## WELCOME FROM THE RECTOR OF UNIVERSITAS INDONESIA

It is both a pleasure and honor for me to welcome you all to the 13<sup>th</sup> International Conference on QiR (Quality in Research) 2013. In this globalization era, mankind's competitive explorations to find new and better ways to enhance their life has often resulted in sacrificing the environment for their convenience. To preserve the environment for our future generations, steps must be made to ascertain that development and innovation of mankind must be more sustainable, balancing both mankind's effort in enhancing their quality of life and fulfilling their needs, with its harmony with nature.

Today, scientists and experts, in particular, people in engineering, architecture and design are looking to develop new environmentally friendly technologies, or eco-technologies. Innovation in eco-based multidisciplinary knowledge and skills becomes the important key, and this central issue should be encouraged for the motivation of current and future development. Eco-technology can help protect, conserve and even restore our precious shared environment. To develop this technology, we need to combine engineering, scientific or technological approaches, with ecology, economics and the social sciences and humanities. The eco-innovation field is now wide open and offers exciting new territories to explore and develop. Creative thinking by our top technical and scientific researchers is giving us a more and more treasures of new workable ideas.

However, innovations require more than just brilliant ideas. Innovations require resources, skills, technology, knowledge, tools, techniques and so much more. But most of all, innovations require people. People are the driving force behind every need of change, changes that are aimed to improve mankind's quality of life, to enhance their living conditions or to simply make life easier and more comfortable. This conference is about learning of the fundamental aspects which can transform the world and society, thinking ahead to possible challenges facing the globe, discovering innovations related to opportunities for industry, and most importantly, this conference is about bringing together interdisciplinary people to accelerate activities in many areas simultaneously. This is what makes the conference exceptional this year in terms of potential impact from this networking.

I extend my sincere thanks to the Faculty of Engineering Universitas Indonesia, supporting parties and institutions for their participation and contributions in QiR 2013. I would also thank the people of Yogyakarta for their gracious support and hospitality. Additionally, I extend a hearty thank you to the members of the organizing committees for dedicating their valuable time so that each one of us enjoys an exceptional conference program over the next several days. May we have a successful, stimulating, fruitful and rewarding conference.

Prof. Dr. Ir. Muhammad Anis M.Met.  
Rector  
Universitas Indonesia

## **WELCOME FROM THE DEAN OF FACULTY OF ENGINEERING UNIVERSITAS INDONESIA**

Welcome to the 13<sup>th</sup> International Conference on QiR (Quality in Research) 2013. The Faculty of Engineering Universitas Indonesia is thrilled that, together with our co-hosts IST-Akprind and Gadjah Mada University, we are able to present an international conference of this magnitude. This two-day conference speaks to the importance of fostering relationships among national and international front liners, thinkers, academics, executives, government and business officials, practitioners and leaders across the globe in an effort to share knowledge and best practices as part of a worldwide network.

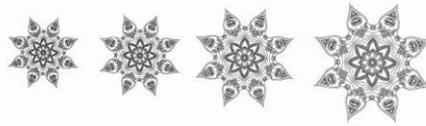

The quest for knowledge has been from the beginning of time but knowledge only becomes valuable when it is disseminated and applied to benefit humankind. It is hoped that QiR 2013 will be a platform to gather and disseminate the latest knowledge in engineering, architectural design and community services. Academicians, scientist, researchers and practitioners of these fields will be able to share and discuss new findings and applications of their expertise. It is envisaged that the intellectual discourse will result in future collaborations between universities, research institutions and industry both locally and internationally. In particular it is expected that focus will be given to issues on innovations for the enhancement of human life and the environment.

In accordance to this year's theme, this conference will cover a wide range of sustainable design and technology issues, especially state of the art information and knowledge of new innovations, ideas, creative methods or applications which can be implemented to enhance the human life and also our environment. The itinerary of the conference over the two days has been carefully planned to ensure a lively exchange of ideas and the development of innovative strategies and there will be many opportunities for everyone in attendance to share their expertise with, and learn from, peers from around the world.

We urge you to spend the next two days in interesting discussions and exchanging ideas among yourselves. We foresee more and more challenges in our future. Challenges in how to improve our life, how can we enhance our society, how can we make our lives and the lives of our society better? These challenges should be answered together by developing collaborations for future research in various engineering and design areas. It is our hope and aim that this conference would be able to provide an international media for exchange of the knowledge, experience and research as well as the review of progress and discussion on the state of the art and future trend of prospective collaboration and networking in broad field of eco-based technology development.

My deepest appreciation to our sponsors, supported parties and various contributors for their never ending supports of this conference. I would also like to convey my humblest thankfulness to all of our distinguished speakers for making the time to share their knowledge with us. To our fellow researchers and/or practitioners from Indonesia and overseas, welcome and enjoy your stay in this amazing historical city, Yogyakarta. I would also like to invite all participants in expressing our appreciation to all members of the QiR 2013 organizing committee for their hard work in making this conference another success.

Prof. Dr. Ir. Bambang Sugiarto, M.Eng.  
Dean Faculty of Engineering  
Universitas Indonesia

## WELCOME FROM THE QIR 2013 ORGANIZING COMMITTEE

Welcome to the 13<sup>th</sup> International Conference on QIR (Quality in Research) 2013. It is a great pleasure for Faculty of Engineering Universitas Indonesia to be co-hosting this biennial event with IST-Akprind and Gadjah Mada University, in the spirit of strengthening of cooperation and mutual growth to be world class institution. For the first time, the QIR 2013 is held in one of the most historical city in Indonesia – Yogyakarta. It is with our utmost pleasure to hold this year’s QIR 2013 in conjunction with the 2nd International Conference on Civic Space (ICCS 2013) and introducing the International Symposium on Community Development 2013 as a forum to share experience on engaging community for a better life and environment.

The aim of this International Conference with our selected theme, “Exploring Innovation for Enhancement of Human Life and Environment”, is to provide an international forum for exchanging knowledge and research expertise as well as creating a prospective collaboration and networking on various fields of science, engineering and design. We hope this conference can be a kick-off for the strengthened action and partnerships on creating a platform for us; national and international thinkers, academics, government officials, business executives and practitioners, to present and discuss the pivotal role of engineers in innovative products which will reduce environmental impacts, applications in sustainable planning, manufacturing, architecture, and many more to grow and ensure the rising prosperity of our society going into the future. Under this theme, the conference focuses on the innovative contributions in science, engineering and design as well as their market perspectives to the existing and future enhancement of human life and environment quality.

Over the period of 15 years, this biennial conference has become an important place of encounter between scholars and practitioners from different countries, cultures and backgrounds discussing contemporary engineering and design issues dealt in their hometown, country or even region. Serving as a platform for an engineering and design dialogue, this conference will have 16 invited speakers and has gathered more than 500 papers from more than 20 countries all over the world:

- 92 papers on International Symposium on Civil and Environmental Engineering
- 51 papers on International Symposium on Mechanical and Maritime Engineering
- 97 papers on International Symposium on Electrical and Computer Engineering
- 111 papers on International Symposium on Materials and Metallurgy Engineering
- 31 papers on International Symposium on Architecture, Interior and Urban Planning
- 57 papers on International Symposium on Chemical and Bioprocess Engineering
- 71 papers on International Symposium on Industrial Engineering
- 25 papers on International Symposium on Community Development

My deepest gratitude to all of our speakers, participants and contributors who have given this conference their generous support. I would also like to thank all members of the Organizing Committee and our distinguished International Board of Reviewers for all of their support and advice. Our thanks to all of our sponsors, supporters, exhibitors, and professional associations for their great support and encouragement through committed funding and any other form of help and support. We also owe our success to the full support of the Rector of Universitas Indonesia and the Dean of Faculty of Engineering. Thank you to IEEE Indonesia Section that has supported QIR 2013 to be approved as IEEE Conference. Last but not least, a special thanks to our co-hosts, IST-Akprind and Gadjah Mada University for all of their immense supports in making this conference a success.

Allow me to wish all of you a meaningful and rewarding conference. We wish you a pleasant and memorable stay in Yogyakarta. Thank you and we hope to see you again at the QIR 2015.

Prof. Dr. Ir. Bondan T. Sofyan, M.Si.  
Chairman of QIR 2013 Organizing Committee

## Table of Contents

### Symposium A

AbstractPlenary2_Study of the Safety Aspects of the Large Scale Use of LNG as a Fuel .....	1
A1.1-Furushima_Study on Mesoscopical Inhomogeneous Material Modeling for Surface Roughening Behavior of Polycrystalline Metal Sheets and Foils.....	2
A1.2-Sumarsono_Development of Gene Gun as Intradermal Vaccine Administration Device for Laboratory and Clinical Applications .....	3
A1.3-Sinaga_Simplified Model Of The Heave and Pitch Motions of an Fling Due to Slohing Effect and Comparison with Some Experimental Results.....	10
A1.4-Whulanza_Characterization of Low Cost UV-Lithography Result for Educational Purpose.....	17
A1.5-Baskoro_Analysis of Microchannels Manufacturing of Acrylic using Low Power CO2 Laser .....	20
A1.6-Widodo_Remaining Useful Life Prognostic of Rolling Element Bearings on Industrial Machinery Using Adaptive Neuro Fuzzy Inference System .....	21
A1.7-Triono_Effect of Phenolic Resin and Alignment to the Quality of Prototype Composite Railway Brake Blocks.....	26
A1.8-Muhajir_The Characteristics of the Sport Car Body Aerodynamics .....	27
A2.1-Experimental Study of Total Hull Resistance of Asymmetrical Pentamaran Model with Separation and Staggered Hull Variation of Side Hull I.....	32
A2.2-Nasruddin_The Study on Environmental Quality Interior, Ventilation and Indoor Air Quality Simulation .....	41
A2.3-Nasruddin_Characteristics of Heat Transfer on Heat Sink using Cross-Flow Synthetic Jet with Frequency Variation of Sinusoidal and Square Wave .....	45
A2.4-Prayudi_Simulation Model Transient Heat Transfers in Hot Box Billet Steel.....	51
A2.6-Putra_Application of Al <sub>2</sub> O <sub>3</sub> Nanofluids on Sintered Copper-powder Vapor Chamber for Electronic Cooling.....	59
A2.7-Harinaldi_Effect of Orifice Shape to Convective Heat Transfer of Impinging Synthetic Jet .....	67
A3.1-Baskoro_Effects of Welding Parameters in Micro Friction Stir Lap Welding of Aluminum A1100....	73
A3.2-Sunaryo_Thickness and Fiber Content Optimization in VARTM Method for High Speed Craft.....	79
A4.1-Manabe_Tube Forming Technology for Lightweight Components Manufacturing.....	83
A4.3-Kiswanto_Development and Testing of 5 kn Micro Forming Machine for Micro Part Manufacturing .....	84
A4.5-Malta_A Modified Rotor Model to Approach the Dynamic Responses of Anisotropic Rotor with Different Shaft Orientation.....	91
A4.6-Supriadi_Real-time Monitoring System for Dieless Bellows Forming using Machine Vision .....	97
A5.1-Tjahjanti_Numerical Modeling of Ship Composite-Based on Aluminum Casting as Alternative Materials for Ship Building.....	104

A5.2-Santosa\_Techno-Economic Review Of Hybrid / Electric Catamaran Fishing Vessel..... 105

A5.3-Priadi\_Determining Risk Accidents based on Shiphandling Difficulty Model for Ferry: A validation approach ..... 110

A5.4-Luhulima\_Selecting Mono- and Multi-Hull Passenger Vessels for Moluccas Waters: Resistance/Powering and Seakeeping Evaluation ..... 117

A5.5-Leksono\_Vane-Turbine as an Energy Conversion in the Propeller Slipstream of Single Screw Ship ..... 125

A5.6-Sunaryo\_The Role Of Multi -Yard Ship Construction Method in Integrated Shipbuilding Cluster .. 127

A6.1-Siswantara\_Combustion Analysis of Proto X-2 Bioenergy Micro Gas Turbine with Diesel – Bioethanol Blends ..... 132

A6.2-Sarjito\_Effect of Dwndraught Mass Flow Rate Generated and The Uniformity of The Velocity and Temperature Profiles Downstream of The Multi-Array Nozzles ..... 139

A6.3-Pujowidodo\_Improving Cooling Performance by Modification of Spray Nozzle on 10 kW Absorption Chiller Model ..... 145

A6.4-Dhiputra\_Experimental Study of Liquid-Vapor Mass Flow Rate Ratio of LPG Through Swirling Nozzle with Variation of Swirling's Chamber Volume ..... 151

A6.6-Lukiyanto\_Low Speed Electric Machine Used for Electric Generating from Savonius Windmill .... 162

A6.7-Wahyudi\_Optimization Design of Tandem Blade Rotor of Savonius Hydrokinetics Turbine Model 163

A6.8-Sugiarto\_Combustion of Diesel-Biodiesel Blend Using OpenFoam: Calculation of Pressure and Temperature in Combustion Chamber..... 171

A6.9-Sukamta\_FlowPatternMap of Steam-Condensate Flow in a Horizontal Double Pipe ..... 177

A6.10-Yabase\_Solar A bsorption Air-Conditioning system..... 182

A6.12-Oh\_CComparison between CFD Simulation and Experimental Heat Transfer Coefficient of Natural Refrigerants in Minichannel..... 190

A7.2-Dhiputra\_Experimental Study of Premix Air/LPG Flame Flashback's Depth Of Penetration in Tube Tubes of Bunsen Burner As A Function of The Tube's Diameters..... 197

# Study of the Safety Aspects of the Large Scale Use of LNG as a Fuel

**L. Vandebroek<sup>a</sup>, J. Berghmans<sup>b</sup>**

<sup>a</sup> *M-Tech, Hasselt, Belgium*  
*l.vandebroek@m-tech.be*

<sup>b</sup> *Katholieke Universiteit Leuven, Leuven, Belgium*  
*jan.berghmans@mech.kuleuven.be*

The use of liquefied natural gas (LNG) as a transport fuel presently is drawing considerable attention, mainly in the marine sector. The reason for this is the benign nature of LNG with respect to the environment as compared to the conventional fuels. LNG does present safety problems however. The results of a risk analysis for the storage and transfer of LNG are presented. The role of risk mitigation measures is analyzed. It is found that the pressure of the LNG at the moment of release has a large influence on the accident effect distances. Releases of LNG at atmospheric pressure lead to accident scenarios very similar to those occurring during the release of conventional liquid fuels. Accidents with pressurized LNG may lead to scenarios with more serious consequences.

### Keywords

*LNG, safety, risk*

## Study on Mesoscopical Inhomogeneous Material Modeling for Surface Roughening Behavior of Polycrystalline Metal Sheets and Foils

### ABSTRACT

Recently, the demand for the miniaturization of components has come from technical applications such as electronic devices, medical equipments, sensor technologies and optoelectronics. The development of a novel micro metal forming technologies with high productivity, by which a large number of small metallic parts can be produced, has been attracted. For quantitative prediction of free surface roughening behavior, an FE model considering mesoscopic material inhomogeneity is developed. New concept of determination method of mesoscopical material inhomogeneity parameter is suggested by two simple experimental tests; microstructure observation and uni-axial tensile test, and the iteration of inhomogeneous FE analysis. The material inhomogeneity parameter expressed by standard deviation of variation in flow stress for crystal grain is determined from suggested determination method. The free surface roughening behavior obtained from the inhomogeneous FE analyses is compared with continuous observation by confocal laser microscope under equi-biaxial and plane strain tensile states for A5052-, SPCC and C1220P-O. Evolution of convex and concave patterns and surface profile can be simulated by the FE analyses considering material inhomogeneity determined by proposed determination method. Actual surface roughness values during equi-biaxial and plane strain tensile deformation can be predicted quantitatively by proposed inhomogeneous FE analyses. Therefore the validity of the inhomogeneous FE analyses and new concept of determination method of mesoscopical material inhomogeneity can be verified.

## ABSTRACT

Vaccine administration via skin tissue gives people globally a promising, novel way to fight diseases and improve health quality. There are many ways to do it; one of them is called particle bombardment. In this technique, nano-sized gold particles are coated with the vaccine formula then shot by a device called gene gun straight into the skin tissue. To make gene gun capable of delivering vaccine into human, further research and development are needed. Thus, we conduct series of research to design, make, and develop desk gene gun for laboratory uses and portable gene gun for clinical applications. We set up an assembly consist of pneumatic lines, valves, a fluid container to be the mechanism of the gene gun, and a nozzle to configure the fluid flow. The development focuses on the designing of each component, especially for non-common components and assembling all of the components to obtain the most effective and efficient design which will gives optimum results. To sum up, prototypes of desk gene gun and portable gene gun have been made, but many developments in many aspects are still needed to fulfill the need of gene gun as intradermal vaccine administration device in laboratory and clinical applications.

*Biolistic, design, gene gun, intradermal, vaccine*

## INTRODUCTION

Vaccination is one of human endeavor to face many contagious and deadly diseases. First vaccination was done by Edward Jenner in 1796 to address chickenpox disease. Vaccination itself means a preventive efforts done by inserting germs or viruses that have been attenuated to the human body. This was done in order to stimulate the antibody cells so it would able to form immunity system against the diseases. Increasing intensity in terms of amounts and types of deadly and infectious diseases in any parts of the world has triggered scientists to develop more effective and efficient ways of delivering vaccine into human body. One of the method is done by putting vaccine into the skin tissue which is known as intradermal method. Vaccine delivery by intradermal method gives people globally a novel and promising way to fight diseases and improve health quality.

Far before intradermal method has been stated, vaccine is inserted into the human body via the blood vessel(vascular) by the help of a syringe. Until now, this method is still the most widely used method to administer vaccine into the human body. However, intravascular technique has potential risks and other things to be cautioned at. The operation of this technique requires skilled and professional medical personnel. A little mistake can cause a dangerous risk for both the patient and the medical personnel. The pain that emerged at the time of process of syringe injection also cause discomfortness and unpleasant feeling for the patient, especially if the patient is a child. This can lead to a psychological trauma that could hinder the healing process. The problem of syringe sterility and disposability are also be the side effect of the use of intravascular techniques. The nature of the hazardous waste of the syringe in terms of both physical and biology that are sharp, not sterile, and could potentially contain diseases can not be simply ignored.

As a solution for points stated above, scientists develop many other ways beside intravascular method to administer vaccine into human body, which are: oral (by mouth), intramuscular (by muscle tissue), transdermal (through skin), and the latest one, intradermal. From all of the mentioned methods, intradermal is one that still needs many developments and research to make it able to be used for human properly. Although some devices have been made an developed as intradermal vaccine administration device, none of them have passed the clinical trial to be used for human. As part of the effort to improve the health quality and help people to fight diseases, we decide to design and develop two models of gene gun which will be used as a laboratory instrument and clinical applications.

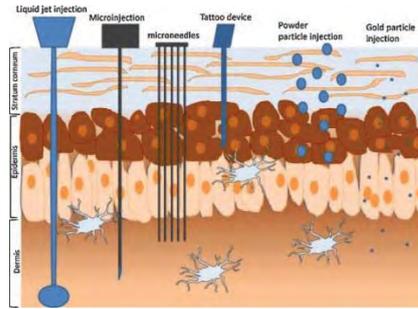

Figure 1. Variation of techniques used as intradermal method

## MATERIALS AND METHODS

The design and development of gene gun are done by following the steps of product design and development principles. Some core principles of new product development (NPD), design function deployment (DPD), and other product design and development methods are combined to obtain the most appropriate way to develop gene gun. The key elements of the design and development strategy then are defined as those which may be used to collate essential information for such areas as follows:

- The establishment of user needs.
- Analysis of the functional requirements of the product.
- Evaluation of existing products.
- Exploration of other avenues for solutions to identified design problems. (Cross, 1994)

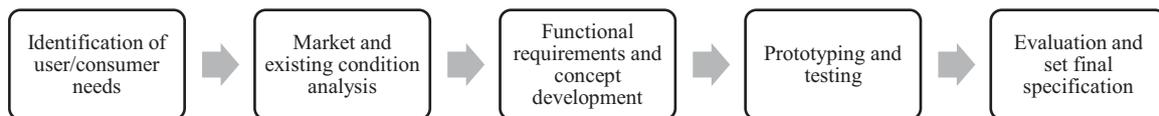

Figure 2. Process design and development steps

In case of gene gun, there are three groups that we consider as our user or customer, which are medical researchers, medical practitioners, and patients. Each of them have their own role and urgencies toward the application of gene gun for intradermal method of vaccine administration. Based on this situation, we decide to design and develop two types of gene gun. One is what we called by desk gene gun. It is designed to fulfill the need of gene gun of medical researchers so they can conduct research and develop other matter that required to make gene gun capable of delivering vaccine into human skin. The main points of this desk gene gun is the ability to read and control some varying parameters with respect of medical laboratory instrument standards, ease of use, and any other factors that should be considered so they can use it as a laboratory instrument. The other is called portable gene gun. It is designed for clinical purposes meaning that the customers are medical practitioners like doctor or nurse and also the patients itself. The main points of designing portable gene gun is the safety and comfortness of the patient and also the medics. Moreover, the compactness, simplicity, and other additional points like aesthetics and environmental issues should be considered to in the designing of portable gene gun with respect of course, to the main function of desk gene gun to deliver vaccine by intradermal method in a more effective and efficient way.

After defining each of customer/user needs, we are trying to formulate the functional requirements of the product and start the design and development of mechanisms and required components to make the gene gun. Gene gun itself was developed for the first time at 1989 by John Sanford, Klein, and Wolfe in Cornell University as a mechanism of introducing new genetic material into plant cells. The original gene gun transfection procedure involved placing the sample in a sealed chamber, which was then placed under vacuum before firing DNA-coated microparticles into the target. Today, gene guns have come in many kinds of forms and mechanisms that are more sophisticated. They have been used successfully to deliver a wide range of tissues and organisms, including whole animals and plants, bacteria, mammalian cells and even organelles. This technique has been particularly successful for biological samples that have previously been difficult or impossible to transfect, such as non-dividing cells or primary neurons. Transfection using a gene gun (often referred to as biolistics) is a simple procedure requiring minimal training; it basically consists of two steps: (i) coating microprojectiles with DNA and (ii) firing the coated microprojectiles into the sample. (O'Brien, 2007)

The fundamental principle of gene gun is to accelerate microparticles using external force that may come from an ignited explosion, electric impulse, or compressed fluid so the microparticles have enough velocity to penetrate skin tissue and reach the antibody cells. We decide to use compressed fluid as the driving force for our gene gun design. As a consequence of using compressed fluid as the driving force, uses of pneumatic components to control the flow are required. Common components like 3/2 NC valve, quick exhaust valve, pressure regulator, and flowmeter are used to control the flow with respect of its own function. Beside common components, we also use a specifically designed components including fluid container and nozzle.

Figure 3. First gene gun developed by John Sanford, Klein, and Wolfe in 1989.

Figure 4. Helios® Gene Gun, first commercialized gene gun

## RESULTS AND DISCUSSION

There are many aspects of both direct and indirect results from the development of gene gun that could be delivered here. Despite of it, to keep the focus straight to the design development of gene gun, we just present the design development activity with prototypes of desk and portable gene gun as the results. In total, we have made one prototype of desk gene gun and three prototypes of portable gene gun.

The current desk gene gun consist of a subassembly of stand as the supporting structure and the main components of gene gun itself that mounted at the top of the structure. We decide to use aluminum as the material of the structure with consideration of its strength, mass, environment condition, ease of production, and aesthetics. The stand subassembly itself consists of two aluminum plates, acts as the base and upper supportive plate, jointed with four hollow aluminum tubes which act as the structure pillar. At each side of the device, leaving one side open as an access to inside area of it, we put a clear acrylic as a wall to reduce the interaction between inside chamber and environment.

For the mechanism of the gene gun, we use pressure regulator and flowmeter to control the fluid flow, an electrical-controlled 3/2 NC solenoid valve, a quick exhaust valve, and a fluid container. All of them are mounted fix to the upper supportive plate except for the fluid container. To direct and configure the fluid flow, we design some nozzles with its own distinctive design and put it right after quick exhaust valve inside the chamber. The target will be placed right under the nozzle with the desired distance.

We have tested the desk gene gun and it worked just like it should. There isn't any leaks at the fluid lines, the fluid can be precisely controlled, and the pressure loss inside the assembly still can be tolerated as well. This makes sure that the architecture of the subassembly is good and appropriate enough. The operation was also easy although it requires supply of both electrical power and compressed fluid lines. Several things that should be consider at are the effect or force from the pressurized fluid. The force when the valve was opened and the fluid flows out of the nozzle cannot be considered low. A well and precise design of support with damper or mounting bracket should be made in order to absorb the vibration. The structure was also a bit unstable because of the lightweight structure and the propotion. The height was just too high and it was just supported by four hollow aluminum tubes. This makes that each time a shot was done, the device receive a moment force and it was like swaying over. The problem can be solved by lowering the height of the device or changing the materials of the structure so it will be more stable.

Based on the evaluation and to improve the performance of the device, we decide to make a computer-aided control system to the device. By using solenoid valve and solenoid pressure regulator, we can control the fluid electrically. The usage of pressure transducer can also be applied to change the pressure gage role so the amount of pressure can also be displayed in the computer. In addition, we are also planning to make a motor-controlled platform inside the chamber using screw system so in the future, users don't have to put the target in specific distance manually. They just have to put the distance into the computer and the system will do it automatically. This addition is also capable to make the inside chamber to be sealed better so it will reduce any interruption from the environment. Hence, it will increase the reliability of the shooting results in the future.

Figure 5. Prototype of desk gene gun

There are three prototypes of portable gene gun that we have made, each of them with their own designs and combinations of components. The core components of gene gun will be the same for each prototypes which are consist of 3/2 valve and quick exhaust valve along with a fluid container and the nozzle. Instead of using electrical controlled 3/2 solenoid valve, we use a mechanical-actuated 3/2 valve. We also use smaller size of valve for the portable gene gun. If the desk gene gun use a 3/8' valve, portable gene gun use 1/4' or 1/8' valve.

We are still using the standard or common components in the market to make it easy to be replaced and assembled. We combines wide range of products to find the most optimum design. We decide to use a mechanical-actuated valve in order to increase the simplicity of the mechanism. If we use a solenoid valve, then it needs an electric power source which could be mean a battery will be needed. This will increase the dimension and weight of the assembly. Thus, in consequence of using mechanical-actuated valve, we have to design the most appropriate handling position and add some linkage so the device can be used easily and without so much effort.

In the gene gun assembly, there are two components that was designed distinctively, which are fluid container and nozzle. Just like its name, the fluid container is used to store some amounts of compressed fluid that will be used to accelerate the microparticles. The most important thing to be considered of the design of the fluid container is the capacity which will determine the dimension. Based on the principle of continuity equation and law for compressible fluid, to obtain the same fluid flow capacity, smaller fluid container capacity would mean higher driving pressure is required, and vice versa. Here, the fluid driving pressure will play a very important role. A pneumatic system with higher operating pressure will be also considered more dangerous than the one with lower operating pressure. A well and precise decision should be taken to obtain the most compact design of fluid container with proportional driving pressure. Until now, we are still trying to find the most appropriate combination of fluid container combination to driving pressure. The requirement of compact and mobile design of portable gene gun will be the challenge of this fluid container design problem.

Figure 6. Prototypes of portable gene gun

Beside the pneumatic mechanisms, another component that has a very important role to successfully make gene gun able to deliver vaccine into human body is the nozzle. Nozzle is used to form and direct the fluid flow so it will give the most optimum result. Not only that, in gene gun, nozzle is also used as the location to put the tube containing microparticles which coated with the vaccine. This will be the constraint yet the key point of the nozzle designing. Based on the user needs and literature, it is known that the nozzle used for gene gun should be categorized as supersonic nozzle.

Supersonic nozzle has its own distinctive rules of design. In general, the form of supersonic nozzle can be considered as a convergent-divergent nozzle (C-D nozzle). The most special thing in this type of nozzle is the existence of throat section. Supersonic nozzle can be divided to three sections: converging sections, throat section, and diverging section. In converging section, subsonic flow developed until it reaches near supersonic flow. Inside the throat area, the fluid flow will develop into fully supersonic flow. In the diverging area, the fluid flow will keep developing, increasing its velocity until it meets the stagnant fluid condition of environment. With these two key points, we design nozzles for gene gun that capable to hold the tube and acted as a supersonic nozzle.

