the variable direction see figure 3.

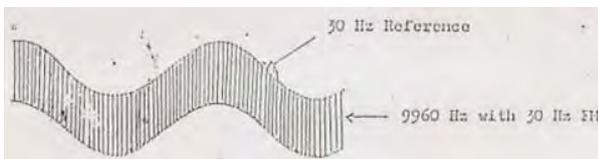

Figure 2. Signals emitted from DVOR

DVOR transmits all directions antenna DVOR have 1 piece of antenna carrier and subcarrier antenna 48 pieces. DVOR antenna signals emitted a high frequency, so any solid objects can reflect signals. Ground bounce signal power radiated by the antenna DVOR. Therefore the receiver aircraft to obtain two signals emitted signals (direct) and the signal beam reflectance (reflected). Both have the same frequency but have different emission lines. The lines transmit the reflected signal is longer than the direct signal transmission lines.

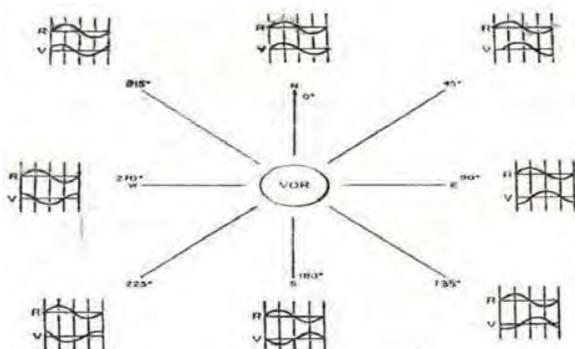

Figure 4. Variable phase difference between the signal and reference signal

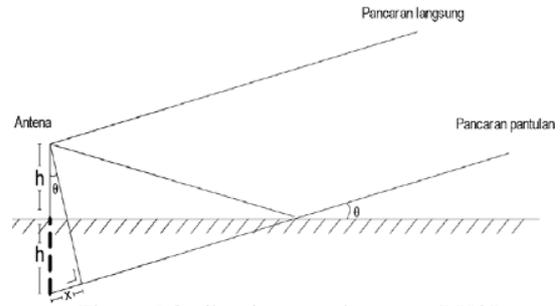

Figure 5 Outline the transmit antenna DVOR

Figure 5. seen that reflected signal transmission line is longer than the direct beam transmission lines are marked by the addition of whole X. Antenna DVOR in principle is to emit 30 Hz variable signal is FM modulated and the reference signal 30 Hz modulated AM. Two signals having the same frequency emitted together but separated from each other. The results of the combination of the two signals emitted form the carrier frequency of 30 Hz. This frequency is obtained from the playback DVOR antenna 30 times rev / sec. In one pair of antennas such as antenna 1 to antenna 25 has a frequency USB (upper sideband) and LSB (lower sideband). Antenna 1 is USB while the antenna 25 is LSB.

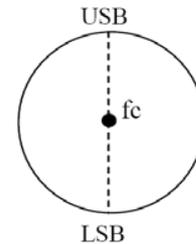

Figure 6. LSB dan USB pada antenna DVOR

The resulting radiation pattern DVOR the radiation pattern that has 3 main lobe to the center in  $8^{\circ}$ ,  $28^{\circ}$  and  $50^{\circ}$ . Figure 7 shows there is a considerable distance between the lobe with one another, leading to the absence of radiation (due to the removal of the direct signal and the reflected signal.) To overcome this it will be installed Counterpoise DVOR additional antenna mounted just below the act as an additional reflective area. If the antenna is mounted above  $\frac{1}{2} \lambda$ . Counterpoise it will result in major energy lobe wide and centered at  $30^{\circ}$ . The combination of radiation signals coming from the ground and from the reflection of the overall radiation produced Counterpoise DVOR which will result in wider coverage at an angle of between  $0^{\circ}$  to  $60^{\circ}$ , while the area

just above DVOR (angle of more than  $60^{\circ}$ ) there is no radiation and is called the area Cone of Silence as shown in figure 9.

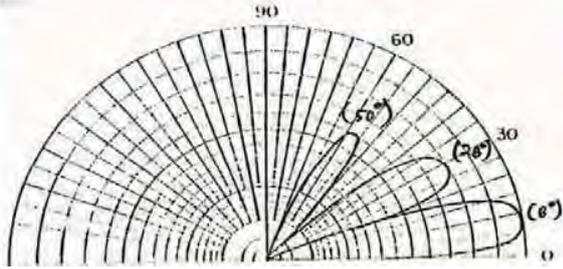

Figure 7. Three major lobe centered

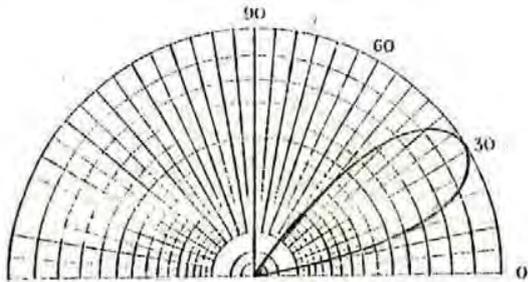

Figure 8. Major lobe centered using the counterpoise

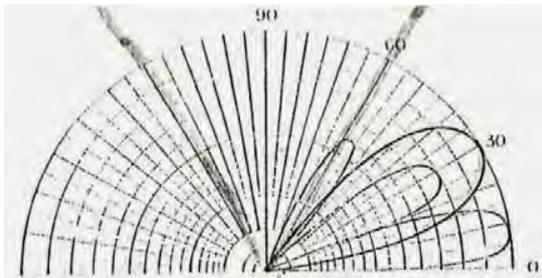

Figure 9 The area of the emission cone of silence

Size of Counterpoise effect on the radiation pattern that will act as a reflector or reflector above a certain angle. While the point of the reflector is ground level. This angle is called the critical angle. Therefore, the low-angle coverage resulting from surface reflection while for high angle coverage resulting from the reflection counterpoise.

### B. Remote Control and Status Equipment

In control DVOR there is a unit that can control the RCSE DVOR (Remote Control Status Equipment) is a module that can control DVOR, while the information that can be provided by the RCSE are as follows: Status transmitter is used, help the transmitter is used, select or move the transmitter is used, select equipment that will be on the controls of (DVOR or DME). RCSE can also be connected via the PC to see DVOR and DME equipment parameters, as well as full control equipment via a data output on a block SIB (Serial Interface Board).

## III. SYSTEM DESIGN

### A. Hardware Design

Overall block diagram design DVOR Status Monitoring. At the Desk Tower at Halim Perdanakusuma Airport Using SMS as a block below

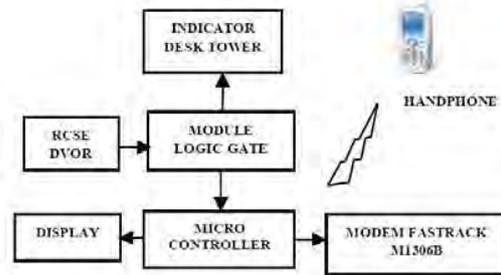

Figure 10. Block System Design

The workings blocks are designed, at RCSE DVOR is off then at that time on the logic gate output LED will turn red on the desk next to that tower will enable the microcontroller, the microcontroller will activate Fastrack M1306B modem and transmit data in the form of SMS to the person in charge DVOR and microcontroller will display the same phone number charge. If when RCSE DVOR under normal conditions the output of the logic gate module only turn green LED on the desk and does not activate the microcontroller.

### B. Logic Gate Module

Logic Gate serves as a monitoring status ON or OFF for the case of the condition of the equipment DVOR transmitter 1 and transmitter 2, then you want only two conditions, namely 1 and 0 only. To get the output and the desired condition then use NAND logic gate. So the output of DVOR can be converted into a truth table NAND gate. The circuit for this design is as follows

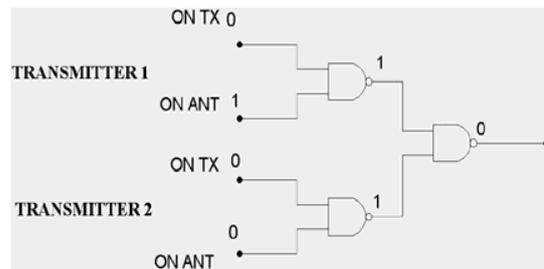

Figure 11. DVOR Transmitter 1 Normal operating conditions and Transmitter 2 Standby

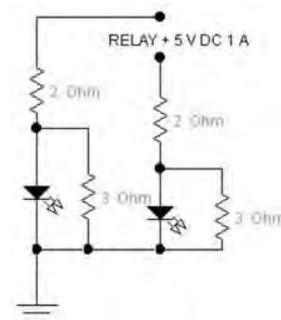

Figure 12. Lowering circuit Voltage and current on Indicator LED Desk Tower

C. Indicator Desk Tower

In the design of the Desk Tower taken from Vcc at 5 Volt DC and 1 A, which is connected to the first switch omron relay, but voltage and current to turn on the LED is too large, while the LED operates at 3 VDC 100 mA. So the decline in the use of voltage and current in the LED, see Figure 12.

D. Microcontroller ATmega 16

In this design ATmega microcontroller used is 16 to control the system, for monitoring system, used in the form of an LCD display and MODEM Fastrack M1306B, transmit information to the condition RSCE DVOR phone number officers, for all the design system see figure 13.

IV. SYSTEM UNDER TEST AND ANALYSIS

A. Desk Tower Data Analysis

The test data on the desk tower begins at 5 Volt DC OMRON relay the switch will be connected so that the voltage on the line green LED will light up with a value of 3 Volt DC voltage on the red LED will otherwise die, otherwise at the time of death DVOR the relay will die so relay switches back to the open position and the switch is connected to the red LED will light up with a 3 Volt DC voltage, see Table 1.

B. Data Microcontroller Test and Analysis

Testing microcontroller begins when the voltage of DVOR logic 0 so that the relay is not working so the relay will switch back to normally open so that at the same time the red LED will light up and the pins 0 and 1 on port B is connected so that it will enable the IC ATMEGA 16 and will work according with

Figure 13. Picture All module in the System

Table 1. LED Indicator on Desk Tower

DVOR	DESK TOWER	
	GREEN LED	RED LED
ON	ON	OFF
OFF	OFF	ON

Table 2. Output Microcontroller

Microcontroller Input	RJ 11
pin 0 and 1 Short	0,5 Volt
pin 0 and 1 Open	0 Volt

instructions that have been uploaded into the microcontroller ATMEGA 16 and RJ 11 produced in the form of a voltage of 0.5 volts per message delivery takes place, which is then sent to the modem to be broadcast in addition it will produce output on Port C are connected to the LCD display 16 x 2 to display the number of short messages sent purposes.

C. Modem FASTRACK M1306B

Modem FASTRACK M1306 modem B is working on a dual frequency on the 900/1800 Mhz and has an input voltage of 5, 5 Volt minimum voltage, current modem power supply given the time it will turn the whole modem component, after the modem is active, will be in a condition standby waiting for input from the microcontroller, if the microcontroller to provide input on the modem, the modem will send data and destination address in the format that has been in ATMEGA 16 and then radiated through the modem to the phone DVOR charge. see Table 3.

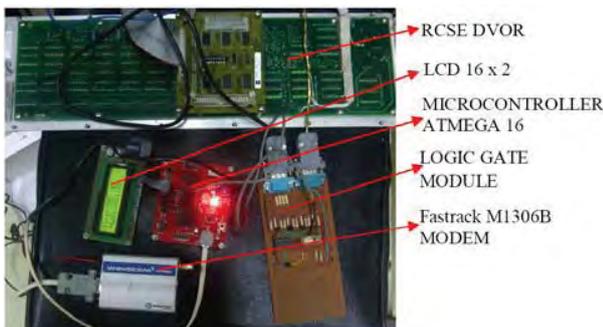

Table 3. Data form testing for all system

INPUT TX 1 AND TX2		OUTPUT LOGIC GATE	OUTPUT MICROCONTROLLER RJ 11	DESK TOWER INDICATOR	
TX	ANT			GREEN	RED
1	1	0	0	ON	OFF
0	1	1	0,5 V	OFF	ON
0	0	1	0,5 V	OFF	ON

Testing and analysis of the overall data began in DVOR ie when it is in normal condition and then output to the TX ANT ON, on Transmitter 1 and Transmitter 2 will control the input to the fourth transistor, and the transistor will produce a combination of input NAND gate, the output of NAND gate will be logic 1 or 0, if logic 1 it will activate the transistor and which serves as a direct current switching because of the NAND gate is not able to activate the relay coil. Green LED will light tower on the desk, if NAND gate transistor logic 0 then it does not work that ultimately will make the relay is not working so the Red LED Desk Tower will be blamed, at the same time switch relay to be short so that the two inputs on port B pin 0 and 1 on ATMEGA 16 microcontroller will be connected so that the microcontroller will work according to the instructions that have been uploaded, then the microcontroller ATMEGA 16 will result in the RJ 11 which will then input data on Fastrack M1306B modem which then sends the data in the form of a short message that "DVOR OFF" to 5 numbers DVOR is responsible, "085255525308, 081389597256, 081380211201, 081522572110, 085649599334" who had been in the previous program in microcontroller ATmega16 see Table 4.

Table 4. Data Test in the form of SMS

Modem Input	Destination Number and Location				
	085255525308 Makassar	081389597256 Depok	081380211201 Bogor	081522572110 Halim Perdanakusuma	085649599334 Halim perdanakusuma
0,5 Volt	DVOR OFF	DVOR OFF	DVOR OFF	DVOR OFF	DVOR OFF
0 Volt	-	-	-	-	-

Table 5. Data Test in system design

INPUT TX 1 AND TX2		OUTPUT LOGIC GATE	OUTPUT MICROCONTROLLER RJ 11	DESK TOWER INDICATOR	
TX	ANT			GREEN	RED
1	1	0	0	ON	OFF
0	1	1	0,5 V	OFF	ON
0	0	1	0,5 V	OFF	ON

1. If the normal operating status DVOR the logic gate output module = 0 Volt and DVOR in OFF condition when the output of the logic gate = 5 Volt so that control the relay input on the microcontroller and LED Desk Tower will be Active.
2. If DVOR status is in normal condition, the green LED will be on the line desk Tower will produce a voltage of 3 volts DC, when DVOR dead at the transmitter is on one or both transmitter off the line the red LED on the desk tower will produce a voltage of 3 volts DC.
3. If the transmitter 1 and transmitter operate normally DVOR 2 standby or vice versa, then the microcontroller does not work, so that the output on an RJ 11 = 0 volts so that the modem does not work and if the transmitter 1 and 2 on the transmitter is off, it will activate the modem to send data in the form of SMS to 5 numbers that have been programmed in the microcontroller.

**Abstract** –In this paper, some development and testing for payload communication board using Transceiver ADF7021, temperature sensor and integration with TNC are proposed. Transceiver ADF7021 is developed for 145.95MHz uplink frequency and 436.915MHz downlink frequency and to be applied for IiNUSAT Nanosatellite payload communication. The payload communication board is developed to be able for 2FSK demodulation and 1200bps data rate for receiver, and 2FSK modulation with 9600bps data rate for transmitter. In addition, the payload communication board is also support for data encapsulation using ADI protocol, and data delivery and must match for uplink frequency. TNC is designed to be able to fulfill the utility as data processing storage FX.25 data protocol, and temperature sensor at TNC board. Temperature monitoring is developed using LM35DZ and is designed for temperature range from 0-100°C. The testing results showed that payload communication board is work at the center frequency of 436.915MHz with -29.2dbm gain and -28.8dbm gain at a frequency of 436.91MHz. TNC is work and can be communicate the data to nanosatellite OBDH system. In addition, programming LM35 temperature sensor has been successfully implemented with the normal conditions of 33°C.

**Keywords** — Payload Communication board, ADF7021, TTC, TNC, Nanosatellite.

## I. INTRODUCTION

IiNUSAT (Indonesian Inter-University Satellite) is a nanosatellite which proposed by researcher from five state university and LAPAN. IiNUSAT Nanosatellite is designed for emergency calls and from the planning, the satellite is to be launched in 2013. The focus of our research related to this research project is to develop payload communication board including data communication interface between payload communication board to OBDH nanosatellite and also to design temperature sensor for payload communication board.

Payload communication is one of the subsystem which consist of Transmitter, Receiver, and TNC [1], [2], [3] [4]. Nanosatellite payload communication must be able to process data delivery, data encapsulation using protocol, and also to manage data delivery to the ground station. There are two kinds of RF which can be used, there are analog RF and IC RF. RF which used IC Transceiver has some benefits, they are easier to set register at processor chip and

the components of transceiver are stronger and reliable for space condition [5]. NC is the storage board of decode data which proposed to receive and communicate the to OBDH satellite system board.

In this paper, some development and testing of payload communication board using Transceiver ADF7021 and integration to TNC board and temperature sensor are proposed. Payload communication board is desinged for 145.95MHz uplink frequency and 436.915MHz downlink frequency and to be applied for IiNUSAT Nanosatellite payload communication. some tests for the parts of TTC payload IiNUSAT nanosatellite. The payload communication board is developed to be able for 2FSK demodulation and 1200bps data rate for receiver, and 2FSK modulation with 9600bps data rate for transmitter. In addition, the payload communication board is also support for data encapsulation using ADI protocol, and data delivery and must match for uplink frequency. TNC is designed using ATMEGA1280 microcontroller and to be able to fulfill the utility as data processing storage FX.25 data protocol, and temperature sensor at TNC board. Temperature monitoring is developed using LM35DZ and is designed for temperature range from 0-100°C. Register settings and simulation for ADF7021 can be performed by using ADIsim software, TNC hardware design using ALTIUM, and temperature monitoring process simulated using ISIS proteus.

The testing results showed that payload communication board is work at the center frequency of 436.915MHz with -29.2dbm gain and -28.8dbm gain at a frequency of 436.91MHz. TNC is work and can be communicate the data to nanosatellite OBDH system. In addition, programming LM35 temperature sensor has been successfully implemented with the normal conditions of 33°C.

## II. IINUSAT COMMUNICATION PAYLOAD

### A. Communication Payload Specification

Payload Communication specification consists of transmitter, receiver, TNC, and antenna and components specification are selected and adjusted for space proven condition. The specification of IiNUSAT payload communication system is shown in Table 1.

TABLE 1. IiNUSAT Payload Communication Specification

Communication Payload Specification	
Parameter	Provision
System	Full Duplex
Delivery Method	Real Time & Store and forward
Protocol	FX-25
Center Frequency	Downlink = 436.915 MHz (bandwidth 30 KHz) Uplink = 145.95 MHz (bandwidth 10 KHz)
Data type	TTC Uplink = Command dan update OBDH Downlink = Telemetry dan house keeping Data = Character Packet (500 character)
Bit rate	Downlink = 9600 Bps (FSK) Uplink = 1200 Bps (FSK)
Minimum BER	$10^{-5}$
Payload Type	Regenerative
Antenna Type	Receiver = Monopole Transmitter = Monopole

**B. IC Transceiver**

IC transceiver ADF7021 for nanosatellite is used and developed for IiNUSAT nanosatellite because this transceiver has fully support for all function of payload communication system that is to be used for payload communication satellite system. The IC Transceiver ADF7021 is much easier to developed circuit to get frequency both uplink and downlink of satellite system. ability to set the frequency much easier, suitable modulation and demodulation. Also, the value of power amplifier can be adjusted that are already include for power amplifier and LNA function. The block diagram of the transceiver ADF7021 is shown in Figure 1 [5].

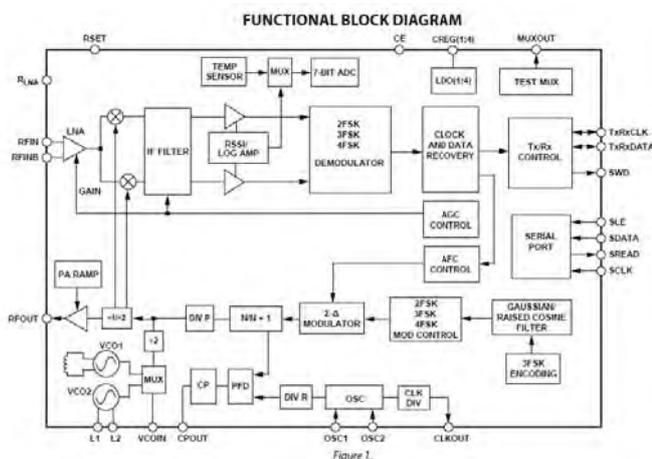

Figure 1. Functional Block Diagram of ADF7021

Transmitter is designed and should be works at 436.915MHz of center frequency, and the receiver should be works at 145.95MHz of center frequency. The type of ADF board that is used for transceiver nanosatellite is ADF7021DBZ3 for transmitter and ADF7021DBZ5 for receiver. The board is developed with with some additional components that is used to fix of both frequency, uplink and downlink frequency of IiNUSAT nanosatellite. To calculate and simulate the board for these frequency, the ADIsimSRD design studio software is used.. The circuit design and the additional component for ADF7021DBZ5 receiver board is shown in Figure 2 as below.

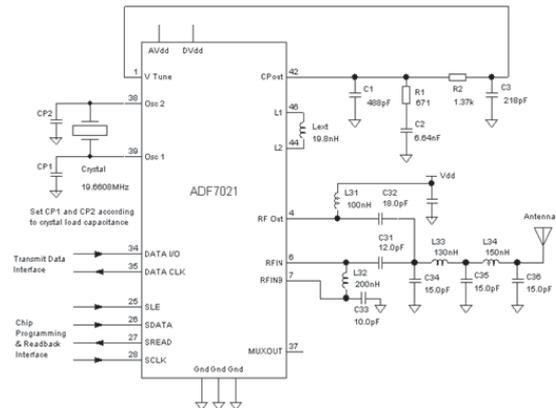

Figure 2. DBZ5 for 145.95MHz center frequency

**C. TNC Microcontroller**

Microkontroller ATMEGA1280 is used for TNC. We used this microcontroller because the this microcontroller has the availability of four-chip UART interface to be able to communicate (send and receive data) with transmitter, receiver, and OBDH system, and also the data delivery overhead which no moe than 10%.. TNC Board needs to be designed to meet the required functions, such as functions of FX.25 protocol storage, interconnection function UART with transmitter, receiver and OBDH system , and also with temperature sensor board.

The TNC board is designed for two layer PCB that be united, where the top layer is a layer of chip mounting ATMEGA1280 and the bottom layer is a layer of interconnections and other utilities as shown in Figure 3 and 4.

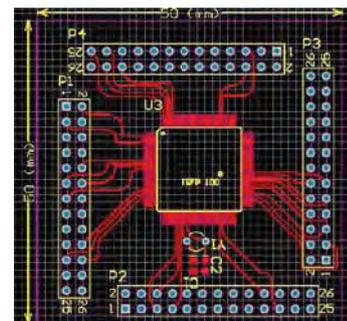

Figure 3. Top layer PCB

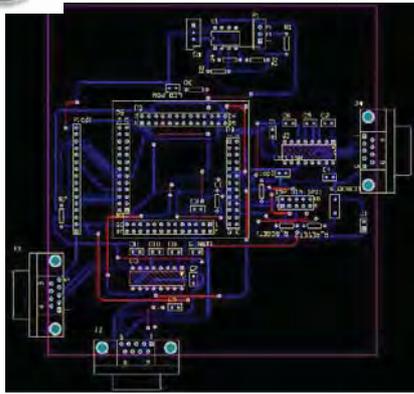

Figure 4. Bottom Layer PCB

### III. SIMULATION, TESTING RESULTS, AND ANALYSIS

The results of testing conducted to measure the validity of the actual device performance and can be analyzed to find the solution of some problems.

#### A. Simulation, testing results ,and analysis of Transmitter

Simulation of the transmitter by using the ADF7021 transceiver IC has been done using ADIsimSRD software design studio. The simulation results obtained of frequency and bandwidth, phase noise, and power transient.

From simulation results showed that the spectrum has 436.915MHz of frequency center. The spectrum peaks occur at  $\pm 5$  kHz from frequency center. But this frequency (436.915MHz) is still be able to work well for IiNUSAT nano satellite specification. From simulation , the phase noise obtained different results at 1kHz, 10kHz, 100kHz, 1MHz, and 10MHz. Transmitter spectrum simulation is shown in Figure 5. Transmitter Phase Noise performance is shown in Figure 6 and we can see that for higher frequency, the phase noise is to be smaller.

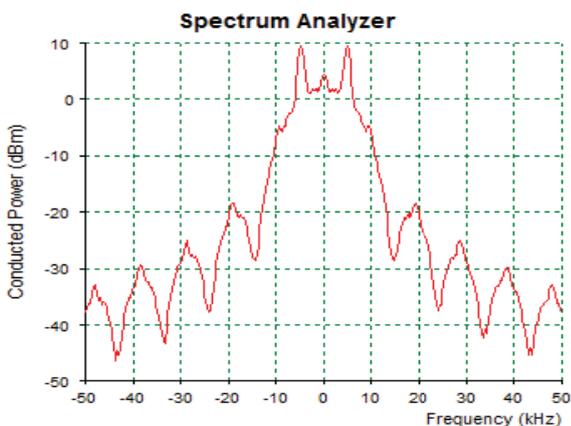

Figure 5. Transmitter Spectrum Simulation

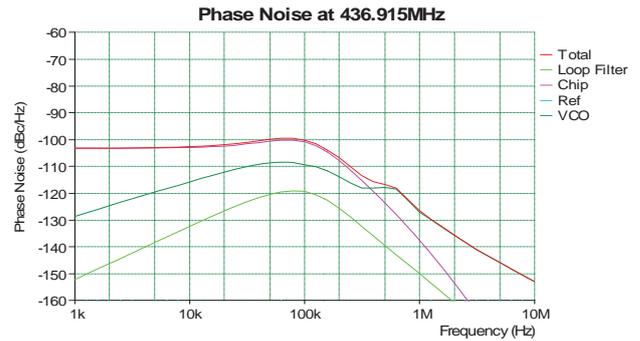

Figure 6. Transmitter Phase noise

Figure 7. Transmitter Power Transient

Figure 7 shows the performance of transmitter power transient. Overshoot is performed at 440 MHz of frequency and saturation is appeared after 20 us.

Measurements and testing results for frequency measurement and transmitter clocking are shown in Figure 8 and Figure 9. Frequency of testing was conducted on the transmitter that indicates for the frequency of 436.915MHz, -29.2dbm of gain is obtained. -28.8dbm of gain can be achieved at a peak of 436.91MHz of frequency. Besides that, 9600bps of clocking data are conducted.

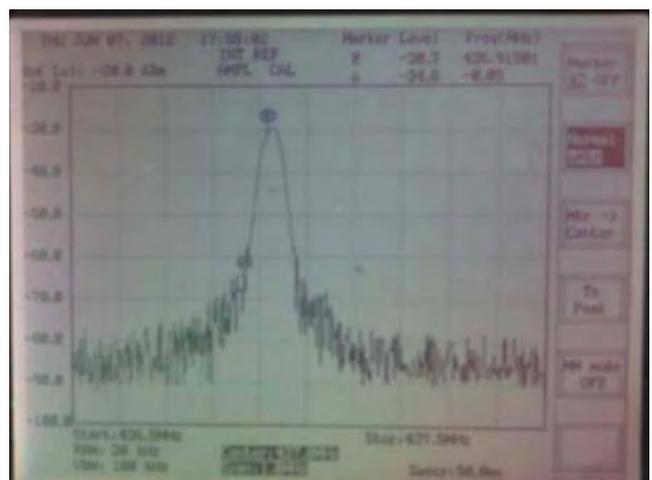

Figure 8. Frequency Center Measurement

From the temperature testing, we can see that the temperature around 33° C for the microcontroller board is achieved and still in normal condition for space characterization.

### III. CONCLUSION

The results of measurements on the transmitter indicates that the ADF7021 has an appropriate working frequency, which is able to work at 436.915MHz of frequency center, with a gain-29.2dbm and-28.8dbm (peak) at 436.91MHz of frequency. For the receiver, based on the results of the simulation, the system is able to work at 145.95MHz of frequency and 64.6km of the distance. TNC interface utility is designed to meet the criteria for Tx, Rx and OBDH. In addition, programming LM35 temperature sensor has been successfully implemented with the normal conditions of 33°C.

# Call Processing Simulation in GSM Network

Yus Natali, Renny Chaerunnisa /Akademi Telkom Jakarta  
Telecommunication Programme,  
Akademi Teknik Telekomunikasi Sandhy Putra,  
Jakarta, Indonesia  
[yus@akademitelkom.ac.id](mailto:yus@akademitelkom.ac.id), [Renny\\_chaerunnisa@yahoo.com](mailto:Renny_chaerunnisa@yahoo.com)

**Abstract**—GSM is a 2nd generation of cellular which mostly used around the world until now, even though it can only bring voice and text data. Through circuit switching based, data process from one mobile station to the other.

This research was about Call processing simulation in GSM network, which aimed to give an overview, assist, facilitate the learning process of call processing in GSM networks and the simulation was intended to increase knowledge about it's own natural cellular telephone network that is now progressing. In addition, the simulation was also designed to calculate cluster, Carried to Interference (C / I) and the general traffic in the GSM network.

Sample data was taken from one of operator GSM in Indonesia. According to call attempt on a BTS ABKS named at BSC JAT 1, the simulation counted that GoS as 0.0147, so the success call was 725,18 erlang, with 4 cell in one cluster. Besides that, the simulation shows the number of C/I as 144 or 21.5836 dB within frequency/cell was 6.25 Mhz/cell

**Keywords**—GSM (Global System For Mobile Communication); MS (Mobile Station); BSS (Base Station Subsystem); Cluster; traffic carried.

## I. INTRODUCTION

Global System for Mobile is one of the second generations of cellular technology. In addition to higher demands of communication, users want to be able to communicate with others – anywhere, anytime. Around the early 1990s, the ITU-R (International Telecommunication Union-Radio) formed a group named Global Special for Mobile to begin setting the standard for digital cellular phones under the coordination of the European Conference of Postal and Telecommunications Administrations (CEPT). Next, further preparation has been carried out by ETSI standards since 1992 through the 'Technical Specification' (TS). At the early times, this technology was tested in the first phase; the name of GSM became popular. However, the name stands for (Global Special for Mobile) was no longer relevant to the applied technology so that the name was changed to Global System for Mobile Communications [1].

The system of GSM consists of 3 parts, namely: Base Station Subsystem (BSS), Network and Switching Subsystem (NSS), and Operation and Maintenance Subsystem (OMS). BSS is a provider and controller of cellular radio transmission system. NSS is a control switch for mobile communication services. OMC is an operational support for each subsystem. Call processing becomes a fundamental requirement for users, that is, a GSM technology which is based on the circuit switching.

This research discussed a call processing that occurs in the GSM technology in the form of simulation which illustrates the architecture of GSM and its system as well. Through this simulation system, it was expected that the study of GSM system can be easier to understand

### A. Research Objective

The objective of this research was to design a simulation of GSM network call processing between a user and other users using software Matlab 7.6.0 R2008a.

Due to the amount of discussion about the calls system of GSM cellular, this research only discusses: GSM cellular networks in a single operator. Simulation using matlab software that simply describes the communication between two users on a GSM network. Mobile phone used by the user of the simulation is Nokia. Parameter used in simulation of calculation is only the cluster, carrier to interference, and traffic. The simulation does not show handover simulation.

### B. Research Methodology

In the implementation of this research, the authors conducted several research methods, namely Literature and Design of Software. The activities the authors conducted aim at designing on how the software displays as well as how to link the software with data. The making of Software was carried out by using the programming language MATLAB 7.6 or version 2008 after the process of program design. Software Testing and Revision Activities – in order to obtain maximum results, the software which has been made is tested. Analysis – doing a research and analysis about what to discuss.

## II. GLOBAL SYSTEM FOR MOBILE COMMUNICATION

This part are consist of two information about GSM.

### A. GSM Network Architecture

GSM system architecture consists of three subsystems which are interconnected each other, so are to the users through a network interface. These subsystems are: a BSS, NSS, and OMS. The cell phone (mobile station) is also a subsystem; however, it is supposed as a part of BSS in the terms of architecture. [2]

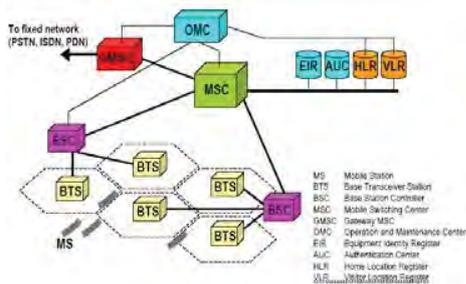

Fig. 1. GSM Network Architecture

BSS is known as the radio subsystem which provides and controls radio transmission path between the mobile phone and MSC. BSS also controls the radio interface between mobile phone and any other GSM subsystem. Each BSS consists of many BTS controllers called Base Station Controller (BSC) which connects the phone to NSS via the MSC. NSS controls the functions of switching to the system and allows the MSC to communicate with other networks such as Public Switch Telephone Network (PSTN) and Integrated Switch Digital Network (ISDN).

In addition to addressing the switching of communication between GSM system and other external networks, NSS also handles BSC in radio subsystem as well as to be responsible in organizing and providing access to exit for some customer data base. MSC is a central part or the center in the NSS which controls traffic among all BSC. There are three different kinds of database in this NSS namely; Home Location Register (HLR), Visitor Location Register (VLR), and the authentication center (AUC). [2]

Each OSS handles one or several operation maintenance center which is used to monitor and maintain the performance of every Mobile Station (MS), BSC, and MSC in the GSM system. This OMC has three functions, namely:

- Handling work / maintaining telecommunications hardware and network operations.
- Setting all telecommunication cost calculation procedures (billing system).

- Setting all the mobile phones that are in the system.

### B. The Structure of GSM Channels

In the GSM networks, there are some components known as channels which are especially used on the radio to transmit information or messages. Those channels are Logic channel and Physical channel.

On the Radio Sub System (RSS), there are two categories of channels which support the logic channels, namely Traffic Channel which carry information such as voice or data; and Control Channel, which carry signaling information or data synchronization.

Traffic channels (TCH) carry information such as voice or data. There are two channels of traffic carried by the speed of information, namely Full (speed) Rate Traffic Channel and Half (speed) Rate Traffic Channel.

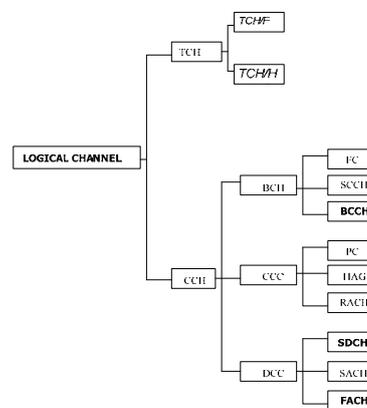

Fig. 2. GSM Logical Channel Structure

Control channel (CCH) is used to carry signal or data synchronization. This channel falls into three categories:

#### 1) Broadcasting Channel or BCH

This logical channel sends a message from the network to the mobile station that causes it gets information about the network configuration on a particular area of the procedure to access the network. This channel consists of:

##### a) Frequency Correction Channel or FCCH.

This channel carries the information to correct the frequency generated by the mobile station so that the mobile station is able to synchronize to get a frequency that is finally able to be used for communication.

##### b) Synchronization Channel or SCH

This channel carries information for frame synchronization from the mobile station to identify a BTS used for operations on the Radio Sub System.

##### c) Broadcast Control Channel or BCCH

This Channel carries general information about concerned BTS cell service. The channel is also used to define the channel configuration of a cell which is part of the information sent.

2) *Common Control Channel or CCCH*

This channel sends information either from the network to the MS or from MS to the network in the form of procedures to access the network which consists of:

a) *Channel Call (Paging Channel or PCH)*

This channel is used by network to call the mobile station during the incoming call that contains the identity of IMSI and TMSI.

b) *Random Access Channel or RACH*

This channel is used by the mobile station to request a signaling channel allocation in the process of establishing a network connection (call set-up).

c) *Hold Channel Access (Access Grant Channel or AGCH)*

This channel is allocated by network to the mobile station to provide the signaling channel.

3) *Specified Control Channel (DCCH Dedicated Control Channel or DCCH)*

This channel serves to transmit important information in the process of establishing a call signaling, authentication, location update, and messaging (Short Message Service or SMS). This channel consists of:

a) *Stand Alone Dedicated Control Channel or SDCCH*

This Channel is used in the signaling procedure to get the traffic channel allocation which is very important to establish the call, authentication, and location updating.

b) *Fast Associated Control Channel or FACCH*

This channel is used by the mobile station at the time of handover so that the capacity of the canal traffic could be replaced by this channel for a moment when the mobile station moves from one cell to another.

c) *Slow Associated Control Channel or SACCH*

During the call, the mobile station always measures the level of acceptance, transmission quality, and distance of the mobile station to the network. Due to information above, the network uses the control channel to transmit information periodically.

Physical channel is defined as a series of radio channel frequencies represented as the physical content of a timeslot, and it is illustrated in terms of bursts. Those bursts are contained in the timeslot which are divided into 156, 25 bytes per period. There are several types of bursts which are used as physical of a logical channel for tasks such as;

4) *Normal Burst (NB)*

Normal Burst (NB) is a type of physical channels that serve data transmission either signaling or speech that carries almost all logic channels, namely; Traffic Channel (TCH), Frequency Correction Channel (FCCH), Synchronization Channel (SCH), Broadcast Control Channel (BCCH), Paging

Channel (PCH), Stand Alone Dedicated Channel (SDCCH), Access Grant Channel (AGCH), Fast Associated Control Channel (FACCH), and Slow Associated Control Channel (SACCH).

5) *Frequency Correction Burst (FB)*

Frequency Correction Burst (FB) functions to transmit Frequency Correction Channel (FCCH). With this channel, the mobile station is able to check the transmitter and its receiver. It is also able to compensate for irregularities that may occur.

a) *Synchronization Burst (SB)*

Synchronization Burst (SB) functions to transmit Synchronization Channel (SCH) which contains the number TDMA and identity of a base station or BSIC.

b) *Access Burst (AB)*

This channel transmits Random Access Channel (RACH) which is used when the MS moves at the first time to ask for access to the network to perform its services. The network will measure the distance from the mobile station to the BTS used to determine the time delay.

c) *Dummy Burst (DB)*

This Physical channel does not transmit any logical channels; however, these channels are extra bytes that do not contain any information. This channel ensures whether the transmitter or receiver is running well. [2]

### III. THE DESIGN OF SIMULATION

The simulation consist of two part, which are stages of design and simulation results.

#### A. Stages of Design

The first step in the development of this simulation is to define the problem. This problem identification has a major influence to the next phases, that is, design. The less accurate of problem identification will affect the design of unfavorable results; therefore, some requirements that should be met to identify the problems are:

- The purpose of software development. This goal setting aims at directions to development which can be determined to the next steps to achieve goal.
- Target of users. In this simulation, the target of users must be recognized in order to meet their needs. The targets of users are either the students learning about wireless communication – particularly GSM, or anyone who wants to know about wireless communication.
- The use of resources. The resources used in making these simulations have certain elements which are certainly designed by using matlab version 7.6.0 or R2008a.
- Flow diagram of simulation

which decide the traffic call for MS. If both MS get call attempt from each BTS so the call processing can be done. Not to mention the parameters which affect in MS or mobile equipment.

The third call processing occurs in different BSC. The process in this case is influent with two BSC condition, two BTS traffic and the MS' parameters. One of the parameters which affect the call processing is the bandwidth, cluster, and bandwidth allocation in one cell. Others parameters is not include in this simulation. This third process calculation is showed on Figure 9 as below here.

Fig. 9. Call Processing Calculation Between Different BTS in Different BSC

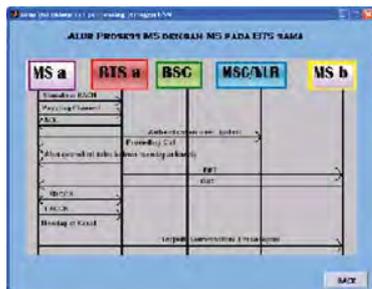

Fig. 10. Call Processing in One BTS

Figure 10 and 11 are part of simulation which can be choosed from Main Menu in Figure 6. In Figure 10, it shows the channels which occur while the call process between MS a and MS b in one BTS.

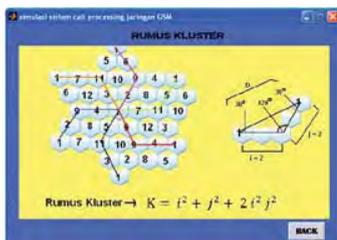

Fig. 11. Help Menu

Figure 11 shows the mechanism of cluster in GSM network. Cluster is a group of cells with different frequency.

The numbers of cell in a cluster will influence the bandwidth allocation in one cluster. The more cell in one cluster will affect the less bandwidth allocation for one cell.

#### IV. ANALYSIS OF DESIGN RESULT

This call processing simulation is from MS to MS (with the same BTS). MS caller is known as Originating Call while MS receiver is known as Terminating Call. Both of them are controlled by the same base station. In this simulation, there are parameters that must be input by the user to make calls and also as a requirement of MS to do a calling. Based on this simulation trial to make a call within the BTS, it can be concluded that:

- Phone credit must be greater than 1000 rupiahs
- There is a caller or the destination (number)
- MS, which is used to call, requires a correct dial to destination.
- MS battery is also must be greater than 40%
- In addition, the signal quality of MS must be at least 3dB.

In extended example, MS with the number 085692294237 is the caller or the originating call. In order to make calls, one must meet the following requirements: having credit at least Rp.1000, dialing a correct destination, having battery/power, and having good quality signal. Importantly, MS with the number 085714809346 is a receiver or terminating call that is in the absence of a call or busy.

Upon MS is eligible, one can make calls then. MS also considers calculating the accessibility of channel, such as MS traffic parameters on the BTS that serves to calculate the amount of traffic that accesses to channel. Traffic channel is a circuit in which an individual communication may pass. The trial presented in this journal is call processing in a single BTS. The conditions of call when it reached BTS will be affected by the BTS traffic condition. Such Traffics can be distinguished into three parts, namely:

- Offered traffic (Ao), is a traffic which is offered or about to access to network.
- Traffic Carried (Ac), is a traffic that gets loaded or channeled.
- Lost Traffic (Ar) is a traffic which is lost or gets no channel.

Call processing simulation MS to MS on the same BTS.

One of the data obtained from the operator about the number of calls that occurs in one BTS is as follows:

To examine this simulation, traffic data in BTS is taken from real condition in one GSM network . The data consist of call attempt, call seizure and call success with 92.4 erlang for traffic design.