Figure 7. Nozzles of gene gun

The manufacturing process to make gene gun nozzle should be distinctively considered too. Conventional manufacturing method using conventional tools and machine are hardly able to be used to make a precise and accurate gene gun nozzle. Considering limitations of manufacturability, we decide to simplify gene gun nozzle to a converging nozzle, as the preliminary study for next research and development. As an addition, based on some developments done by the other about gene gun nozzle, we also decide to put baffle holes angle variations and shooting distance to our development. The main purpose of baffle holes angle is to deflect the fluid flow so it will not hit the target, leaving only the microparticles that hit the target. This was done to minimize the side effect of the high velocity fluid flow which will cause an impact force that may destroy the target tissue. In terms of vaccination into human skin, this impact force would mean harm and cause pain to the patient. We use three variations of baffle holes angle which are:  $30^\circ$ ,  $90^\circ$ ,  $150^\circ$ . Each of the nozzles will be tested at three different shooting distances, which are: 0 mm, 10 mm, 20 mm.

Figure 8. Impact force to variations of shooting distances

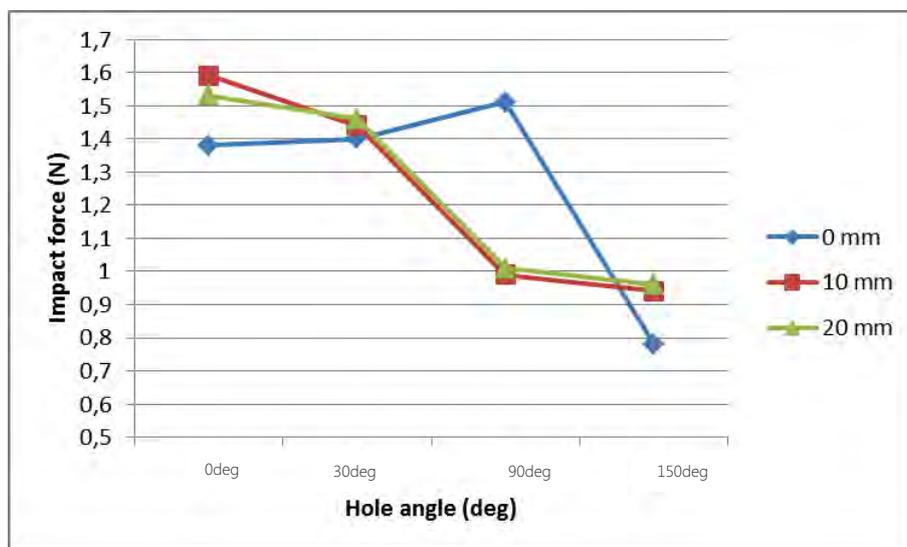

Figure 9. Impact force to variations of holes angles

The test to determine the effect of baffle holes angle and shooting distance variations to impact force has been done. From the results, it is known that the lowest impact force was created by nozzle with 150° of baffle holes angle shot in shooting distance of 0 mm. This result will be put as one of the considerations of gene gun nozzle designing. For the material, we decide to use aluminum. Later, to fulfill the standard of medical equipment, development of nozzle made by medical-approved material will be done. The testing of the gene gun has also been done to the agarose to determine the effect of driving pressure to the depth of penetration and spread diameter. Research to find the most effective combination of driving pressure and shooting distance are still in progress.

## CONCLUSION

The initial prototype of desk gene gun and portable gene gun have been made as a mark of our involvement of the development of intradermal vaccine administration device. Further development like adding computer-aided system, more precise controls and readings, appropriate material selection, and design of the architecture will be done to enhance the reliability of desk gene gun as medical laboratory equipment. For the portable gene gun, many developments are still needed, especially for non-common parts to find the most optimum design in terms of dimension, weight, looks, and ease of operation with heed to the main function of the gene gun.

## **ACKNOWLEDGMENT**

This research is a part of and funded by Incentive Research Funding of Ministry of Research and Technology 2011-2012. Many gratitudes and thank you are delivered to the team of Department of Mechanical Engineering - University Indonesia, Department of Microbiology- University of Indonesia, Institute of Human Virology and Cancer Biology (IHVCB) – University of Indonesia, and others who have involved direct and indirectly for all of their helps and supports in this research activity.

## ABSTRACT

The coupled heave and pitch motions of a simplified sloshing effect at the FLNG on still water surface and subjected to induced by sloshing have been investigated. The FLNG was considered to be rigid body supported by non permanent pole with distributed spring damper. Based on the general equation of the ship motion in waves, and various wave amplitude, period governing equation induced by sloshing were derived. For the case of various fluid level on the cargo tank and various wave period, wave amplitude “ exact solution “ was obtained. For the purpose of comparison and more general studies, a numerical approach was also introduced. The influences on the dynamic responses of FLNG of some factors such as sloshing effect, heaving, various fluid level on cargo tank initial velocity and acceleration, were studied. To check the reliability of the numerical result a simple model was conducted and validated with some experimental result. The reason for discrepancies between experiments and theory are discussed. For simplicity, the damping effect and sloshing effect to the FLNG induced waves are replaced by damping ratio in this study.

## Keywords

*simplified, sloshing, coupled heave and pitch, damping, and waves*

## 1. INTRODUCTION

There are two primary concerns related to sloshing flows in ship hydrodynamics: the prediction of sloshing-induced impact loads on ship structures, and the dynamics of ship motion coupled with sloshing-induced excitation. The former is an important task in the design of internal cargo structure. In particular, this is an essential element in the design of membrane-type liquefied natural gas (FLNG) carriers or FLNG platforms. The latter has been of interest for the prediction of dynamic behavior of ship motion. Meanwhile the design load of the main hull structure is governed by the external wave load and inertial load due to ship motion, the sloshing impact load due to liquid motion inside the tank governs the design load for the FLNG containment system and surrounding bulkheads.

Many studies on the ship sloshing problem were carried out in 1970's and early 1980's for the design of FLNG carriers. Recently, the demand of sloshing analysis is rising again for the design of larger FLNG carriers and LNG floating-production-storage-offloading (FPSO) vessels. Many numerical studies on sloshing flows have been reported during last two decades. Some representative works have been introduced by ([1], [2]), [3], [4], [5], and [6]. Despite numerous studies, not many methods are applicable for actual engineering use such as the simulation of violent flows and the prediction of impact loads. However, recent experimental and numerical study shows that even at the milder sea states, the sloshing load at the filling level near the 30% of tank height can be as high as the sloshing load at the high filling level at the North Atlantic ([7]);([8]).

This study aims to observed on the physical phenomena involved in violent sloshing flows, and the development of proper numerical models for practical use. To this end, both the experimental observation and numerical computations are carried out ([10], [11]).

## 2. MODEL SET-UP AND ITS PARTICULAR

The FLNG model was produced according to a scale 1:70 .The model consists of hull body (barge shape structure) completed with cargo tank, normal bilge tank. The FLNG model was made from wood and steel frame which is required strengthen the hull body. The model should be statically and dynamically balanced to adjust the position centre of gravity and radii gyration. The Cargo tank are made of acrylic transparent glass 1 cm wall thickness. In the following lines plan and table of principal dimension of FLNG with scale factor:

The model test were carried out in regular and random waves. The random waves were adjusted to represent Pierson-Moskowitz wave spectrum. The waves in basin were generated by means of a wave generator.

### 3. PROCEDURE CALIBRATION

All from the recorded decay curves of the various motion decay or free extinction tests natural periods have been derived to used for evaluated. The damping coefficients were derived from the decrease of motion amplitude for two successive oscillations as follows: (See Figure 3)

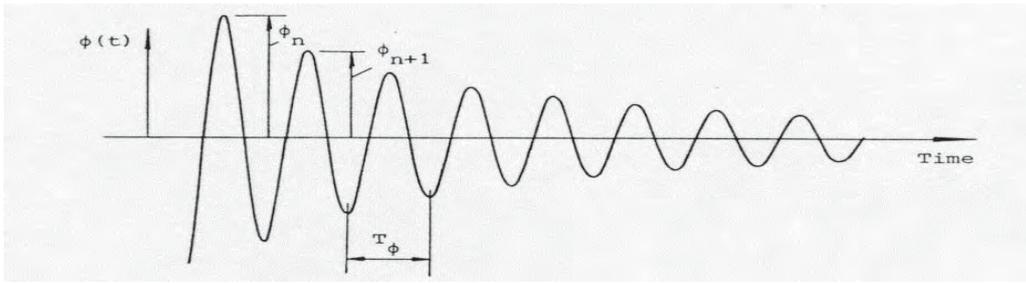

Figure 3: Decay Test

$\phi(t)$  = time trace of motion  $\phi$   
 $\phi_n$  = motion amplitude of n-th oscillation  
 $T_\phi$  = natural period of motion  $\phi$ .

The logarithmic decrement  $\Delta$  can be determined:

$$\Delta = \ln(\phi_{n1}/\phi_{n2})$$

The dimensionless damping coefficient or damping ratio to critical damping is expressed by:

$$k = b/b_{critical}$$

Which can be calculated from the logarithmic decrement by:

$$k = \Delta / (4\pi^2 + \Delta^2)^{1/2}$$

### Linear (Equivalent) Damping

When the system behaviors is almost linear (equivalent) damping can be derived as follows:

The linear motion  $x(t)$  during a free extinction test can be described by, assuming a linear system:

$$(m + 1) \cdot \frac{d^2x}{dt^2} + B_x \cdot \frac{dx}{dt} + C_x \cdot x = 0 \quad \dots\dots(1)$$

$$(I + I_A) \cdot \frac{d^2\phi}{dt^2} + B_\phi \cdot \frac{d\phi}{dt} + C_\phi \cdot \phi = 0 \quad \dots\dots(2)$$

Where:

- |                                    |     |  |
|------------------------------------|-----|--|
| $m$ = vessel mass                  | and | $I$ = vessel inertia for rotation      |
| $A$ = added mass                   | and | $I_A$ = added inertia for rotation     |
| $B_x$ = linear damping coefficient | and | $B_\phi$ = angular damping coefficient |
| $C_x$ = linear spring coefficient  | and | $C_\phi$ = angular spring coefficient  |

The spring coefficients are a combination of the hydrostatic spring and the stiffness of the mooring system.

The non-damped natural period of this system can be calculated as:

$$T_\phi = 2\pi \sqrt{\frac{I + I_A}{C_\phi}}$$

$$T_x = 2\pi \sqrt{\frac{m + A}{C_x}}$$

For such a system the critical damping  $B_{crit}$  is defined as:

$$B_{x_{crit}} = 2\sqrt{(m + A) \cdot C_x}$$

$$B_{\phi_{crit}} = 2\sqrt{(I + I_A) \cdot C_\phi}$$

If the damping is equal to, or larger than, the critical damping, no overshoot of dynamic amplification occurs in the system. To determine the degree of damping in a system, the damping is sometimes expressed as a ratio  $B_\beta$  of the linear damping coefficient  $B$  and the critical damping  $B_{crit}$ :

$$B_\beta = \frac{B}{B_{crit}}$$

## 5. ANALYSIS AND DISCUSSION

### 5.1 Response Amplitude Operator

The prediction of responses structure of an FLNG is generally made in regular wave. In currently work various heading angle (90,180) degree and filling of the water 30 % for simplicity analysis. In this model test sort term response calculation of linier non linier are given natural Response Amplitude Operator (RAO) of FLNG. Based on linier theory it is assumed that for each wave period the relation between input wave amplitude and motion always the same. From the test were carried out at beam seas 180 degree the wave amplitude increase compare to head seas 90 degrees (See Figures 5 and 6). For heaving motion at beam seas 180 degrees and head seas 90 degrees, there is not many different (See Figures 7 and 8).

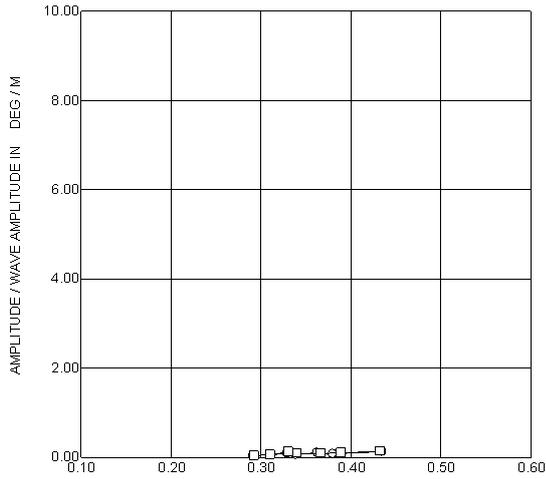

Figure 5: RAO Pitch (Angle 90 deg)

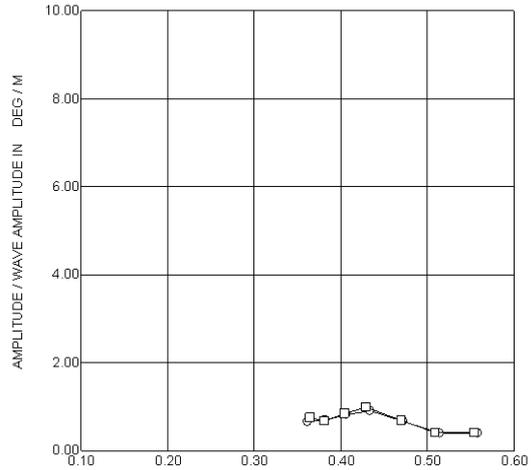

Figure 6: RAO PITCH (Angle 180 deg)

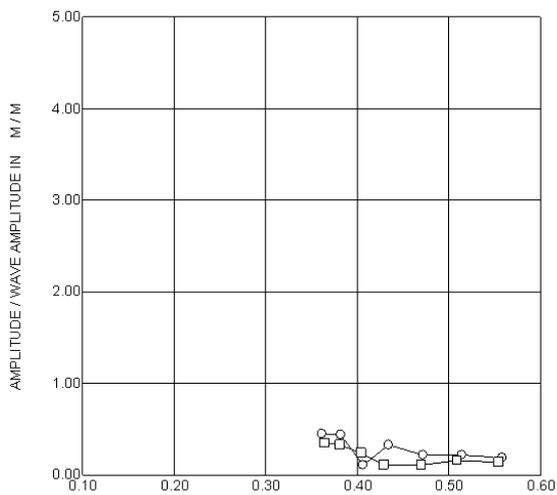

Figure 7: RAO Heave (Angle 90 deg)

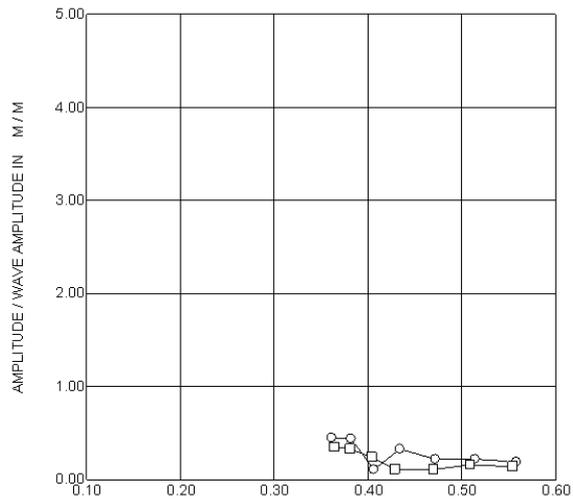

Figure 8: RAO Heave (Angle 180 deg)

## 5.2. Time Traces of Wave Spectrum and Impact pressure at Sloshing Tank

Figures 9 and 10 show an actual time history of wave spectra and impact pressure to support the analysis of natural frequency of the ship motion as particular for pithing and heaving motions. And also the correlation between wave spectra and the maximum impact pressure.

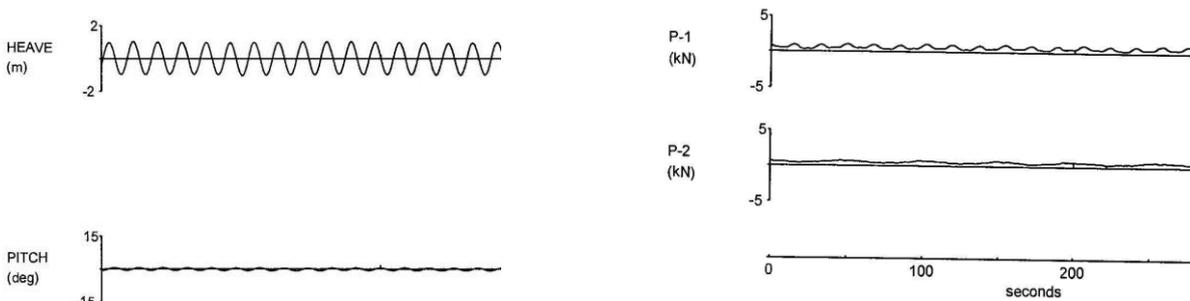

Figure 9 Wave Spectrum and Impact pressure with heading 180 deg

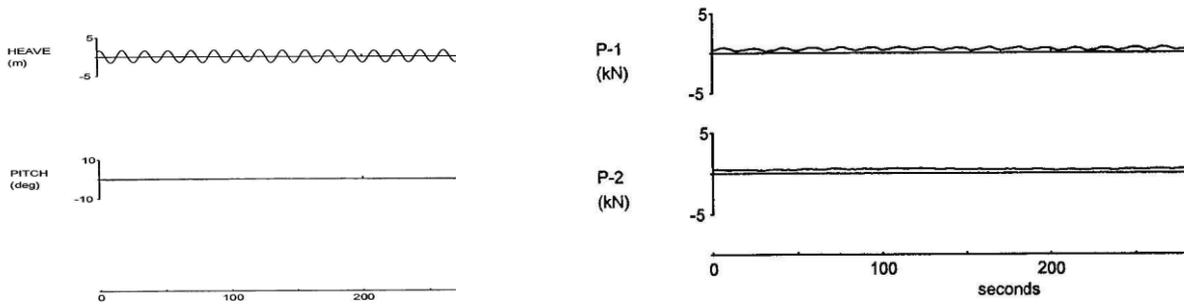

Figure 10: Wave Spectrum and Impact pressure with heading 90 deg

## 6. CONCLUSIONS

In the present study, the physical and technical issues of sloshing flows in FLNG the ship are described. The physical phenomena in violent sloshing flows have been carefully observed in experiments, which was carried out at IHL Surabaya. Based on the present study, the following conclusions are drawn:

- There are several physical issues which should be considered in sloshing analysis. These issues include the effects of cushioning due to air pocket, local wave breaking, splashes. To understand their effects is critical to develop numerical models for sloshing analysis is need to study more detail.
- There are several technical issues in the numerical simulation of violent sloshing flows. Due to discrete spatial and time domain, proper numerical techniques are essential to make the solution more continuous, stable, and realistic.
- The nonlinearity of sloshing flow plays a critical role in the ship motion coupled with sloshing. The sloshing-induced force and moment are not linearly proportional to excitation amplitude. Therefore, the ship motion coupled with sloshing does not vary in a linear manner with respect to wave amplitude.
- The coupled problem is well predicted by the linear theory based on the impulsive response function. This method is accurate and robust, and particularly very efficient in computational time.
- The coupled Pitching and heaving problem is well predicted by the linear theory based on the impulsive response function must be continued with mathematical modeling to validated and solve the instrumentation error. Specially for pitching, heaving motion induced by sloshing dynamic.

## ACKNOWLEDGEMENTS

The authors wish to thank Indonesia Hydrodynamic Laboratory (IHL) staff for providing the experimental data of the current paper.

## ABSTRACT

A common UV lithography technology uses a series of instruments which are spin-coater, hot plate and UV curing system. This had restrained the application of UV lithography technology in a laboratory with limited resource. The purpose of this work is focused on how to produce and characterize microstructures with our home-made instruments. The thickness of around 100 $\mu\text{m}$  was achieved by our system. Furthermore, an optimum condition for UV curing was also characterized in term of exposure dose ( $\text{J}/\text{cm}^2$ ).

### Keywords

*UV lithography, MEMS, photoresist, spin-coating sytem, UV Box.*

## 1. INTRODUCTION

Ultra violet (UV) lithography is the most common microfabrication technique to realize microstructures with high resolution for Micro Electronic Mechanical System (MEMS) applications. UV light is emitted by electric arcs and specialized lights such as mercury lamps and black lights. The UV light is illuminated through a predetermined mask and is then transmitted onto silicon wafer coated with photoresist. Hence, the mask intercepts UV light corresponded with the pattern and detained the light onto photoresist material. During the exposure stage, the photoresist polymer is crosslinked and permanently unremoved at subsequently developing stage. On the other hand, the unexposed area is washed away altogether with developing solution. Thus, the remaining photoresist form a structure corresponded with the mask [1].

The critical knowledge of this process is the characterization of the UV light intensity and the interaction with the polymer photoresist material. A common photoresist material such as SU-8 is reported to have resolution in the range of 15-270  $\mu\text{m}$  width with a thickness up to 275  $\mu\text{m}$  [2]. Furthermore, Hsieh successfully correlated the photoresist thickness and exposure dose. He reported that a dose of 16-20  $\text{J}/\text{cm}^2$  is required to expose the photoresist layer with thickness of 200  $\mu\text{m}$  [3]. Currently, the interest of researchers is realizing high precision result with lowest cost as possible. A conventional lithography process requires a set system of spin coater, uv exposure and mask aligner system. Here, we present a result of our home made spincoater and UV exposure system during laboratory course work of microfabrication.

## 2. EXPERIMENTAL PROCEDURES AND APPARATUS

Photo lithography process in this paper was conducted with following procedure:

### 2.1 Spin Coating

Liquid negative photoresist AL-217 from Aldrich Chemical was soaked onto wafer silicon. The wafer silicon was attached to the spin coating and was then rotated at 500 RPM in the 5 seconds (level 1) and 1000 RPM in the next 10 seconds (level 2). Low cost spincoater machine contains only motor with speed controller. The substrate attach to the spincoater disc by adhesive band. Utilization of adhesive band to substitute the function of vacuum suction that reduces cost significantly.

### 2.2 Pre Baking

Prebaking process is to evaporate photoresist solvent and to solidify resist on the wafer. Wafer coated with photoresist was placed on a hot plate for 15 minutes at 70  $^{\circ}\text{C}$ .

### 2.3 UV Exposure

In order to expose the photoresist, a wooden box with a dimension of 30x20x10  $\text{cm}^3$  is prepared. The purpose of UV exposure is to active crosslinking agent. In this work, five TUV Philips lamps with 11 W were installed inside the box. Moreover, simple mask with predetermined pattern was contacted directly on the top of photoresist film. Dose, D, or energy ( $\text{J}/\text{cm}^2$ ) was adjusted by tuning the exposure time (seconds) at the surface of film. In this work, exposure time was set at 5,10, and 15 minutes.

### 2.4 Development

Development is a process to remove uncrosslinked part on the wafer, while the linked photoresist will remain on the wafer. The developer agent used throughout was from also Aldrich Chemical. The exposed wafer was dipped into beaker glass filled with developer solution for 30-60 seconds.

### 2.5 Post Baking

Post baking is applied to cure the photo resist. After exposure, a post exposure baking was performed on a hot plate for 20 minutes at 70 °C. This step is defined to stabilize photoresist film.

The experimental result was conducted in the scanning electron microscope EVO MA10 Zeiss Germany was used to determine the thickness and line width of resulted pattern.

## 3. RESULTS AND DISCUSSION

### 3.1 Spin Coating Characterization

Spin coater was mainly composed of DC motor controlled with a DC voltage supply. By regulating the voltage supplier, angular speed of motor can be determined thus correlation of angular speed and thickness is known. Figure 1 depicts a cross section of sample and thickness measurement of photoresist film via SEM. Note that the measurement was made after prebaking the wafer. Hence, it can be assumed that the excess solvent is removed. Figure 1 also demonstrates that photoresist thickness is distributed quite evenly with some deviation. Moreover, a more complete result is tabulated in table 1.

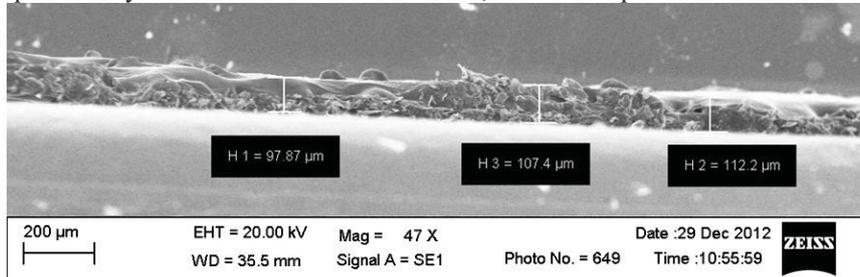

Figure 1: A sample of thickness measurement of photoresist film via SEM

Intuitively, table 1 show that slower angular speed gives thicker photoresist film. The result also demonstrates that at 500 RPM speed gives the highest standard error. It can be inferred that at this low angular speed, a uniform thickness is harder to achieve. On the other hand, thickness measurement at above 1000 RPM confirms that the standard error is lower than 7%.

Table 1: Result of thickness measurement

No	Speed at level 1 [RPM]	Speed at level 2 [RPM]	Voltage Output [V DC]	Thickness [ $\mu\text{m}$ ]
1	500	500	5.5	$140.80 \pm 26.88$
2	500	1000	5.8	$105.67 \pm 7.10$
3	500	1500	6.5	$64.45 \pm 2.39$

### 3.2 UV Exposure Characterization

The exposure experiments were performed with 5 parallel TUV lights that assembled inside a wooden box. The intensity of incident UV light was measured as about  $0.2 \text{ W/cm}^2$ . Subsequently, an exposure scenario was conducted to find optimum working condition. The measurement shows that the optimum exposure time is at 10 minutes. During developing time, a weak bonding between photoresist and substrate was observed at 5 minutes exposure time. Additionally, a significant temperature increasing of UV box was also indicated during UV exposure stage at 15 minutes exposure time.

Performance of the process was tested by varying structure dimension. The result shows that the propose photo lithography apparatus is able to produce photoresist structure up to  $100 \mu\text{m}$ . Simple quadratic pattern was tested in this study to observe the result of UV exposure. Figures 2 (a), (b), and (c) illustrate the predetermined mask that designed with various line widths from 100; 150 and  $200 \mu\text{m}$ . Later on, figures 2 (d), (e), and (f) depict the realized pattern after the post bake process under microscope observation. These results shows that the propose photolithography system is able to produce micro-structures.

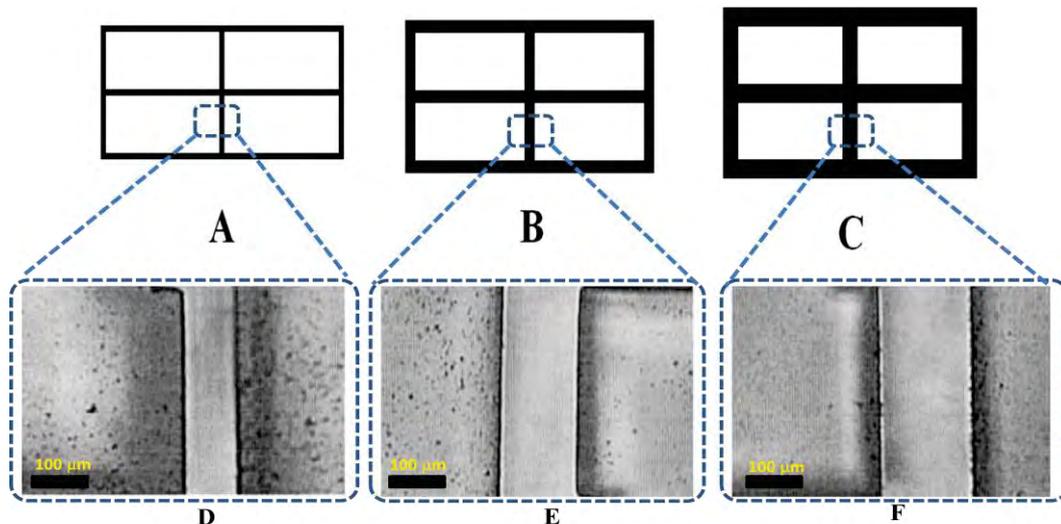

Figure 2.: Predetermined mask with various line width: (a) 100  $\mu\text{m}$  (b) 150  $\mu\text{m}$  and (c) 200  $\mu\text{m}$  Realized line width of photoresist after post baking stage (d) 100  $\mu\text{m}$  (e) 150  $\mu\text{m}$  and (f) 200  $\mu\text{m}$

The SEM photograph of developed photoresist structure is shown in figure 3. A gear structure with about 100  $\mu\text{m}$  thick is released but some cracks can be observed in the bottom of the structure. The cracks are formed in the residual of the exposed photoresist. Until now, the development conditions are still not optimized, therefore, some exposed photoresist are remained on the bottom of structure occasionally.

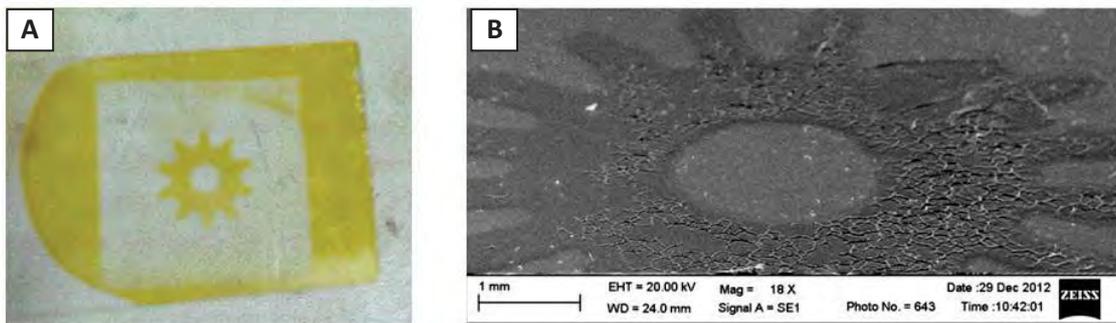

Figure 3: (a) Photograph and (b) SEM graph of product from lithography process for micro gear project

The contact masking method was indicated to damage the resist structure during mask removal stage. An improvement in masking method is obviously needed in further improvement. Additionally, a better light adjustment is also an area of improvement to have more focused and intensity of the UV luminance.

#### 4. CONCLUSION

Our educational lithography process that utilized a handmade spin coating and exposure systems shows a promising result. The system attains the thickness up to  $140.80 \pm 26.88$  and a line width in the range of 100  $\mu\text{m}$ . However, it is indicated a low aspect ratio during the project of realizing micro gear part. A further adjustment is proposed to improve this system which at this moment cost less than \$500.

### **ABSTRACT**

Several studies have demonstrated the ability of laser for microchannels fabrication. There are some important aspects that must be considered to use laser for machining process, such as machining method, type of laser and interaction between laser and workpiece. In this research, CO<sub>2</sub> laser machine was used as a tool to fabricate a microchannels on acrylic. Some parameters that can influence the outcome of the cuts were setup, which are focus distance on Z axis, laser power, cutting speed, and the repetition of cutting process (number of pass). Cutting results were width and depth of cut. Observation was made by using digital microscope as measuring tool, and measurement results was analyzed by using Anova method. The results of the analysis shows that the parameter of laser power has a dominant influence on depth of cut, and then parameter of cutting speed and number of pass. By determining width and depth of the cut based on given parameters, it will be easier to take a shape and size on microchannel fabrication.

## ABSTRACT

Remaining useful life prognostic of rolling element bearings on industrial machinery is important to be applied for determining the condition of its health during the operation. By knowing the remaining useful life, the ultimate failure is inevitable and the maintenance cost also can be optimized. Monitoring vibration conditions that generate time series data is a good method to indicate the beginning of defect that occurs in rolling element bearings. The vibration data are used to extract relevant features. This paper presents an intelligent capability to perform the remaining useful life prognostic which the input data are from the extraction of multiple features. Intelligent capabilities conducted by using adaptive neuro fuzzy inference system (ANFIS). The data input are derived from several features extracted from vibration data. ANFIS output would be worth accurate when showing values less than the root mean square error (RMSE). Result shows that the ANFIS output has the average error which is smaller than RMSE. Trial testing data may indicate that remaining useful life can be performed with good performance.

## 1. INTRODUCTION

CBM (condition based maintenance) is a maintenance technique used to determine the current condition of the machine. CBM supports the scheduled maintenance reporting which performed mechanical condition continuously, so that the failure of the industrial machinery can be avoided. Another benefit using this CBM technique, is to reduce the maintenance cost. Prognostic is one method that supports CBM to know RUL (remaining useful life) of industrial machinery [1-6].

Prognostic of industrial machinery can be performed on multiple elements of the machine. One of the important element in the industrial rotating machinery is bearing. This paper will discuss about RUL prognostic of rolling element bearings. Rolling element bearings are major elements of bearing that serve to rivet shaft and give the possibility of rotating shafts on it. The existence of rolling element bearings damage that is not known as early as possible can result in total failure, because the machine cannot spin optimally.

Prognostic of rolling element bearings that will be discussed is time series analysis to predict the RUL based on time domain vibration data. RUL means the time remaining before the final failure occurred. Measurement of vibration is an excellent method to determine the condition of rolling element bearings due to vibration can indicate the beginning of a defect on a rotating machinery such as rolling element bearings. This paper focuses on an intelligent system that can do the prognostic for rolling element bearing failure with adaptive neuro fuzzy inference system (ANFIS) method. Vibration data is used for training and testing hybrid in ANFIS after data preprocessing with feature extraction vibration data.

In the next section of this paper will be discussed as follows: Section two will discuss the features extraction from time series vibration data. Section three will discuss how the ANFIS support RUL prognostic. Section four discusses the result and discussion. Furthermore, section 5 is conclusions and suggestions.

## 2. FEATURE EXTRACTION

Feature extraction is an important step to do prognostic. Features used can affect both good and poor prognostic outcome. Good features will produce accurate results [3]. In this paper, the following feature extraction will be used: mean, RMS, skewness, kurtosis and betakurtosis. Some of these features can be written as follows:

$$Mn = \frac{1}{N} \sum_{k=1}^N (x_k - \bar{x})^n \quad (1) [4]$$

$$RMS = \sqrt{\frac{1}{N} \sum_N x^2(t)} \quad (2)$$

$$S = \frac{M_3}{\sigma^3} \quad (3) [4]$$

$$K = \frac{M_4}{\sigma^4} \quad (4) [4]$$

$$BK = \frac{M_4}{(\sigma^2)^2} \quad (5) [5]$$

Eq.1 is mean, eq. 2 RMS, eq.3 skewness, kurtosis and eq.5 eq.4 betakurtosis. N is the number of data points.

## 3. ANFIS TIME SERIES PREDICTION

ANFIS is a combination of fuzzy logic and artificial neural network (ANN). Fuzzy logic has advantages in modeling the qualitative aspects of human knowledge and decision-making process by applying the rule base. ANN has advantages in recognizing patterns, learn and practice to solve a problem without the need for mathematical modeling and works based on historical data that is entered to it and be able to predict upcoming events based on the data. So that ANFIS has the ability both [2]. The basic structure of ANFIS is shown in Figure 1 and ANFIS modeling is shown in figure 2.

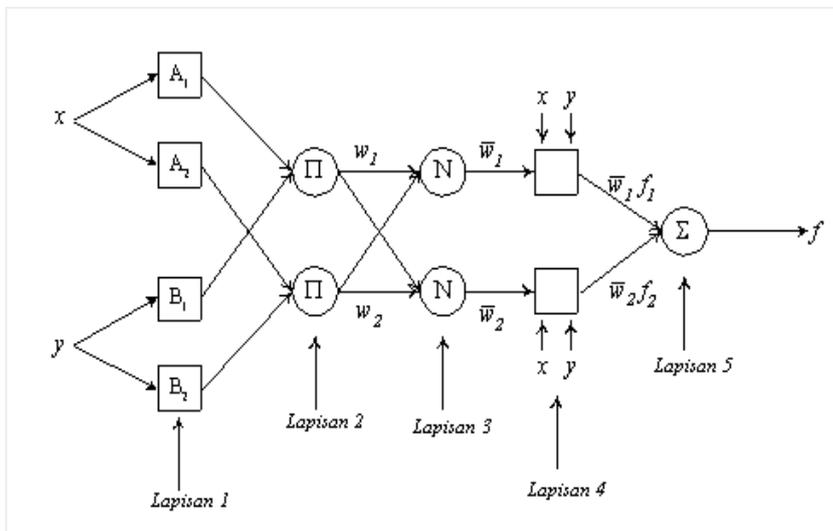

Figure 1: ANFIS structure

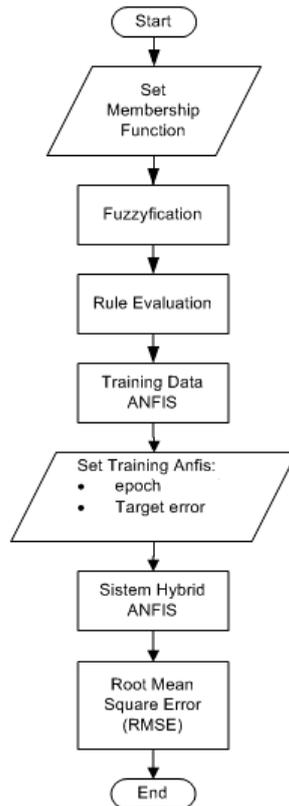

Figure 2. Flowchart ANFIS modeling

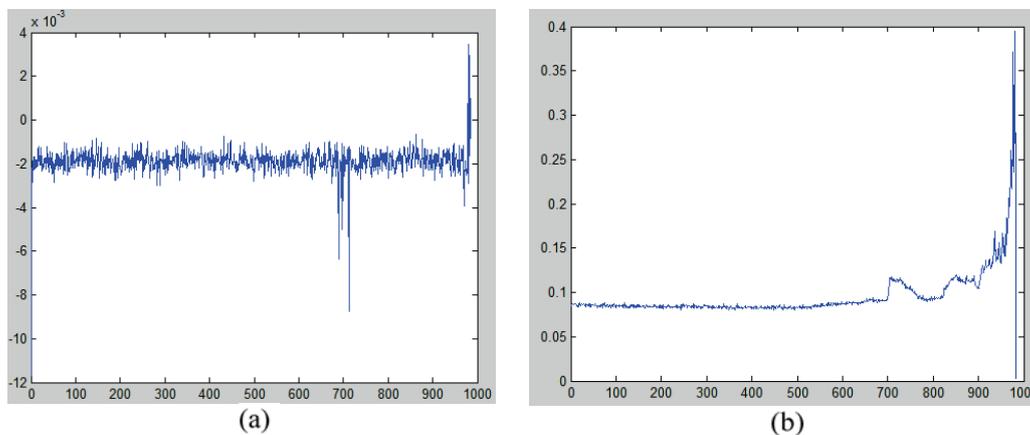

In time series prediction, it should be known the value from a certain time to time (t), to predict the value in the future (t + P). The standard method for this prediction is the mapping of the data sample points (D), sample of each unit in time ( $\Delta$ ),  $(x(t-(D-1)\Delta), \dots, x(t-\Delta), x(t))$ , to predict the future value  $x(t + P)$  [2].

To start the training data needed FIS structure that determine the structure and parameters of FIS beginning to learn. Genfis1 function handles this specification.

```
fismat = genfis1 (trnData);
```

#### 4. RESULT AND DISCUSSION

In this case, the prognostic by using ANFIS intelligent system is done by inserting 5 features extracted vibration data as input. Features used are the mean, rms, skewness, kurtosis and betakurtosis. Figure 3 shows the results of the data extraction vibrations into 5 features.

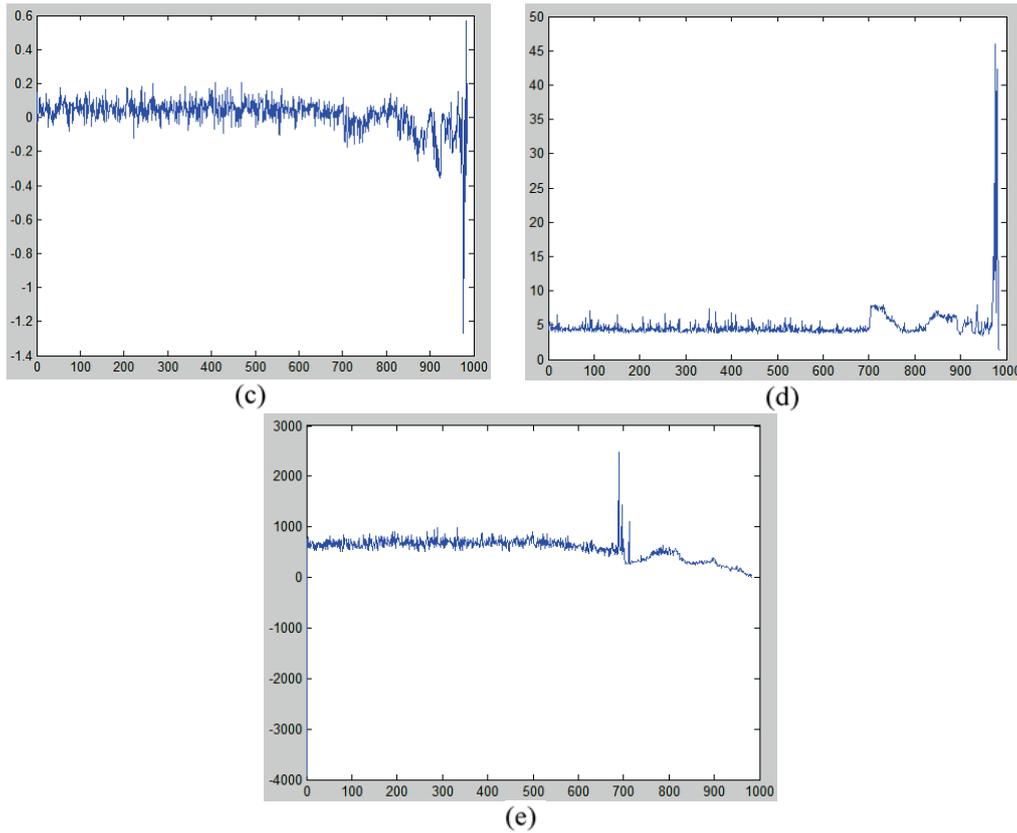

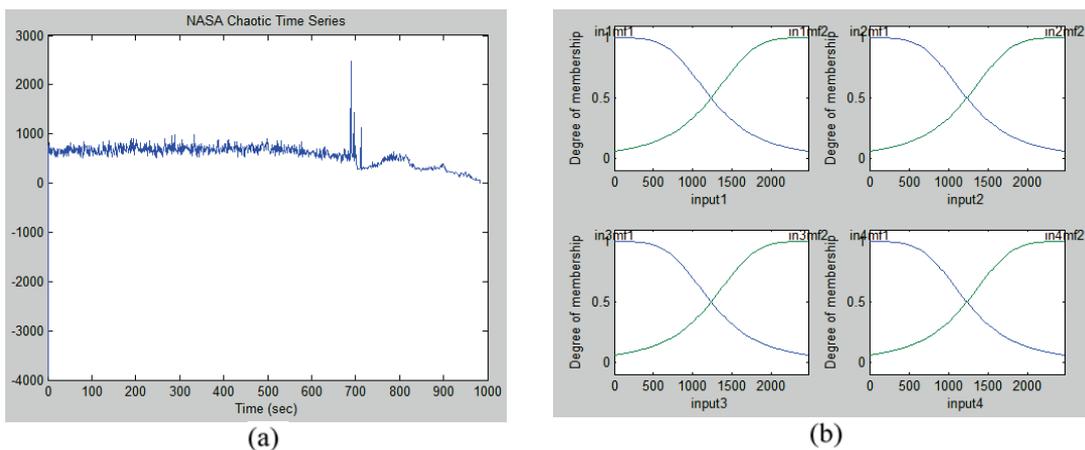

Figure 3. Plotting 5 features extracted from time series vibration data, (a) mean, (b) RMS, (c) skewness, (d) kurtosis, (e) betakurtosis

From the results of plotting to five features in Figure 3, the features of RMS, kurtosis, and betakurtosis has a good overview for doing prognostic. It can be seen that there is a sharp rise uphill to describe the failure.

The number of time series vibration data which used in this research as much as 20480. After the feature extraction, generating matrix of  $984 \times 5$ , which shall mean that each feature has a number of 984 data. From 5 features ANFIS is used as input by taking a number of 800 for training data and 150 for checking data. Figure 4 shows the results of plotting output ANFIS time series prediction.

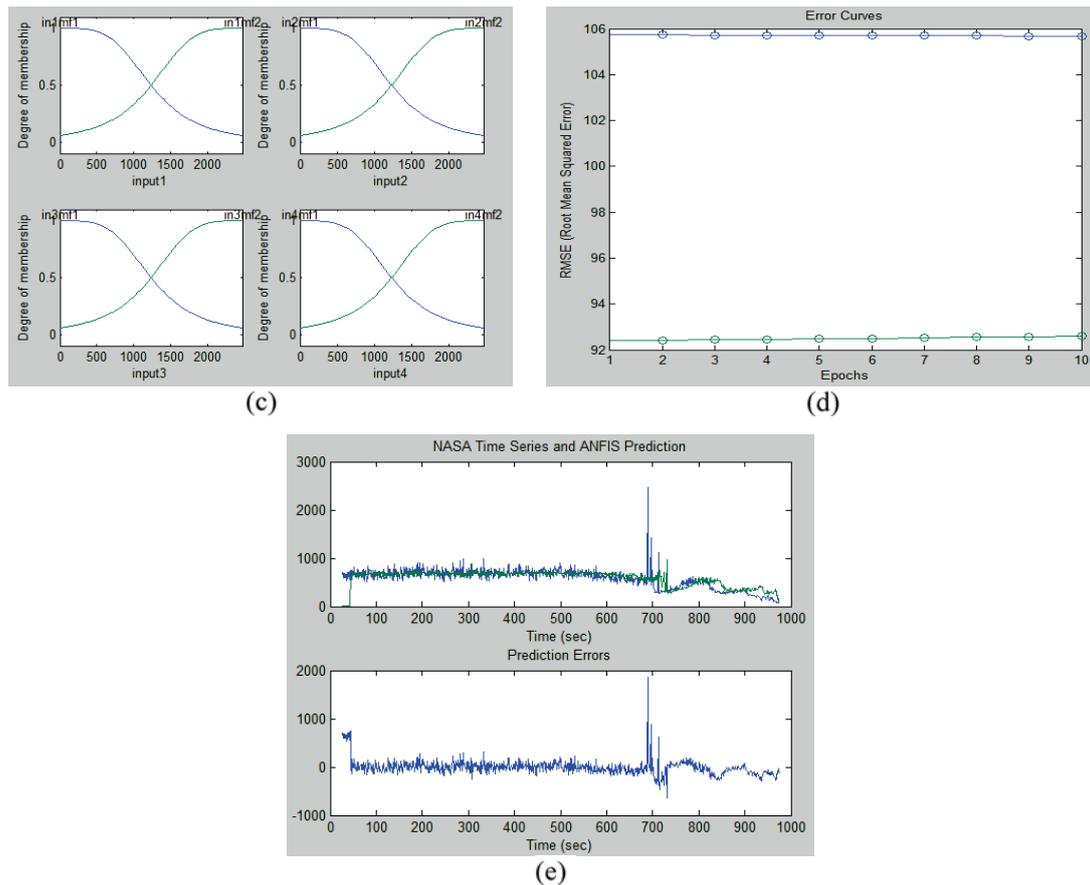

Figure 4. Plotting the results of ANFIS time series prediction, (a) input ANFIS of 5 features, (b) initial membership functions, (c) new membership functions, (d) error signals, (e) FIS output versus the training or checking of data  
 From the results of plotting in Figure 4 (e), ANFIS can show the prediction error curve described by a sharp increase in vibration at  $\pm 700$  seconds.

## 5. CONCLUSION

Prognostic remaining life of rolling bearings function on industrial machines is very important in supporting the CBM. By knowing the RUL, the total failure can be avoided.

ANFIS is a method that is suitable for prognostic. With 5 data input form features extraction (mean, rms, skewness, kurtosis, betakurtosis) of time series vibration data, ANFIS can clearly describe the condition when the failure occurred, so that the remaining life of the function can be determined. This method can run well and as expected as indicated by the value of the error is smaller than RMSE.

This research can be developed online and can also be developed using other feature extraction.

### ABSTRACT

The use of composites for railway brake provides several benefits among others: five times lighter than cast iron, install easily, lifetime five times longer, lower wear rate, cost to lifetime ratio better than other. Studies about composite brake have been done before. Optimum composition have been found also. But when the composition is applied to the manufacture of the prototype, the results are unsatisfactory. Therefore it needs advanced research about composition and procedure of process. In this studies, effect of phenolic resin and alignment would be researched. Results of that studies shows that addition of phenolic resin improve the quality of the prototype. Crack would be occurred if position of the prototype was not alignment with the axis of dies.

## ABSTRACT

This study aims to discover design and car body structure which stream line and aerodynamics and also have the low drag coefficient in order to give economic fuel consumption with minimum side force coefficient and low drag force coefficient to keep out the skidding.

The experimental methods used in this study with a subsonic wind tunnel by model dimensions as 30 cm x 30 cm x 48 cm with experimental specimen on the scale of 1/33 than the actual dimensions. The simulations of this study used ANSYS fluent 13.0 program to make the vector visualization analysis for the velocity vectors and the form of air flow with the pressure distribution and the streamlines.

The result of this experiment showed that on the normal angle or (0°) give the drag coefficient as 0,311259, the lift forced coefficient as 0,045312 and the number of side forced coefficient as 0.415493 that showed the car body has very aerodynamically. The form of flow pattern at the car body which designed has in streamlines conditions that it was showed on the low turbulence flow presentation. The number of drag coefficient and the number of lift coefficient from the result simulation was not so far different than the experimental study which of 0,318525 for the drag coefficient and the lift coefficient of 0,04206875.

### Keywords

*Characteristics, Sport Car Body, aerodynamics.*

## 1. INTRODUCTION

Vehicle body shape is closely related to the aerodynamic load. Range of aerodynamic loads are grouped into 3 drag force, lift force and side force. Drag force is the force that are inhibiting the direction the vehicle. Lift force is the force that are raising vehicles side force is the force pushing the vehicle laterally nature. Drag force, lift force and side force is affected by the shape of the contours of the vehicle body, vehicle dimensions and speed of the vehicle.

## 2. REFERENCES

Viscosity caused by the molecular friction between the fluid particles. According to Newton's law for flow in a parallel plate is

$$\tau = \mu \frac{du}{dy} \dots\dots\dots(1.)$$

Shear stress  $\tau$  is proportional to the magnitude of the velocity gradient .

$\mu$  is constant factor properties of the fluid is called the dynamic viscosity. In general, this constant factor is temperature dependent.

$$\nu = \frac{\mu}{\rho} \dots\dots\dots(2.)$$

Continuity Equation. The basic principle of this equation is the mass can not be created and can not be destroyed, in which the mass in a system constant can be expressed in the formula:

$$Q = A_1 \cdot v_1 = A_2 \cdot v_2 \dots\dots\dots(3.)$$

Momentum Equation. Newton's second law equation for a system used as a basis to seek a linear equation for a control volume.

$$F = \frac{d(mv)}{dt} \dots\dots\dots(4.)$$

Bernoulli Equation :

$$gz + \frac{v^2}{2} + \frac{P}{\rho} = \text{konstan} \dots\dots\dots(5.)$$

The amount of aerodynamic drag can be formulated:

$$F_D = C_D \cdot \frac{\rho}{2} \cdot A_F \cdot V^2 \dots\dots\dots(6.)$$

The magnitude of the lift force has a formula:

$$F_L = C_L \cdot \frac{\rho}{2} \cdot A_F \cdot V^2 \dots\dots\dots(7.)$$

Great addition to the aerodynamic force is can be formulated:

$$F_S = C_S \cdot \frac{\rho}{2} \cdot A_F \cdot V^2 \dots\dots\dots(8.)$$

### 3. RESEARCH METHODS

Specimens used in size (L x W x T) is 12.6 cm x 5.9 cm x 4 cm, or 1/33 times the actual size.

Fig. 1<sup>st</sup>. Sport Car Body Model.

Experimental method is done using a wind tunnel. Wind tunnel used to study the interaction between objects moving relative to the air against the body. The type of wind tunnel used is kind of low turbulence subsonic wind tunnel.

Fig. 2<sup>nd</sup> . Low turbulence subsonic wind tunnel.

#### 4. DISCUSSION AND THE RESEARCH RESULTS

Experimentally test results demonstrate the value of the coefficient of drag force on a scaled body as shown below.

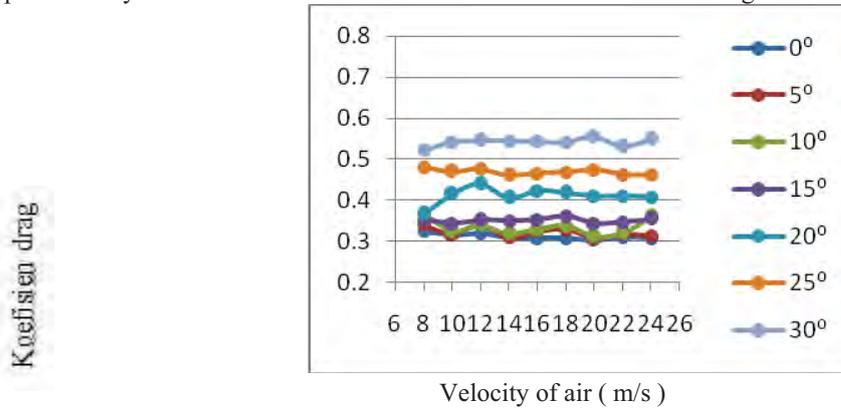

Fig. 3<sup>rd</sup>. Graph drag force coefficient correlation of test results versus of velocity of air.

Curve at an angle of attack  $0^\circ$ ,  $5^\circ$  and  $10^\circ$  drag coefficient indicates the difference is not too big a difference. In contrast to the curve with the angle of attack  $15^\circ$ ,  $20^\circ$ ,  $25^\circ$  and  $30^\circ$  showed a considerable difference in terms of the difference is due to the increase frontal area large enough so that the drag force caused magnification value. curve at angle of attack  $15^\circ$ ,  $25^\circ$  and  $30^\circ$  shows the drag coefficient is quite stable, this is caused airflow stable and so that the coefficient of drag is much influenced by the style of sliding surface, in contrast to the curve with the angle of attack  $0^\circ$ ,  $20^\circ$  and  $30^\circ$  coefficient of drag fluctuations.

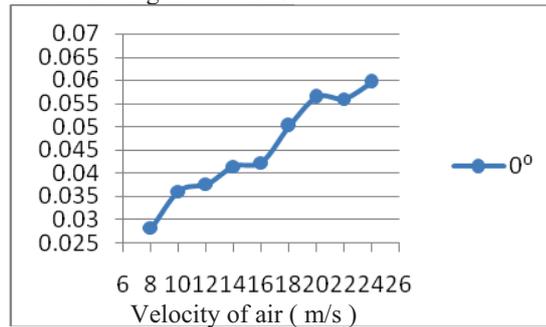

Fig. 4<sup>th</sup>. Graph lift force coefficient correlation of test results versus velocity of air

The graph above shows the curve of the ratio between lift coefficient with air velocity. of the image is visible lift coefficient increases quite sharply at a flow rate of 8 m / s to 20 m / s it is comparable to the value of the coefficient of drag.