TABLE I. SAMPLE DATA SIMULATION FROM OPERATOR

B S C	S i t e	Call Attempt	Call Seizure	Call Success	Fail	Traffic Carried
K 5 T	K A A	1182	1181	917	264	7.4
K 5 T	K G C	2034	2030	1423	607	12.7
K 5 T	G A A	1763	1759	1161	598	8.8
K 5 T	I A A	1428	1426	881	545	4.4
K 5 T	D Y A	1907	1908	1115	793	11.4
K 5 T	G K A	1315	1312	922	390	7.1
K 5 T	A N B	4172	4167	3060	1107	26.3
K 5 T	G R A	198	196	143	53	1.4
K 5 T	R P B	537	539	351	188	2.3

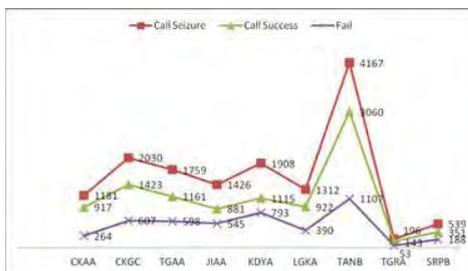

Fig. 12. Sample Traffic in JK5T BSC in GSM Network

To be able to make a call, the BTS traffic conditions (ABKS) should not be so full that MS gets the channel and BTS condition which is dialed. At BSC JK5T, both call seizure and the lowest call success is found in the BTS TGRA. The highest call seizure or call success is found in BTS TANB. This simulation discusses only to the traffic conditions at the BTS in one of the operators in Indonesia.

A. CONCLUSION

This simulation mainly discusses a call processing communication. It consists of theory with three basic views on the GSM network namely: Simulation MS to MS at the same BTS, different BTS with the same BSC, and different BTS for different BSC.

The success of call processing is initiated by the MS eligibility to make a proper call. This simulation facilitates the understanding of call processing in GSM, and helps operators count the traffic conditions at the BTS. The success of call processing in the simulation is determined not only from a connectivity building process from a caller to the receiver and the web structure, but also from a traffic condition in the originating BTS and the terminating BTS.

ACKNOWLEDGMENT

Thank you for Akatel Jakarta lecturers who encouraged to publish this research. Special thanks for the company which has shared its' data to examine in this simulation.

### ABSTRACT

The generation of synthetic rainfall is useful for the planning, design, and operation of water resource systems due to lack of data. Most rainfall series are periodically stationary; namely; their mean and covariance functions are periodic with respect to time. The objective of this paper is to generate the sequences of monthly rainfall using Stochastic-Autoregressive Model (SAM). Monthly rainfall is provided from Blang Bintang Rainfall Station for ten year records. The monthly rainfall time series is developed by an additive model with trend, periodic and stochastic as their components. Each component is identified and, if found, removed from the original series. The turning point test is applied for detecting the trend, variance analysis is applied to identify the number of significant harmonics. The series is then tested for stationarity and dependent part of the stochastic components. The results found that the series is free trend series, is well expressed using six harmonics coefficient for periodic components, and third order autoregressive for stochastic components. The adequacy of fit is judged by the insignificant correlation and normal distribution of the obtained residuals. So, The SAM might be well used for representing the rainfall time series in Blang Bintang Rainfall Station.

### Keywords :

Time series, Trend, Periodic, Stochastic, Autoregressive.

### 1. INTRODUCTION

The generation of synthetic rainfall data being able to reproduce the essential statistical features of historical rainfall is useful for the planning, design, and operation of water resource systems. To provide long sequence records of data is very difficult, so it is necessary to extend them by generating the historical record. Various methods have been used by engineer to provide this information. Most of the existing methods are either deterministic or probabilistic in nature, not considering the random effects of various input parameters. With the ever increasing demand for accuracy of analyzing rainfall data, these methods are no longer sufficient.

At present, many publications that study the stochastic modelling have been published, such as: analysis of time series of streamflow, waves, evapotranspiration and irrigation requirement as in [2][3] and [6]. The stochastic model approach also have been used for generating the rainfall data. The Rainfall is one of the significant parameters in many hydrological models. They are stochastic in nature because they are affected by climatological parameters, namely, stochastic climate variations are transferred to become stochastic component of rainfalls. These series are a complex atmospheric process and periodically stationary in which their mean and covariance functions are periodic with respect to time as in [4][7] and [11]. Considering all other factors known or assumed the rainfall is a function of the stochastic variation of the climate. Hence stochastic analysis of rainfall time series should be computed using a mathematical model that account both for the deterministic and stochastic parts of the process, as stated in [7]. However, most rainfall data is not continue or discrete, so this method fits only for generating annually or monthly data. For example, reference [10] used autoregressive model (AR) to generate the annual rainfall, using the autoregressive moving-average models (ARMA) [8] and stochastic modelling of monthly rainfall [9]. But the former study has been done on the synthetic generation of rainfall using stochastic structure of the time series without combining both periodical and stochastic component.

The aim of research is to generate the sequences of monthly rainfall using stochastic autoregressive model (SAM) by combining the periodical and stochastic component in the developed model.

The scope of research consist of testing the monthly rainfall time series for stochasticity, identifying and removing trend and periodic components, studying the structure of dependent stochastic component, and diagnostically checking for the independent stochastic component.

## 2. MATERIALS AND METHODS

### 2.1 Data

The point rainfall data is collected from Blang Bintang rainfall station, Aceh, The data provided was on the basis of daily record during 10 years (1987-1996). The data, then, was analyzed to be a monthly base in accordance with the purpose of study. Generally, in Aceh the climate is divided into two season, that are; rainy season and dry season. Rainy season start from September to December, which is maximum rainfall in December, while in June to August are dry with a little rain. Whereas the rest in between January up to May, as the second mayor peak of monthly rainfall. The monthly distribution pattern in Aceh can be seen in the Figure 1. The amount of yearly rainfall is in between 1200 up to 1900 mm. The characteristic of rainfall in Blang Bintang was described more detail in section result and discussion.

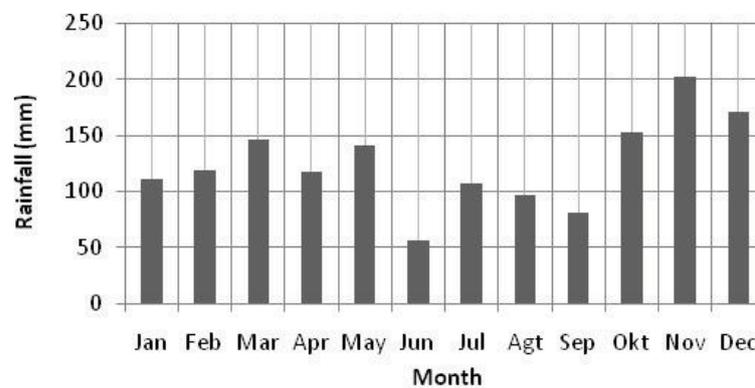

Figure 1. The Pattern of Monthly Rainfall Distribution

### 2.2 Model Structure Methods

Generally a time series can be constructed by deterministic component consisted of trend and periodic factor, which could be formulated in manner that allowed exact prediction of its value. And a stochastic component, which is always present in the data and can not strictly be accounted due to random effects in [4][6] and [9]. The time series,  $X_t$ , was represented by a decomposition model of the additive type, as follows:

$$X_t = T_t + P_t + S_t \tag{1}$$

where  $T_t$  = the trend component at time,  $t$ , for  $t = 1, 2, \dots, N$ ,  $P_t$  = the periodic component,  $S_t$  = the stochastic component having dependent and independent parts, and  $N$  = the number of data points. Eq. 1 was systematically identified and its components removed.

#### 2.2.1 Trend Component

The component of trend  $T_t$  was identified using the seasonal values ( $Z_i, i = 1, 2, 3 \dots n, n =$  number of seasons) obtained by the algebraic sum of monthly data of each season [6]. For detecting trend, a hypotheses of no-trend was made using Turning Point Test to test the hypotheses [6]. The procedure is to determine the number of times,  $p$ , occurs at time  $i$  if  $Z_i$  is either greater than  $Z_{i-1}$  and  $Z_{i+1}$  or lesser than the two adjacent values. The expected number of  $p$  in a random series is

$$V = \frac{2(n-2)}{3} \tag{2}$$

where variance ( $V$ ) can be computed as

$$\text{var}(V) = \frac{(16n-29)}{90} \tag{3}$$

and standard measure ( $m'$ ) can be expressed as

$$m' = \frac{(p - V)}{\sqrt{[\text{var}(V)]}} \quad (4)$$

which is treated approximately as a standard normal variate. The value of  $m'$  was compared with its table value at 5 % level of significance [5]. If the calculated value of  $m'$  is within the limits, the hypotheses of no-trend is not rejected or accepted.

### 2.2.2 Periodic Component

The component of periodic ( $X_t$ ) can be expressed in Fourier form as described in [4] and [7], as follows :

$$X_t = A_o + \sum_{k=1}^{\infty} \left[ A_k \text{Cos}\left(\frac{2\pi kt}{P}\right) + B_k \text{Sin}\left(\frac{2\pi kt}{P}\right) \right] \quad (5)$$

In which P is time span of periodicity; k is number of harmonics,  $1 < k < P/2$ ; M is number of significant harmonics,  $1 < M < P/2$ ; and N is number of data points, and  $A_k$  and  $B_k$  are Fourier coefficients, expressed as;

$$A_k = \frac{2}{N} \sum_{t=1}^N \left[ X_t \text{Cos}\left(\frac{2\pi kt}{P}\right) \right] \quad (6)$$

$$B_k = \frac{2}{N} \sum_{t=1}^N \left[ X_t \text{Sin}\left(\frac{2\pi kt}{P}\right) \right] \quad (7)$$

and

$$A_o = \frac{1}{N} \sum_{t=1}^N [X_t] \quad (8)$$

Where, K = number of significant harmonics, p = base period, N = number of observation points and  $A_k$  and  $B_k$  = Fourier coefficients. These coefficients were obtained by a least square fit of the data to the  $K^{\text{th}}$  harmonic components, then a least squares approximation could be given by the finite series.

$$P_t = A_o + \sum_{k=1}^M \left[ A_k \text{Cos}\left(\frac{2\pi kt}{P}\right) + B_k \text{Sin}\left(\frac{2\pi kt}{P}\right) \right] \quad (9)$$

Where, M is the number of significant harmonics (maximum, P/2). In Eq. (5) if  $M \rightarrow \infty$ ,  $P_t \rightarrow X_t$ , then  $X_t$  could be represented satisfactorily by Eq. (9) only. However it may not be practical or desirable to allow the condition,  $M \rightarrow \infty$ . Thus the appropriate approach would be the selection of a value of M which contains only those harmonics which are significantly contributing towards  $X_t$ . With this as the objective two tests namely test of analysis of variance and Fourier decomposition of mean square were conducted. In this test, the null hypothesis was that the variance explained by harmonic k, which was  $(N/2)(A^2 + B^2)$ , is zero. Computations were made to test the  $A_k$  and  $B_k$  values for  $k = 6, 5 \dots 1$  in order to obtain the F-ratio, which was then compared with its table value of F distribution at 0.01 level of significance,  $F_{(a,v1,v2)}$  [5]. If  $F_{\text{cal}} > F_{(a,v1,v2)}$ , the harmonic coefficient is significant and can be put into the equation 5 to obtain the periodic component.

### 2.2.3 Stochastic Component

The component of stochastic ( $S_t$ ) was assumed that the value of  $S_t$  at time t is the combined effect of the weighted sum of the past values so that the dependent part of  $S_t$  as in [4][7] and [11], may be represented by the following equation :

$$S_t = \left[ \sum_{k=1}^{\infty} \Phi_{p,k} S_{t-k} + a_t \right] \quad (10)$$

$a_t$  = the independent normally distributed error variable. Because of the diminishing effect of past values of the present, the upper limit of Eq. 10 may be made finite, say p, resulting in a finite order Markov model equation as follows:

$$S_t = \Phi_{p,1} S_{t-1} + \Phi_{p,2} S_{t-2} + \dots + \Phi_{p,p} S_{t-p} + a_t \quad (11)$$

The model in Eq. (11) is known as the autoregressive model of order p, AR (p). The fitting procedure of this model involves two stages, namely, selection of the model order, p, and estimation of autoregressive coefficients,  $F_{p,k}$ . For selection of order p, the residual variance method is used where residual variance,  $S^2_z(p)$  was computed using the following equations :

$$S^2_z(p) = \frac{1}{N - 2p - 1} S(\mu, q_1, q_2, \dots, q_p) \quad (12)$$

in which

$$S(\mu, q_1, q_2 - q_p) = (N - p)(C_0 - A_1 C_1 - A_2 C_2 \dots A_p C_p) \quad (13)$$

$A_1, A_2 \dots A_p =$  AR-parameters and  $C_0, C_1 \dots C_p =$  autocovariance function at lag p,  $p = 0, 1, 2 \dots k$ . The value of  $C_p$  for any p is computed as,

$$C_p = E [(S_t - \mu) (S_{t+p} - \mu)] \quad (14)$$

where

$$\mu = E (S_t) \quad (15)$$

or can be described as

$$C_p = \sum_{i=1}^{N-k} (x_i - \bar{x})(x_{i+p} - \bar{x}) \quad (16)$$

In the present analysis,  $C_p$  was computed for  $p = 0, 1, 2$  and  $3$ . The minimum value of  $S^2_z(p)$  computed by Eq. (12), gave the appropriate order of the model, p, for representing the dependence structure of time series. The autocorrelation coefficients,  $r_p$  were determined as :

$$r_p = \frac{\sum_{i=1}^{N-k} (x_i - \bar{x})(x_{i+p} - \bar{x})}{\sum_{i=1}^{N-k} (x_i - \bar{x})^2} \quad (17)$$

The autoregression coefficients  $F_{p,k}$ , were expressed as a function of  $r_p$  and are computed by using the following recursive formula as in [4] and [7] :

$$\Phi_{p,p} = \frac{r_p - \sum_{k=1}^{p-1} \Phi_{(p-1,k)} r_{p-k}}{1 - \sum_{k=1}^{p-1} \Phi_{(p-1,k)} r_k} \quad (18)$$

and

$$\Phi_{p,p} = [\Phi_{(p-1,k)} - \Phi_{(p,p)} (\Phi_{(p-1,p-k)})] \quad (19)$$

in which  $k = 1, 2 \dots p$ . The first three linear autoregressive models (i.e.,  $p = 1, p = 2$  and  $p = 3$  of Eq. (19)) usually are good approximations for representing a time series, and hence were tried for analyzing the  $S_t$  of the rainfall time series. The dependent part of  $S_t$  was obtained by Eq. (11) and then was removed, leaving the independent part as follows :

$$a_t = S_t - \sum_{k=1}^p \Phi_{(p,k)} S_t \quad (20)$$

#### 2.2.4 Diagnostic Checking

Diagnostic checking means statistically verifying the adquacy of the formulated model. For this checking, the residual series was examined for any lack of randomness. Autocorrelation coefficients of residual series for lag 1 ( $l = 30$ ) were computed and were drawn against 1 with 95 % tolerance limits. If the correlogram thus obtained is well within the limits, then it can be

derived that residuals are normally distributed with zero mean and var (1/I). Various other tests, details of which are not given here due to lack of space, were also done to confirm the randomness of the residuals, which is the condition for accepting the formulated autoregressive model.

### 3. RESULTS AND DISCUSSIONS

#### 3.1 The Characteristic of Rainfall

The above mathematical method of analysis was used in investigating the structure of the time series of rainfall in Blang Bintang, Banda Aceh. The monthly rainfall values were obtained by computing the daily rainfall record during the 10 years (1987-1996) from Blang Bintang Station. Figure 2 shows the mean values of the monthly rainfall over the 10 periods under analysis. Based on analysis, mean monthly rainfall ranges from 56.47 to 202.38 and the deviation standard in between 33.87 to 141.30, while the coefficient of variation ranges from 0.37 to 1.19, which signifies the importance of time variability of monthly rainfall values. Again the values of SCC are also significantly different from zero ranging in between -0,30 to 0.35, which shows that the rainfall is mutually dependent.

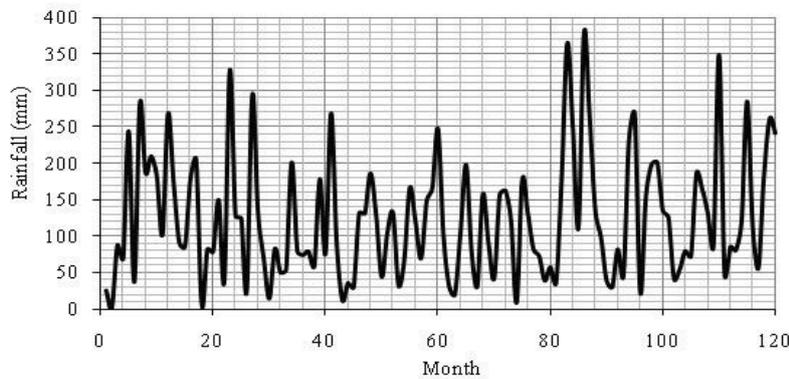

Figure 2. Monthly Rainfall during 1987-1996

This confirms that the rainfall process is time-variant and not independent, so the rainfall time series can be modeled on stochastic theory.

#### 3.2 Trend Component.

The seasonal values,  $Z_t$ , for 10 years is drawn in the Figure 3. Based on the figure is found 5 turning points, namely; in 1989, 1991, 1992, 1994 and 1995. The computed  $m'$ , for the Turning Point test is  $-0.276$ , which are within the limits of  $\pm 1.960$  at 5 % level of significance [5]. It reveals the absence of  $T_t$  in the rainfall time series, hence the  $X_t$  in the equation (1) may be treated as the trend-free series, or, the SAM was developed by periodic ( $P_t$ ) and stochastic ( $S_t$ ) component only, as follows,

$$X_t = P_t + S_t \tag{21}$$

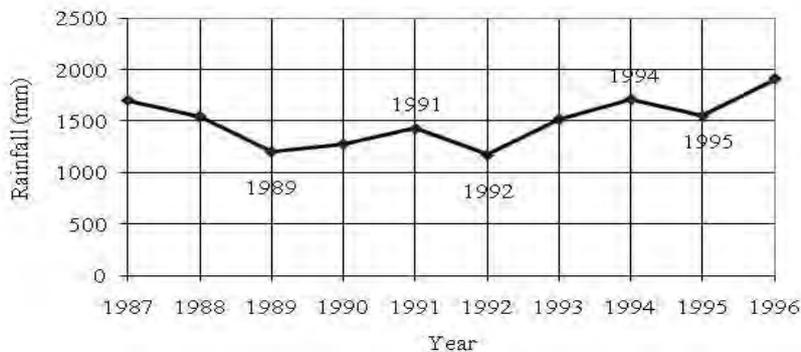

Figure 3. Turning Points in Yearly Values of Rainfall

#### 3.3 Periodic Component.

For representing the periodic component of the rainfall series the numbers of significant harmonics were determined by analyzing by cumulative periodogram. Using Equations (6), (7) and (8) the Fourier coefficients  $A_k$  and  $B_k$  were estimated. The value of  $A_k$  and  $B_k$  were found as shown in the Tabel 1. The table show that no one single of harmonic is more than 95 % of the total variance, so it is recommended that the use of the six harmonics in estimating the periodic component is necessary in order to find 95% of the total variance. Presence of  $P_t$  in the rainfall series was confirmed by the oscillating shape of the displayed figure. Using Eq. (22),  $P_t$  was computed for  $k=1,2,3,4,5$  and 6 and the result as shown in Fig. 4 below. The figure showed that the line was depicted closely between measured and generated rainfall. This confirm that the selection of the six harmonics ( $k = 6$ ) was significant for representing the  $P_t$  of rainfall time series.

Table 1: Harmonic Analysis of Monthly Rainfall Series

Harmonic (K)	Fourier Coefficients		Variance K-Harmonic (%)	Total Variance (%)
	$A_k$	$B_k$		
1	33.41	4.242	35.41	35.41
2	6.282	-26.085	22.48	57.89
3	9.568	-20.332	15.77	73.66
4	-11.350	-10.101	7.21	80.87
5	14.474	7.657	8.37	89.24
6	-12.463	0	4.85	93.09

$$\begin{aligned}
 P_t = & 125.2167 + 33.41 \cos\left(\frac{\pi}{6}\right) + 4.242 \sin\left(\frac{\pi}{6}\right) + 6.282 \cos\left(\frac{\pi}{3}\right) - 26.085 \sin\left(\frac{\pi}{3}\right) \\
 & + 9.568 \cos\left(\frac{\pi}{2}\right) - 20.332 \sin\left(\frac{\pi}{2}\right) - 11.350 \cos\left(\frac{2\pi}{3}\right) - 10.101 \sin\left(\frac{2\pi}{3}\right) \\
 & + 14.474 \cos\left(\frac{5\pi}{6}\right) + 7.657 \sin\left(\frac{5\pi}{6}\right) - 12.463 \cos(\pi)
 \end{aligned}
 \tag{22}$$

After estimating the periodic component it was removed from by subtracting the periodic component from historical time series. This process obtained a new stationery series,  $S_t$ , resulting from stochastic non-deterministic process as a new stationary series  $S_t$ .

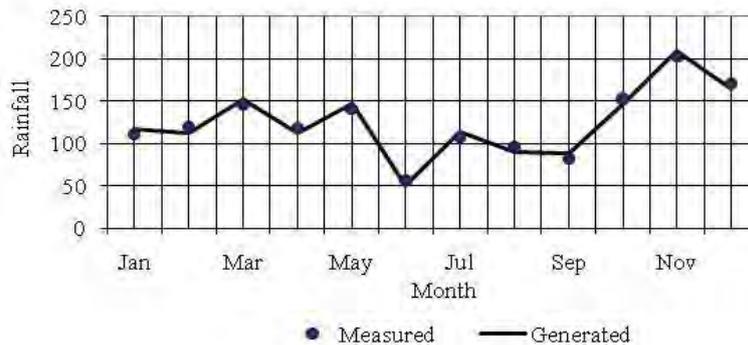

Figure 3. Monthly Measured and Generated Rainfall.

### 3.4 Stochastic Component.

$S_t$  was analyzed by fitting the autoregressive or Markov schemes to the series, as outlined in Eq. (11). The order of the model was determined by the procedure explained in the previous section.  $S_z^2(p)$  was computed using Eq. 12 for  $p = 1, 2,$  and 3. The results were given in Table 2. It shows that  $S_z^2(p)$ , 0.9900 is minimum at  $p = 3$  or third order; hence  $S_t$  can be suitably approximated by the third order Markov model, as shown in the equation (23).

$$S_t = 0.139168S_{t-1} - 0.02861S_{t-2} - 0.023586S_{t-3} + a_t \quad (23)$$

Table 2. Residual Variance for Different Orders of Markov Model

Order (P)	Model AR(p)	Autocorrelation coefficient, $r_p$ at lag p	Residual variance $S^2_z(p)$
1	AR(1,1)	0.135519	0.9908
2	AR(2,1) AR(2,2)	0.139843 -0.031908	0.9903
3	AR(3,1) AR(3,2) AR(3,3)	0.139168 -0.028610 -0.023586	0.9900

The autoregression coefficient (p,k where p = 3 and k = 1, 2, and 3) was computed using Eqs. (18) and (19). As the rainfall time series,  $X_t$ , is a trend-free series, the developed model describes the periodic-stochastic behavior of the original series. It is a superposition of a harmonic-deterministic process and third order Markov model. The developed model, so called SAM, can be denoted as follows :

$$\begin{aligned}
 X_t = & 125.2167 + 33.41 \cos\left(\frac{\pi t}{6}\right) + 4.242 \sin\left(\frac{\pi t}{6}\right) + 6.282 \cos\left(\frac{\pi t}{3}\right) - 26.085 \sin\left(\frac{\pi t}{3}\right) \\
 & + 9.568 \cos\left(\frac{\pi t}{2}\right) - 20.332 \sin\left(\frac{\pi t}{2}\right) - 11.350 \cos\left(\frac{2\pi t}{3}\right) - 10.101 \sin\left(\frac{2\pi t}{3}\right) \\
 & + 14.474 \cos\left(\frac{5\pi t}{6}\right) + 7.657 \sin\left(\frac{5\pi t}{6}\right) - 12.463 \cos(\pi t) + 0.139 S_{t-1} - 0.02861 S_{t-2} - 0.023586 S_{t-3} + a_t
 \end{aligned} \quad (24)$$

In which the first to twelfth terms in the formulated model represented by Eq. (24) constitute the deterministic part of the rainfall time series. The first term is a constant, indicating the arithmetic mean of the rainfall. The second are the harmonic portions of the deterministic part, and are functions of time. The thirteenth to fifteenth terms represent the dependent stochastic part of the model. The current value,  $S_t$ , depends on the weighted sum of its preceding three values. The last term,  $a_t$ , is the random independent part of the stochastic component with a zero mean. The formulated model was subjected to various checks to test its adequacy for representing the time dependent structure of the rainfall. The autocorrelation coefficients of the residuals for lags (1 = 30) were computed. They are displayed in Figure 4 in the form of a correlogram with 95 % tolerance limits.

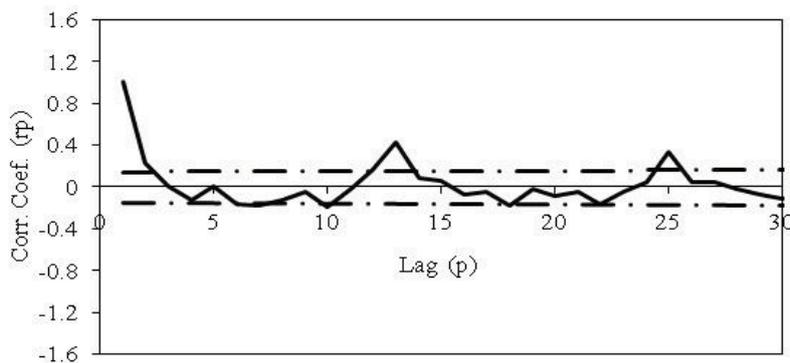

Figure 4. Correlogram of Residual Series with 95 % Tolerance Limits

The correlogram shows that almost all the coefficients are very small under tolerance limits, therefore the correlation coefficient can be treated as non-significant. The residuals are normally distributed with a mean value of closing to zero (0.0008), and variance of 0.0188 less than  $(1/l=1/30 = 0.033)$ . This leads to the conclusion that the residuals are independent

normally distributed. The rainfall, generated by the formulated model, are plotted with the corresponding observed and generated values as displayed in Figure 5.

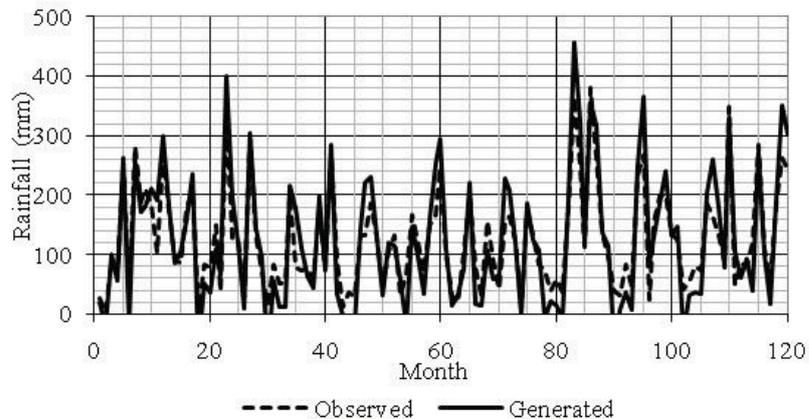

Figure 5. Comparison of Observed and Generated Data of Monthly rainfall

The plot indicates closeness of both observed and generated values, and thereby reflects the appropriateness of the formulated rainfall model. Therefore, the Stochastic-Autoregressive Model (SAM) is one of alternative synthetic model which might be employed to generate monthly rainfall at Blang Bintang Rainfall Station for use in planning hydrologic studies or water resources systems.

#### 4. CONCLUSIONS

The SAM rainfall in Blang Bintang was developed under free trend series, six harmonics as periodic component, and the third order autoregressive as stochastic component.

The models developed in this study seem promising in the analysis of rainfall in Aceh for planning hydrologic studies or water resources systems. A rigorous data collection scheme is need to get reliable data for such analysis.

The models need some improvements and comparison with other hydrologic model to see how fit the results. The authors are considering these issues in their future studies.

#### ACKNOWLEDGEMENT

 E-mail: [listyani\\_theo@yahoo.co.id](mailto:listyani_theo@yahoo.co.id)

## ABSTRACT

The saline/brackish groundwater phenomena was found at Paris and its surrounding area, Bantul District, Yogyakarta Special Province. At this area, saline water found at dug well and hot spring of Parangwedang. Whereas, fresh to brackish water can be found at several dug wells along Parangtritis Coastal Plain. Hydrogeological survey has been carried out completed with hydrochemical analysis to know genesis of saline/brackish water.

Saline water of Parangwedang area usually has chloride or natrium chloride type, included in saline class (Cl content are 6.528 - 7.498 ppm). Whereas, groundwater at Parangtritis Coastal Plain found as fresh water class, indicated by 20 – 23,9 ppm, but sometimes it ever changes to be brackish. This brackish water of coastal plain may be originated from mixing of fresh and saline (sea) water by flushing process. This brackish water flows in Merapi sand sediments aquifers directed from sand dunes behind coastal plain. The saline water of Parangwedang area predicted originated from deeper aquifers, involve breccia of Nglanggran Formation, or the older rocks, rose up to the surface after taken several hydrochemical processes like chemical evolution, cation exchange, seawater intrusion, and may be influenced by magmatic activity for long time.

## Keywords

Groundwater, hydrogeology, saline, brackish, hydrochemical.

## 1. INTRODUCTION

At the southern end of Yogyakarta Special Province (Fig. 1), on the physiography of Yogya - Bantul Plain [10] there is saline and brackish groundwater phenomena. Saline groundwater in the area can be found at Parangwedang as the hot springs (Fig. 2) and in dug well near from the hot springs. Meanwhile, brackish groundwater can be found in the dug wells at Parangtritis Beach (Fig. 3).

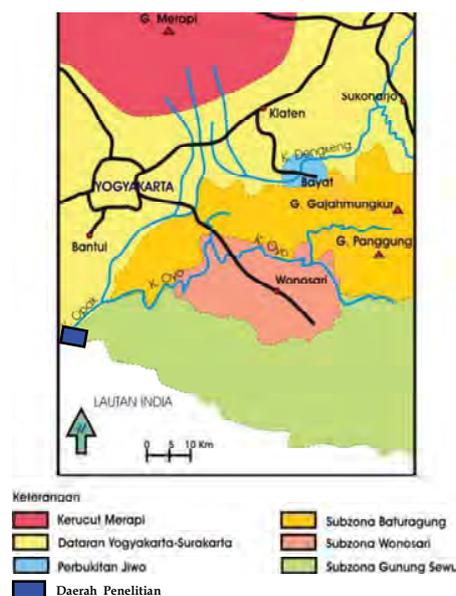

Figure 1. The research area in geomorphological map of Yogyakarta [2].

In the field, some wells showed the brackish water in taste. There is also fresh water from wells in coastal plain, but at longer time it will tasted salty in the mouth. Both saline and brackish water in the research area make interest to study about its genesis. This genesis of salinity can be studied by approaching of hydrochemical and hydrogeology.

The study of groundwater salinity is very interesting to determine the origin and the processes that occur during the water flowing beneath the surface. This study can be done by looking at the chemical constituents of groundwater.

Figure 2. Photograph of hot spring at Parangwedang.

Figure 3. Example of dug well with fresh – brackish groundwater at Parangtritis Beach.

## 2. BASIC THEORY

Groundwater in nature can be found in fresh to saline. Salinity level is varied, and can be determined based on the element of chloride (Cl) or the total dissolved solid (TDS) of water (Table1).

Table 1. The salinity level of groundwater (PAHIAA, 1986, in [3]; Carroll, 1962, in [9]).

Water characteristic	TDS (mg/l) [3]	TDS (mg/l) [9]	EC (µmhos/cm) [3]	Cl (mg/l) [3]
Fresh	≤ 1,000	0 – 1,000	≤ 1,500	≤ 500
Almost brackish	> 1,000 - ≤ 3,000		> 1,500 - ≤ 5,000	> 500 - ≤ 2,000
Brackish	> 3,000 - ≤ 10,000	1,000 – 10,000	> 5,000 - ≤ 15,000	> 2,000 - ≤ 5,000
Saline	> 10,000 - ≤ 35,000	10,000 – 100,000	> 15,000 - ≤ 50,000	> 5,000 - ≤ 19,000
Brine	> 35,000	> 100,000	> 50,000	> 19,000

As long as the water flows below ground level, the different hydrochemical processes can occur. The hydrochemical processes that occur in groundwater systems include dissolution - hydrolysis - precipitation, adsorption, ion exchange, reduction -

oxidation, mixing, membrane filtration and metabolism microbiology [9]. The chemical composition of groundwater depends on the chemical composition of water in the recharge and many reactions that occur in the flow system [5]. Genesis of saline water is also determined by a variety of hydrochemical processes which occur along the path flow.

Mixing occurring in the groundwater at coastal areas could be seawater intrusion or flushing. There are different types of brackish water chemistry caused by the intrusion of seawater or flushing process (Fig.4). Seawater intrusion generally change the type of water from NaCl into  $\text{CaCl}_2$  type. The reverse process occurs when fresh water from the brine aquifer goes leaching (flushing), where brackish water will generally has the  $\text{NaHCO}_3$  type. When seawater intrudes in a coastal fresh water aquifer, an exchange of cations takes place. Sodium is taken up by the exchanger, and  $\text{Ca}^{2+}$  is released. The water quality thus changes from NaCl to  $\text{CaCl}_2$  type water. The reverse process takes place with refreshing, i.e. when fresh water flushes a salt water aquifer, where  $\text{Ca}^{2+}$  is taken up from water, in return for  $\text{Na}^+$ , with a  $\text{NaHCO}_3$  type as result [4].

In addition to the mixing, the chemical evolution is often a major cause of groundwater salinity. Evolution of groundwater is generally followed by regional changes of anion dominance as indicated by the Chebotarev sequence (1955, in [4]) as follows:

To the right sequence is characterized by an increasingly distant flow path of groundwater accompanied by increasing age.

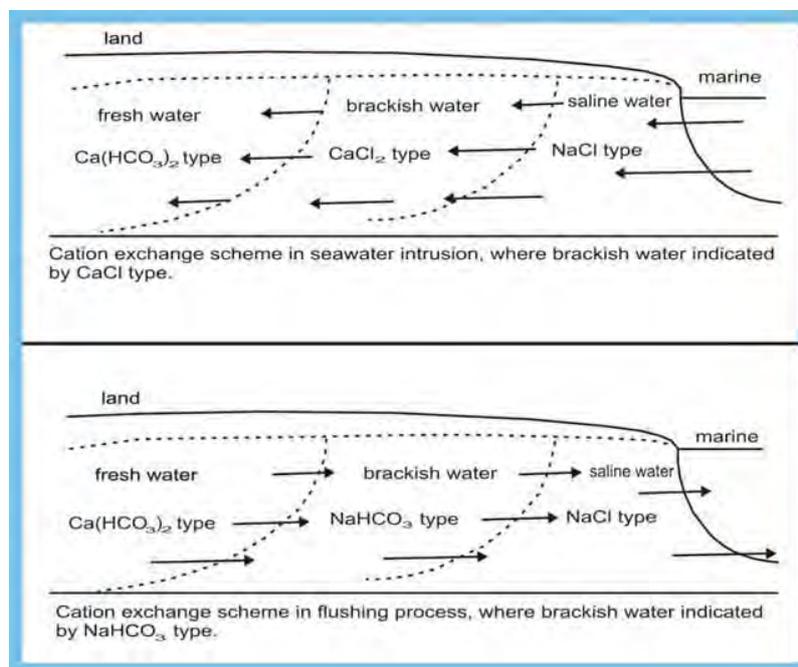

Figure 4. The groundwater chemical type caused by hydrochemical processes in the aquifer [3].

### 3. METHODOLOGY

To answer the problem of the genesis of saline groundwater at Parangtritis, geological field survey has been conducted with an emphasis of hydrogeology. This hydrogeological field survey aims to find the data and the physical properties of groundwater aquifers. The field work was carried out by measurements of groundwater table, completed with groundwater sampling. Mapping of groundwater table is useful to know the general direction of groundwater flow. Then, the groundwater samples should be tested in the chemical laboratory. Furthermore, an hydrochemical and hydrogeological analysis used to answer about the genesis of saline/brackish water in the study area.

### 4. RESULT AND ANALYSIS

#### 4.1. Hydrogeological Analysis

To understand the potential intrusion of seawater we must do shallow groundwater table mapping. By looking at the level of the groundwater table in the Parangtritis area, it has been known that generally groundwater flows direct to southward to the sea, it means that the possibility of seawater intrusion is almost imposible. On the other hand, there may be caused by flushing of saline/seawater by fresh water from the mainland.

The groundwater at Parangtritis Beach flows in the alluvial aquifer, especially in the beach sand deposits that form the plain sand and sand dunes morphology, which are loose, porous and permeable [6]. Groundwater comes from meteoric water, generally has young age (the present groundwater). Under the alluvial deposits, there are Nglanggran Formation breccia and other older aquifers zones. Groundwater is emerging as wells and hot springs in Parangwedang usually flows in this aquifer. The appearance of springs in the area is controlled by the inter-grain and joint/fracture rocks porosity. Groundwater should be mixing of meteoric water, volcanic water and past seawater intrusion. The presence of seawater intrusion is not supported by the present pattern of groundwater flow direction.

#### 4.2. Hydrochemical Analysis

Some groundwater chemistry data related to this paper are summarized in Table 2 below. Sample 1 is the data from the hot springs Parangwedang (T =35oC), the second sample was taken from the wells which is located ± 20 m to the east from spring, with hot temperature (T =45° C). Samples 3 & 4 were taken from dug wells at Parangtritis Beach.

Table 2. The chemical data of groundwater at Parangtritis and vicinity [7,8].

Parameter	Sample			
	1	2	3	4
Cl	6,528.6	7,498	20	23.9
TDS	-	17,500	-	-
Type	Chloride	CaNaCl <sub>2</sub>	NaMg –HCO <sub>3</sub>	CaMg – HCO <sub>3</sub>
Salinity level	Saline	Saline	Fresh (sometimes changes to be brackish)	

The four groundwater samples showed varying levels of salinity. Samples 3 and 4 which were taken from dug wells in Parangtritis indicate fresh water, but sometimes it can be brackish. According to information from the local citizens, water is sometimes saline especially when the tide. Beside the two wells sampled, some dug wells in the study area identified contain brackish water.

The test results showed that the water chemistry of groundwater in Parangwedang is chloride type, characterizing the intrusion of seawater or groundwater chemical evolution in advanced stages. This chemical type of water is usually indicate an old groundwater or groundwater has undergone a long journey and a long time. However, mixing with young meteoric water or the Tertiary volcanic/magmatic water may also occur. Volcanic activity usually enriches the element of chloride in groundwater. Meanwhile, mixing with meteoric water less intensive, characterized by a little bicarbonate ions.

Based on the chemical type, the groundwater in Parangtritis interpreted as the result of freshwater flushing (see mixing models in Figure 4). Seawater intrusion is unlikely in this area because it is not supported by the groundwater flow pattern. Fluctuating of salinity levels caused by the infiltration of seawater below the surface at high tide. It is strongly supported by rocks aquifer consists by loose, fine - medium sand deposits. In summary, the hydrogeological cross-sectional illustration of study area is shown in Figure 5.

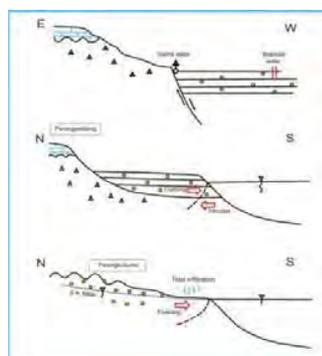

Figure 5. Illustration of aquifer and hydrochemical processes at Parangtritis and its vicinity.

## 5. SUMMARY

The saline/brackish groundwater at Parangtritis and surrounding area found in Parangwedang and Parangtritis Beach. Genesis of saltwater /brackish is different, and can be summarized briefly as follows.

1. Saline water at Parangwedang is originated from mixing of meteoric water and old groundwater, influenced by magmatic activity and the intrusion of seawater through the aquifers.
2. The salinity of groundwater at Parangtritis caused by infiltration of tidal seawater and controlled by the flushing of seawater by fresh water.

## ACKNOWLEDGMENT

This paper is done by compilation of many data, especially based on research which has been funded by Kopertis Region V Yogyakarta in 2008 and 2009, so the author want to give thanks to goverment through Kopertis Region V.

### ABSTRACT

Dispersant reduces interfacial tensions of oil and water turning oil spill into droplets that makes crude oil easier to be degraded by hydrocarbonoclastic bacteria such as *Pseudomonas aeruginosa*. Objective of study is to assess the effect of dispersant utilization (solvent-based and water-based) related its performance efficiency in the presence of *Pseudomonas aeruginosa*. The research was carried out in lab-scale varying the Oil Spill Dispersant (OSD)-oil ratio in 3 levels (1:8, 1:20, 1:25) and carbon source adaptation into 3 levels (0%, 1%, 2%). The total number of samples prepared was 84 consist of 21 samples without *Pseudomonas aeruginosa* addition and 63 samples with *Pseudomonas aeruginosa* addition. Total petroleum hydrocarbon (TPH) measured using gravimetric method to determine the biodegradation of crude oil. Also measured pH samples with *Pseudomonas aeruginosa* addition and COD of samples with dispersant. Data were analysis using ANOVA. The result shows *Pseudomonas aeruginosa* has the ability to degrades crude oil despite the presence of dispersant, whereas the use of water-based dispersant showed better biodegradation ability than solvent-based dispersant usage. Dispersant effectiveness of solvent-based and water-based is 33% and biodegradation by *Pseudomonas aeruginosa* achieved 25% in 72 hours periode.

### ABSTRACT

Azo dye is one of the synthetic organic dye groups most widely used in the textile industry. The release of this component into the environment can be harmful to the living organisms and the ecosystems. Therefore, it is necessary to treat wastewater that contains dye before it is discharged into the water bodies. The decolorization using mono or mixed culture has been developed since decades because environmental friendly and completely mineralization. 16 species of pure culture bacteria derived from aerobic-anoxic membrane bioreactor were used for biodegradation of azo dye Remazol Black 5 using tempe industrial wastewater as co-substrate. The optimum co-substrate concentration for biomass growth under shaking condition was 40% v/v or 2,560-2,720 mg COD/L, while dye decolorization was not significant. The azo dye biodegradation in anaerobic condition showed that dye was decolorized best by Isolate A1A, *Exiguobacterium* sp. A2, and *Bacillus* sp. A4 with efficiency of 43.82%, 29.94% and 35.91% respectively. The highest color degrading bacteria were also the highest organics removing bacteria. It was confirmed that dye decolorization process required carbon source addition.