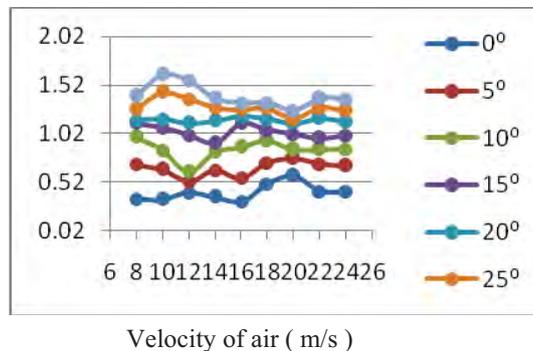

Fig. 5<sup>th</sup> Graph relations side force coefficient versus velocity of air test results.

Side force coefficient at 25o and 30o angle of attack decreased and this is because the speed of stream flow momentum increases. Coefficient of side force on the angle of attack 0°, 5°, 10°, 15° coefficients tend to be unstable. On the curve with the angle of attack 20o side force coefficient tends to be stable. Value Coefficient Drag Force and Lift Force Research with fluent was made to resemble the actual conditions on the highway where the ambient temperature is expected to range from 40° C, while the value of the coefficient of drag force and lift force shown in below. The research with fluent was made to resemble the actual conditions on the highway where the ambient temperature is expected to range from 40 ° C, while the value of the coefficient of drag force and lift forcenya shown in below. From the above table it can be seen that the average value of the coefficient of drag force simulation results in the range of 0.3185. The figure below shows the speed of the air flow on the surface of the body with the air flow velocity parameters at the inlet surface of 69.44 m / s.

Fig. 6<sup>th</sup> Velocity of air flow at the front body interface.

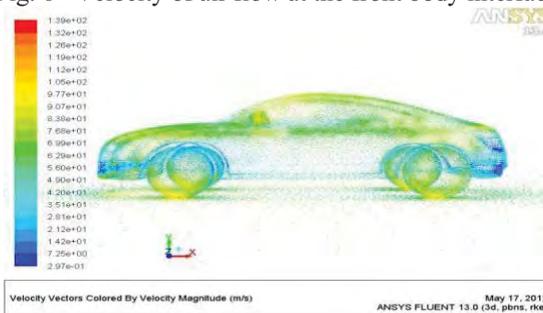

Fig. 7<sup>th</sup> Velocity of air flow at the side body interface.

The top image shows that the greatest pressure on the front surface, and the windshield and rear view mirror car. This affects the value of the coefficient of drag. While the lowest pressure occurs in the bottom of the front body, rear view mirror, roof and rear body upper body.

## 5. CONCLUSIONS

The results scale car body using wind tunnel and simulation using fluent ANSYS 13.0 can be concluded as follows:

1. Experimental results on a normal angle (0°) obtained drag coefficient of 0.311259, and 0.045312 for coefficient of lift force and side force coefficient value of 0.415493. which means the body of the car is very aerodynamic.
2. Coefficient of drag force and side force will increase with increasing angle of attack this is due to the increase in the frontal area of the angle of attack will increase.
3. Based on the analysis carried out by the program ANSYS fluent indicate a change in the value of the pressure at the surface of the body, caused by changes in fluid flow velocity.
4. Shape the flow pattern on the body that planned already streamlined, it can be seen in the percentage of very small flow turbulence.
5. Drag and Lift coefficient value simulation results do not very much with the results of experimental testing. ie 0.318525 to coefficient of drag and coefficient of lift at 0.04206875.

## ABSTRACT

Application of multi-hull ships as marine transportation began to grow rapidly at the present. Advantages of pentamaran due to lower draught with the same displacement of monohull. This study aimed to determine the effect of variations in separation and staggered of side hull I to the total resistances to get the configuration with the lowest resistance interference. Configuration varied by adjusting the separation and staggered of side hull I. Method of towing tank experiments are used with variations of Froude number from 0,10 to 0,70. Conclusion, the highest drag reduction of Fr less than 0,40 is II.a configuration (S/L = 3/16, R/L = 1/20) with a maximum percentage of 46,14%, the Fr around 0,50 is III.B configuration (S/L = 2/16, R/L = 3/20) with a maximum percentage of 43,94%, but, while the Fr higher than 0,55 back to II.a configuration. The influence of the configuration to the resistances depends on the value of Fr, the influence of hull separation indicates the closer hull with the other gives a high interference resistance, while the influence of staggered hull indicates the position of side hull I in optimal separation will give the lowest resistance in mid staggered positions.

## Keywords

*Pentamaran, resistance, side hull I, hull separation, staggered hull.*

## 1. INTRODUCTION

Pentamaran with five hulls is the development of multihull ships catamaran, trimaran and quadrimaran. Determination of the number of hull in multihull ships will give different characteristics. Pentamaran recently started to be developed in Europe as freight transport (High Speed Cargo Ship), passenger transport (High Speed Ferry), troops transport (Sea lift), patrol boats (Combatant), and other high speed craft.

Development of the research in multihull associated with one of the efforts to reduce ship resistances by modifying the ship hull form which is an example of passive control resistances, which passive control can provide relatively high reduction percentage of resistances. Characteristics of pentamaran ship that can have much smaller resistances at high speed compared to monohull vessel will give efficiency in fuel consumption, time and operational costs in the voyage.

Researches on total hull resistance in pentamaran ship model is still a significant challenge for researchers in determining the precise characteristics of the interactions that occurred in each hull, so it is still being developed better configuration to get the lowest resistance interference.

This study aimed to determine the effect of variations in the distance of side hull I longitudinally (staggered hull) and transversely (hull separation) to the total resistance asymmetrical pentamaran models for wave and viscous resistance interference that produces the lowest resistances.

## 2. MULTIHULL AND PENTAMARAN CONCEPT

The effect of hydrodynamic hull form type, side-hull configurations, position, displacement, transverse and longitudinal location can be varied to obtain the lowest resistances and better seakeeping characteristics. Displacement of side-hull influences on frictional resistance and stability, position can determine the effects of the interaction between side-hull and main hull, stability, and rolling parameters. There are three types design of multi-hull ship, symmetric, asymmetric inboard and asymmetric outboard as shown in figure 1. Symmetric side-hull much influences on the magnitude of the interference effect between main hull and side-hull. Asymmetric inboard configuration is likely to show the greatest variation in the magnitude of the interaction and produce interference effects are very high or very low on some speed and position of side-hull. Symmetric side-hull configuration also showed variation but not as extreme asymmetric inboard configuration. Eventually, for asymmetric

outboard configuration produces the smallest interference variations [Oller et al, 2003].

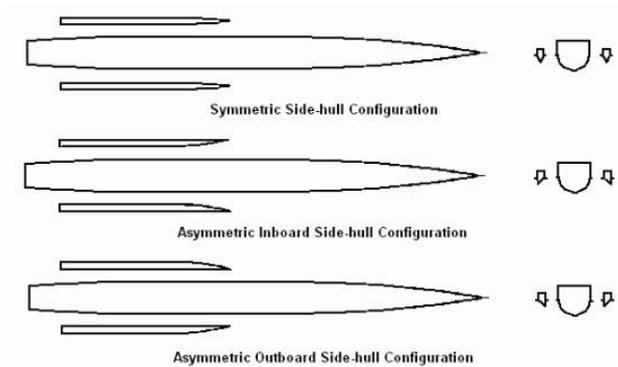

Figure 1: Hull form type of trimaran [Acker et al, 1997]

The type of body plan hull form is divided into :

- Round Bilge
- Hard chine

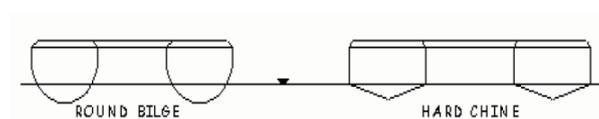

Figure 2: Hull form type of catamaran body plan

Type of hard chine hull form is simple and straightforward in construction work. This hull type has a larger static wetted surface area so that it improves frictional resistance at low speeds. While at high speed, the wetted surface area will lose due to the presence of dynamic lift. Round bilge hull types are suitable for more loads and low speed. This hull type has a relatively small movement, and not prone to the waves (slamming) so as to provide comfort to the extreme wave conditions. Usually this type of hull fitted with sprayer on the bow to reduce the effects of water spray.

Pentamaran is a type of multihull ships, slender hull (high ratio L/B) with one main hull and four side hulls [Gee, 2005]. Main hull is optimized to get the minimum resistances for deadweight and certain speeds. Side-hull configuration is designed and arranged to deliver the expected stability characteristics. The use of four side-hulls to replace the two side-hulls of the trimaran provides better stability at minimum drag and rolling resistance, Pentamaran provide the possibility of power constraints and most small and seakeeping characteristic is better.

Pentamaran design advantage is [Gee, 1999]:

- a) The need for low power
- b) Loss of speed due to waves is lower
- c) Very good of seakeeping characteristics

### 3. EXPERIMENTAL SET-UP

Referring to R.V. Triton trimaran [Research Vessel Triton, 2001] which uses asymmetric outboard configuration of side-hull, then on the model in this study used asymmetric outboard configuration pentamaran model for side hull I and side hull II, while the body plan hull form is designed for ships with more load, so, the selected types Bilge round. Displacement models of multihull for towing tank test are same as monohull displacement. Pentamaran ship models are designed as shown in Figure 3 - 6. Model specifications as shown in Table 1.

Table 1: Model hull specification

Main Measure	Main hull	Side hull I	Side hull II	Mono hull
L <sub>OA</sub>	2,00 m	1,00 m	0,75 m	2,00 m
B <sub>I</sub>	0,20 m	0,10 m	0,07 m	0,54 m
T	0,07 m	0,07 m	0,06 m	0,07
H	0,15 m	0,15 m	0,14 m	0,15
C <sub>B</sub>	0,57	0,59	0,58	0,58
C <sub>D</sub>	0,58	0,61	0,60	0,61
WSA	0,39 m <sup>2</sup>	0,18 m <sup>2</sup>	0,11 m <sup>2</sup>	0,83 m <sup>2</sup>
Δ	12,50 kg	3,25 kg	2,75 kg	24,5 kg

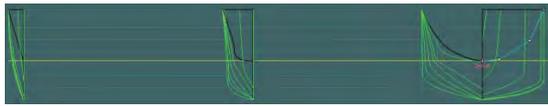

Figure 3: Round bilge type body plan of pentamaran model

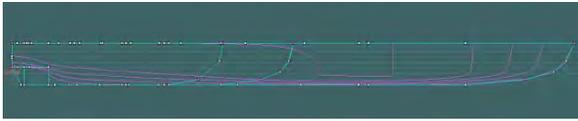

Figure 4: Sheer plan of pentamaran model

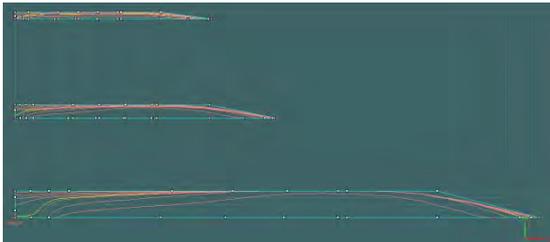

Figure 5: Half breadth plan of pentamaran model

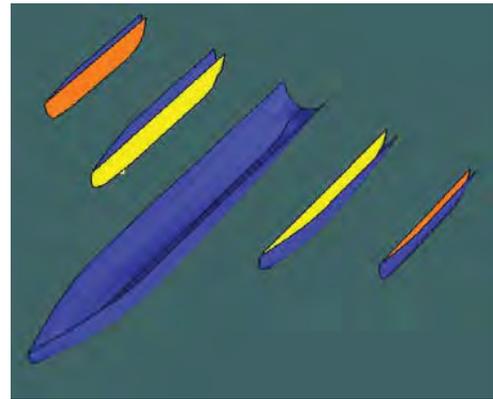

Figure 6: Isometric view of pentamaran model

Towing tank test is performed in the towing tank with a size of 20 m x 8 m x 2 m, Using an electric motor which equipped with voltage regulator to control the velocity, load cell transducer is mounted on the model and associated with the acquisition data to read the value of the model resistance, as shown in figures 7 and 8.

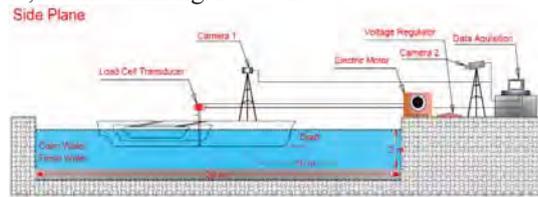

Figure 7: Side plane view of towing tank test set-up

Configuration of pentamaran model is arranged by transverse distance variation (hull separation, S/L) and longitudinal distance variation (staggered hull, R/L). S is transverse separation distance between side hull I to main hull, R is midship longitudinal separation distance between side hull I to main hull, and L is length over all of the model as shown in figure 9 and 10 below.

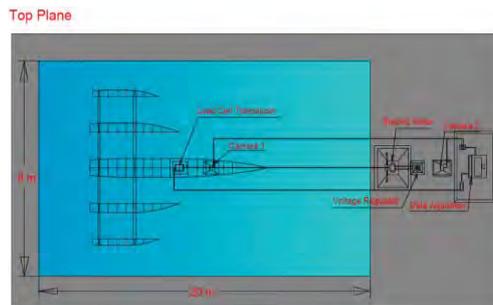

Figure 8: Top plane view of towing tank test set-up

#### 4. TEST ANALYSIS

International Towing Tank Conference (ITTC) classifies ship resistance in calm water into two components, these are viscous resistance which related with Reynolds number and residual resistance, those are wave resistance which related with Froude number, component of air resistance as residual resistance can be ignored because in the model testing, superstructure is not used, only the characteristic of the hull resistance is tested, so the coefficient of total resistances can be defined as :

$$R_T = R_V + R_W \tag{1}$$

$$C_T = C_V + C_W \tag{2}$$

$$C_T = (1 + \phi k) \sigma C_F + \tau C_W \tag{3}$$

$$C_T = (1 + \beta k)C_F + \tau C_w \quad (4)$$

Which  $R_T$  is total resistance,  $R_V$  is viscous resistance,  $R_w$  is wave resistance,  $C_T$  is the total resistance's coefficient,  $C_V$  is the viscous resistance's coefficient,  $C_W$  is the coefficient of residual wave resistance,  $C_F$  is the frictional resistance's coefficient,  $k$  is the hull shape factor,  $\phi$  is the factor of pressure change in the hull,  $\sigma$  is the increasing factor of velocity-stream around the hull,  $\tau$  is the interference factor of wave resistance. For practical purpose,  $\phi$  and  $\sigma$  can be combined [Insel and Molland, 1991 and 1992] into viscous resistance's interference, that is  $\beta$  factor, which  $(1+\phi k)\sigma = (1+\beta k)$ . From the towing tank test results, total resistance's coefficient  $C_T$  can be calculated with formula below :

$$C_T = \frac{R_T}{0.5\rho S V^2} \quad (5)$$

which  $\rho$  is the density of water and  $S$  is the wetted surface area,  $V$  is the velocity of the ship. Total resistance can be defined as :

$$R_T = \frac{1}{2} C_T \rho V^2 S \quad (6)$$

Froude number and Reynolds number defined it as :

$$Fr = \frac{V}{\sqrt{gL}} \quad (7)$$

$$Re = \frac{VL}{\nu} \quad (8)$$

where  $L$  is the length of the ship,  $g$  is the acceleration of gravity and  $\nu$  is water kinematic viscosity. The drag reduction of pentamaran model to model *monohull* stated as :

$$DR(\%) = \left| \frac{C_T - C_{TO}}{C_{TO}} \right| \times 100\% \quad (9)$$

which  $DR$  is the percentage of Drag reduction,  $C_T$  is the coefficient of pentamaran model's total resistance.  $C_{TO}$  is the coefficient of monohull model's total resistance (displasemen monohul equal to displasemen pentamaran).

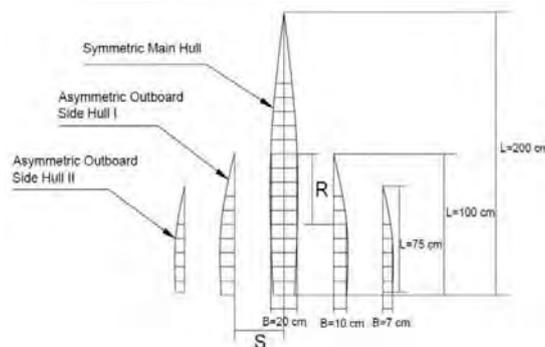

Figure 9: Configuration of asymmetrical pentamaran model

## 5. RESULTS AND DISCUSSION

### 5.1 Influence of Hull Separation (S/L) of side hull I

#### 5.1.1 Hull Separation (S/L) in The Configuration I

From the graph that shows relation between  $Fr$  and  $C_T$ , as shown in figure 12, generally, I.c configuration has the highest total resistance's coefficient value compared to the other configuration, while I.a configuration is the lowest.

#### 5.1.2 Hull Separation (S/L) in The Configuration II

From the graph below, shows relation between  $Fr$  and  $C_T$  as shown in figure 14, II.c configuration generally has the highest total resistance's coefficient value compared to the other configuration, while II.a configuration is the lowest.

#### 5.1.3 Hull Separation (S/L) in The Configuration III

From the graph below, shows relation between  $Fr$  and  $C_T$  as shown in figure 16, generally, III.a configuration has the highest total resistance's coefficient value, while III.b configuration has the lowest resistance coefficient.

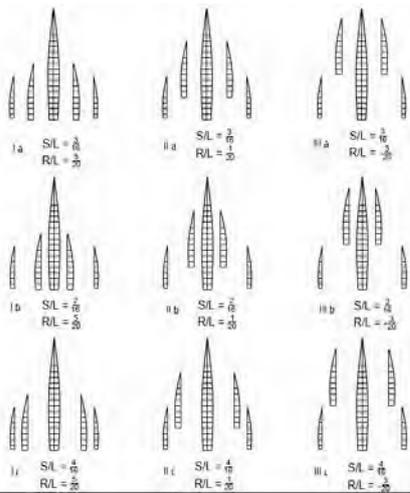

Figure 10: Separation and staggered hull configuration of side hull I

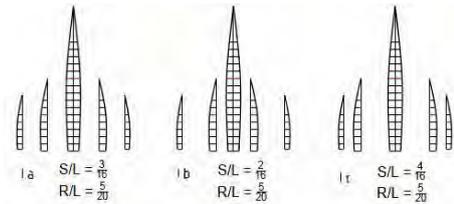

Figure 11: Hull separation (S/L) in the configuration I

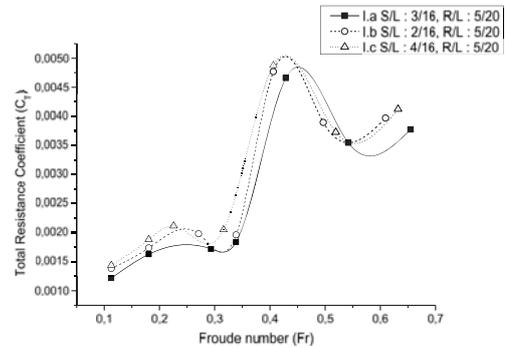

Figure 12: Comparison of Froude number (Fr) with total resistance's coefficient ( $C_T$ ) of hull separation (S/L) in the configuration I

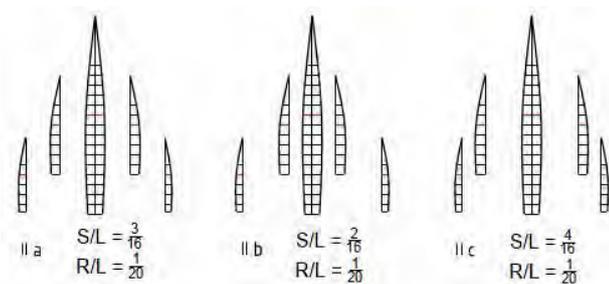

Figure 13: Hull separation (S/L) in the configuration II

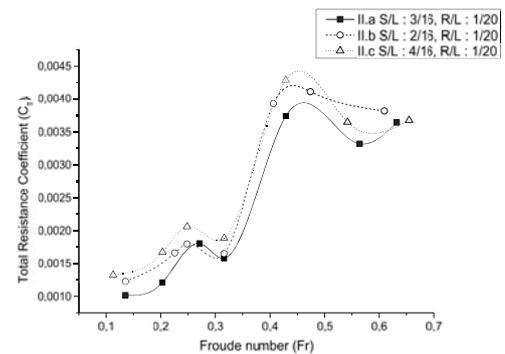

Figure 14: Comparison of Froude number (Fr) with total resistance's coefficient ( $C_T$ ) of hull separation (S/L) in the configuration II

## 5.2 Influence of Staggered Hull (R/L) of side hull I

### 5.2.1 Staggered Hull (R/L) in The Configuration (a)

From the graph below, shows relation between Fr and  $C_T$  as shown in figure 18, generally, III.a configuration has the highest total resistance's coefficient value, while II.a configuration is the lowest.

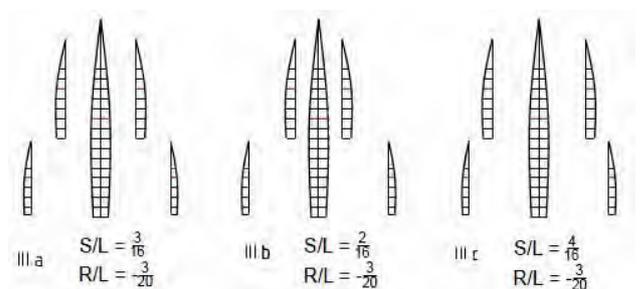

Figure 15: Hull separation (S/L) in the configuration III

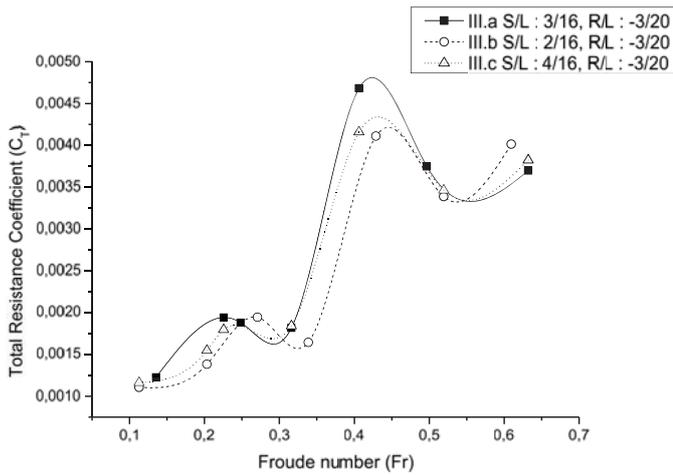

Figure 16: Comparison of Froude number (Fr) with total resistance's coefficient ( $C_T$ ) of hull separation (S/L) in the configuration III

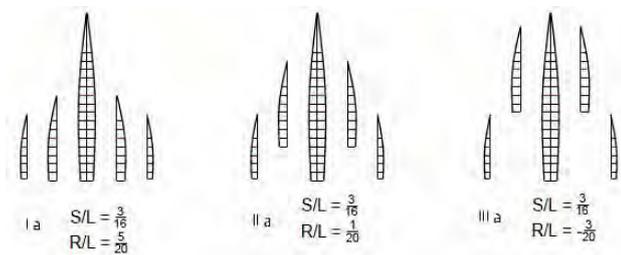

Figure 17: Staggered hull (R/L) in the configuration (a)

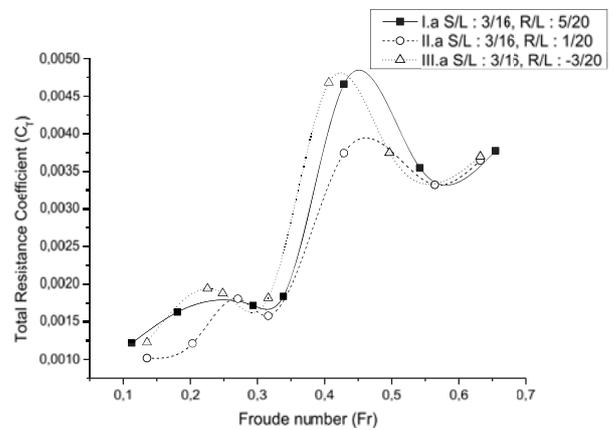

Figure 18: Comparison of Froude number (Fr) with total resistance's coefficient ( $C_T$ ) of Staggered hull (R/L) in the configuration (a)

### 5.2.2 Staggered Hull (R/L) in The Configuration (b)

From the graph below, shows relation between Fr and  $C_T$  as shown in figure 20, the characteristic of the resistance in each configurations are more varied to Froude number. When the Froude number are lower than 0,40, I.b configuration is tend to has highest resistance but when the Froude number are more than 0,40, II.b configuration has the highest resistance. The lowest resistance is belong to III.b configuration.

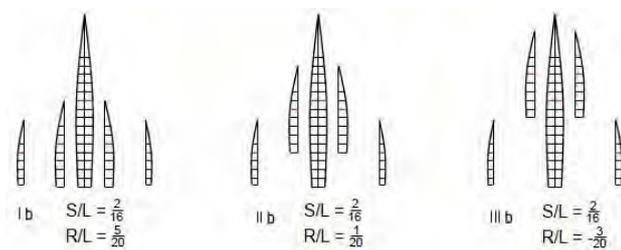

Figure 19: Staggered hull (R/L) in the configuration (b)

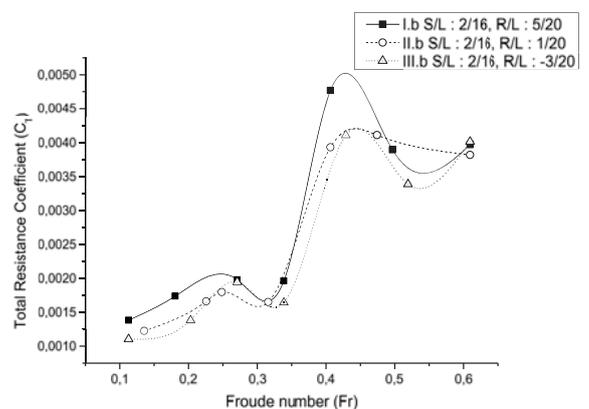

Figure 20: Comparison of Froude number (Fr) with total resistance's coefficient ( $C_T$ ) of staggered hull (R/L) in the configuration (b)

### 5.2.3 Staggered Hull (R/L) in The Configuration (c)

From the graph below, shows relation between Fr and  $C_T$  as shown in figure 22, generally in all range of Froude number I.c

configuration are tend to has highest resistance, while the lowest resistance occurred in III.c configuration.

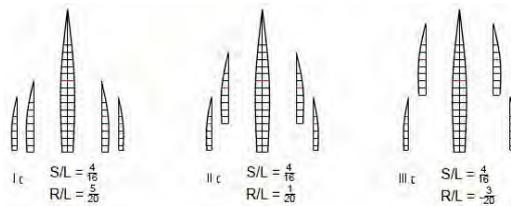

Figure 21: Staggered hull (R/L) in the configuration (c)

### 5.3 Comparison of Multihull Configuration and Monohull with Total Hull Resistance

In figure 23 and 24 show the relation between Froude number and total resistance's coefficient in each various configuration to monohull. In a low Froude number, monohull has relatively lower resistance compared to multihull pentamaran's model, it's because viscous resistance greatly affected the ship model, when the ship model's in the low velocity multihull's model has larger wetted surface area than monohull. When the velocity and Froude number increase, model's resistance of monohull rise and become higher than multihull, because the component of wave resistance is more dominant in the high velocity. In the pentamaran's multihull model which the L/B's ratio is larger (Slender Body) than monohull, will give advantage with the drag reduction of the wave's occurred, because of the L/B's ratio of the ship, wave pressure factor to the ship hull decrease and also can reduce the occurrence of transversal and divergent wave which affected by hull's shape factor. It's also clear that in the multihull's model graph appeared Hump and Hollow phenomenon, that's occurred because wave interference factor, which Hump, because of constructive interferences, so the wave resistance rise drastically, Hollow, because of destructive interferences so the wave resistance will fall drastically. In the graph of  $Fr$  vs  $C_T$ , for the transverse variations I (a,b, and c) Hump occurred dominantly around Froude number 0,40, while in the longitudinal variations II dan III (a,b, and c), Hollow, are tend to occurred dominantly in the range of Froude number between 0,30 dan 0,55. That's occurred because in the configuration I, which all of the hulls are longitudinally aligned, in the back side, there's occurred high wave resistance interferences compared when the position of side hull I more ahead. While in the medium velocities, configurations II and III, destructive interferences are tend to occurred.