### ABSTRACT

*The growth of urban public service infrastructure never keep up with their population growth in developing countries. Residential water use (RWU) over half of total municipal water consumption in most urban within developed countries. RWU requires higher quality and reliability, which in turn leads to higher costs. Historically, RWU is directly linked with the health of the general public and is crucial to the well being of a society. RWU shows a strong positive correlation with living standards and is one of the important proxies for economic development. Many factors affect residential water demand. such as water tariff; education level; income; water storage media; water metering; temperature and precipitation; household size, people numbers at a house, house age, number of families in a house, the rise in employment and the number of labor force in urban areas. These attributes and their interrelationship have dynamics characteristic.*

*PDAM Bandung for example, in this last 5 years, the average of the urban water coverage services growth 0.65%, and Bandung municipal population growth is 1.42% per year. Total RWU is 72% from PDAM total water allocation. It serves 1.6 milion (66%) from the total registered population.*

*The water supply capacity is 2706 liter/ second. The water sources are from surface water (86.51%), ground water and springs (13.49%). The production and distribution capacity usage is 84.7%. The non revenue water is decreased, from 50.6% in year 2006 into 38% in year 2010; However, that number is still higher than PDAM target (20%). In financial management point of view, the tariff adjustment is done twice within 10 years and the billing lifecycle always late around 42 days. PDAM Bandung never have profit at all. In human resource performance, an employee serve 5.5 customers in average.*

*The above information is based on previous research. The primary data is obtained thru series of interview with PDAM management. Medium long term and long term plan (RJPM and RJPP) of Bandung municipal and PDAM are treated as the secondary data. PDAM and Bandung Municipal RJPM, RSJPP data are treated as the secondary data.*

*If Bandung population historical data is extrapolated until year 2020, with the current PDAM Bandung performance, Bandung will experience water scarcity in year 2016. and impossible for PDAM Bandung to expanding the coverage services until it reaches 80%.*

*This research is to figure out the current condition of PDAM Bandung, the challenges faced by them and the recommendation to overcome the challenges. This research is part of the overall research which will figure out the dynamics behavior of urban water coverage services expansion programme and to determine the most optimal program to enlarge PDAM coverage services .*

## 1. INTRODUCTION

In many part of the Globe, population growth and urbanization are increasingly becoming challenge to governments. According to the information from the International Year of Freshwater (2003), by the year 2020, around 60% of the global population will live in urban areas[26]. Currently, more than 80 countries, with 40% of the global population suffer from severe water shortages. In Asia developing countries, within the last 20 years, the progress of urban water supply program are slow, the comparison between the service coverage with the demand tend to be lower, the average

of non Revenue Water (NRW) is around 35% of production. Water Supplies in Asia will be of greater challenge to government agencies, local administrations and planners in the coming years. Condition in Indonesian cities is growing worse compared to other Asian countries because of tremendous population growth in urban.

Based on BPPSPAM data[3], from 335 total PDAM throughout Indonesia, 144 is categorized as healthy company, 105 less healthy, and sick 86 PDAM. Only 12 PDAM which have service coverage above 80% of population. Total direct connection customers are 7,574,154. The lowest service coverage in regency Seruyan Sulawesi that is 3.8% only. In average, the coverage services of PDAM West Java only 33.25%. By using year 2000 until year 2010 data[3],[25], the coverage services of PDAM Bandung municipality only ranged in 61.1%. The low access to drinking water will cause serious problems not only for individuals, but also for the city and the state. Effort to raise the level of health and economics of the individual and society, and raise the level of education for children and women, will be hampered by the lack of access to drinking water. Conflict between population and economics's losses are happened due to the low access to drinking water. [32],[20] .

The need for water is very dependent on the characteristic of the households of customers, such as number of people in the house, house's age, house's distance to reservoir, number of families in a house, education and income level, water tariff. ([9],[10],[21],[22],[29],[30]). Socio-economic factors including regional economic development, income growth in real estate industry, level of health services, increasement of job opportunities and growth rate of workers in urban areas, use of energy also contribute to the determination of the water needs volume.[5],[7],[24],[27]

The low coverage of drinking water service is influenced by the PDAM's performance, politics, energy, reliability of infrastructure, willingness to pay, water quality, billing system, PDAM operation, human resource's effectiveness, PDAM's financial condition, new distribution investment, and level of customer satisfaction. ([1], [10], [11],[13],[18]). A lot of RWU studies for developed countries are done and produce the research that the water tariff is the main driver to improve demand management. [6]. In developing countries where the economic growth in urban runs rapidly, and not in line with the infrastructure development growth, the main attribute that causes water consumption pattern is not in price factor, but the water sources accessibility.[5]. With a difference of attributes and the interaction among attributes in each study conducted in different cities, drinking water management system can not be generalized for all urban areas.

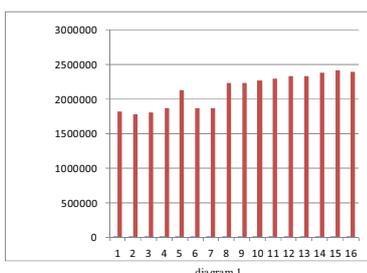

This research reveals the condition of Bandung municipal and its projection as well as the challenges faced by PDAM Bandung to be able to provide drinking water for its residents. This research is the first step of further research: Dynamics Behaviour of PDAM Coverage Services Program.

### 1.1. Bandung Profile.

Population growth is more prevalent in urban areas, as it provides better economic opportunities. Better of education, employment and health facilities in cities, always encourage people to migrate from rural into urban areas, and this has become a major social, environmental and political issue in Indonesia. an example Bandung Municipal.

Bandung city is located in region of West Java and constitute Capital city of Province of west Java. The area of Bandung city divided by a). 26 districts, b). Villages, c). 1498 community associations and d). 9215 neighborhood associations. Population density per km<sup>2</sup> maximum is 38,686 population per km<sup>2</sup>; The population density grow over year with the average growth rate is 0.92%. The population density of Bandung regency region:11.471, Sumedang:1025 and Cimahi: 24,067 population/km<sup>2</sup>. Bandung municipal population is 2,394,873 (58.43%), Cimahi 1091,323 (26.63%) and Sumedang 612,168. (14.94%). [4]

The areas around Bandung being a hinterland. The total population of West Bandung regency, Cimahi and Sumedang reach more than 6 million. With a role as a center for orientation, then the movement of population between the center and the hinterland be intermingled. The reality of the population activities in Bandung municipal are likely to exceed the number of registered residents.

The diagram 1 is a figure of Bandung registered population. The population grow 2.08% annually and the GDP grow 18.84% annually. They make Bandung over crowded. Urban land has become extremely scarce. When viewed from the age structure of Bandung population, the prominent segment is the early working age (25 – 34 years) and the age of higher education (20-24 years). A spike at those ages indicate the migration occurred in Bandung city; i.e. students who continue their studies in Bandung, simultaneously places looking for work as beginners in workforce. he economic structure of Bandung municipal is dominated by the services and process industries sector. Their growth rate is relatively high compared to the national and west java cities. The unemployment rate is around 15%. [4]

The average temperatur of Bandung municipal is 23 C; However, An average of maximum air temperatur in the city rise 2C within last 20 years. This is a significant increase based on world of meteorology assessment. Bandung air quality has exceeded a threshold, especially seen from the levels of dust, HC and Pb. The all locations have HC level that has surpassed the quality threshold. This condition might be as an impact of the vehicle growth which is 12% per year. Currently, Bandung transportation are facing serious problems and is increasingly become a major threat in the future, if there is no significant inroads. Moreover, some irregular business development locations and so much garbage from domestic which is not be able to transported spread on streets.

By so complex condition and the high pace of growth, Bandung municipal public services become bogged down, city management is often ineffectual, human misery has increased beyond imagination. The urban infrastructure has become outdated. The similar challenges faced by PDAM Bandung as well.[4]

## 1.2. Perusahaan Daerah Air Minum (PDAM) Bandung

### 1.2.1. Water Supply

Water Supply	Production capacity (l/s)	Production actual (l/s)	idle
<b>Surface water</b>			
IPA Badak singa	1800	1783.98	16.02
IPA Dago Pakar	600	595.25	4.75
MP Dago Pakar	40	42.78	-
MP Cibeureum	40	34.75	5.25
MP Cipanjalu	15	15.49	
MP Cirateun	0	0	
<b>Ground water</b>	221	111.63	109.37
<b>Springs</b>	216	123	93
<b>Total</b>	<b>2937</b>	<b>2706.88</b>	<b>230.12</b>

diagram 2

The supply of water for drinking in Bandung municipal are filled by domestic drilling and partly served by PDAM. PDAM water sources are obtained from the surface water and ground water. PDAM use the 10 water springs and 19 wells to pump out the ground water. They flow into the reservoir.[17]. Water shall meet a certain conditions in order to be eligible for consumption and can be used to meet daily needs.. The conditions that must be met in the services of PDAM are: quality, quantity and continuity. Water quality standard comprise of physical, chemical and biology quality standard that are regulated by ministry of health: No. 417/MENKES/PER/IX/2002. PDAM use the chemistry material to penetrate the water quality and . its impacted to the PDAM operational cost (OPEX).

### 1.2.2. Water Treatment and Distribution

PDAM has 2 water treatment instalation units. They serve 4 regions, i.e. western, northern, central and eastern of Bandung area. PDAM use the gravitation system to intake the surface water, and pump system to obtain the ground water. To accomodate the water processed, PDAM has 6 reservoirs with total capacity 42,600 m3. Although the IPA operate 24 hours, the distribution operation only lasted 15 hours a day. This is because the water supply is not stable, very low supply especially during the dry season. This limited water supply insist PDAM require a waiver to its new customers not to insist on PDAM, if PDAM service is not optimal. An affidavit must be signed off by the prospective new customer as a condition when they apply a new connection. [17],[25]

### 1.2.3. Idle Capacity, Non Revenue Water (NRW), Customer and employees

Description	Volume (m3)
<b>production capacit (liter/ second)</b>	
installed production capacity	92,621,232.00
Actual production capacity	75,166,458.00
Idle capacity (*1)	17,454,774.00
<b>Distribution Volume</b>	
Actual Production volume	75,166,458.00
Production loss	(11,880,456.00)
total distribution volume	63,286,002.00
Billable volume	33,202,155.00
Non Billable water	30,083,847.00
<b>Non Revenue Water (NRW)</b>	
NRW to distribution volume	15.81%
NRW to distribution volume	47.54%
NRW water to actual production volume	55.83%

diagram 3: source from PDAM Tirtawening Kota Bandung, 2009

The idle capacity (\*1) is happened because the lack of potential customers in several branches of the unit or there is no distribution network installed around the water sources. In year 2009, the percentage of leakage in PDAM Bandung's water distribution system reach 56% from its total production capacity. This is too high as based on BPPSPAM rule, the tolerable level of leakage on a water distribution system is approximately 18%-20%. This NRW rate can be calculated from the difference between the amount of water that is distributed by PDAM with the amount of water that is paid by the customer. The leakage level consist of the physical and non physical. The physical leakage is caused by the leakage of pipes and or its equipment, while the non physical leakage is caused by water's theft, the unregistered and unregulated connection, meter's accuracy is low or error in reading water meter as well as error in billing system. Many cases of RWU such as, about 30,000 direct conection (DC) with 0 m3 and about 60,000 DC RWU volume that are less than as usual. Its

predicted the number of non physical leakage exceed from physical leakage.

The total customer of PDAM Bandung in year 2011 is 150,236 DC, comprise of active subscribers 150,236 DC, 126, 442 DC, Social 2109 DC, Commercial 18,786 DC, industries 473 DC and government agencies 2427 DC. Total employee of PDAM is 824 people, consist of national servants 15, PDAM permanent employee, honorary employee 3, contracted employee are 4. [17]

### 1.2.4. PDAM Revenue and Cost

Based on Data from Perpamsi year 2011, operational cost of PDAM Bandung before depreciation and interest rate is 153,791,909,156 IDR. OPEX after depreciation and interest rate is 160,176,796,912 IDR and the revenue of PDAM is 159,416,126,802 IDR. It means PDAM Tirtawening does not have profit at all.[14],[17],[25]

## 2. METHODOLOGY

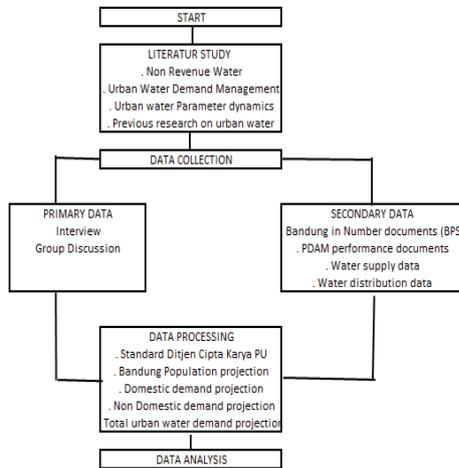

diagram 4. Methodology

Literature study was done by collecting all journals relating to the urban water management system, its challenges faced by developed countries as well as developing countries and Asian cities. The attributes that influence demand and supply of Residential Water Usage (RWU) are identified. The attributes behaviour resulted from the previous researches are assessed. The interrelationship among researches results are identified. The attributes that are not covered in the previous urban water and residential water usage researches are defined. The journals that pertain to water leakage problem in order to overcome the leakage issue on are gathered as well. Primary data is obtained by conducting interview and discussions with the water system experts from ITB, UI, BPPSPAM, and Public Work key players as well as PDAM Bandung key players and their top management. Informal discussion also held with Bapeda, Pusat Air Bandung. Secondary data were obtained from historical data of PDAM as well as from BPS Bandung. BPS data more concentrate on figure of Bandung's temperature, GDP, population, employment level, non domestic figures. while PDAM data contain performance of PDAM since year 1996 until year 2011. Diagram 4 figure out the research methodology

## 3. DATA PROCESSING, ANALYSIS AND DISCUSSIONS

### 3.1. Projection of Residential / Domestic Water Demand

Year	Arithmetic approach	Geometric approach	Population projection	Household Connection Demand	Public Hydrant	total domestic demand (liter/year)	total domestic demand (liter/second)
2011	13,043,048,494	13,010,793,673	13,026,921,083	91,783,507,725	7,867,157,805	99,650,665,530	3160
2012	13,394,047,521	13,155,633,001	13,274,840,261	93,475,089,390	8,012,150,519	101,487,239,910	3218
2013	13,920,546,061	13,302,084,715	13,611,315,388	95,186,525,664	8,158,845,057	103,345,370,721	3277
2014	14,622,544,116	13,450,166,765	14,036,355,440	96,918,229,522	8,307,276,816	105,225,506,338	3337
2015	15,500,041,683	13,599,897,301	14,549,969,492	98,670,622,530	8,457,481,931	107,128,104,461	3397
2016	16,553,038,764	13,751,294,674	15,152,166,719	100,444,135,022	8,609,497,288	109,053,632,310	3458
2017	17,781,535,359	13,904,377,439	15,842,956,399	102,239,206,284	8,763,360,539	111,002,566,823	3520
2018	19,185,531,467	14,059,164,359	16,622,347,913	104,056,284,738	8,919,110,120	112,975,394,858	3582
2019	20,765,027,089	14,215,674,405	17,490,350,747	105,895,828,134	9,076,785,269	114,972,613,402	3646
2020	22,520,022,224	14,373,926,758	18,446,974,491	107,758,303,741	9,236,426,035	116,994,729,776	3710
2021	24,450,516,873	14,533,940,816	19,492,228,844	109,644,188,552	9,398,073,304	119,042,261,856	3775
2022	26,556,511,035	14,695,736,189	20,626,123,612	111,553,969,476	9,561,768,812	121,115,738,288	3841
2023	28,838,004,711	14,859,332,707	21,848,668,709	113,488,143,553	9,727,555,162	123,215,698,714	3907
2024	31,294,997,900	15,024,750,422	23,159,874,161	115,447,218,160	9,895,475,842	125,342,694,003	3975
2025	33,927,490,603	15,192,009,607	24,559,750,105	117,431,711,229	10,065,575,248	127,497,286,478	4043

Tabel 1 : Domestic (household and public hydrant connections) demand with the 80% service level

domestic demand is figure out at tabel 1.

### 3.2. Non Domestic Segments

Year	Population	Worship places	Student at school	Student at univ	Big hospital	Small clinic	Hotel (bed)	Commerci- als places	Industry	Total Non Domestic Demand (l/year)	Total Non Domestic Demand (l/second)
2010	2,417,288	4006	468,669	84,888	32	237	11,184	778	147,606	12,867,548,980	408

tabel 2. non domestic places

Diagram 1 is a description of Bandung municipal population from year 1996 up to the year 2011. The growth rate can be derived from those data. The population projection can be obtained by Geometric, Exponential & arithmetic approaches. Based on Ditjen Cipta Karya PU standard, a city that has population above 1 million, has minimum 150 liters water consumption per persons per day. The comparison between household and public hydrant connections are 70:30 and the consumption of people who use public hydrant is 20 - 40 l/ person / day. (The hydrant supply 30 l/person/ day in the above calculation). the projection of

A city always has a commercial and industries as well as public places. They are established as an employment as well as the fulfillment of the daily needs of the population. tabel 2 figure out the BPS data of commercial and public places number from year 2000 - 2010. The water demand of non domestic segment can be calculated using Ditjen Cipta-karya PU standard.

### 3.3. Projection of Urban water demand

From the BPS data figure out at tabel 2 above, the water demand of each non domestic places can be calculated using Ditjen Cipatakarrya PU standard. The projection of the water demand for year 2011 – 2025 can be derived from the water demand figure, using the same approaches. The tabel 3 below is a projection of the total urban water demand figure for year 2011 – 2025. Based this the figure, and the water capacity figured out at diagram 2, at this current time, PDAM Bandung could not able to deliver the 80% service level. (80% is the PDAM Bandung target in order to fulfill the MDG standard).

Year	Gemotric approach	Population projection	total domestic demand (liter/ second)	total non domestic demand (l/second)	Total demand (100 service level)	80 % service level	72% service level
2011	13,010,793,673	13,026,921,083	3160	408	3568	2854	2569
2012	13,155,633,001	13,274,840,261	3218	413	3631	2905	2614
2013	13,302,084,715	13,611,315,388	3277	421	3698	2958	2663
2014	13,450,166,765	14,036,355,440	3337	432	3768	3015	2713
2015	13,599,897,301	14,549,969,492	3397	445	3842	3074	2766

tabel 3. Urban water demand

### 3.4. Non Revenue Water

Year	Distributed volume (m3)	Billed Volume (m3)	Billed in %	NRW in %
1,995	68,368,977	37,525,943	54.89%	45.11%
1,996	68,123,035	37,390,952	54.89%	45.11%
1,997	70,113,132	38,483,264	54.89%	45.11%
1,998	71,067,511	38,469,520	54.13%	45.87%
1,999	74,552,593	39,634,852	53.16%	46.84%
2,000	74,270,653	40,228,096	54.16%	45.84%
2,001	75,124,000	41,751,699	55.58%	44.42%
2,002	77,902,342	35,828,311	45.99%	54.01%
2,003	79,522,079	33,508,022	42.14%	57.86%
2,004	79,927,566	33,013,954	41.30%	58.70%
2,005	79,927,566	33,013,954	41.30%	58.70%
2,006	84,746,149	34,295,686	40.47%	59.53%
2,007	82,955,111	33,508,022	40.39%	59.61%
2,008	83,646,580	33,508,022	40.06%	59.94%
2,009	83,646,580	33,013,954	39.47%	60.53%
2,010	79,176,222	35888185	45.33%	54.67%
2,011	79,132,469	43,617,254	55.12%	44.88%

Non Revenue Water data is very difficult to be obtained. The NRW amount can be derived by subtracting the amount of distributed water to residential by the amount of water that is paid by residential. Tabel 5 describe the NRW profile.

From the results of an interview with PDAM management, the leakage in administration type is larger than the physical leakage. The administration leakage is a). The metter accuracy. b). Wild/ unregistered connection, c). Theft. d). Error in reading and data handling [2]. A follow up interview with the PDAM management has strong indications that the administration leakage case has greater than physical leakage. Currently, there are several accounts have zero water usage. Among that number, 51,522 account from business, such as hotels and restaurants. Beside that, there are about 21% from 140,000 PDAM customers who use water less than 10 m3 per year. These leakage cases give impact in lost revenue to PDAM until 82.200 milyar IDR.

## 4. CONCLUSIONS

The study reveals that water shortage is increasingly becoming a serious issue in Bandung municipal. Demand has been growing fast linear with the growth of population while the water availability is fast decreasing due to pollution, land use changes, shared water supply with Bandung hinterlands that are developing very rapidly aswell. Both surface and spring water in the city have been polluted. The Ground water supply considerably reduced due to the presence of the ground water are more deeper or dry.

Since at this present time, amount of water supply and the maintenance of the delivery system are quite inadequate. Suggestions for 1). Control properly the production system and 2). Control properly the non revenue water. To implement this suggestion, PDAM should do a technical audit to make sure the all equipment run well, especially to check the loss amount from water supply to production and water production to water distribution. This activity might cover the installation a monitor system in the input and output of production system, to make sure that the production

output volume match with the distribution input volume. Proper and timely maintenance of the public water system, Control of unauthorized use of public water, proper filtering of tanks, Reducing water loss in distribution system. Reward and penalty system to manage PDAM human resources especially to eliminate the administration water leakage. [8],[15],[16],[19],[23]

Since the the water supply is coming from the hinterland area which is outside of Bandung Municipal authority, the joint strategy and implementation with the hinterland's PDAM should be done effectively.