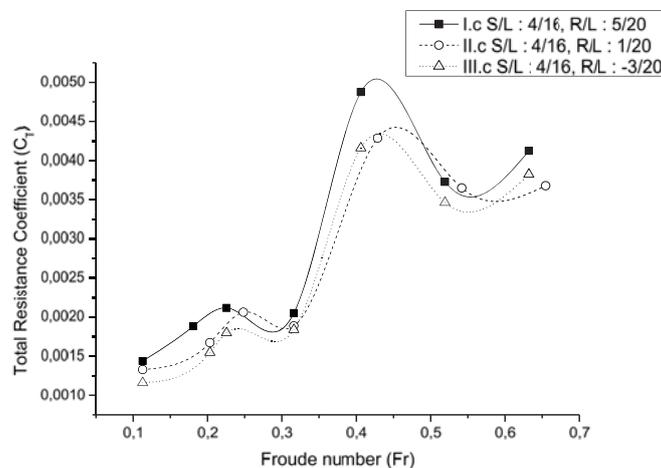

Figure 22: Comparison of Froude number ( $Fr$ ) with total resistance's coefficient ( $C_T$ ) of staggered hull (R/L) in the configuration (c)

In figure 24 shows the relation between configuration and total resistance's coefficient which shows the characteristic of each resistance in velocity levels. in the range of Froude number up to 0,35, the value of the resistance is still quite low due to hollow's occurring . then when the range of Froude number are between 0,35-0,45, a very impressive increasing of resistance-value's occurred. And it's caused by hump phenomenon, and then when the Froude number is more than 0,45, resistance's values of multihull are tend to fall because the hollow phenomenon is occurred again, but that doesn't happen in monohull, where resistance's values are still rising. The II.a configuration looks like the configuration which has the lowest resistance's values in almost all of Froude number range.

### 5.4 Drag reduction

The drag reduction in each configurations can be compared with resistances in monohull. Figure 25 shows percentage of drag reduction in each pentamaran configurations to monohull in the range of Froude number. In the low Froude number around

0,20, drag reduction are negative, these mean that in the low velocity, pentamaran's model has larger total resistance than monohull. But in the medium or high velocity, the percentage of drag reduction is tend to rise, caused by the domination of wave resistance factor so the pentamaran multihull-ship's model has lower total resistance. From that graph, we can conclude that the highest drag reduction in the low velocities (Froude number are less than 0,40) is II.a configuration with maximum percentage is 46,14 %, while in the Froude number 0,50 is III.b configuration with maximum percentage is 43,94 %, and in the Froude number more than 0,55 is II.a configuration with maximum percentage is 37,18 %. For the lowest drag reduction in the low velocities (Froude number are less than 0,40) is I.c configuration with minimum percentage is -34,26 %, while in the high velocities (Froude number are more than 0,40) is I.c configuration with minimum percentage is -12,08 %.

Those drag reduction's values are the approach to estimate drag reduction in pentamaran multihull's model. As shown in the graph that the percentages always change to Froude number, as shown in figure 25. in II.a configuration, the highest drag reduction is not always happened, in the Froude number around 0,5, III.b configuration creates higher drag reduction than the other configurations, and then when the Froude number are more than 0,55 II.a configuration creates highest drag reduction again. III.b configuration with position of side hull I is leading longitudinally and closer to main hull transversely with the distance from side hull I to side hull II is also the farthest. This configuration can create high drag reduction, because in the high velocities, waves interactions in one hull to another are so small.

## 6. CONCLUSION

- 1) Effect of variation indicates transverse configuration with  $S/L = 3/16$  have the lowest resistances on each configuration I and II, this is because the ratio of the distance side hull I by other hull was not too close so that the interaction of the incoming and outgoing waves are also more lower.
- 2) Effect of longitudinal variation more varied when compared to the transverse variation, therefore the analysis is restricted to the longitudinal variation of the transverse variation of (a) ( $S/L = 3/16$ ). In the longitudinal variation I.a, II.a, and III.a lowest resistance are II.a configuration ( $S/L = 3/16, R/L = 1/20$ ) with the position of side hull I was in the middle longitudinally. This happens may due to the configuration of the transverse and longitudinal wave interference occurred destructively when waves flow through the hull, resulting in the phenomenon that occurs Hump and Hollow is also relatively low compared to other configurations.
- 3) In the low Froude number, monohull model has relatively lower resistance than multihull pentamaran model, it happens because viscous resistance is greatly affected the ship model when its velocity is low, cause multihull model has grater wetted surface areas than monohull. In the high Froude number the resistance of monohull model is higher than multihull model because the component of wave resistance is highly dominated in the high velocity.
- 4) In the graph  $Fr$  vs  $C_T$  for longitudinal variations, I (a,b,and c), Hump are occurred dominantly in the range of Froude number around 0,40, while in the transverse variations, II and III (a,b, and c), Hollow are tend to occurred dominantly in the range of Froude number between 0,30 to 0,55. These are because configuration I, which all of the hull are aligned longitudinally in the back side, higher wave resistance interferences will be occurred than when position of the side hull I are relatively ahead.
- 5) We can conclude that the highest drag reduction in the low velocities (Froude number are less than 0,40) is II.a configuration with maximum percentage is 46,14 %, while in the Froude's value 0,50 is III.b configuration with maximum percentage is 43,94 %, and in the Froude number more than 0,55 is II.a configuration with maximum percentage is 37,18 %. For the lowest drag reduction in the low velocities (Froude number are less than 0,40) is I.c configuration with minimum percentage is -34,26 %, while in the high velocities (Froude number are more than 0,40) is I.c configuration with minimum percentage is -12,08 %.
- 6) The percentage of drag reduction the approach to estimate drag reduction in pentamaran multihull modell. In determining the optimal configuration to get the lowest total resistance on the pentamaran's hull spacing variation, is affected by its Froude number, where in the high or low velocities, waves resistance interference and viscous are varies.

## ABSTRACT

Formaldehyde is one of the gaseous pollutants, pollutants produced from cigarette smoke. Medically, smoke can cause health problems, irritation and even the risk of death, lung cancer. The importance of the study of air quality provides information of quantity of pollutants in the air also contains information on human health risks. Conditions actual at the site, installed one unit mechanic ventilation system simple flow hygro, in simulation were performed using transient weather conditions for locations in Mériadec, France. Sources of pollutants, formaldehyde, generated from cigarette smoke which produced by one person and five people in the room. Furthermore, pollutants placed in bedroom number 1 with the properties of the pollutants, molecular weight of 30.03 kg / kmol, another information one smoker produces 3.7 µg formaldehyde per second. By using a numerical method, quantity of pollutants will be discovered at each part of the room which determined at a specific time period. The content of formaldehyde at previous condition will be compared with conditions in tropical region, Depok, Indonesia.

## 1. INTRODUCTION

The room modern architecture around the chambers made of glass, the air temperature in a room maintained at a certain temperature, equipped with air freshener, comfortable, does not cause sweating. It will unconsciously cause health problems sick building syndrome symptoms can be experienced physically as sore throat, body fatigue, dizziness, eye irritation and so commonly seen in buildings that do not noticed aspects of the ventilation. Without realizing, the source of pollution is inside the building itself. Therefore the role of ventilation is necessary here.

Residential building ventilation, especially referring to the air exchange occurs between the outside and inside, it can also refer to the air distribution between the rooms or in connection with the flow of air in the room. Indoor ventilation can occur naturally or mechanically. Natural ventilation commonly refers to movement of the air that is affected by the opening of doors and windows, also infiltration. As for mechanical ventilation, there are three types of systems; insufflation mechanical ventilation systems, mechanical ventilation systems simple flow and mechanical ventilation system double flow.

According to the study of human activity, nearly 80% of the time, used to perform activities indoor (at home, in offices, restaurants, mostly (at transport, etc.)<sup>1</sup>. Therefore it is very important to ensure the availability of fresh air for indoor areas which have good quality and sufficient quantity.

The purpose of this research studied the extraction of pollutants by using a simple flow mechanical ventilation. The reference based on the standard ASHRAE (American Society of Heating Refrigerating and Air Conditioning Engineers) 2009 Fundamentals (SI Edition).

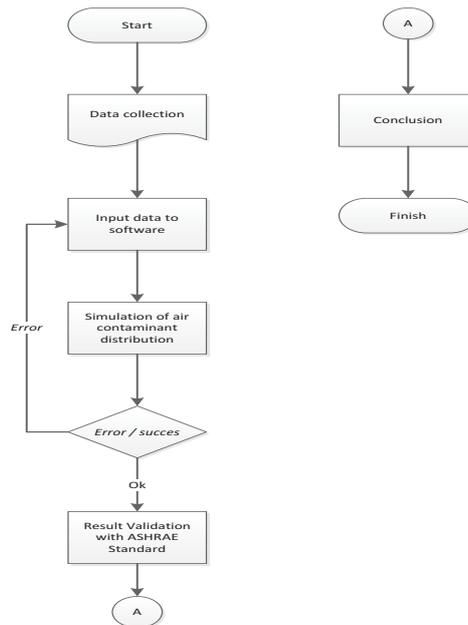

Figure 1: Simulation flowchart

In the early stages before performing numerical simulations, the first thing to do is drawing a building model for simulation. After that, input parameters with the necessary data. The data parameters can be obtained from the literature or the recommendations of previous study. Then the next step is simulating model to see the results. If there are errors, it has to do a review of the parameters entered. Further repeat the simulation to see the results running or not. If the results obtained in accordance with the ASHRAE standards, the installation of mechanical ventilation simple flow system is sufficient to extract air pollutants to outdoor.

## 2. SIMULATION ASPECT

### 2.1 Preparation of Simulation.

CONTAM is a multizone indoor air quality and ventilation analysis computer program designed to help for determine airflows, contaminant concentration and personal exposure. CONTAM version 3.0 is tools to simulate the models.

#### 2.1.1 Transient Weather Data.

The type of weather data which require for a simulation depends on the type of simulation. For this simulation using a transient airflow simulation. Transient weather data is implemented through the use of weather files or WTH files.

#### 2.1.2 Basic Model

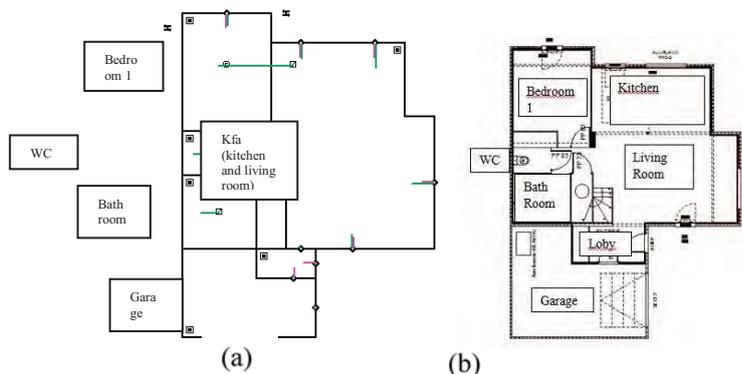

Figure 2: (a)Basic model sketch pad CONTAM, (b)Layout of the house

Basic model is a models which use in simulation.

#### 2.1.3 Elements of Airflow

Airflow paths : Airflow through various airflow elements provided by CONTAM is modeled using either a powerlaw or quadratic relationship between airflow and pressure difference across the flow path. These relationships are models

themselves, and care should be taken when implementing them to represent building features within models idealized buildings.

Leakage area : The powerlaw model can be used with the component leakage area formulation which has been used to characterize openings for infiltration calculations [ASHRAE 2001, p. 25.18]. The leakage area is based on a series of pressurization tests where the airflow rate is measured at a series of pressure differences ranging from about 10 Pa to 75 Pa. The effective leakage area is based on a rearrangement of equation (1).

$$L = \frac{Q_r \sqrt{\rho / 2\Delta P_r}}{C_d} \quad (1)$$

Where  $L$  is equivalent or effective leakage ( $m^2$ ),  $\Delta P_r$  is reference pressure difference (Pa),  $Q_r$  is predicted airflow rate at  $\Delta P_r$ ,  $C_d$  is discharge coefficient. There are two common sets of reference condition  $C_d=1$  at pressure difference 4 Pa and  $C_d=0.6$  at pressure difference 10 Pa.

The CONTAMW Library Manager, shown in the following figure, is a dialog box that is displayed when access data elements from the Data menu or by clicking on a "Library" button when editing the properties of one of the building components that utilizes library data elements. This dialog box is divided into three sections: Library File, Library Elements and Local Project Elements sections. The Library File section displays the name of the currently displayed library file and allows you to save, rename and open new and existing library files. The Library Elements section displays the data elements contained in the library file that is currently listed in the Library File section. The Local Project Elements section displays the data elements that are contained in the current project file.

### 2.2 Contaminant Source and Sink

User can define an unlimited number of contaminants within a single project with a practically limitless number of sources associated with the contaminants. CONTAM can simulate contaminant transport via airflow between zones, removal by filtration mechanisms associated with flow paths, and removal and addition by chemical reaction. CONTAM can also implement several source and sink models to generate contaminants within or remove contaminants from a zone. These models include: constant generation, pressure driven, decaying source, cutoff concentration, reversible boundary layer diffusion, and burst models.

Steady: The steady contaminant option can only be used in conjunction with steady airflows and will run until the system reaches equilibrium. Contaminant sources are modeled as continuous sources with a constant generation rate. If any sources have schedules associated with them, then schedule values will be determined by the Day Type set in the Steady State Weather Data (see Weather Properties under Working with Weather and Wind) and the Steady Simulation Time. Burst sources will be ignored. Ambient contaminant concentrations will be the Default Concentration values of each contaminant.

### 2.3 Schedule

Use this control element to apply a schedule via the control network. A schedule can be applied to airflow paths, simple air handling systems, inlets and outlets of simple air handling systems and source/sinks. Control schedules will override schedules that are defined as a parameter of an element.

Days	No. Of Smoker	Hour
Sunday	1	18 to 20
Monday	1	18 to 20
Tuesday	1	18 to 20
Wednesday	1	18 to 20
Thursday	5	20 to 22
Friday	0	-
Saturday	0	-

Figure 3: Schedule control air handling system source/sink

### 3. SIMULATION RESULT

#### 3.1 Condition Weather France

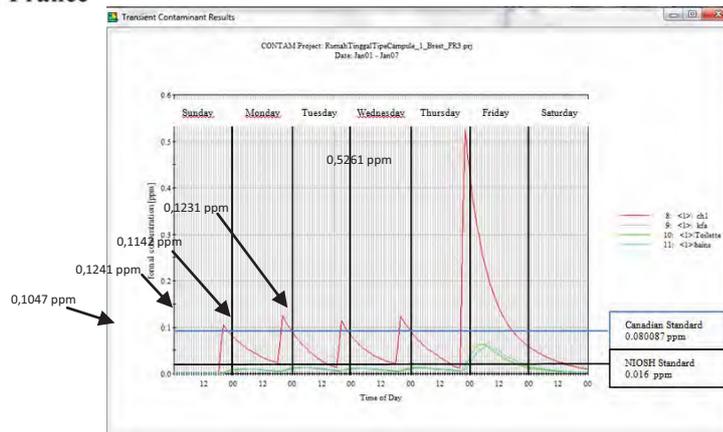

Figure 4: Transient formaldehyde result, condition weather France

#### 3.2 Condition Depok Indonesia

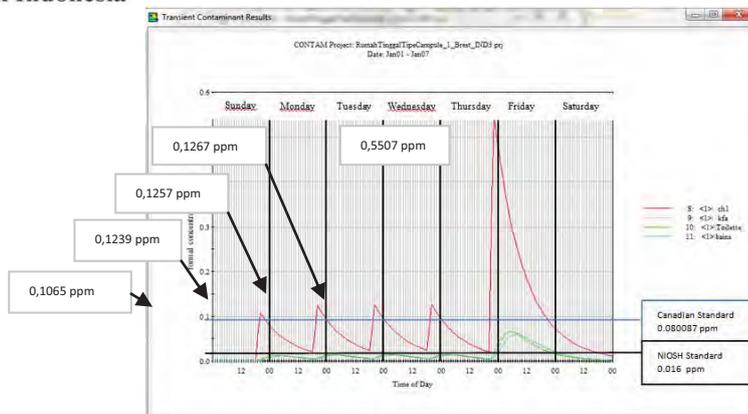

Figure 5: Transient formaldehyde result, condition weather Depok, Indonesia

### 4. DISCUSSION

At bedroom 1 from the graph above (figure 5 and figure 6), the formaldehyde content of pollutants distribution scenario shows results that vary according to the number of sources of pollutants during limited hours. For example, on Monday when the concentration reaches 0.1241 ppm formaldehyde use condition weather France and 0.1239 ppm formaldehyde at condition Indonesia. Both variable values, has passed from the standard maximum verge concentrations of formaldehyde by the Canadian standard of 0.080087 ppm and a maximum threshold set by NIOSH at 0.016 ppm. Content of formaldehyde in the air when the threshold has reached its maximum limit of the standards set, will cause the risk of eye irritation.

### 5. CONCLUSION

To solve formaldehyde levels that exceed the value limits NIOSH and Canadian standards, steps can be taken to increase the amount of fresh air into the room by opening a window. Fresh air enters the room will decrease the number of high formaldehyde levels. This process is maintained until there is no more content of formaldehyde that can be felt physically. The process of lowering the high levels of formaldehyde in the room by opening the window is classified as a type of natural ventilation.

## ABSTRACT

Along with rapid technological advances in the electronics industry, there are many new emerging advanced products which getting smaller in dimension with high space efficiency and work relying on components such as transistors and integrated circuit (IC). However, these conditions also cause new challenges to overcome, one of which is how to cope with the heat generated by the operation of the electronic components in the product with sophisticated cooling system. The cooling system, hence, needs less space and energy consumption but has high thermal efficiency. This is why the synthetic jet with zero net mass flux and non-zero net momentum flux sounds practicable as the new cooling system. This research will discuss the characteristics of flow and convective heat transfer in the cross-flow synthetic jet with two membranes that oscillate using combination of sinusoidal and square wave. It was conducted in two stages, computational and experimental stage. The experimental stage was executed using the function generators to drive the upper and lower membranes by sending functions of sinusoidal and square frequency variations with multiple oscillation frequency of square80 Hz-sin80 Hz, square80 Hz-sin120 Hz, square80 Hz-sin160 Hz, square120 Hz-sin80 Hz, square120 Hz-sin120 Hz, square120 Hz-sin160 Hz, square160 Hz-sin80 Hz, square160 Hz-sin120 Hz, square160 Hz-sin160 Hz at fixed amplitude of 0,002 m/s to see the characteristics of convective heat transfer on the heat sink at each trial. Computational stage was conducted by Fluent CFD software with  $k-\omega$  SST turbulence model with Tet / Hybrid Tgrid meshing elements type to see the flow distribution in cross-flow synthetic jet. The results showed the significant influence of waves mode and frequencies to the heat transfer rate of cross-flow synthetic jet, with the best result is on sin 120 Hz– square 80 Hz waves.

## Keywords

Cross-Flow Synthetic Jet, CFD Fluent, Convective Heat Transfer Rate, Function Generator,  $k-\omega$  SST turbulence model

## 1. INTRODUCTION

As we know, technology is growing rapidly in this modern era, especially in the electronics industry. Growing sophisticated technology should certainly be supported by the hardware in it. Over time, developments in the electronics industry demands products with higher efficiency & performance. One of the developments is in terms of electronic cooling systems (cooling devices). Along with the challenges of energy efficiency, we need a new system capable of fulfilling the demands. The common cooling method used today is the conventional fan / blower cooling with air as working fluid. Most medium to large scale electronic devices still use this method on the application of the cooling system for air circulation or increasing local cooling rate.

Synthetic jet is a characteristic of fluid flow in which a series of vortex rings formed by the vibration of the membrane / diaphragm in a cavity which causes the incoming and outgoing movement of fluid through the narrow opening / orifice [1]. Synthetic jets can be visually seen as in Figure 1.

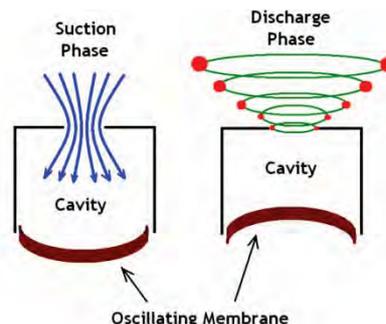

Figure 1: Working principle of Synthetic Jet

The basic principle of synthetic jet is zero net mass input of the fluid around it, but the momentum output is not zero. A synthetic jet actuator consists of cavity that contains the diaphragm, may be a piston, piezoelectric membrane, as well as electromagnetic, which moves air in it, where the fluid air move out from the cavity in the form of a series of vortex with high turbulence intensity which accelerate the rate of heat transfer and produce a cooling effect on the intended media.

Synthetic jet is currently being developed because it has advantages over conventional fan cooling system. On the conventional fan system, there is a need of supply flow of air from one place to another. Synthetic jet system offers major advantage that is just using the same air that continues circulated by the system [2]. Besides, fan is considered less efficient referring to the amount of heat rejected to the large volume of flow [3]. Another advantage of using synthetic jet cooling compared to fan for the same heat transfer performance, i.e., [4]:

- The noise level is much lower
- Better in thermodynamics efficiency, only half or less power needs
- Much better form-factor (design-friendly)
- Reliability (test stand), intrinsically higher
- Lower fouling problems, mechanics can be protected from the ambient
- Product miniaturization is easier than fan
- Have the possibility of a more simple noise reduction

But the synthetic jet is not also free of disadvantage, particularly on the impinging model. Its main weakness lies in the ease of heat containing fluid sucked back on the suction phase. This will result in the confinement effect which the heat will accumulate in synthetic jet cavity [5]. This has directed the synthetic jet research to cross-flow models in the hope of reducing the impact of the confinement effect.

## 2. METHOD

In this study, the synthetic jet actuator is required to conduct an experiment so that a prototype was designed & prepared. This prototype is expected to be able to produce synthetic jet stream that has good heat transfer coefficient. The design of synthetic jet actuator that were made and used in the experiments described in Figure 2

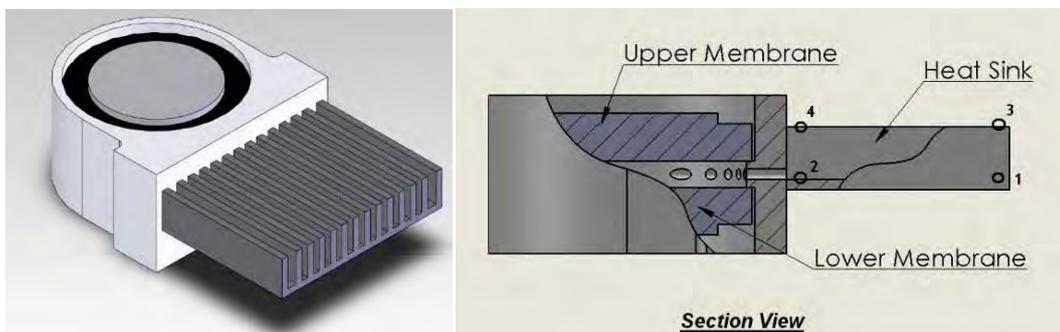

Figure 2: Synthetic jet actuator model with the points of data collection

This research has been conducted in computational and experimental stages to get the characteristics of heat transfer on the heat sink using a cross-flow synthetic jet actuator.

### 2.1 Computational Stage

Computational stage in this research is conducted in order to get an idea of the flow and thermal contour in the flow pattern of cross-flow synthetic jet. This stage is completed by using CFD Fluent software. The computational model was designed before and then meshed using the Gambit software as in figure 3

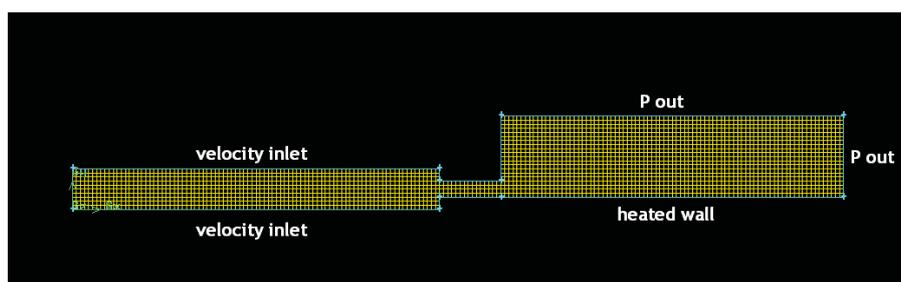

Figure 3: Overview of computational area of synthetic jet

The computational model was used to analyze the thermal contour of synthetic jet using  $k-\omega$  SST (Shear Stress Transport) mathematical model. In the work area, the air is assumed to be isothermal and incompressible. The ambient temperature is assumed 30°C and the temperature of the bottom heat sink wall is heated, maintained at an isothermal temperature of 60°C. Boundary wall on either side of the actuator is assumed to have a constant static pressure with a pressure of 1 atm. The movement of the diaphragm is modeled with a user defined function (UDF). Another detail of the computational conditions are written in Table 1.

Table 1: Computational Conditions

Computation Condition		
Model settings	2DDP, Unsteady	
Fluid	Air	
Fluid Properties	Density	1.225 kg/m <sup>3</sup>
	Viscosity	1.7894 e <sup>-05</sup> kg/m-s
	Cp	1006.43 J/kg-k
	Thermal Conductivity	0.0242 w/m-k
Boundary Condition	Velocity Inlet 1,2	UDF
	Pressure Outlet (Gauge pressure)	0 Pascal
	Heated wall	60°C
	Frequency	80 Hz, 120 Hz, and 160 Hz
	Amplitude	1 m/s

### 2.2 Experimental Stage

The experimental stage was conducted to obtain temperature data on a heat sink which is cooled using synthetic jet. Experimental system made in this study can be described in Figure 4

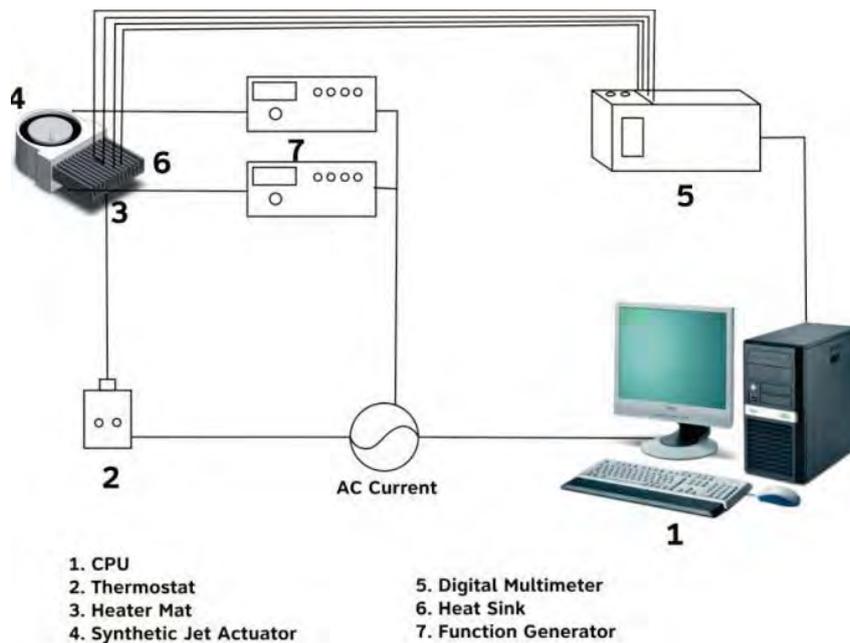

Figure 4: Experimental Set-up

Data acquisition was done by measuring the temperature of the heat sink in the four points using a digital multimeter with measurement accuracy of 0.1°C. Temperature setup was performed on the heat sink prior to the experiments. The heat source of heat sink obtained by placing the heater mat at the bottom of the heat sink with a temperature of 60°C regulated using a thermostat. Measurements were performed at 27°C ambient temperature. And after that, the membranes used in this experiment was set for sinusoidal and square waveforms, as well as arrangements of wave frequency combinations of 80 Hz, 120 Hz and 160 Hz using a function generator. After all settings were done, it was ended by placing the data acquisition thermocouple on the four-points on the heat sink which was then read using a digital multimeter. The data acquisition of experiments performed in 1 hour with one second of data interval.