After all, there should be a strong government policy for urban water management, an appropriate adaptation strategy and a political will to implement the strategy.

## 5. RECOMMENDATION

This study of the PDAM challenge should be continued by the subsequent research so that the management model of PDAM to enlarge services to their customer can be achieved and can be applied in all PDAM, especially PDAM Bandung. It should be noted that the all attributes that affect the PDAM management such as, population, income, education, water supply, NRW, climate, number of city infrastructure are very dynamics. Model that is projecting the balance between demand and supply of drinking water should be developed with considering the dynamics of those attributes and the dynamics intensity of attribute interrelationship.[5],[8],[28]. The simple regression for attributes projection with ignoring the dynamics behaviour of attributes and their interconnection will produce a model of PDAM management that does not solve the PDAM challenges.

### ABSTRACT

Cirata reservoir which covers 6000 hectares is one of the 800 reservoirs in Indonesia which has 2 very strategic function, economic and ecological functions. The most dominant of economic function are (1) source of water for hydro electric power plant (HEP) to meet the electricity needs of Java and Bali. of total water volume 2,160,000,000 m<sup>3</sup> it is expected for producing 1008 megawatt (MW) power and (2) place of fish farming for the local community with the floating cage net system (Keramba Jaring Apung : KJA). While the most important of ecological function are (1) water balance system and micro-climate, and (2) water sources of irrigation. The biggest problems of Cirata reservoir today is the height of sedimentation and degradation of water quality due to pollution of water reservoirs caused by the growth of floating cage net (KJA) out of control, as a result is upwelling that makes massively the fish deaths and disorders of the turbine power plants.

This paper describes selection the best strategy of sedimentation and water pollution control in accordance with the objective conditions of local community using AHP method.

#### Keywords:

Floating cage net (KJA), sedimentation, water pollution, upwelling, AHP method.

### 1. BACKGROUND

Cirata Reservoir is one of the biggest reservoir in West Java which has a vital function for the Jakarta, Bekasi, Cianjur and Karawang, since the reservoir has a economic and ecological functions. According to documents released by BPWC (Cirata Reservoir Management Board) in 2010, Cirata Reservoir which established in 1988 has completely 6,200 hectares which derives from 28 villages and of 8 counties that includes 3 municipality : Cianjur, Purwakarta and Bandung. Water capacity is roughly about 2.160.000.000 m<sup>3</sup>, with a depth average of 34,9 m, maximum depth can reach 106m. Most ultimate economical function is working as Water Power Electrical Generator/hydro power to provide electric power for 1008 MW to supply Bali and Java electric power need (BPWC 2003).

In addition Cirata reservoir is also become breadwinner for 50.000 families through fish farming activities with a floating cage net system (Keramba Jaring Apung : KJA). At the time of the inauguration in 1988 the number of KJA 12.000 involving 4000 people. During 24 years periods (1988-2012) the number of KJA has reached about 53.000 (average increase of 14.32% per year), and the number of households who are directly involved about 50,000 people as both a guard labor of KJA, and other workers or porters.

KJA is a pool of fish farming which is made of nets and placed in the water, it is allowed an exchange of water from the KJA to the surrounding areas. One unit of KJA consists 4 pools and a guard house, the size of each pool is 7x7 m<sup>2</sup> or with a total area is 15.8x15.8m<sup>2</sup>. Fish farming with KJA is an intensive system, three times feeding a day some even more. Feed fish are given only about 30-50% are used and the rest went into the water as a sediment and pollutant source of water (Midlen and Redding: 2000). Accumulation of sediment and water pollution will cause upwelling, which causes mass of fish deaths.

Cirata reservoir is also become a tourism destination that attracts many tourists for touring the reservoir using speed boat whilst enjoying the panorama scene, whereas the first function of ecological side is as water balance, the source of raw water and water supply for farming and plantation irrigation for Cianjur, Purwakarta, Karawang, Bekasi and Jakarta.

Cirata reservoir issues faced at the moment is the height of sedimentation and degradation water quality due to pollution of water reservoirs caused by uncontrolled growth of KJA. Estimated the current number of KJA reached 53.000, beyond the amount allowed for around 12 -15 thousand of KJA. (Cirata Reservoir Management Board, 2012).

Sedimentation is occurred because of erosion, solid waste of industry and accumulated sediment remnants of fish feed due to the rising number of KJA. While water pollution was caused by increasing polluting agent particularly BOD (*Biological Oxygen Demand*), COD (*Chemical Oxygen Demand*), Amonia and Phosphate of industry waste and household garbage around the reservoir. Pollution of water has induced a corrosion to hydro power plant turbine and it would give an impact to electrical power resulted. In addition, it will also encourage an *upwelling*, the reversal of the toxic lower layers to the upper layers that caused a death of thousand tones of fish, so that fish farmers suffered huge losses. This was occurred in 2010 when death of the fish reach 150 tons with the lost of 2,25 billion rupiah (Cirata Reservoir Management Board; 2010).

The Most urgent problem that should be resolved is how to control the growth of KJA and managing existing KJA, so that sedimentation can be reduced and water quality is maintained. Therefore in order to control KJA growth and maintain water quality for avoiding upwelling, this research is required. The purpose of this research is to select the best strategy for controlling sedimentation and water quality of reservoir in accordance with objective condition of community around using AHP method.

## 2. Literature Review

### 2.1 Reservoir Function

Reservoir has a very strategic role in supporting human life as water resources, or water balance. There are 2 main functions; economics, and ecological functions. Water resource availability has a significant role in constructing a regional economy. Limited water resource in area which had an implication to this activity that will give an impact to people prosperity. The existency of reservoir has giving an economical benefit, especially for irrigation, water resource and electrical generator/hydro power plant. This is main function of economics. On the other side ecological function of the reservoir is micro-climate control, water balance for the surrounding areas. Besides two functions, reservoir also been attractive tourist destination. Some reservoirs that have become a tourist destination: Saguling, Kedung Ombo, Reservoir Dharma etc. In addition the existence of this reservoir has also become a fish farming place for local community through floating cage net (KJA) system. Reservoir can also be interesting tourism object from social aspect, while from ecological aspect this reservoir can give many function as water balance system, and flood controlling (Kartamiharja, 1998).

Act No.7 of 2004 on Water Resources explained that the management of the reservoir/lake has 3 main components, namely: (1) for conservation, (2) for the utilization of water resources, and (3) for flood control. Many related regulation or another law namely : Government Regulation No.51 of 1997, on the Environment; Regulation No.82 of 2001 on the Management of Water Quality and Water Pollution Control; Regulation No.32 of 1990 on Protected Areas; Presidential regulation No.123/2001 Coordination of Water Resources Management at the provincial level, the River Region, Municipality and City.

In the beginning of its establishment in 1998, KJA is only 21,000, nevertheless, according to Krismono (1999) KJA development in Cirata Reservoir will reach to 140% in short time (1988 – 1994). In 2012 KJA has reached number of 53,000 by estimation owner around 3500 people ( Cirata Reservoir Management Board, 2012). KJA development for 25 years (1987-2012) as the following table :

Table 1. KJA number and percentage which active and inactive (2012)

Region	Farmers	Floating Net Keramba ( KJA)				
	Number	Number	Active	Inactive	SPL (%)	NON SPL (%)
Bandung	1,198	21,766	21,314	45	9.0	91.0
Purwakata	492	10,104	8,643	1,461	7.6	92.4
Cianjur	821	21,161	18,634	2,527	12.7	87.3
TOTAL	2,511	53,031	48,591	4,033	10.4	89.6

Description : SPL (Site license /Location permit) ,

Non SPL : Non location permit

Source : Cirata Reservoir Management Board (2012)

Based on the table above, it appears that most of the cages are not licensed or illegal. There only 10.4 % had allocation permit and most of the rest (89.6 %) are do not have permission.

One of the factor caused the KJA increase rapidly and uncontrolled is weak of licencing system. Despite licence procedure has been made, nevertheless, since Cirata Reservoir is consist of 3 administrative region (Bandung, Cianjur and Purwakarta), this implementation is still low (Cirata Reservoir Management Board, 2011). In addition almost of people consider that Cirata Reservoir is belonged to them, so as anybody can use or exploit it (Widayati, D. Setyanto, D.G Bengendam Kholil, 2011).. According to Bromley (1991), Scott and Gordon (1988) and Hardin (1988) in S Hanna and Munasinghe (ed) (1995) claim that usage of natural resources without management and controlling in a long term tends to be "The tragedy of the commons" (Medow, 1977 and Kim, 1988) which had given an impact to environment damage. The best way to overcome the tragedy of the common is by constructing a regulation to manage and regulate natural resource usages (Medow, 1977 and Kim 1988).

## 2.2 Floating Cage Net (KJA) of fish farming system

Fish farming system by Floating Cage Net (KJA) is cultivation system which is technically and economically efficient. Since it don't take much cost and space but the results is multiplied. The fish placed in the water bounded by net to form the pool of 7 x 7 meters, so water circulation running smoothly and feeding is done 3 times a day. Fish farming system through KJA is frequently conducted at reservoir or lake. Hardjamulia (1991) claim that fish farming activities at reservoir is one of alternative way to use water resources of reservoir. KJA system has already begun in Indonesia since 1974 at Jatiluhur reservoir, then expanded to another reservoir such as Saguling Reservoir, Cirata Reservoir, Wonogiri Reservoir and Kedung Ombo Reservoir, because the results are doubled, then the growth of KJA is very high in all these reservoirs (Dahuri 1996).

KJA growth in Cirata reservoir already exceeded the amount allowed 12 000, during 25 years the number of KJA shown in figure below (Cirata Reservoir Management Board, 2012).

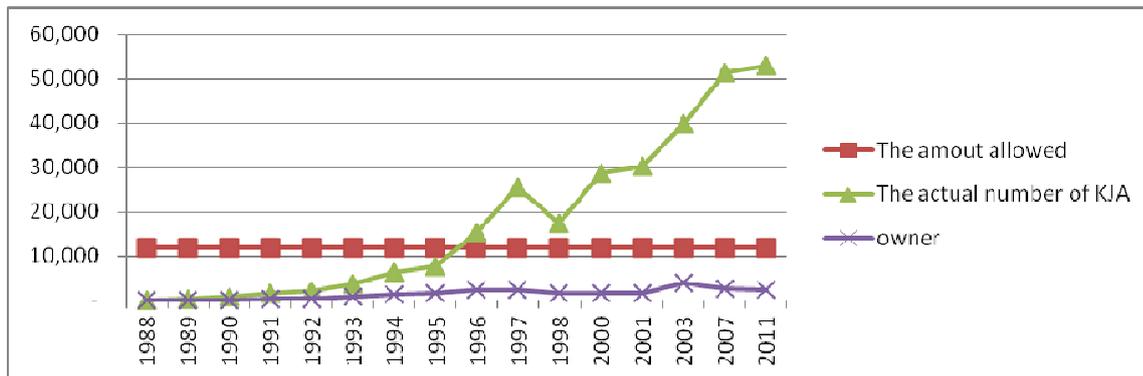

Figure 1. KJA

growth during 24 years (1988-2011), (Cirata Reservoir Management Board, 2012)

## 2.3 Reservoir Issue

Cirata Reservoir is a collection of 5 Citarum creek rivers: Cimeta, Citarum, Cisokan, Cikundul, and Cibalong flowing through settlements, agriculture, and industry. Suhata (2010) stated that increased sedimentation at Cirata reservoir has far exceeded planning design so the sedimentation in 2007 is reached to 146 million cubic meters, with an average rate of 3.9 millimeters sediment/year. The average rate is about three times faster than the average rate of just planning to reach 1.2 millimeters/year. Annual increased sediment in Cirata reservoir estimated 7.3 million cubic meters, over 2 million cubic meters of design made 5.30 million cubic meters. It will have an impact decreasing reservoir age of 20 years planned (Citarum Reservoir Management Board, 2010)

The feed given to the fish in the floating cage net (KJA) systems were used only 60-70%, the remaining of 40% into waters. Estimated the rest of feed into the water contain 10% of P and 65% N in the dissolved form, whereas 65% P and 10% N in the form of particles (Kartamiharja, 1998). Peace (2011) stated that increased sedimentation caused by blue algae has reduced the volume of water in the lake Kansas America. Kishiwai (2011) also stated that sedimentation has caused some reduction in the volume of water in the reservoir in Japan.

The impact of reservoir water pollution due to the residual contamination of feed and waste are the upwelling. It usually occurs regularly, especially at the beginning of the rainy season when the weather is overcast, with the sun very low

intensity. Upwelling can be divided into 3 types, namely (1) permanent upwelling, where it occur all over the year, such as in Ivory and Peru. (2) upwelling periodically, as in the northwest coast of Australia, and (3) successive upwelling (alternating type), Hardjamulia (1991) and Dahuri, (1996),

### 2.3. Metode AHP

AHP (Analytical Hierarchy Process) is an expert-based approach that can be used to select the best choice of many choices based on multiple criteria. The basic principle of this method is structuring a complex problem into simpler in the form of hierarchy, through pairwise comparisons by experts, so that it becomes easy to select the best. Saaty (1988) stated that through the structuring and pairwise comparisons, AHP method make us able to identify a hierarchy of options based on multiple criteria, and making it easy to determine the best option.

There are four main principles of AHP method, (1) Decomposition, dividing a whole problem into smaller elements, (2) Pairwise Comparison Judgment, making judgments about the relative importance of two elements in a certain level to the higher rating scale using a scoring system, which developed by Saaty (1986), as the following table

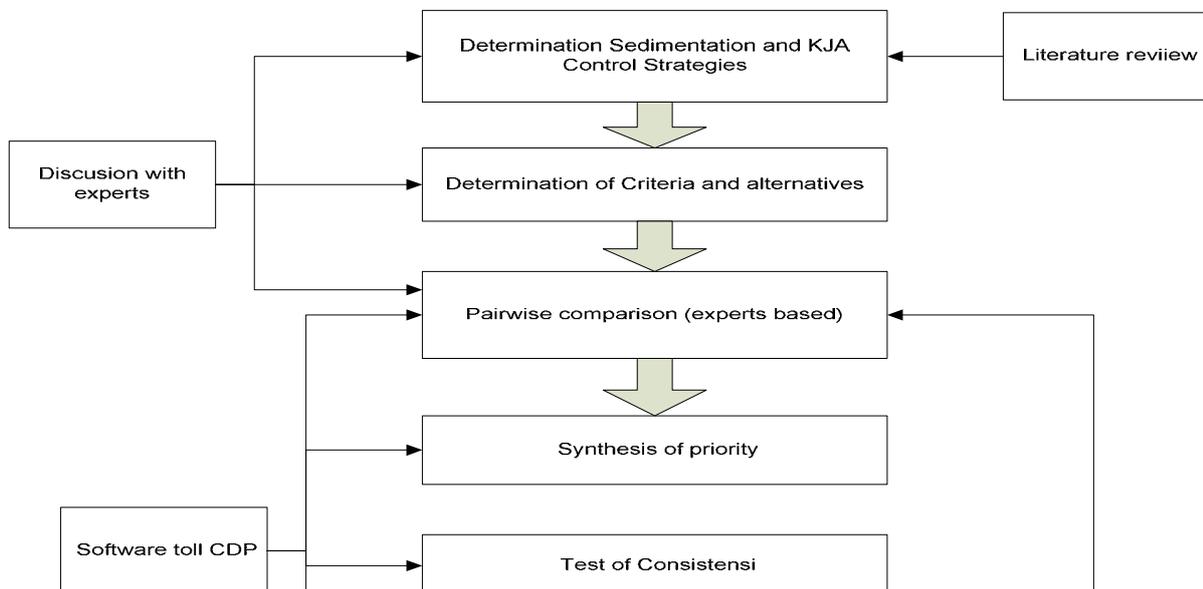

Tabel 2. Skala penilaian kepentingan relatif

Importance	Description
1	Equal important
2	Slightly important
3	Weakly more important
4	Weakly to moderately more important
5	Moderately more important
6	Moderately to strongly more important
7	Strongly more important
8	Greatly more important
9	Absolutely more important

(3) Synthesis of Priority, selection the best priorities based on the greatest of eigenvalue, and (4) Logical consistency, is to examine the consistency of each matrix weight pairs. Consistency assessment of pairs can be viewed from two aspects: (a) by looking at the multiplicative preferences, for example when A twice heavier than B and B two times heavier than C, then A should be four times heavier than C, and (b) by viewing preferences transitive, ie if A is less than B and B is less than C, then A must be smaller. Since AHP method was introduced by Saaty in 1977, it has been widely used to select the best alternatives in many research fields, such as economics, management, engineering, social and environmental.

### 3. METHODOLOGY

Determination of sedimentation and upwelling control strategies in Reservoir Cirata largely done through several stages as shown in figure 1. Analysis using software tools CDP (Cretirium Decession Plus) :

## Figure 2. Steps and method determination of priority strategies using AHP

Data input in the CDP is a single data, so for more than one expert to get a single data, the first step is making an average value using geometric mean.

### 4. RESULT AND DISCUSSION

Experts as resource persons in this study are 5 people, they are (1) Head of Cirata Reservoir Management Board, (2) Head of Planning and Program of Cianjur marine regional office (3) fish farming expert from Bogor Agriculture University (IPB), (4) Head of evaluation and program of PJB (Power Java-Bali) in Purwakarta, and (5) Fish farmer group leader of KJA. Results of expert discussions showed that to control sedimentation and floating cage net (KJA) in Cirata reservoir there are 7 criteria as a basis of determination the strategy, namely: (1) reservoir water quality, (2) reservoir water volume, (3) employment, (4) KJA business sustainability, (5) sustainability of tourist destination, (6) sustainability of hydropower and (7) sustainability of water source for irrigation. Based on the criteria, there are 5 possible alternatives: (1) standardization of KJA and fish farming system, (2) KJA zoning restrictions, (3) tightening of licensing, (4) fish farmer participation and (5) restriction on the number of KJA. Goal, criteria and alternative hierarchy based on the results of discussions with experts as shown below:

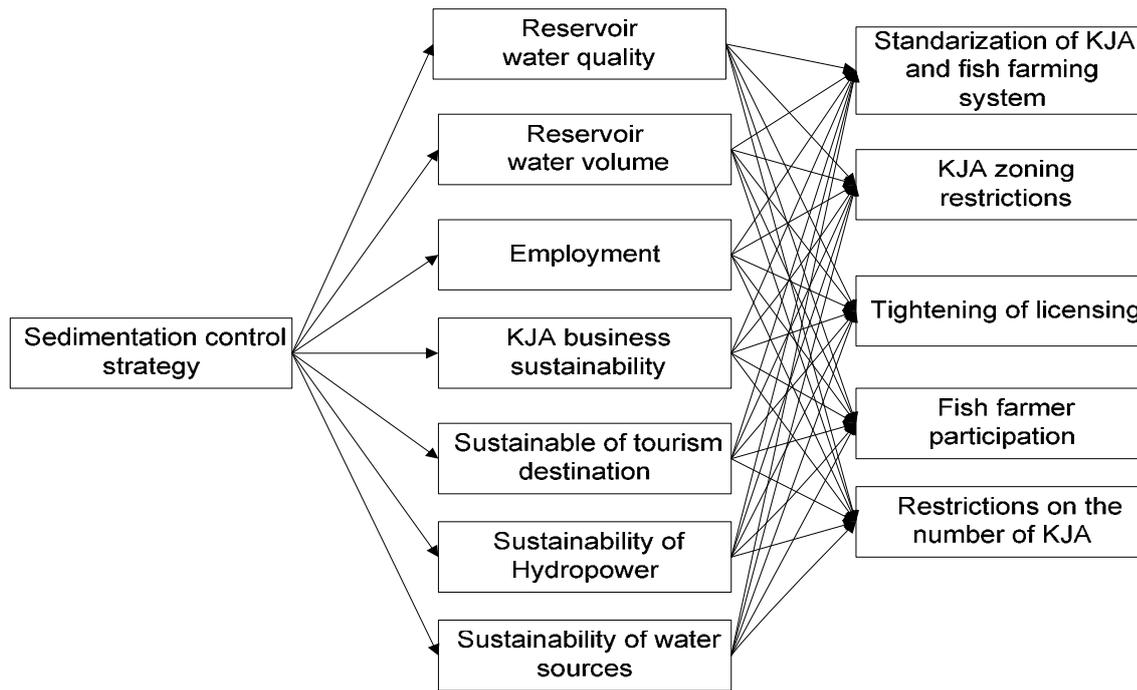

Figure 3. Hierarchy of goal, criteria and an alternatives sedimentation control in Cirata Reservoir KJA : Floating cage net (*KerambaJaringApung*)

The result an experts judgment to the criteria and refer to strategy as table 3 follow:

Table 3. Experts judgment to the criteria refer to strategy

	A	B	C	D	E	F	G
A	1	3	1	1	1	1/3	1
B	1/3	1	5	3	5	1	1
C	1	1/5	1	1	1	1	1/4
D	1	1/3	1	1	3	2	1
E	1	1/5	1	1/3	1	2	3
F	3	1	1	1/2	1/2	1	3
G	1	1	4	1	1/3	1/3	1

Descriptions :