### 3. ANALYSIS

At this stage of experiment, data acquisition was done by noting the temperatures changes on four test points on the heat sink due to the cross-flow cooling by synthetic jet actuator. The experiment was conducted in a closed room with ambience

temperature around 27 to 30 Celsius degrees. Test points consist of 4 areas where the thermocouples attached, as referred by figure 2. Point 1 and point 2 are located at the base of the heat sink, while point 3 and point 4 are on the top of the fins. Both thermocouple points that located at the same level were distinguished by the placement towards the orifice hole. Point 1 and point 3 are the most distant from the orifice while point 2 and point 4 were right in front of the orifice. It was considered fair enough to describe the characteristics of heat transfer on the heat sink as result of cross-flow synthetic jets cooling.

A total of 9 wave variations were executed from piezoelectric membranes on synthetic jet actuator, resulting in 36 data sets, which are distinguished from the locations of the thermocouple and wave variations. In this section, the data sets will be grouped into four graphs, which is the analysis of the graph based on the thermocouple point, point 1, point 2, point 3 and point 4.

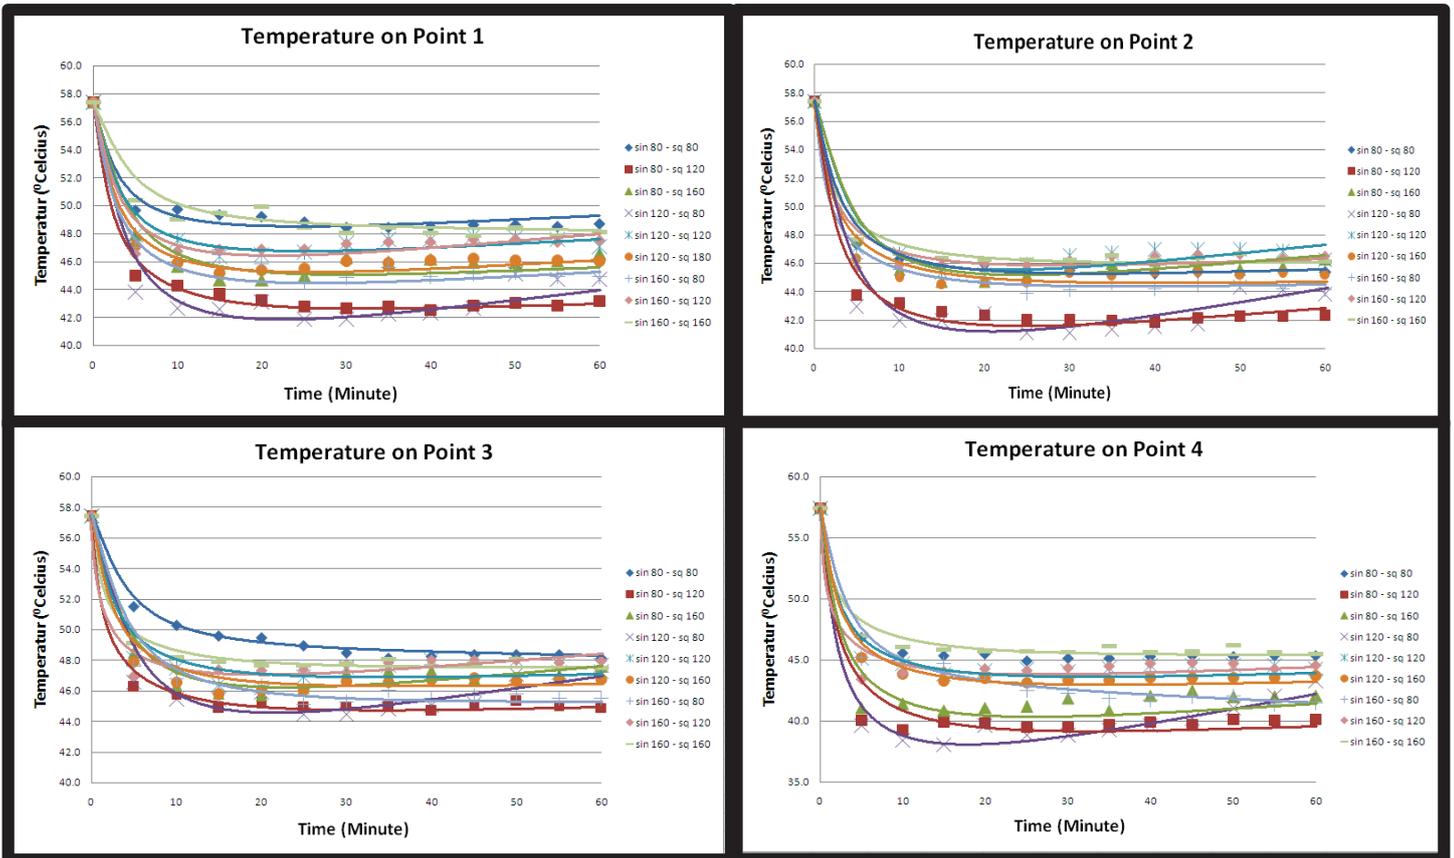

Figure 5: Heat Sink Temperature on each Test Point

The biggest temperature decrease recorded at point 1 was 15.6 Celsius degrees which occurs in wave variation of sin 120 Hz – square 80 Hz. But until the 60 minutes period the temperature in this frequency variation increased again so that the total value of reduced temperature only reached 12.7 degrees, smaller than the wave variation of sin 80 Hz – square 120 Hz which achieved total temperature reduction of 14.2 Celsius degrees.

At point 2, the largest temperature reduction was also achieved by wave variation of sin 120 Hz – square 80 Hz with the value of temperature decrease of 16.3 Celsius degrees from 57.4 degrees to 41.1 degrees. However a slight increase in temperature after 20 minutes made the value return to 43.8 Celsius degrees in the 60th minute, with an increase of 2.7 degrees.

Temperature at point 2 decline relative greater than point 1, though both of locations are set directly on the base of the heat sink. This is most likely happened due to the location of the second point is closer to the orifice than point 1, so it can also be said that the area of point 2 has higher turbulence intensity than point 1, resulting in the emergence of higher heat transfer coefficient than point 1.

The results of temperature measurement obtained at point 3 are also written in the form of graphs. At this point the highest value of temperature decrease was also achieved at sin 120 Hz - square 80 Hz wave variation, with a value of reduced temperature of 12.9 Celsius degrees. While the greatest temperature reduction achieved in 60 minutes was 12, 5 Celsius degrees at wave variation of sin 80 Hz – square 120 Hz.

The temperature decrease at point 4 due to cross-flow synthetic jet cooling is shown in graphical form of Figure 5. The biggest temperature reduction at point 4 was also achieved at sin 120 Hz - square 80 Hz wave variation which decreased the

temperature by 19.3 Celsius degrees. The biggest drop for 60 minutes achieved at sin 80 Hz – square 120 Hz which decrease the temperature by 17.3 degrees.

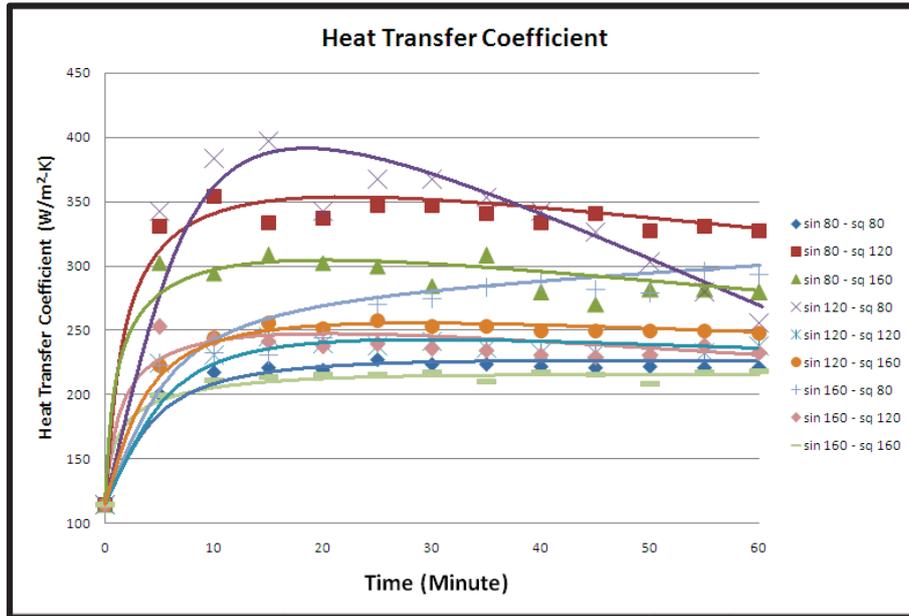

Figure 6: Heat Transfer Coefficient

Figure 6 shows heat transfer coefficient on the best test point, which is point 4. The graph shows that the value of heat transfer coefficient rose to an extreme value in the early period of synthetic jet operation, then after reaching a certain value in about 15-25 minutes, the heat transfer coefficient values showed stable character around that value. It happens to almost all of the wave variations of Sinusoidal - Square, except on sin 160 Hz – square 80 Hz which rose a little, and the variations of sin 120 Hz – square 80 Hz which showed a declining trend. The largest value of heat transfer coefficient recorded in this study was achieved by wave variation of sin 120 Hz – square 80 Hz at the 15th minute which valued 396.7 W/m<sup>2</sup>K.

At the computational stage, simulation of cross-flow synthetic jet actuator design was conducted using Fluent CFD software. This section discusses the analysis of the contours of temperature of the prototype. Synthetic jet simulated in a period of time-step of 0.025 second which is a least common multiple of signal variation and combination of 80 Hz, 120 Hz, and 160 Hz, at which time all wave ends meet in a point.

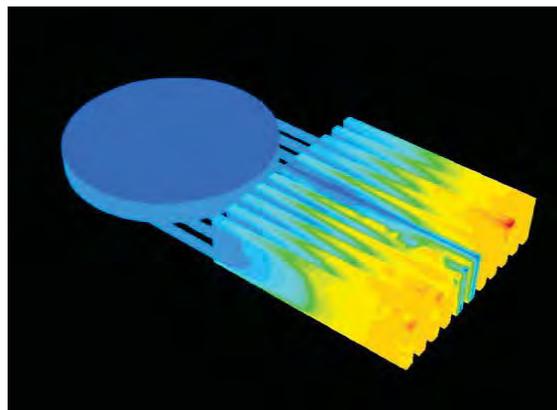

Figure 7: 3D Simulation

In the early stages of this research, computational simulation with three-dimensional computational models was conducted. But this was done only to prove that there is no significant difference in the flow pattern on the 3-three-dimensional model so that the flow can be analyzed as a two-dimensional flow to lighten the computational load and shorten iteration time. It is shown in figure 7. From the results of the 3D simulation, it was decided to further simulate on 2D because it was already sufficient to describe the heat transfer characteristics of the heat sink.

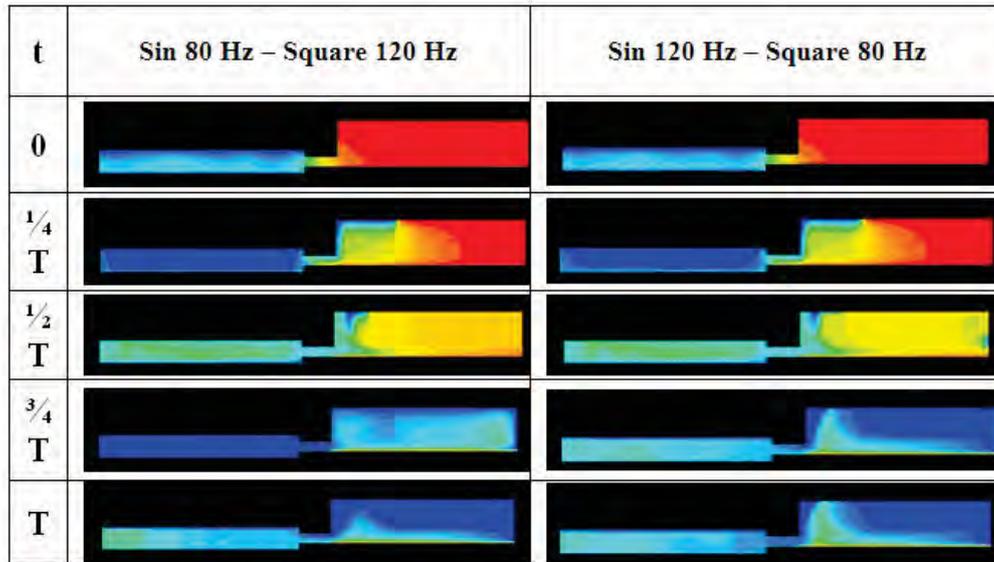

Figure 8: Temperature Contour

The temperature contour of heat sink at sin 80 Hz - square 120 Hz and sin 120 Hz - square 80 Hz wave variation is shown in figure 8. Extreme heat sink cooling on the top side of fin began in the period of 0.25 T. The start of this period to period 0.75 T shows the movement of the synthetic jet cooling to the heat sink. In the first full period of T, temperature decrease at the heat sink began to spread to all area of the heat sink significantly.

#### 4. CONCLUSION

Research on the effects of cooling and flow characteristics using a cross-flow synthetic jet actuators have been undertaken and successfully demonstrated the characteristics of heat transfer in heat sinks to variations sinusoidal and square waves at a frequency combination of 80Hz, 120Hz and 160 Hz.

The results showed that the cooling effect of cross-flow synthetic jet membrane has reached a pleasing value and can reduce the negative impact of confinement effects. The experimental result shows that membranes driven using function combination of sinusoidal 120 Hz – square 80 Hz has a better cooling effect than other frequencies wave variations. It was marked by a decrease in temperature better sinusoidal function of 120 Hz - 80 Hz square wave where the variation can lower the temperature up to 19.3 Celsius degrees.

## ABSTRACT

One of the products of PT. Krakatau Steel is a steel Billet, the raw material for the manufacture of wire in Wire Rod Mill (MRM). The average temperature at the exit of the Billet Steel Plant (BSP) about 900°C, was reduced to 130°C before entering MRM. Billet is heated again so it can be processed in WRM. Several studies have been done to reduce the rate of temperature decrease Steel Billet, including modifying the billet transportation system, which makes the system ambient temperature is kept high enough billets. With the approach of isolated cooling average rate of temperature decrease is 6.5°C per minute. From the results experiment is known that the temperature of the surrounding air and the rate of speed of the transport system effect significant decrease in temperature billet, where the temperature dropped to 450°C. The phenomenon of decrease temperature billet can be simulated using state transient conduction heat transfer equation. Decrease the temperature is at least influenced by several variables such as air temperature around, speeds pace of billet transportation system, long transport time, and the coefficient of thermal conductivity of billet. In this study created a numerical model of experiment study to determine the effect of air temperature around Billet Steel, long billet transport rate to the rate of temperature decrease. Expected outcomes of this research is derived parameters can be used to create models of Hot Box Billet to reduce the rate of decline temperature. The making design Hot Box Billet Steel that convection heat transfers from environment as little..

## 1. PREFACE

PT. Krakatau Steel is a company engaged in manufacturing steel casting. Production facilities consist of Direct Reduction Plant, Slab Steel Plant, Steel Billets Plant, Hot Steel Plant, Cold Rolling Mill, Wire Rod Mill and (WRM) [1]. In division WRM, raw materials such as steel billet cross-sectional area measuring 130mm x130 mm to 180 mmx180 mm and a length of 9m. The process of producing billets into wire rods into three phases, are reheating, deformation and transformation [1]. The Billet Steel Plant (BSP) is one plant in PT. Krakatau Steel that produces billets for the production of wire rods in the Wire Rod Mill (WRM) plant. The average billet temperature exiting the roller caster system at BSP is 900°C. In BSP cooling system, the billet heat is reduced from 900°C to 450°C, and then while waiting for transferring to WRM and charging to Reheating Furnace the billet temperature naturally goes down to 130°C. The cooling bed contributes significantly to the billet heat loss, and this heat was not utilized. The option proposed was a modification of the billet transportation system between the BSP and the WRM plants, whereby the billet temperature is kept as high as possible, before charging to reheating furnace in WRM. Three alternative systems were evaluated and the tunnel/underground transportation system was the preferred system. Three alternative billet transportation systems were considered: movable box storage/furnace, high temperature conveyor, tunnel/underground transport system. Implementation of the three alternatives will require considerable investment costs [13].

Another approach to reduce the temperature drop is making hot charging (isolated cooling) conducted by team BTP BPPT for Steel Billet automation program, that the condition is passed on certain hot tunnel. Experimental done is billet that has gone out of his way to BSP WRM with a temperature of 1000°C conditioned into a sort of tunnel or hallway can set the frequency of the tunnel is that of 10-50 Hz and the results of each frequency is different vary according to the characteristics of the frequency used. The first, the billet is heated to a temperature of 1000°C, then the calculated temperature or ambient temperature environment and recorded using a thermal imager per unit of time [3].

Hot box is designed to close the system in a state that is used as an insulator of the billet, the isolator is used to withstand the heat of the billet that has come out of the BSP so that the temperature remained high in condition before unloading. So that the billet is currently arriving at WRM still in high temperatures. In designing the isolation of the hot box, the approach used several parameters of the real condition of his (real). From the experimental results stretcher Billet temperature dropped from 700°C to 530°C [3]. This last approach, there are several variables that are used to

simulate the temperature drop at Hot Charging Steel Billet, BBPT the surrounding air temperature, high heat transfer rate. The phenomenon of the decline of billet can basically be observed using Fourier law approach. According to the Fourier law of conduction heat transfer, the rate of change of temperatures are the material thermal conductivity, heat transfer surface area, surrounding air convection coefficient, density, heat production is generated, and the specific heat of the material [4].

Research on the phenomenon of two-dimensional conduction heat transfer, particularly the decline of temperature on Steel Slab by L. Buchori, et al. In this research studied the effects of a combination of convection and radiation boundary conditions on the computational thermal cooling processes steel slabs by the computing method the finite volume. Numerical method to used solve transient heat transfer model of two-dimensional.

Based on this, it is still wide open to do some research to simulate the phenomenon of decline in billet steel heat well with the experimental and numerical simulation approach. Issues transient conduction heat transfer can be backwardly steel billet non-linear or a constant depending on the physical properties of materials, the temperature or the heat generated source (heat flux). The study of transient heat transfer event of non-linear and two-dimensional cooling events slabs of steel with a combination of convection and radiation limits had been done by L. Buchori et al. [5]. In the simulation study is the temperature drop in steel billets by applying finite difference method to solve two-dimensional heat transfer in the cooling process of steel billets with boundary convection and thermal conductivity constant. Validation of the model used experimental results that have been carried out by previous researchers.

The parameters that will be used is the temperature of the object, and thermal conductivity, specific heat, density, convection coefficient and air temperature around. Simulations performed using MATLAB program. This research is a preliminary study that is part of the research to study the phenomenon of heat drop in billet with boundary convection, radiation, conduction, and the thermal conductivity is a function of temperature.

## 2. MATHEMATICAL MODEL FOR THE STEEL BILLET

### 2.1. Conduction Heat Transfer and Convection Boundary

Heat transfer is the science of predicting the energy transfer occurs because of the temperature difference between the object or material. Heat transfer that occurs in the steel billet happen karea no significant temperature each difference between the temperature of billet material and the surrounding air. Transient heat transfer is an important phenomenon in the process of heating or cooling of billets or other metallurgical industries. In this case, there are three types of heat transfer is conduction occurs in a billet steel, convection and /or radiation from the surface of the billet to round or vice versa. In the event of heating steel billets, round billets temperature of moved to the surface by convection and / or thermal radiation, conduction and then transferred from the surface to the inside of the steel billet. The same phenomenon occurs in the cooling process of steel billets. Convection and thermal radiation will determine the heat flux through the surface of the steel billet. Type of heat transfer that occurs depending on what is most dominant phenomena, can be purely convection or thermal radiation.

In the case of steel billets transient heat transfer, the temperature drop occurs in the transport process that uses roll billets. Sectional square billet size 180mmx180mm 9m length can be very long. So the two-dimensional heat transfer occurs in the billet cross section as shown in figure 1.

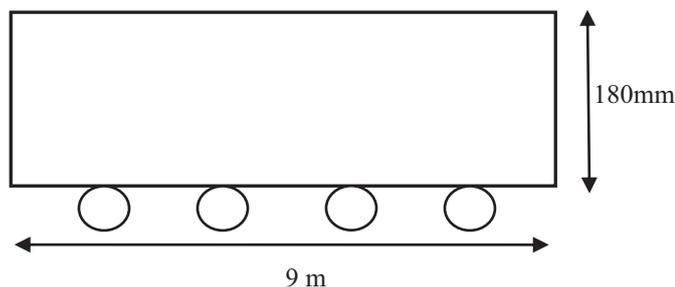

Figure 1. Dimensional Steel Billet

Heat transfer on the inside of the steel billet is conduction heat transfer given by the Fourier equation,

$$k \left( \frac{\partial^2 T}{\partial x^2} + \frac{\partial^2 T}{\partial y^2} \right) = \rho C_p \frac{dT}{dt} \quad (1)$$

In conditions of transient heat transfer, thermal konduktivitas equation (1) is essentially a function of temperature, but in this preliminary study assumed constant thermal conductivity of steel billet which is the average of the thermal

conductivity of the highest and lowest temperatures of the previous experimental results. Thermal equilibrium at the sides and the top, the convection and radiation boundary, the equation is,

$$\rho C_p \frac{dT}{dt} = hA(T_w - T_f) + F\sigma(T_w^4 - T_f^4) \quad (2)$$

As has been explained that the preliminary study, it is assumed conversion of the surrounding air is more influential than the thermal radiation [2]. With these assumptions, the second right-hand side of equation (2) is considered zero. While thermal equilibrium at the take limit is convection, thermal radiation and conduction between the bottom of the steel billet wheels roll, the equation given by.

$$\rho C_p \frac{dT}{dt} = hA(T_w - T_f) + F\sigma(T_w^4 - T_f^4) + k_r \left( \frac{\partial^2 T}{\partial r^2} + \frac{1}{r} \frac{\partial T}{\partial r} + \frac{\partial^2 T}{r^2 \partial \phi^2} \right) \quad (3)$$

From Figure 1, it appears that the surface conduction between the bottom and the top of the steel billet roll surface is quite small, the displacement factor of conduction between the billet and roll can be assumed not to exist. So at the bottom of the billet affect the heat transfer is convection, so that the second and third right-hand side of equation (2) is considered zero.

## 2.2. Mathematic Model Steel Billet

Problems mathematical model temperature distribution to be simulated in this study were transient heat transfer assuming thermal conductivity is constant and convection boundary limit. From equation (1), (2) and (3), simulating the reduced temperature steel billets used equations,

$$\frac{\partial^2 T}{\partial x^2} + \frac{\partial^2 T}{\partial y^2} = \frac{1}{\alpha} \frac{dT}{dt} \quad (4)$$

and

$$\rho C_p \frac{dT}{dt} = hA(T_w - T_f) \quad (5)$$

where,  $\alpha = k / \rho C_p$  called thermal diffusitas. Equation (4) also known as Fourier-Biot equation. [5]. One approach that can be used to solve partial differential equations of distribuasi temperature equation (4) and (5) is a numerical method, it is necessary for numerical discretization. Consider the volume of the object set in the case of two dimensions is divided into a few sections, and the volume element is given by Figure 2. following.

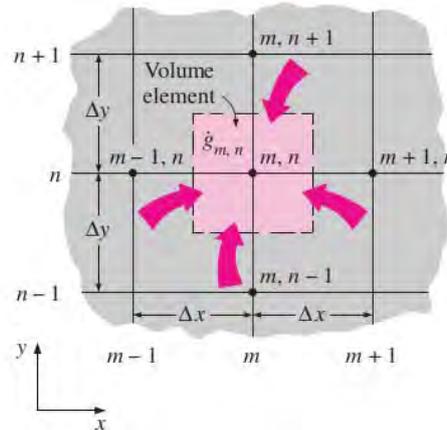

Figure 2. Element Two Dimension Volume Set

Partial derivatives, temperature gradient in (4) approximated by Taylor series expansion,

$$\frac{\partial^2 T}{\partial x^2} \approx \frac{T_{m-1,n} - 2T_{m,n} + T_{m+1,n}}{(\Delta x)^2} \quad (6)$$

$$\frac{\partial^2 T}{\partial y^2} \approx \frac{T_{m,n-1} - 2T_{m,n} + T_{m,n+1}}{(\Delta y)^2} \quad (7)$$

While the temperature gradient with time can be approximated by,

$$\frac{\partial T}{\partial t} \approx \frac{T_{m,n}^{p+1} - T_{m,n}^p}{\Delta t} \quad (8)$$

With scheme Crank-Nicolson full implicit, and when taken  $\Delta x = \Delta y$ , and to facilitate the writing, defined Biot number (Bi) and Fourier (Fo), that is  $Bi = \frac{h\Delta x}{k}$ , and  $Fo = \frac{\alpha\Delta t}{(\Delta x)^2}$  [6]. By substituting (6), (7) and (8) in (4) and condition  $Fo \leq 0.25$  equation (4) to estimate the temperature in the node (m,n), written as :

$$T_{m,n}^{p+1} = \frac{\alpha\Delta t}{(\Delta x)^2} (T_{m+1,n}^p + T_{m-1,n}^p + T_{m,n+1}^p + T_{m,n-1}^p) + \left[ 1 - \frac{4\alpha\Delta t}{(\Delta x)^2} \right] T_{m,n}^p$$

or,

$$T_{m,n}^{p+1} = Fo (T_{m+1,n}^p + T_{m-1,n}^p + T_{m,n+1}^p + T_{m,n-1}^p) + (1 - 4Fo) T_{m,n}^p \quad (9)$$

Furthermore, for the case of temperature on the sides of the steel billet with convection boundary shown in Figure 3. Following

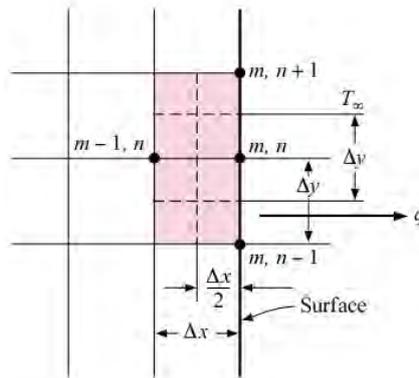

Figure 3. Convection Boundary Element Sides

In terms  $Fo(2+Bi) \leq 0.5$ , of equation (5) temperature convection boundary points (m, n) as shown in Figure 3. calculated by the formula:

$$T_{m,n}^{p+1} = \frac{\alpha\Delta t}{(\Delta x)^2} \left( 2 \frac{h\Delta x}{k} T_f + 2T_{m-1,n}^p + T_{m,n+1}^p + T_{m,n-1}^p \right) + \frac{\alpha\Delta t}{(\Delta x)^2} \left[ \frac{(\Delta x)^2}{\alpha\Delta t} - 2 \frac{h\Delta x}{k} - 4 \right] T_{m,n}^p \quad (10)$$

Using Biot numbers, Fourier equation (10) written as,

$$T_{m,n}^{p+1} = Fo (2BiT_f + 2T_{m-1,n}^p + T_{m,n+1}^p + T_{m,n-1}^p) + (1 - 4Fo - 2FoBi) T_{m,n}^p \quad (11)$$

Further to the convection boundary, specifically at the corner of a wall of steel billets as shown in Figure 4. The following

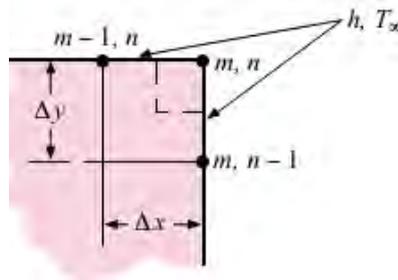

Figure 4. Corner Boundary Element Convection

In terms  $Fo(1+Bi) \leq 0.25$ , of equation (5) the temperature at the point (m, n) is shown in Figure 4. calculated by the formula.

$$T_{m,n}^{p+1} = \frac{2\alpha\Delta t}{(\Delta x)^2} \left\{ \left( 2 \frac{h\Delta x}{k} T_f + 2T_{m-1,n}^p + T_{m,n-1}^p \right) + \left[ \frac{(\Delta x)^2}{\alpha\Delta t} - 4 \frac{h\Delta x}{k} - 4 \right] T_{m,n}^p \right\} \quad (12)$$

By using Fo and Bi, equation (12) written as,

$$T_{m,n}^{p+1} = 2Fo (2BiT_f + T_{m-1,n}^p + T_{m,n-1}^p) + (1 - 4Fo - 4FoBi) T_{m,n}^p \quad (13)$$

By using equation (9), (11) and (13) further developed the system of linear equations used to estimate the temperature distribution in the steel billet.

### 3. METHODOLOGY

The research was carried out starting with a review of the results of analyzes of previous studies, followed by simulation modeling, programming with MATLAB programs, and finally analyzed by comparing the experimental results of previous studies. The analysis was done by comparing the results of model simulations with experimental results that have been obtained previously. The assumptions used are,

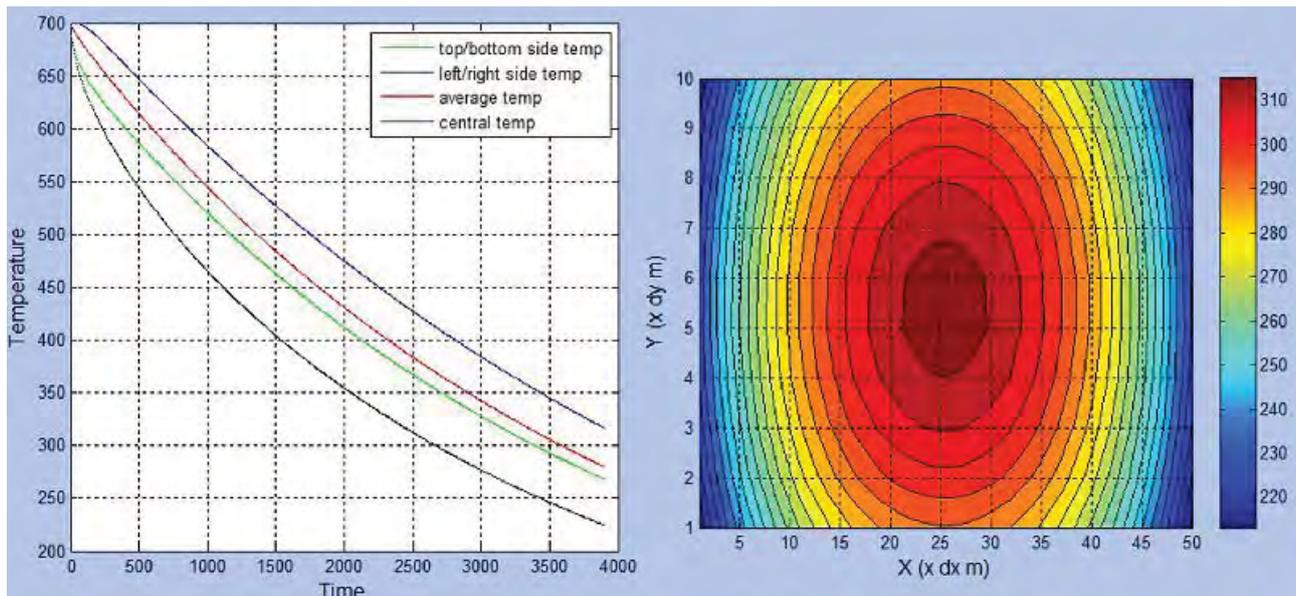

- 1). Conduction heat transfer is two-dimensional in the direction of the x axis and y axis, where  $x = 1000\text{mm}$ , and  $y = 180\text{mm}$ ,  $dx = dy = 0.02\text{ mm}$ , so that the matrix is used sized (10x50);
- 2) Physical properties and thermal homogeneous steel billets, assumed thermal conductivity  $k = 31\text{ W / m.}^\circ\text{C}$ , density  $\rho = 7795\text{ kg/m}^3$ , and  $C_p = 0.475\text{ kJ / kg}$ ;
- 3) .Ambient temperature or the temperature of the fluid is constant, not as a function of time;
- 4). Convection heat transfer coefficient  $h$  is not dependent on the fluid temperature.

By using equation (9), (11) and (13), computational algorithms are as follows

- 1.Start;
2. Read  $dt, dx, dy, \rho, C_p, k, h$ ;
3. Cek the value of  $Fo, Fo(2+Bi), Fo(1+Bi)$  ;
4. Read  $T_f, T_o$  and time
5. Set  $time=0$ ; 5.t. Set  $time < t$
6. Calculate the temperature  $T(x,y)$
7. Calculate the average of temperature
8. Print the average temperature as time function
9. Set  $time=time+dt$
10. Print temperature contour map
11. Finish

### 4. RESULT AND DISCUSSION

Assuming the physical properties of steel billets,  $\rho = 7795\text{ kg/m}^3$ ,  $k = 31\text{ W / m.}^\circ\text{C}$ ,  $C_p = 0475\text{ kJ / kg}$ , and the boundary condition  $h = 55\text{ W/m}^2.\text{K}$ ,  $dx = dy = 0.02\text{ m}$ ,  $T_f = 30^\circ\text{C}$ , and  $T_o = 700^\circ\text{C}$ , the simulation results to verify the results of previous studies for a time  $t = 3600$  seconds is given in Figure 5 below

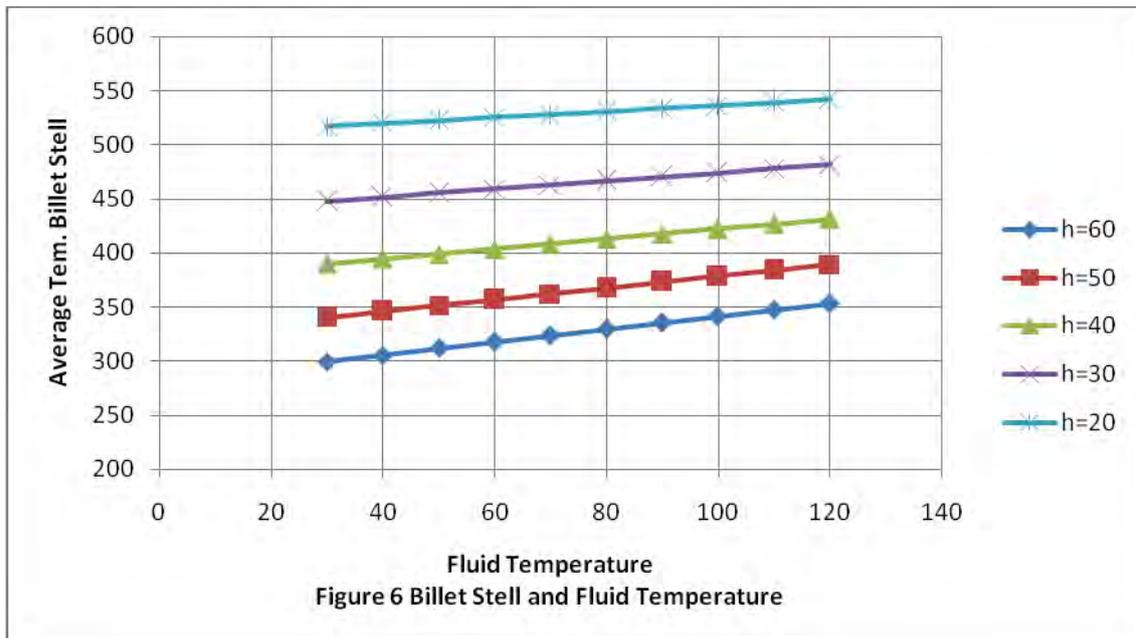

(a). Billet Temperature

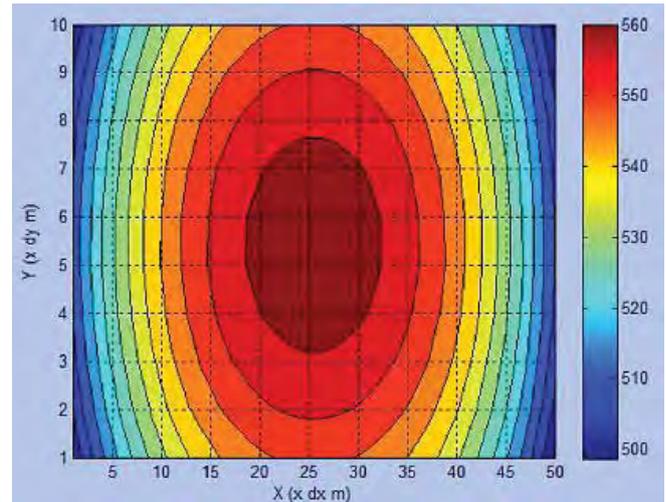

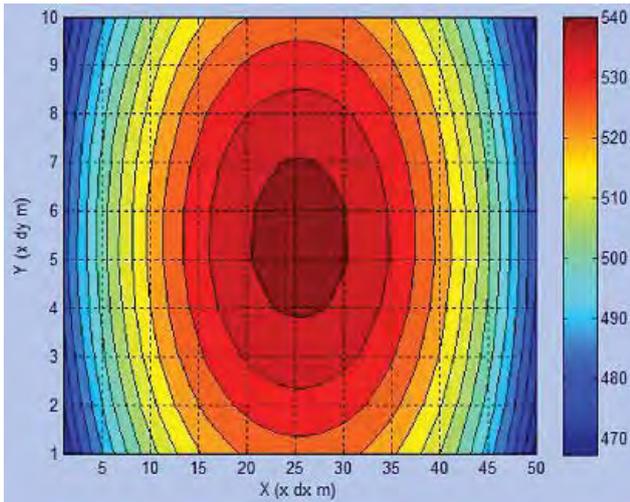

(b). Contour Temperature

**Figure 5. Simulation of Temperature Distribution,  $h=55 \text{ W/m}^2 \cdot \text{°C}$ ,  $T_f=30 \text{°C}$**

From Figure 5 (a) to the side adjacent to the outside air, the temperature went down whilst the temperature on the inside, and the average relative down not sharp. From Figure 5 (a), the average temperature of steel billets every 5 minutes down  $33,37 \text{°C}$  or  $6.671 \text{°C}$  per minutes, and after 3600 seconds, the average temperature Steel Billet is  $299,56 \text{°C}$ . The average temperature at bellow ot top Billet Stell under  $250 \text{°C}$ , at right or left side under  $300 \text{°C}$  after 3600 second. Simulation results are relevant to the research conducted by the team BBPT result that within 3600 seconds billet temperature in the Hot Box Billet down from  $700 \text{°C}$  to  $300 \text{°C}$  [3]. Mean while, from Figure 5 (b), shows that the temperature contour at time  $t = 3600$  seconds, the bottom and the top of Billet Steel, temperature ranges from  $230 \text{°C}$ - $320 \text{°C}$ , while at right or left side of steel billet temperature range between  $230 \text{°C}$ - $250 \text{°C}$ , and Billet steel on the inside of the temperature range between  $320 \text{°C}$ - $350 \text{°C}$ . The difference in temperature is due to convection heat transfer surface area at the top of Stell Billet larger than the surface area on the bottom or top Steel Billet. The results of the simulation the average temperature as a function of Steel Billet fluid temperature air around with a variety of convection coefficient, which is presented Figure 6.

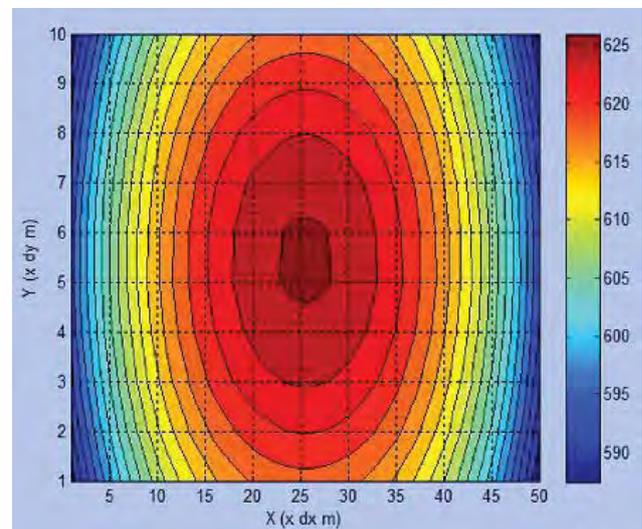

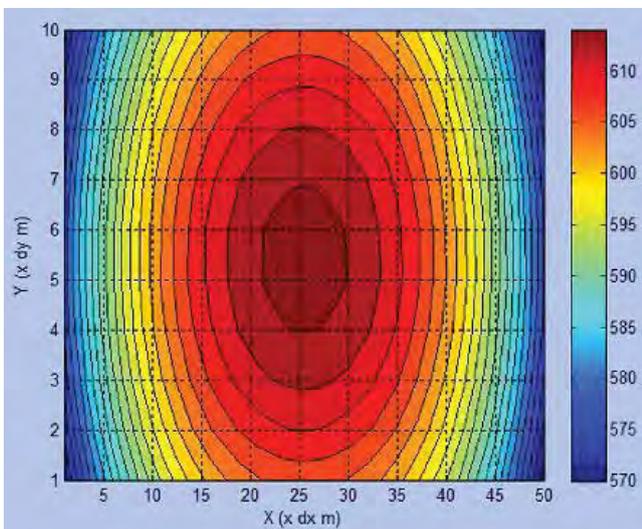

From Figure 6 shows that the air temperature around the convection coefficient and temperature effect on the decline Steel Billet. From Figure 6, every increase in temperature of  $10 \text{°C}$ , Steel Billet temperature at time 3600 seconds on average increase  $5,98 \text{°C}$  for  $h = 60 \text{ W/m}^2 \cdot \text{°C}$ ;  $5,41 \text{°C}$  for  $h = 50 \text{ W/m}^2 \cdot \text{°C}$ ;  $4,63 \text{°C}$  for  $h = 40 \text{ W/m}^2 \cdot \text{°C}$ ;  $3,76 \text{°C}$  for  $h = 30, \text{ W/m}^2 \cdot \text{°C}$  and  $2,73 \text{°C}$  for  $h = 20 \text{ W/m}^2 \cdot \text{°C}$ . Overall increase temperature of the fluid at  $10 \text{°C}$ , the average temperatures are Billet Steel at  $t = 3600$  seconds increase  $4,94 \text{°C}$ . Similarly, from Figure 6, each decrease by  $10 \text{ W/m}^2 \cdot \text{°C}$  convection coefficient, the average temperature of steel billets at time  $t = 3600$  seconds up to  $50,31 \text{°C}$ . This suggests that the increase in fluid temperature did not significantly affect the average temperature Steel Billet, while the smaller convection coefficient of heat transfer it will lead to a rise in temperature Steel Billet, that is to make so that the temperature remains high steel billets to consider is the convection transfer coefficient .

**Figure 7. Contour Temperature,  $h=20 \text{ W/m}^2 \cdot ^\circ\text{C}$ ,  $T_f=30^\circ\text{C}$**

**Figure 8. Contour Temperature,  $h=20 \text{ W/m}^2 \cdot ^\circ\text{C}$ ,  $T_f=120^\circ\text{C}$**

Furthermore, to find out on what conditions should order Hot Box didesaian Steel Billet temperature remains high, consider Figure 7 to 10. From Figure 7 and Figure 8 shows the simulated contour of temperature at time 3600 seconds with the boundary condition  $T_f=30^\circ\text{C}$  and  $T_f=120^\circ\text{C}$  with heat transfer coefficient convection respectively  $h = 20 \text{ W/m}^2 \cdot ^\circ\text{C}$ . From Figure 7 shows that the contour of temperature Steel Billet, it seems that after 3600 seconds the temperature range between  $470^\circ\text{C}$ - $540^\circ\text{C}$ , and from Figure 8 contour of temperature steel billets ranging from  $500^\circ\text{C}$ - $560^\circ\text{C}$ , seen that the difference was significant between the fluid temperature  $30^\circ\text{C}$  and  $120^\circ\text{C}$ . From the two images shows that the temperature at the bottom or the top of the Billet temperature is above  $500^\circ\text{C}$ , but in the left or right side still below  $500^\circ\text{C}$ . From Figure 7 and Figure 8, there are significant difference temperature at  $x=0.1 \text{ m}$ ,  $x=0.2 \text{ m}$ ,  $x=0.3 \text{ m}$ ,  $x=0.4 \text{ m}$  and  $x=0.5 \text{ m}$ . To according Figure 6, the average temperature simulation with  $h = 20 \text{ W/m}^2 \cdot ^\circ\text{C}$ ,  $T_f=30^\circ\text{C}$  is  $517,04^\circ\text{C}$ , and for condition  $h = 20 \text{ W/m}^2 \cdot ^\circ\text{C}$ ,  $T_f=120^\circ\text{C}$  the average temperature is  $541,61^\circ\text{C}$ , overall the average temperature above  $500^\circ\text{C}$ . Mean while, according to research results BTMP BPPT, Steel Billet to close temperature above  $530^\circ\text{C}$ , so parameters the simulation is not in accordance with experimental results.

**Figure 9. Contour Temperature,  $h=10 \text{ W/m}^2 \cdot ^\circ\text{C}$ ,  $T_f=30^\circ\text{C}$**

**Figure 10. Contour Temperature,  $h=10 \text{ W/m}^2 \cdot ^\circ\text{C}$ ,  $T_f=120^\circ\text{C}$**

While from Figure 9 and 10, showing contour of temperature at time 3600 seconds with the boundary condition  $T_f= 30^\circ\text{C}$  and  $120^\circ\text{C}$  with convection heat transfer coefficient constan  $h=10 \text{ W/m}^2 \cdot ^\circ\text{C}$ . From Figure 9, Steel Billet contour of temperature at time 3600 seconds, overall temperature range from  $570^\circ\text{C}$ - $610^\circ\text{C}$ , and from Figure 10 overall temperature range between  $585^\circ\text{C}$ - $625^\circ\text{C}$ , and there are the difference was significant between fluid temperature  $30^\circ\text{C}$  and  $120^\circ\text{C}$ . From Figure 9 and Figure 10, there are not enough significant difference temperature at  $x=0.1 \text{ m}$ ,  $x=0.2 \text{ m}$ ,  $x=0.3 \text{ m}$ ,  $x=0.4 \text{ m}$  and  $x=0.5 \text{ m}$ . The average temperature with condition  $h = 10 \text{ W/m}^2 \cdot ^\circ\text{C}$ ,  $T_f=30^\circ\text{C}$  is  $600,06^\circ\text{C}$ , and for condition  $h = 10 \text{ W/m}^2 \cdot ^\circ\text{C}$ ,  $T_f=120^\circ\text{C}$  the average temperature is  $613,48^\circ\text{C}$ . From Figure 9, Figure 10 and the average temperature, simulation shows that the temperature Steel Billet over time 3600 seconds everything above  $530^\circ\text{C}$ , that it is compliant with the experimental results, where the temperature Billet Steel after 3600 seconds is still

above 530°C. So that parameters in the simulation for this case can be used as a starting point to determine designed Hot Box Billet Steel.

On the basis of the simulation results is reduced temperature steel billets, in making design Hot Box Billet Steel to consider is the amount of convection transfer coefficient, not enough the air temperature around Billet Steel. Hot Box Design steel billets as possible to prevent a the entry of air infiltration around, so that the convection heat transfer is made as low as possible. Referring to the findings of TIM BTMP BPPT, the Hot Box isolated design prevents temperature decrease Steel Billet become 500°C after 3600 seconds [3], this suggests that the convection heat transfer is low enough temperature significantly affects Billet Steel. The existence of Hot Box or tunnel to prevent the entry of outside air infiltration and reduce the amount of convection heat transfer coefficient, it can also reduce costs for steel billet reheating so it can be processed further in the process is the next step.

## 5. CONCLUSION

Computational method finite difference method with pure implicit scheme can be used to simulate the temperature decrease Steel Billet. From the simulation results shown that the reduced temperature Steel Billet significantly affected by convection coefficient of heat transfer, and fluid temperature around Billet steel did not significantly affect the temperature decrease Steel Billet. Thus, in making design Hot Box Billet Steel that convection heat transfer from the environment as little as possible.

The numerical simulation is based on the approach of the two-dimensional model of heat transfer, convection and boundary assuming no influence of radiation and conduction heat transfer coefficient is constant. To obtain optimum results suggested the model was developed with the assumption that boundary convection and radiation, as well convection and conduction coefficient heat transfer is a function of time.

## ACKNOWLEDGMENTS

This paper is the preliminary research of the part of the research to study the phenomenon of heat drop in billet steel was supported by STT-PLN Jakarta under the contract No. 293.SK/1/1/2012. The authors thank Dr. Ir. Supriadi Legino for helping to funding this research, and Mr. Fahmi Ari Aditya for helping to install the simulation programming with Matlab Program setup

## ABSTRACT

The development of electronic devices pushes manufacturers to create smaller microchips with higher performance than ever before. Microchip with higher working load produces more heat. This leads to the need of cooling system that able to dissipate high heat flux. Vapor chamber is one of highly effective heat spreading device. Its ability to dissipate high heat flux density in limited space made it potential for electronic cooling application, like Central Processing Unit (CPU) cooling system. The purpose of this paper is to study the application of  $Al_2O_3$  Nanofluids as working fluid for vapor chamber. Vapor Chamber performance was measured in real CPU working condition.  $Al_2O_3$  Nanofluids with concentration of 0.1%, 0.3%, 0.5%, 1%, 2% and 3% as working fluid of the vapor chamber was tested and compared with its base fluid, water.  $Al_2O_3$  Nanofluids shows better thermal performance than its base fluid due to the interaction of particle enhancing the thermal conductivity. It is expected that application of  $Al_2O_3$  Nanofluids as working fluid would enhance thermal performance of Vapor Chamber, compared to other conventional working fluid being used before.

## Keywords

Vapor Chamber, Nano-fluid,  $Al_2O_3$ , CPU cooling

## 1. INTRODUCTION

Based on Moore's law, the number of transistor in a microchip is predicted to be doubled every 24 month [1]. The prediction made by Gordon Moore, co-founder of Intel, is proven to be accurate. The Intel® i7 "Sandy Bridge" consist about one billion transistors. As the number of transistor rises, the amount of heat that is produced also rises [2]. Meanwhile the trend of computer and gadget development goes to the miniaturization of the product. It made smaller yet with high performance enables them to play high definition videos and doing intensive computing tasks like graphic design [3]. These leads to the need of a compact cooling system that is able to dissipate high heat flux.

Vapor chamber basically is a two phase heat spreading device. Similar to heat pipe, it has excellent ability of dissipating heat through the working fluid phase change, with advantages over cylindrical heat pipe as geometry adaptation and ability for much localized heat dissipation. Its flat shape made vapor chamber ready to be applied as Central Processing Unit (CPU) cooling system [4-6]. Attia and El-Assal [7] investigated the use of pure water, water with surfactant and methyl alcohol at different fill charge ratios to 2-mm high and 50-mm diameter vapor chamber. The study showed the superiority of water over methyl alcohol on the application as working fluid of vapor chamber. The use of surfactant propylene glycol added to water also decrease the thermal resistance of vapor chamber. 0.3 is discovered to be the best filling ratio for this design. Go [8] investigate the performance of vapor chamber with a metal-etched microwick using acetone as working fluid. Chen et al. [9] studied the 58 mm x 58 mm x 6 mm aluminum vapor chamber with radial grooved and sintered powders wick structure with water as working fluid. Wong [10] studied vapor chamber with parallel-grooved wick structure and found that the grooved wick shape could improve the anti-dryout characteristics. Ji [11] built and tested copper foam based vapor chamber with water, ethanol and acetone as working fluid. The result showed that vapor chamber with water showed the best thermal performance among the three variations and charge ratio as well as inclined angle influenced the thermal performance of vapor chamber. Naphon [12] used refrigerant R-141b as working fluid of vapor chamber the refrigerant yield better thermal performance than water as much as 10.73%. Li [13] used infrared thermography to study the thermal performance of plate-fin vapor chamber heat sink. It was found that by vapor chamber, the heat is being transferred with better uniformity to the base plate compared to conventional aluminum heat sink and led to the reduction of maximum temperature. Wong [14] tested vapor chamber with sintered plus mesh wick with water, methanol and acetone as working fluid. The experiment showed that the use of different working fluid has little influence on the thermal performance since the design has short cycling distance of working fluid. Naphon [15] also tested vapor chamber under real operating condition of personal computer to see the performance of vapor chamber on cooling the central processing unit (CPU). The result showed that vapor chamber could reduce the temperature of the CPU and lower the energy consumption.

Meanwhile by the writer's knowledge there is no publication studied the use of nanofluids as the working fluid of vapor chamber. Nanofluids is fluid consist of base fluid and nanometer-sized particle [16]. Its thermal performance over the base

fluid and its application on several heat exchanging devices like thermosyphon and heat pipe has already been studied. Suresh [17] studied the heat transfer characteristics of  $\text{Al}_2\text{O}_3\text{-Cu/water}$  nanofluids. The study revealed that the nanofluids added friction factor to the fluid and enhanced the convective heat transfer by increasing Nusselt number. Hung [18] evaluate the effect of  $\text{Al}_2\text{O}_3\text{/water}$  nanofluids in enhancing the thermal performance of straight heat pipe. The result showed disagreement with the concept of higher nanofluids concentration leads to the higher thermal conductivity since the heat transfer process at the heat pipe mostly happened by convection. Qu [19] evaluate the thermal performance of oscillating heat pipe (OHP) using  $\text{Al}_2\text{O}_3$  nanofluids. The result showed that the enhancement of the OHP thermal performance is mainly due to the nanofluids enhanced the boiling phenomenon at the evaporator by stabilizing the nucleation. It is showed by sedimentation of  $\text{Al}_2\text{O}_3$  nanoparticle at evaporator side. Teng [20] study the use of alumina nanofluids as straight heat pipe working fluid. It was said that the use of alumina nanofluids enhanced the thermal efficiency of heat pipe and there were optimum parameters in each different experimental condition like tilting angle, charge ratio and nanofluids concentration. Saleh [21] investigated the effect of concentration and particle size of  $\text{ZnO}$  nanofluids to the thermal conductivity and to the heat pipe thermal performance. The experiment showed that up to 0.5% fraction volume, the increment of  $\text{ZnO}$  particle concentration on nanofluids enhanced thermal conductivity and larger particle size increased the conductivity. The experiment also showed that the enhancement of thermal conductivity positively affected the thermal performance of the heat pipe. Putra [22] tested five different nanofluids on screen mesh wick heat pipe. The test revealed that  $\text{Al}_2\text{O}_3\text{-water}$  nanofluids has the best influence to the thermal performance of heat pipe and there was a significant coating of nanoparticles found at the screen mesh, produced good capillary structure.