- A : reservoir water quality
- B : reservoir water volume
- C : employment
- D : KJA business sustainability
- E : sustainability of tourist destination
- F : sustainability of hydropower
- G : sustainability of water source for irrigation

While an experts judgment to the alternatives refer to all criteria together, as shown below

Table 4 : Experts judgment to the strategy refer to criteria

	A	B	C	D	E
A	1	3	1/5	1/3	1/5
B	1/3	1	5	3	3
C	5	3	1	1/3	3
D	3	1/3	3	1	3
E	5	1/3	1/3	1/3	1

Descriptions :

- A :standarization of KJA and fish farming system,
- B :KJA zoning restrictions,
- C : tightening of licensing,
- D :fish farmer participation and
- E : restriction on the number of KJA

based on expert assessment above, the results of CDP output on criteria and alternatives over all as follows:

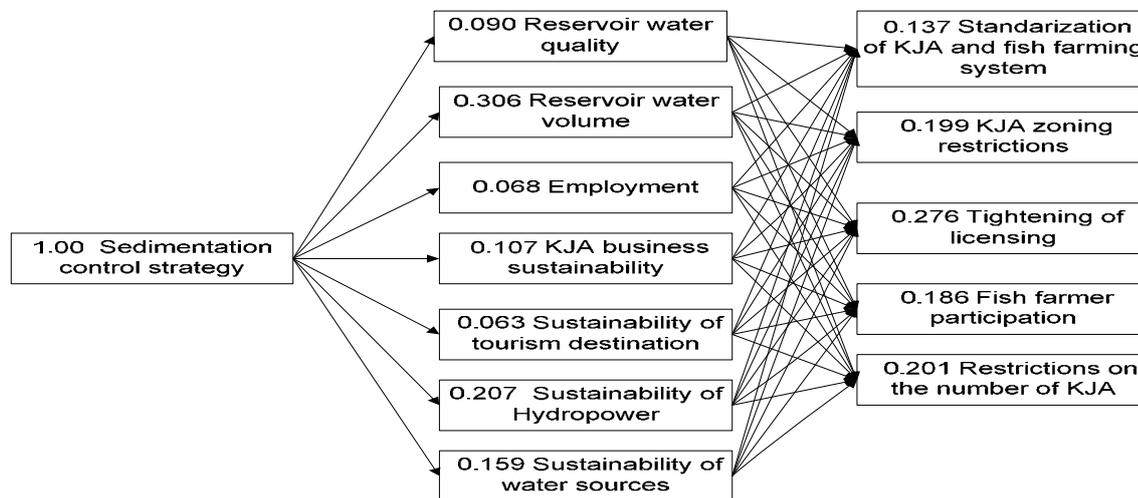

Figure 4. Out put of synthesis priority by CDP (based on experts judgment)

Based on the values obtained (figure 4) showed that the main criteria should be the basis in determining the sedimentation control strategy and control KJA is reservoir water volume as the highest value (0.306), followed by sustainability of hydro power (0.207). This criteria will support the preservation of the main functions of the reservoir or economic function, generating electricity for the Java and Bali. Based on selected criteria, the best alternative is the tightening of licensing strategy (0.276) followed by restriction on the number of KJA (0.201). Tightening of licensing strategy will facilitate the manager easier than the other strategies. When tightened of licensing the restrictions on number of KJA will be easily done, KJA placement on allowed or appropriate location can be set up easily. KJA structuring and control strategies in the field will be difficult, because it will receive challenge from KJA farmers.

Final result of priority strategy choices based on 7 criteria, more clearly as shown in Figure 5 below:

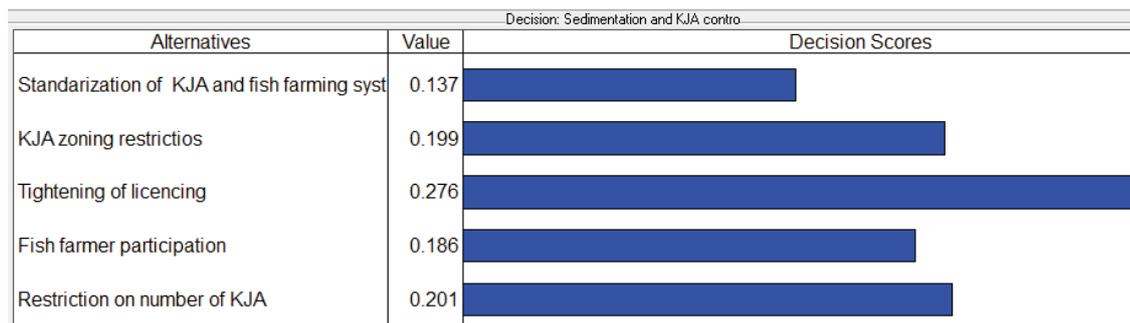

Figure 5. CDP out put for priority strategy based on expert assesment

Figure 5 showed that tightening of licencing is the highest of all, through tightening licencing system, existing floating cages net (KJA) that do not have a license must apply for a permit. Of 53,031 KJA current showed only about 10,40% (5,517), which has a permit and the remaining 89,60% (47,514) did not have a license. Most of KJA which do not have permission could be reduced with strict requirements. The results of research also showed that more than 65% of 2511 KJA owner are willing to complete the permit when any regulations oblige. This means that the government will have the opportunity to reduce and organize KJA through licencing. Reducing of KJA will affect to the reduction of sediment, finally upwelling can be reduced.

## 5. Acknowledgements

I would like to thank all those who have helped smooth the study, especially to the Ministry of Education for the research grants and BPWC who has given researchers the opportunity to conduct a study.

## 6. Conclusion

The best strategy for controlling sedimentation is by reducing the KJA through the tightening of licencing. KJA reduction will lower the level of water pollution, and reduce the risk of upwelling.

### ABSTRACT

Wastewater Treatment Plant (WWTP) Sewon Bantul with capacity planning 15,500 m<sup>3</sup>/day, but data quality control for wastewater debit is 106 97.53 m<sup>3</sup>/day to serve 23,000 homes connection with used capacity on average 9700 m<sup>3</sup>/day. Biological treatment process intended to reduce the organic matter content by using microorganisms. Problems often occur in treatment process is WWTP only planned for treating domestic wastewater, but in fact the WWTP often accept non-domestic wastewater particularly taken by a fleet of feces. Modeling on 13 simultaneous systems of nonlinear differential equations, solved by the Runge-Kutta-Fehlberg (RKF45). Data validation is measured by facultative pond at a distance of 0 m, 25 m, 50 m and 75 m, the inlet and outlet of the pond to the concentration of bacteria, algae, zooplankton, organic matter, detritus, organic nitrogen, NH<sub>3</sub>, organic phosphor, dissolved phosphorus, Dissolved Oxygen (DO), total coliform, faecal coliform and Biochemical Oxygen Demand (BOD). Research results show that the time correlation toward observation and count data there are 11 concentration have a relative error <20% and 2 concentrations > 20% namely Chemical Oxygen Demand (COD) and faecal coliform. Wastewater quality is predicted with angle charts 45° and tolerance ± 20% for BOD (76.8%), COD (57.7%) and DO (81.9%). The model as the tool of performance evaluation of WWTP is appropriate with water quality standard Class II.

**Keywords :** Domestic wastewater, environmental modelling, facultative stabilization ponds

### 1. INTRODUCTION

Characteristics of urban wastewater that stands out is the high content of organic matter, the processing is done biologically which is aimed to reduce the organic matter content by using microorganism. Facultative stabilization pond used to improve the quality of wastewater. By relying on natural processes for wastewater treatment namely using the presence of bacteria, algae, and zooplankton to reduce organic pollutants contained in wastewater ([1], [2], [3], [4]).

Waste stabilization ponds is very suitable to be applied in developing countries (especially the tropics where the climate is warm), for the operation of the pond does not require investment and high operating costs, as well as requires no special operator personnel to operate it ([3], [4] [5], [6]).

The basic principle of stabilization ponds is to balance and maintain the organic load fluctuations and hydraulic load of waste water, precipitate solid particles from wastewater in the first pond, taking advantage of the photosynthesis process by algae as a major source of oxygen, the process of biological decomposition of organic matter by microorganisms (both aerobic and anaerobic), and reduction of pathogenic organisms through multiple interactive processes [7].

Common problems and much bother in the process of wastewater treatment is WWTP planned just to treat domestic wastewater or wastewater from households. But in reality WWTP Sewon often receive non-domestic wastewater especially carried by the feces vacuum fleet that sucks wastewater from small industries or home industry that actually their wastewater before being discharged to the WWTP should be processed first. This will bother the wastewater treatment process at the WWTP. Processing system is made two rows parallel, each are 2 facultative ponds and 1 maturation pond presented in Figure 1.

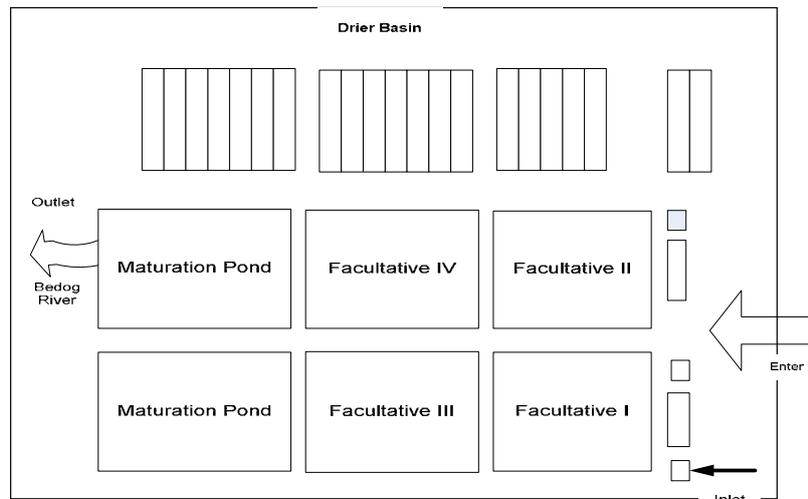

Figure 1. Layout Stabilization Pond WWTP Sewon

The purpose of this research is (a) to develop kinetic model process of the reform organic materials based on the rate of change of the concentration from biochemical models at facultative stabilization ponds, (b) validation and model simulations using the model parameters in (a).

## 2. MODELING

Forms of mass balance equations for each component of the biochemical model that is built in 13 (thirteen) equation which consists of 11 (eleven) nonlinear differential equations and 3 (three) order kinetics equation-1. With the 13 (thirteen) developed equation which is applied from Monod equation to the time correction as a maximum growth ([8], [9], [10], [11]):

### 1. Bacterial biomass (B) mass balance

$$\frac{dB}{dt} = \left( \frac{B_i}{\theta} - \frac{B_e}{\theta} \right) + Y_B \mu_B \frac{OM}{K_{BOM} + OM} \frac{DO}{K_{BDO} + DO} \frac{NH_3}{K_{BNH_3} + NH_3} \frac{SP}{K_{BSP} + SP} \left( 1 - \frac{B}{\eta_B} \right) B - (K_{BR} + K_{Bd})B \quad (1)$$

### 2. Algae (A) mass balance

$$\frac{dA}{dt} = \left( \frac{A_i}{\theta} - \frac{A_e}{\theta} \right) + \mu_A f(T) f(pH) f(L) \frac{NH_3}{K_{ANH_3} + NH_3} \frac{SP}{K_{ASP} + SP} \left( 1 - \frac{A}{\eta_A} \right) A - (K_{AR} + K_{Ad} + S_A)A \quad (2)$$

### 3. Zooplankton (Z) mass balance

$$\frac{dZ}{dt} = \left( \frac{Z_i}{\theta} - \frac{Z_e}{\theta} \right) + \mu_Z f(T) f(pH) \frac{NH_3}{K_{ZNH_3} + NH_3} \frac{SP}{K_{ZSP} + SP} \frac{DO}{K_{ZDO} + DO} \left( 1 - \frac{Z}{\eta_Z} \right) Z - (K_{ZR} + K_{Zd})Z \quad (3)$$

### 4. Organic Matter (OM) mass balance

$$\frac{dOM}{dt} = \left( \frac{OM_i}{\theta} - \frac{OM_e}{\theta} \right) - \mu_B \frac{OM}{K_{BOM} + OM} \frac{DO}{K_{BDO} + DO} \frac{NH_3}{K_{BNH_3} + NH_3} \frac{SP}{K_{BSP} + SP} \left( 1 - \frac{B}{\eta_B} \right) B \quad (4)$$

### 5. Detritus (D) mass balance

$$\frac{dD}{dt} = \frac{1}{d} (S_B B + S_A A) + U_r D \quad (5)$$

### 6. Organic Nitrogen (ON) mass balance

$$\frac{dON}{dt} = \left( \frac{ON_i}{\theta} - \frac{ON_e}{\theta} \right) - \alpha_{ON} ON + T_B BK_{Bd} - T_A A (S_A - K_{Ad}) + T_Z ZK_{Zd} \quad (6)$$

7. Ammonia Nitrogen (NH<sub>3</sub>) mass balance

$$\begin{aligned} \frac{dNH_3}{dt} = & \left( \frac{NH_{3i}}{\theta} - \frac{NH_{3e}}{\theta} \right) - T_B B \left\{ Y_B \mu_B \frac{OM}{K_{BOM} + OM} \frac{DO}{K_{BDO} + DO} \frac{NH_3}{K_{BNH_3} + NH_3} \frac{SP}{K_{BSP} + SP} \left( 1 - \frac{B}{\eta_B} \right) - K_{BR} - K_{Bd} \right\} \\ & - T_A A \left\{ \mu_A f(T) f(pH) f(L) \frac{NH_3}{K_{ANH_3} + NH_3} \frac{SP}{K_{ASP} + SP} \left( 1 - \frac{A}{\eta_A} \right) - K_{AR} - K_{Ad} \right\} \\ & - T_Z Z \left\{ \mu_Z f(T) f(pH) \frac{NH_3}{K_{ZNH_3} + NH_3} \frac{SP}{K_{ZSP} + SP} \frac{DO}{K_{ZDO} + DO} \left( 1 - \frac{Z}{\eta_Z} \right) - K_{ZR} - K_{Zd} \right\} + \alpha_{OP} ON + \frac{U_r D}{d} T_A \end{aligned} \quad (7)$$

8. Organic phosphor (OP) mass balance

$$\frac{dOP}{dt} = \left( \frac{OP_i}{\theta} - \frac{OP_e}{\theta} \right) - \alpha_{OP} OP + \psi_B BK_{Bd} - \psi_A A(S_A - K_{Ad}) + \psi_Z ZK_{Zd} \quad (8)$$

9. Soluble Phosphor (SP) mass balance

$$\begin{aligned} \frac{dSP}{dt} = & \left( \frac{SP_i}{\theta} - \frac{SP_e}{\theta} \right) - \psi_B B \left\{ Y_B \mu_B \frac{OM}{K_{BOM} + OM} \frac{DO}{K_{BDO} + DO} \frac{NH_3}{K_{BNH_3} + NH_3} \frac{SP}{K_{BSP} + SP} \left( 1 - \frac{B}{\eta_B} \right) - K_{BR} - K_{Bd} \right\} \\ & - \psi_A A \left\{ \mu_A f(T) f(pH) f(L) \frac{NH_3}{K_{ANH_3} + NH_3} \frac{SP}{K_{ASP} + SP} \left( 1 - \frac{A}{\eta_A} \right) - K_{AR} - K_{Ad} \right\} \\ & - \psi_Z Z \left\{ \mu_Z f(T) f(pH) \frac{NH_3}{K_{ZNH_3} + NH_3} \frac{SP}{K_{ZSP} + SP} \frac{DO}{K_{ZDO} + DO} \left( 1 - \frac{Z}{\eta_Z} \right) - K_{ZR} - K_{Zd} \right\} + \alpha_{OP} SP + \frac{U_r D}{d} S_A \end{aligned} \quad (9)$$

10. Dissolved Oxygen (DO) mass balance

$$\begin{aligned} \frac{dDO}{dt} = & \left( \frac{DO_i}{\theta} - \frac{DO_e}{\theta} \right) + \frac{K_L(DO_s - DO)}{d} \\ & - K \alpha_B B \left\{ Y_B \mu_B \frac{OM}{K_{BOM} + OM} \frac{DO}{K_{BDO} + DO} \frac{NH_3}{K_{BNH_3} + NH_3} \frac{SP}{K_{BSP} + SP} \left( 1 - \frac{B}{\eta_B} \right) - K_{BR} \right\} \\ & + \alpha_A A \left\{ \mu_A f(T) f(pH) f(L) \frac{NH_3}{K_{ANH_3} + NH_3} \frac{SP}{K_{ASP} + SP} \left( 1 - \frac{A}{\eta_A} \right) - K_{AR} \right\} \\ & - \alpha_Z Z \left\{ \mu_Z f(T) f(pH) \frac{NH_3}{K_{ZNH_3} + NH_3} \frac{SP}{K_{ZSP} + SP} \frac{DO}{K_{ZDO} + DO} \left( 1 - \frac{Z}{\eta_Z} \right) - K_{ZR} \right\} \end{aligned} \quad (10)$$

11. Total Coliforms (TC) mass balance

$$\frac{dTC}{dt} = \left( \frac{TC_i}{\theta} - \frac{TC_e}{\theta} \right) - K_{TC} TC \quad (11)$$

12. Faecal Coliforms (FC) mass balance

$$\frac{dFC}{dt} = \left( \frac{FC_i}{\theta} - \frac{FC_e}{\theta} \right) - K_{FC} FC \quad (12)$$

13. Biological Oxygen Demand (BOD) mass balance

$$\frac{dBOD}{dt} = \left( \frac{BOD_i}{\theta} - \frac{BOD_e}{\theta} \right) - kBOD \quad (13)$$

### 3. MATERIALS AND METHODS

#### 3.1. Development Assumptions Model

Wastewater treatment process at the WWTP unit is illustrated as a biochemical process represented as simultaneous differential equations. Dynamic modeling of water quality in the domestic waste at facultative stabilization ponds, it is assumed that the pond is not active. The process of biochemical model is illustrated as the following flowchart.

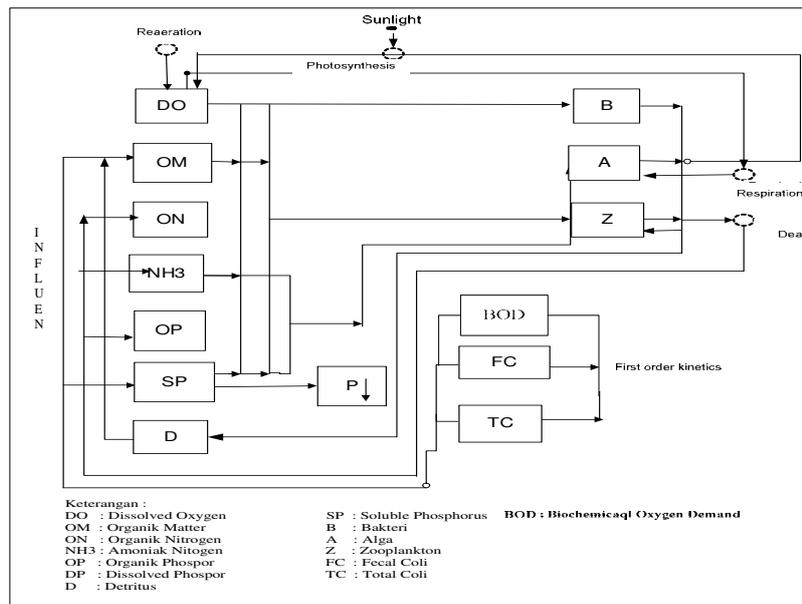

Figure 2. Flowchart The process of Biochemical Model

From Figure 2 is developed biochemical model for the rate of change / growth from variable *mass balance* equations former in system of simultaneous differential equations with index *i* is influent and *e* is effluent.

### 3.2. Runge-Kutta-Fehlberg method (RKF45) and program model

From 13 (thirteen) non-linear differential equations is solved by the method of Runge-Kutta-Fehlberg (RKF45) as integration techniques to get the concentration of each component against the time. These methods belong to the family of Runge-Kutta order-4 methods, but has the accuracy to order-5. In the 13 systems of simultaneous nonlinear differential equations contained 44 (forty-four) parameters are optimized by using the “fmincon” in Matlab (R2008a). As the initial data input is :  $B_0, A_0, Z_0, OM_0, D_0, ON_0, NH_{30}, OP_0, SP_0, DO_0, TC_0, FC_0, BOD_0$  [12].

### 3.3. Validation model

Model validation test use field measurement data and count data from the model. Field data include bacteria, algae, zooplankton, organic matter, detritus, organic nitrogen, NH<sub>3</sub>, organic phosphor, dissolved phosphor, DO, total coliform, faecal coliform and BOD. Line graphs predictions with angle 45° and tolerance of

± 20% is used for quality control of wastewater. With regression statistic analysis with confidence intervals 95% is used to observational data and count data toward the determination  $R^2$  for the validation of the model indicates the model is fit with field conditions.

### 3.4. Sample and analysis

Wastewater samples measured at 08.00, 10.00, 12.00, 14.00, and 16.00 and the model input samples is measured in facultative pond at a distance of 0 m, 25 m, 50 m and 75 m, and the inlet as well as outlet of the variable bacteria, algae, zooplankton, organic matter, detritus, organic nitrogen, NH<sub>3</sub>, organic phosphor, dissolved phosphor, DO, total coliform, faecal coliform and BOD. Sampling point presented in Figure 3. The test method of wastewater used [13] for parameters analysis of BOD, COD, DO, phosphate, nitrate, total coliform and faecal coliform. SNI test method (2004) is used for the analysis of nitrite and NH<sub>4</sub>-N, while for the analysis of phytoplankton and zooplankton used SNI test (1995).

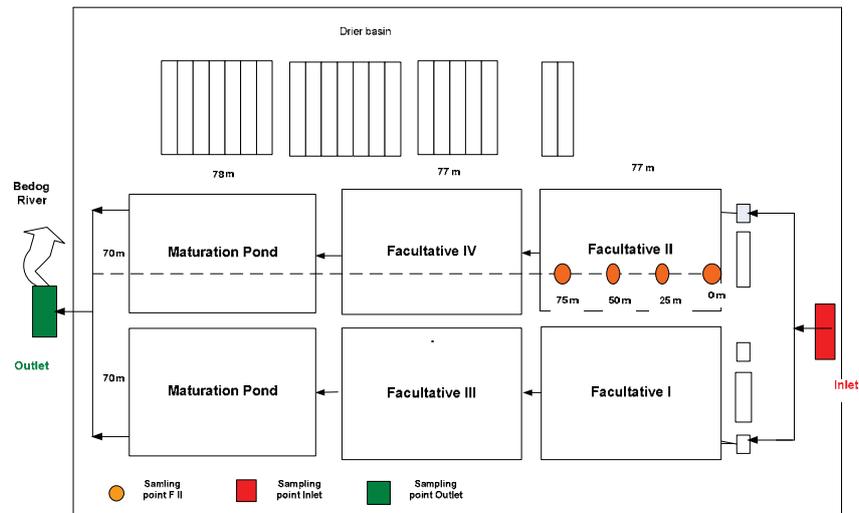

Figure 3. Sampling Point

## 4. RESULTS AND DISCUSSION

### 4.1. The waste stabilization pond

In accordance with the capacity planning Wastewater Treatment Plant (WWTP) Sewon is 15500 m<sup>3</sup>/day, based on the data quality control debit wastewater entering the WWTP amount to 10697.53 m<sup>3</sup>/day is not yet exceeded capacity planning. In practice WWTP Sewon is to serve 23,000 homes connection, with an average capacity utilization in 2010 amount to 9700 m<sup>3</sup>/day is to serve 11,000 homes connections. Urban waste is treated in the WWTP will be discharged into the river Bedog through concrete pipes and canals or open channels. River Bedog included in wastewater control unit Class II, stated in Decree of the Governor of Yogyakarta Special Region No. 214/KPTS/1991 about Standard Local Environmental BOD value output (effluent) is below 50 mg / liter ([14], [15]).

City's WWTP prevents wastes pollute rivers and groundwater that drain the city. Wastewater treatment systems biologically by using aeration facultative pond which is a very simple and aims to prevent seeds of diseases caused by waste contaminating surface water. WWTP Sewon operationally is just capable of serving 23% of the existing network. The data type of waste water quality control at the inlet of the Center WWTP Public Works Department, Housing and Energy and Mineral Resources Local Government Yogyakarta in July 2010 - December 2011 for Category II quality standard parameters for BOD, temperature, pH and DO are presented in the following figure:

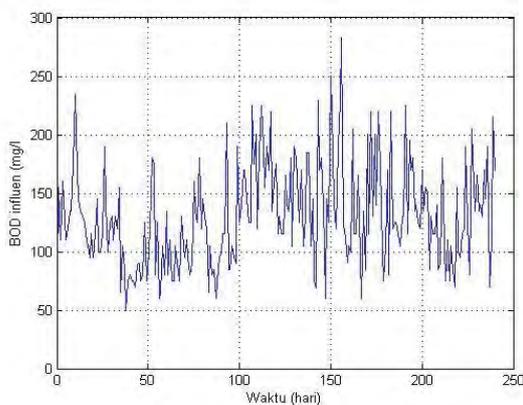

Figure 4. Typical data BOD inlet

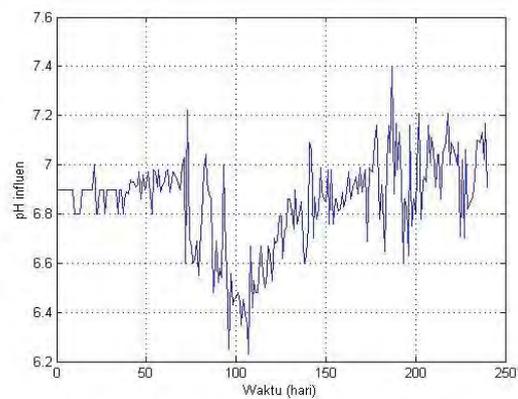

Figure 5. Typical data pH inlet

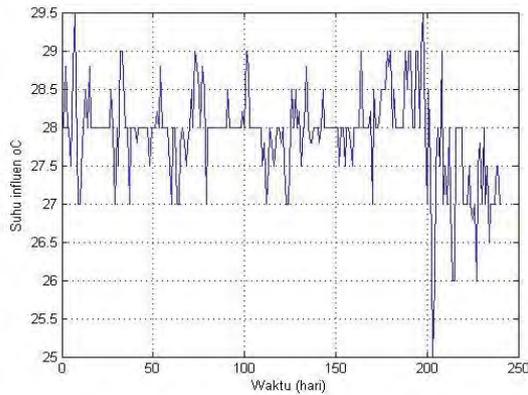

Figure 6. Typical data temperature inlet

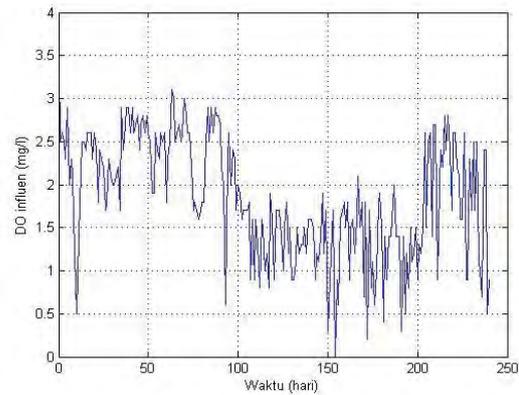

Figure 7. Typical data DO inlet

#### 4.2. Quality control pond water facultative stabilization

Based on typical data on WWTP Sewon, so it's necessary to do evaluation of the pond performance related to waste water quality standard Class II as it's established. Data measurement of pH, temperature, DO, BOD and COD are presented in the following table.

Table 1 : Wastewater quality inlet and outlet WWTP Sewon

Times	pH		Temperature ( <sup>0</sup> C)		DO (mg/l)		BOD (mg/l)		COD (mg/l)	
	inlet	outlet	inlet	outlet	Inlet	Outlet	inlet	outlet	inlet	outlet
08.00	7,09	7,12	27,8	28,8	0,9	4,2	250	16	752	48
10.00	7,19	7,28	27,5	28,0	1,5	3,4	165	20	346	72
12.00	7,19	7,14	27,0	29,5	0,8	4,2	200	18	700	70
14.00	7,19	7,18	28,0	30,5	1,7	4,2	155	19,5	364	64
16.00	7,35	7,50	28,0	30,0	1,8	3,7	130	19	368	76

Source : Primer Data, 15 February 2012

Table1. Indicates that the waste water out of the pond meets Quality Standards (BM) Group II: pH between 7.09 to 7.35 (BM = 6-9), temperatures between 28<sup>0</sup>C - 30<sup>0</sup>C (BM = 38<sup>0</sup>C), BOD between 18 mg / l - 20 mg / l (BM = 50 mg / l) and COD between 48 mg / l - 76 mg / l (BM = 100 mg / l).

The results of model simulations of the BOD concentration is order kinetics equation -1 that describes the degradation process of organic pollutants. Comparison of observational data and count data by the relative error is amount to 12,72%, it indicates that the decrease of BOD sufficiently representative in the model (Figure 8.)

The parameter *k* constitutes coefficient of rate degradation is very sensitive parameter model. In the simulation model of the *k* value is 0.6 (the calibration) after being optimized to 1.85; there are value differences amount to 1.25 that there is a substantial change in the value of *k* parameter. This indicates BOD concentration is very sensitive to the model depends on the size of the incoming wastewater stream at pond.

To determine whether the model can be applied to the concentration of BOD in the field and can be used as a performance evaluation tool of WWTP Sewon, following chart is presented in the chart tolerance of 20% for the pollutants concentration as domestic waste water quality with Class II criteria as presented in Figure 9.

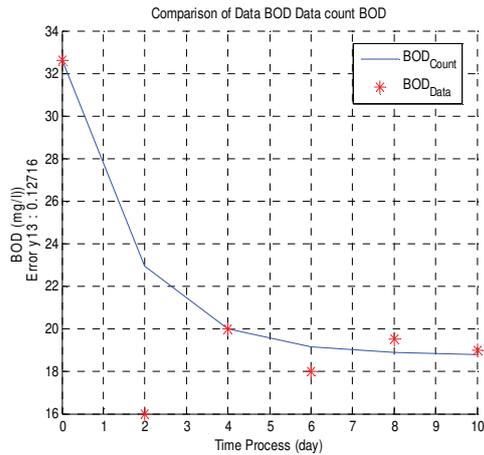

Figure 8. Comparison of data and count BOD

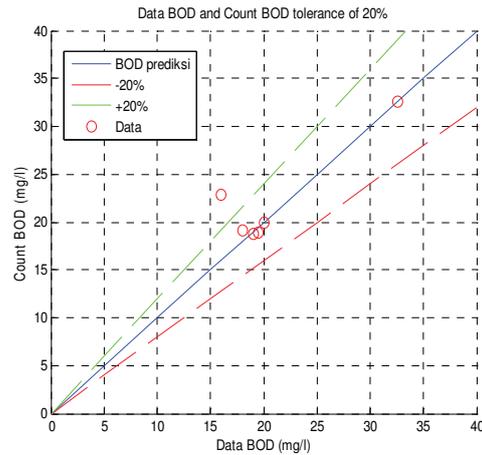

Figure 9. data and count BOD tolerance of 20%

DO concentration in the pond than, is determined by the role of these sensitive parameters to the model of the metabolism of oxygen consumption for: bacterial biomass ( $C_{BA}$ ) = 2.0 [16] and optimized to 1.2; algae ( $C_{AA}$ ) = 1.0 [16] optimized to be 1.244, and zooplankton ( $C_{ZA}$ ) = 1.244 [8] optimized to 0.5. Moreover DO concentration is also determined by 4 (four) role in the mechanism are: (a) consumption of oxygen by aerobic metabolism of the die bacteria, (b) the generation and consumption of oxygen by algae photosynthesis and respiration processes, (c) oxygen consumption by the metabolism of zooplankton and (d) reaeration between the air surface and water. Reaeration between air surface and water is  $K_L$  at 0.8566 [17].

At high DO, effect on growth of aerobic micro-organisms that will thrive and adequate nutrition is also an important factor in the growth of bacteria. DO observational data ranged from 3 to 4.2 mg / l and DO for life on the water is 2 mg / l, mean aerobic microorganisms still alive. From the results of model simulations to DO initially 3 mg / l showed that data and count DO have relative error of 12.72%, it's presented in Figure 9.

To determine whether the model can be applied to the DO concentration in the field and can be used as a performance evaluation tool of IPAL Sewon, here is presented in the chart tolerance of 20% for the concentration of pollutants as domestic waste water quality with Class II criteria as presented in Figure 10.

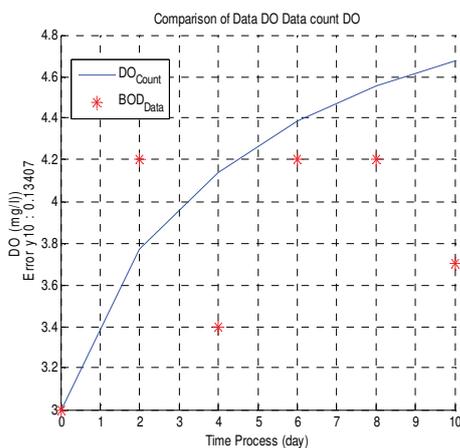

Figure 9. Comparison of data and count DO

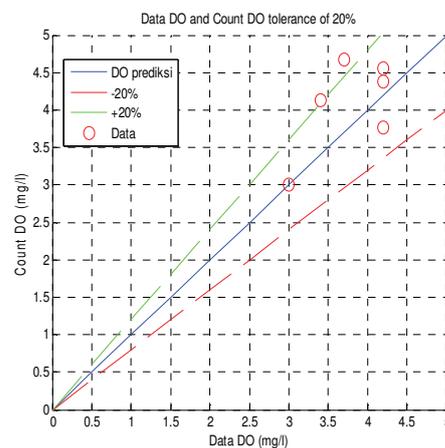

Figure 10. Data and count DO tolerance of 20%

Based on the results of model simulations to concentration of BOD, then performed statistical F-tests by using linear equation analysis to data and count BOD have determination ( $R^2 = 0.768$ , significant  $p = 0.022$ ) means the ability of the wastewater treatment process at the pond to degrade organic matter at 76, 8% and only 23.2% is influenced by other factors.

In the dissolved oxygen (DO) is the amount of oxygen contained in the water that is used as a sign of the contamination degree of the existing waste, the more oxygen is dissolved, so it shows a relatively small contamination degree. By using equation

quadratic analysis (such as model pattern), between data and count DO with determination ( $R^2 = 0.819$ , significant  $p = 0.077$ ), which means that the wastewater treatment process to DO concentration as a sign of the contamination degree of the existing waste by 81.96% and only 18.04% is influenced by other factors. This indicates the concentration of DO in the pond to the life of aerobic microorganisms is a good.

## 5. CONCLUSION

Biochemical Model with 13 (thirteen) system of simultaneous nonlinear differential equations is shown through charts time relation process with the concentration observation and count data, there are 11 (eleven) concentrations have relative error below 20%, and 2 (two) concentrations have relative error over 20% that is COD (37.06%) and faecal coliform (37.67%). In both these concentrations contained sensitive parameters to the model, that is specific growth rate of bacteria ( $\mu_{FE}$ ) and the specific growth rate of faecal coliform at a temperature of 20°C ( $\mu_{FC}$ ).

Through the charts of wastewater quality control as a line prediction on an angle of 45° as the upper and lower limits with tolerance of  $\pm 20\%$ . With chart is used as tool of evaluation of the performance WWTP with wastewater quality standard Class II. This is also demonstrated by the high determination test for BOD ( $R^2 = 76.8\%$ ,  $p = 0.022$ ), COD ( $R^2 = 57.6\%$ ,  $p = 0.08$ ), and DO ( $R^2 = 76.8\%$ ,  $p = 0.08$ ) which can describe the model in accordance with the conditions in the field.

## ACKNOWLEDGMENT

Thanks to the Leaders and staff WWTP Sewon, Public Works Department, Housing and ESDM Local Government Yogyakarta who have given permission for the research and data collection quality control wastewater WWTP Sewon.

### ABSTRACT

Plastics are synthetic polymers, made from petroleum and its derivatives which are non biodegradable. Today, more people used plastic bags to support their activities, which caused the supply of plastic shopping bags to increase in large number. Plastic bags, eventually, are usually used as garbage which would cause negative impact on the environment. Environmental friendly plastic bags are made from renewable raw materials, such as starch from cassava, corn or others. There are the ones entirely starch based such as Enviplast (biodegradable); the ones with partial mixture of starch with plastic ores such as Ecoplas (biodegradable), the ones plastic ores are formulated with additives Oxium (oxodegradable), and conventional made from plastic ores only. Distinguishing characteristics of samples plastic shopping bags were taken from domestic and abroad supermarkets can be seen from the result of FTIR, SEM, and AAS analysis along with burial in soil medium. Density of domestic plastic bag ( $1.119 \text{ g/cm}^3$ ) are 49.55% smaller than samples abroad  $2.258 \text{ g/cm}^3$ . This means that in the country, a space to hold trash bags in the same weight needed almost 2x larger. Another discovery are some plastic shopping bags are labeled eco-friendly and related but had conventional plastic characteristic.

## ABSTRACT

*Numerous research studies have demonstrated the catastrophic consequences of global warming caused by unabated carbon dioxide emissions. It is acknowledged that construction and the operational aspects of buildings are significant contributors to energy consumption and have a direct impact on CO<sub>2</sub> emissions.*

*Application of concepts such as Life Cycle Analysis and Embodied Energy with a direct link to buildings and construction has been proposed by many policy makers and researchers. Furthermore there are building rating systems such as BREEAM (Building Research Establishment Environmental Assessment Method) and LEED (Leadership in Energy and Environmental Design) for evaluating the sustainability status of any proposed design. However the successful implementation of these systems in the alleviation of CO<sub>2</sub> emissions has not been fully realised.*

*This paper is an attempt to explore the possibility of Local/Planning authorities imposing mandatory requirements that would lead to sustainable environmentally friendly developments. The paper suggests that limits should be placed on the embodied energy, the operational energy and water use when issuing building permits. These steps would be just the initial steps that must be taken towards mitigating the negative impacts that accumulate from buildings during construction and their operational phase.*

## 1. INTRODUCTION : THE ENVIRONMENT, CO<sub>2</sub> EMISSIONS AND CLIMATE CHANGE

Climate change has now become a reality that cannot be ignored or denied. Extreme climatic events such as unprecedented heavy rainfall leading to floods and high temperatures far above the normal average temperatures which have caused destructive forest fires are now a common phenomenon in certain parts of the world. This has had its toll on agricultural crop yields and on ecosystems undermining the health and stability of all forms of life on earth.

Most scientists except for a few sceptics believe that the changes observed in the climatic conditions can be directly attributed to an increase in atmospheric greenhouse gases. That this is anthropogenic and is due to increased use of fossil fuels is acknowledged. World leaders as well as scientists in developed countries who have to balance this concern with the needs and desires of a burgeoning population as well as the commitment towards technological progress found that there were no easy solutions.

The call for concerted action resulted in the unanimous adoption of the Kyoto Protocol in 1997 by the member countries of the Framework Convention on Climate Change. The Protocol's major feature was that it set mandatory targets on greenhouse-gas emissions for the world's leading economies. The Kyoto Protocol, set binding obligations for about 35 industrialised nations to cut their greenhouse gas emissions until the end of 2012.

Unfortunately these countries have fallen far short of the proposed targets. The United Nations Climate Change Conference in Doha addressed these issues once again December 2012. But the measures taken this time were not considered to be strong enough to halt rising world greenhouse gas emissions. The Kyoto Protocol to which the environment ministers of over 200 nations were signatories, was extended until 2020. That keeps the pact alive as the sole, legally binding climate plan.

"Much, much more is needed if we are really going to address climate change and reduce emissions," said Kieren Keke, foreign minister of the Pacific island state of Nauru on behalf of the Alliance of Small Island States. "He warned against endless talk that "locks in the death of our nations and of our children" [1].

## **2.CONSTRUCTION AS A MAJOR CONTRIBUTOR TO CO2 EMISSIONS.**

Large amounts of natural resources are used in the production, maintenance, and operation of buildings. The construction industry consumes more than one-third of global resources, including 12 % of all freshwater use. Buildings also use 25–40 % of all produced energy sources, accounting for approximately 30–40 % of global carbon dioxide (CO<sub>2</sub>) emissions. In addition to natural resource consumption, buildings produce and unload 30–40 % of solid waste into the environment. [2].

Once a building is constructed and occupied it is difficult to make changes that would reduce its impact on the environment. It will not be easy to modify a building which has been originally designed for air-conditioning later for cooling through natural ventilation. Furthermore the impact that a building has on the environment is long lasting since it is a process which continues throughout the life cycle of the building which could be many years. For instance the design life of many modern buildings would be in the range of a hundred years. It is imperative then to consider the use of environmentally friendly materials, construction techniques and building operational systems that are less detrimental to the environment during its construction phase and its operational phase.

These are some of the considerations that led to the development of the concept of “Green Buildings”. A green building is a building that is designed, constructed and operated in an environmentally responsible manner. The design whilst addressing the standard concepts of comfort, utility, durability and cost will endeavour to do so with the least detrimental impact on the environment. The main strategies in green building would include the reduction of energy consumption, conservation of water and the recycling of waste.

To facilitate such design, construction and operation processes, environmental assessment methods and building rating systems have been developed. These rating tools enable the designer to judiciously select the materials, construction techniques and methods of operation which provide for a sustainable end product that will have the least non-beneficial impact on the environment. Of the more common assessment tools among many others are LCA (Life Cycle Analysis), LCEA (Life Cycle Energy Analysis), Embodied Energy and rating systems such as LEED (Leadership in Energy and Environmental Design) and BREEAM (Building Research Establishment Environment Assessment Method)

## **3. SOME OF THE ENVIRONMENTAL ASSESSMENT METHODS, RATING SYSTEMS AND THEIR APPLICATION**

LCA is defined as the assessment of environmental impacts of products, buildings or other services throughout their lifetimes. The assessment includes the entire life-cycle of a product, process or system encompassing the extraction and processing of raw materials; manufacturing, transportation and distribution; use, reuse, maintenance, recycling and final disposal.

Whereas LCA assesses the overall impact, a derivative, life-cycle energy analysis (LCEA) focuses on energy as the only measure of environmental impact of buildings or products. The purpose of LCEA is to present a more detailed analysis of energy attributable to products, systems or buildings, to enable decision-making strategies concerning energy efficiency and environmental protection. LCEA has not been developed to replace LCA but to compare and evaluate the initial and recurrent embodied energy in materials, energy used during the operational phase, and during recycling and disposal [3].