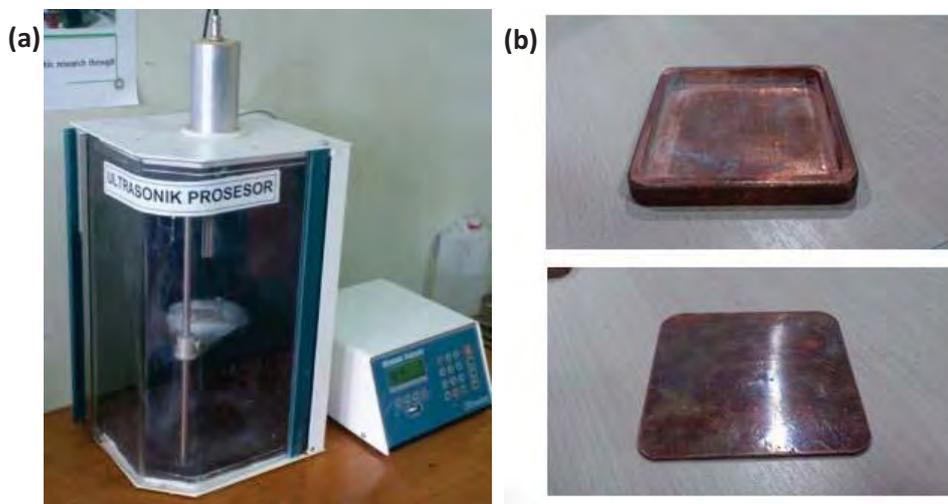

Figure 1 : (a) Ultrasonic processor; (b) Vapor Chamber Container and Top Plate

This study evaluated the effect of  $\text{Al}_2\text{O}_3\text{-water}$  nanofluids to the thermal performance of sintered copper-powder wick vapor chamber. The nanofluids were given at different volume fraction concentration and the inclination effect of vapor chamber were also tested.

## 2. METHODS

### 2.1 Preparation of vapor chamber and nanofluids

The  $\text{Al}_2\text{O}_3$  nanofluids being used in this experiment was produced and tested by the same method being used by Putra [22].  $\text{Al}_2\text{O}_3$  nanoparticles were dispersed in the base fluid of distilled water by ultrasonically for 30 minutes in ultrasonic processor (Figure 1a). The volume fraction concentration of nanoparticle in nanofluids is calculated by using equation (1):

$$\% \text{ volume fraction} = \frac{\frac{W_{np}}{\rho_{np}}}{\frac{W_{np}}{\rho_{np}} + \frac{W_{bf}}{\rho_{bf}}} \quad (1)$$

where  $W_{np}$  and  $\rho_{np}$  are the weight and the density of nanoparticle, and  $W_{bf}$  and  $\rho_{bf}$  are the weight and the density of base fluid respectively.

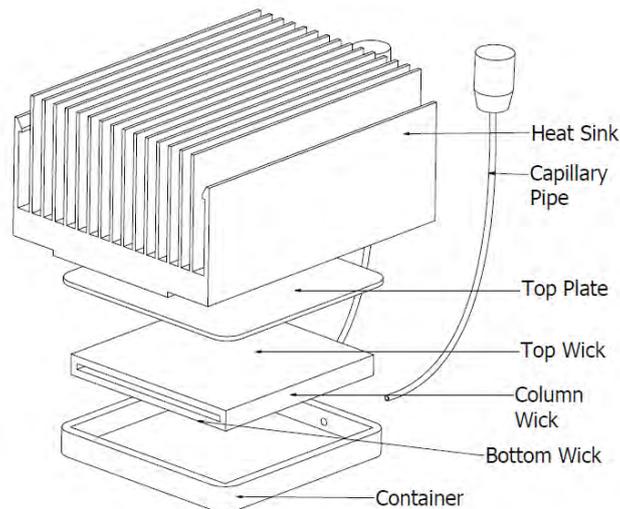

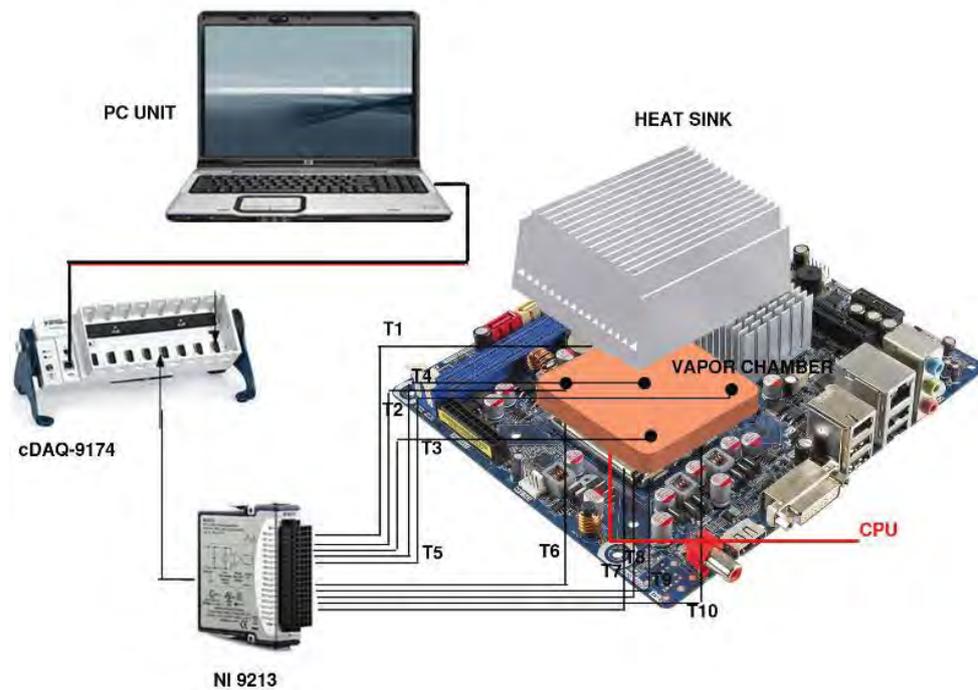

Figure 2 : Vapor chamber assembly for the experiment

Vapor chamber designed for this experiment made from copper with total dimension of 60 mm x 60 mm x 8 mm, assembled of bottom container, top plate and wick structure (Figure 1b) The evaporator and condenser thickness were 1.2 mm with 2 mm sintered copper-powder wick on the inner side of both, creating the bottom and the top wick. The sintered copper-powder made from copper-powder with the mesh of 300  $\mu\text{m}$ . The bottom and the top wick were connected by column wick providing path for the liquid to flow back from the evaporator to the condenser (see figure 2). The bottom container and the top plate were welded together along with capillary pipe attached to insert the working fluid and do the vacuum process. The heat sink fan being used in this experiment is the standard heat sink fan for microprocessor Intel® Pentium 4 socket 478. The heat sink was grooved so the vapor chamber can fit in snugly. The fluid insertion and vacuum process helped by vacuum pump model VE110 1/8 HP. The working fluid injected to the vapor chamber has charge volume ratio of 0.6 or 3.45 ml. The vacuum process itself was conducted at the special vacuum chamber device at the Applied Heat Transfer Research Group Laboratory.

## 2.2 Experimental setup

The evaluation of vapor chamber thermal performance was conducted by arranging the experimental setup as shown in figure 3. The vapor chamber integrated heat sink fan was plugged to the standard heat sink holder to ensure the same condition for all parameter variations. At the evaporator of the vapor chamber, central processing unit (CPU) of Intel® Pentium 4 socket 478 2.4GHz were placed as the heat source. Having 13.1 Watt at the idle condition and 48.3 Watt at the maximum load condition, the CPU was being loaded by running software called Prime95. This software could set the CPU to its maximum working capacity, thus maximum heat load. The thermocouples being used is the type K thermocouple, five mounted on the surface of the CPU and five at the condenser surface of vapor chamber. To minimize the thermal gap at the junction of the vapor chamber

and to ensure the validity of the data being acquired, the surface of the CPU and the condenser were grooved to the size of the

thermocouple. All the

Figure 3: Experimental Setup

thermocouples were connected to the high precision NI 9213 data acquisition module. As the experiment undergone, the ambience temperature is being kept at  $25 \pm 0.5$  °C.

The variations of nanofluids volume fraction concentration were 0.1 %, 0.3%, 0.5%, 1%, 2% and 3% to see the effect of concentration to the enhancement of thermal performance. The inclination angles being used are 0° or horizontal position, 45° and 90° or the vertical position.

### 3. RESULT AND DISCUSSION

#### 3.1 Effect of working fluid to the thermal performance

To evaluate the effect of working fluid in thermal performance of vapor chamber, different working fluid was tested. Firstly, vapor chamber without working fluid was tested at CPU with no load for 10 min, continued with full load condition for 20 min and back to the no load condition for 10 min. Then, water and  $\text{Al}_2\text{O}_3$ -water nanofluids were tested with the same loading condition. The result then compared with cooling performance of conventional heat sink without vapor chamber. The result is presented in Figure 4.

It can be observed from Figure 4a. that vapor chambers vividly have better thermal performance than conventional cooling system heat sink fan, shown by the lower CPU temperature with  $\Delta T$  around 3°C at no load condition. But can be seen that at the effect of working fluid has not significantly give impact to the thermal performance of vapor chamber at no load condition. This is due to the heat transfer phenomenon that was dominated by conduction and free convection. At this level of load, the heat from the CPU was not enough to ignite the boiling phenomenon inside the vapor chamber. Thus, the heat transfer was being conducted mostly by conduction and, in the small amount, by free convection. Since dominated by conduction, the effect of working fluid become less impactful, which can be seen from the result that empty vapor chamber produced only slightly higher CPU temperature than fluid-charged vapor chamber. This also validated by the fact that nanofluid-charged vapor chamber did not yield better performance than water-charged vapor chamber. Although nanofluids has better conductivity than its base fluid, the vapor chamber works efficiently when the phase change occurs so the enhanced thermal conductivity of nanofluids only had small effect on this loading condition.

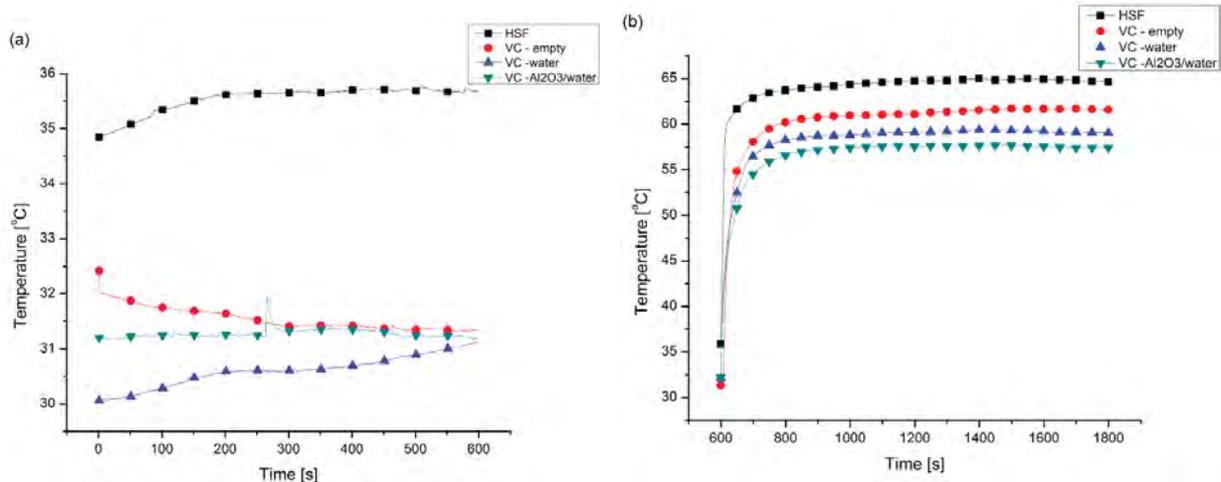

Figure 4 : Effect of working fluid to the thermal performance of vapor chamber at (a) no load, and (b) full load condition

While at the full load CPU operating condition, shown by Figure 4b, the effect of working fluid was greatly impact the thermal performance of vapor chamber. At this loading condition, it can be seen that vapor chamber without working fluid shows worse thermal performance than the vapor chamber with working fluid as can be seen from its higher CPU temperature compared to that on the vapor chamber with working fluid. The average CPU temperature for empty vapor chamber and water charged vapor chamber is 61.36 °C and 59.12 °C respectively. This happened because at this loading condition, the heat from the CPU intensifies the boiling phenomenon inside the vapor chamber, making the heat transfer at the fluid-charged vapor chamber undergone efficiently. While at the empty vapor chamber, the heat transfer depended only on conduction, increasing the thermal resistance. It also can be observed that nanofluid-charged vapor chamber shows better thermal performance than water-charged vapor chamber at this loading condition, producing average CPU temperature of 57.52 °C. This indicates that the enhancement of thermal characteristics of nanofluids affected the thermal performance at the greater amount on high heat load condition, rather than at low heat load condition. As the enhancement of thermal conductivity only affected the performance at the small amount, the other improvement of the nanofluids over its base fluid should be analyzed.

### 3.2 Effect of nanofluids concentration

To observe the nanofluids enhancement to the thermal performance of vapor chamber, variations of volume fraction concentration of Al<sub>2</sub>O<sub>3</sub>-water nanofluids were being tested. The volume fraction concentration of 0.1%, 0.3%, 0.5%, 1%, 2% and 3% were tested under the same CPU loading condition. The result is presented in Figure 5. From Figure 5a. can be observed that at no load condition, increment of volume fraction concentration of Al<sub>2</sub>O<sub>3</sub>-water nanofluids from 0.1% up to 1% did not give significant effect on vapor chamber thermal performance as the temperature of CPU scattered randomly at the temperature range of 29.8 °C – 31.5 °C. But at the volume fraction concentration of 2% and 3%, significant improvement of thermal performance was noted. At these volume fractions of nanofluids, CPU temperature fell below 29 °C. This showed that at certain amount of nanoparticles suspended at the base fluid, nanofluids can increase significantly the thermal performance by enhancing the heat transfer by conduction greatly. At the concentration of 2% and 3%, there were denser formations of nanoparticles at the evaporator so the thermal conductivity were greatly increased and reduce the thermal resistance. This help the heat transfer and reduce the average CPU temperature.

At the full load condition, shown by Figure 5b, it can be observed that along with the increment of volume fraction concentration of nanofluids, the thermal performance increased. The 3% nanofluids concentration yields the best thermal performance, producing average CPU temperature of 54.64 °C. The lower nanofluids concentration produces higher average CPU temperature, that is 57.31 °C, 57.52 °C, and 57.94 °C for 2%, 1% and 0.5% volume fraction concentration. The 0.3% and 0.1% nanofluids concentration produced no significant improvement of thermal performance, showed by the slight difference in average CPU temperature compared to water as working fluid.

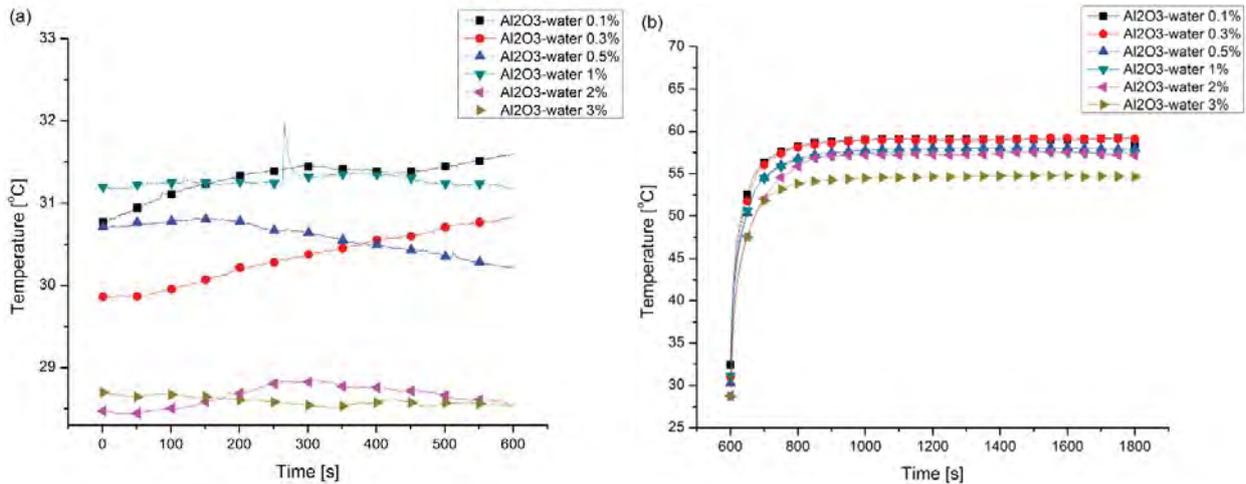

Figure 5 : Effect of Al<sub>2</sub>O<sub>3</sub>-water nanofluids concentration to the thermal performance of vapor chamber at (a) no load, and (b) full load condition

The 0.3% and 0.1% nanofluids concentration for vapor chamber working fluid produced average CPU temperature of 59.02 °C and 59.04 °C respectively, while water produced 59.12 °C. Since the thermal conductivity only affects the thermal performance at the small amount in this loading condition, the enhancement brought by the nanofluids were explained by the improvement of boiling phenomenon at evaporator. As discussed by Qu [19], the nanoparticles suspended at base fluid can enhance and stabilize the nucleation at the evaporator and increase the bubble release frequency, decreasing the thermal resistance of evaporator. This phenomenon increased as the concentration of nanofluids increased. This explained the higher thermal performance showed by the higher nanofluids concentration.

### 3.3 Effect of inclination angle

As its application for CPU cooling system, the effect of inclination angle to vapor chamber thermal performance has to be observed since the use of electronic device tend to be mobile and at many possible angle of operating position. The investigation conducted by testing vapor chamber with two different nanofluids concentration at three different inclination angles. The result is presented in Figure 6.

The results shows that for both concentration, inclination angle brought similar effect on the thermal performance of vapor chamber. For 2% nanofluid concentration, inclination angle of 45° only brought slight increase at the average CPU temperature over the horizontal position. Average temperature of CPU at horizontal position and at 45° inclination angle is 56.06 °C and 56.34 respectively. While at the vertical position or 90° inclination angle, vapor chamber produce significantly higher average CPU temperature as much as 57.32 °C. The same trend happened for the 3% nanofluids concentration. Vapor chamber charged with 3% Al<sub>2</sub>O<sub>3</sub>-water nanofluids yielded average CPU temperature of 53.72 °C, 53.83 °C, and 53.93 °C for horizontal, 45° inclination angle and vertical position. This is due to the different amount of working fluid available at the evaporator at different inclination angles. At horizontal position, evaporator is flooded with working fluid, ensuring the availability of fluid which absorbs heat and doing the phase change process. This made the heat transfer undergone efficiently and prevented dry-out. At 45° inclination angle, the working fluid of the evaporator decreased due to gravity. The working fluids were moved to the lower side of vapor chamber. Less working fluid means less amount of mass undergone the phase change, leading to the less amount of heat absorbed. This also multiply the possibility of dry-out, which happened because of the gravity hamper the ability of wick to pump liquid. The phenomenon is getting worse for the 0° inclination angle since the gravitational force become larger. At this vertical position, there was very little amount of working fluid left at the evaporator side, letting the heat transfer dominated by conduction and increasing the thermal resistance.

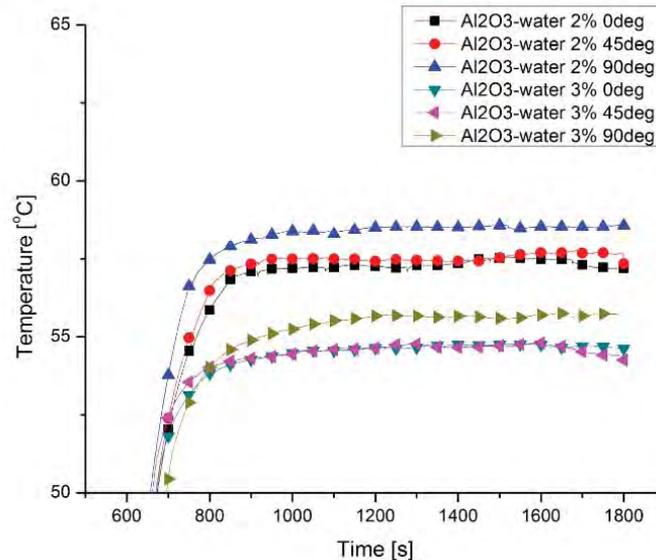

Figure 6 : Effect of inclination angle on thermal performance of vapor chamber

#### 4. CONCLUSION

The effect of working fluid on the vapor chamber was investigated. It was revealed that at a lower heat load, effects of working fluid are small due to the domination of conduction in vapor chamber heat transfer process. The effects become more and more significant as the higher heat load applied. The higher heat load intensify the boiling process and made the heat transfer process undergone efficiently. The effect of nanofluids concentrations were also observed. It was discussed that higher concentration of nanofluids enhance the thermal performance of vapor chamber due to the nanoparticles suspended at the working fluid enhancing and stabilizing the nucleation process, increasing the bubble release frequency and improving boiling phenomenon at the evaporator. This reduce thermal resistance and increase the thermal performance of vapor chamber. The effect of inclination angle was also observed that the effect of gravitational force made the horizontal position as the best working position for vapor chamber.

## ABSTRACT

Nowadays, a greater heat load due to miniaturization of electronic products causes the need for a new cooling system that works more efficient and has a high thermal efficiency, Synthetic jet is potentially useful for cooling of electronic components. This paper reports the results of our experimental studies, the influence of orifice shape for Impinging Synthetic Jet cooling performance. The effect of shape of the orifice of an impinging synthetic jet assembly on apparatus cooling of a heated surface is experimentally investigated. It will be seen the characteristics of convective heat transfer by moving the piezoelectric membrane. The prototype of synthetic jet actuator with two piezoelectric membrane that operate by 5 volt electrical current and creates a sinusoidal wave. The orifice shapes considered are square and circular. The results showed the significant influence of orifice shape and sinusoidal wave frequencies to the heat transfer rate that obtained. The temperature drop with a square orifice is found to be larger than that with circular shapes. Square orifice has larger covered area if compared to circular orifice at the same radius, thus resulting in larger entrainment rate that leading to an increase of heat transfer performance.

## Keywords

Cooling, Impinging Synthetic Jet, Orifice, Temperature drop

## 1. INTRODUCTION

Today, the requirement for proper thermal management which is perhaps the most crucial part of the electronic system design due to miniaturization is emphasized. One of the major causes for failure of electronic devices is thermal overstressing. A major challenge for thermal engineers is to create new alternative cooling system for such high heat flux components. In this study, synthetic jet with impingement type which can potentially be used for cooling of hot-spots is investigated. Synthetic jet works as jet of vortex generated from the continues vibration of the piezoelectric membrane which is driven by function generator to produce flow separation at the outlet of a cavity. A synthetic jet can be defined as zero-net-mass flux device commonly formed by suction and blowing of fluid from a small cavity [1]. Due to pulsating nature of the flow, the entrainment of ambient fluid into the jet is high as compared to that in a continuous jet, which helps in effective cooling mechanism [2]. Synthetic jet was driven by a piezoelectric actuator membrane that has a zero net mass input but produce non-zero momentum output.

In previous study about orifice parameter, Gulati et al. [3] discussed the effect of shape of orifice on local heat transfer enhancement for different jet impinging distance and Reynolds numbers. Moreover, Amitay et al. [4] experimentally investigated the efficiency and mechanism of cooling at constant heat flux surface by impinging synthetic jet. In their measurements, high frequency (1200 Hz) jets were found to be more effective at smaller axial distances and the low frequency (420 Hz) jets were found to be more effective at larger axial distances. In that work, a comparison with continuous jet was also presented. Chaudhari et al. (2010) discussed the effect of different shapes of orifice on the heat transfer characteristics of impinging synthetic jet. It was noticed that the rectangular orifice gives better heat transfer performance as compared to both square and circular orifice, at small axial distances. However, at large axial distances the square orifice outperformed other orifice shapes investigated. Lee et al. [5] studied the influences of orifice diameter on impinging jet heat transfer and fluid flow. They reported that local Nusselt numbers in the region corresponding to  $0 \leq r/d \leq 0.5$  increased with increasing orifice diameter. Many prior studies were focused on the role of orifice parameter on impingement heat transfer. Lee et al. [6] investigated the effect of orifice configuration for  $l/d$  of 0.2 with three different types of profiles at orifice exit, i.e., square edged, standard edged and sharp edged orifices. The tests were carried out for unconfined air jets impinging normally on smooth flat surface and the heat transfer results agree that at stagnation region sharp edged orifice performs better than others. Convective heat transfer is a very important aspect in synthetic jet cooling system since the generated vortices tend to dissipate the heat from surface to be cooled. McGuinn et al. [7] investigated synthetic jet as a current potential technology for microelectronics cooling with focusing on the distribution of flow and heat transfer characteristics from jet sprayed on the surface by blowing with jet at the Reynolds number range of 1100-4900 and orifice diameter of 1-6 mm, as result is a deal between measured average and fluctuating heat transfer distributions and local acceleration of synthetic jet. Travnicek and

Tesar [8] recommended that the basic goal in convective heat transfer is to mobilize the cooling fluids as near as the surface to be cooled and the synthetic jet impinging mechanism are influenced by the actuator configuration such as the orifice and cavity parameters.

In the present work, a comprehensive study was done by computational and experimental method on an original design of synthetic jet actuator that operate based on piezoelectric membrane which driven by function generator. In the current stage, the main focus of the study was to characterize the temperature field of an impinging flow configuration with variation of orifice shape and driving frequency of membrane to generate turbulence flow.

## 2. METHODS

The present study was done comprehensively by computational and experimental works in order to investigate effect of orifice shape to cooling performance of an impinging synthetic jet in cooling system for microeletronic component. The detail of each works are explain in detail as follows.

### 2.1 Computational work

This computational model is used to analyze the thermal flow at synthetic jet by using a mathematical model k- $\omega$  SST (Shear Stress Transport). Ambient temperature is assumed 27 °C and the temperature of the bottom wall is heated, maintained at isothermal temperature of 60 °C. Boundary walls on both sides of the actuator is assumed to have a constant static pressure with a pressure of 1 atm.

After that, the movement of the diaphragm is modeled with a user defined function (UDF). In this modeling, it will be seen some turbulent flow regions, while others remain at the laminar flow conditions indicated by the low value of Reynolds. The parameters used at this simulation are model arrangement, fluid properties and the boundary conditions.

At the beginning ( $t = 0$ ), the position of the diaphragm is at the bottom of the cavity. The diaphragm movement is assumed equal to the movement of the piston in a cylinder, in which upper membrane uses variation of square Waves and lower membran uses variation of sine waves. The motion of upper and lower membran are approached with equation (1) to (4).

Deflection of upper membran expressed as

$$Y(t) = \frac{4k}{\pi} \left( \sin(2\pi ft) + \frac{1}{3} \sin(2\pi ft) + \frac{1}{5} \sin(2\pi ft) \right) \quad (1)$$

Therefore, velocity of upper membrane expressed as,

$$V(t) = \frac{4k}{\pi} \left( 2\pi f \cos(2\pi ft) + \frac{2\pi f}{3} \cos(2\pi ft) + \frac{2\pi f}{5} \cos(2\pi ft) \right) \quad (2)$$

Whereas, deflection of lower membrane expressed as

$$Y(t) = k(\sin(2\pi ft)) \quad (3)$$

And, Velocity of lower membrane expressed as

$$V(t) = k(2\pi f \cos(2\pi ft)) \quad (4)$$

where k represented maximum velocity actuated by oscillated motion of membrane in a cavity, t is time operation both of membrane and f is frequency of wave function that given by function generator.

### 2.2 Experimental work

The quality of cooling results is verified by time history of convective heat transfer studies, and the results are validated against existing experimental data. Experimental activities were carried out by measuring the temperature at the heatsink using a digital thermometer for 120 minutes. The heatsink module used in this study has circular form with 32 fins. The material was made of aluminum. The heatsink diameter was 11 cm and height of 5 cm. Heat source was obtained from the heater mat at 60°C which was controlled by using a thermostat. Measurements were performed using k-thermocouple under open conditions at ambient temperature 30°C. The impinging synthetic jets modul used in this study were constructed in the form of a cylinder cavity having two piezoelectric membrane at the top and bottom. Piezoelectric wass working to move the surrounding fluid in order to remove the air from the nozzle, with square and circular shape of orifices. The casing was made of nylon material that could be assembled easily. Sinusoidal and square wave function was generated by a sweep function generator with the frequency of 80 Hz, 120 Hz and 160 Hz. The experimental work was conducted using variation of orifice shape, that is square and circular orifice at the same diameter, 2 mm.

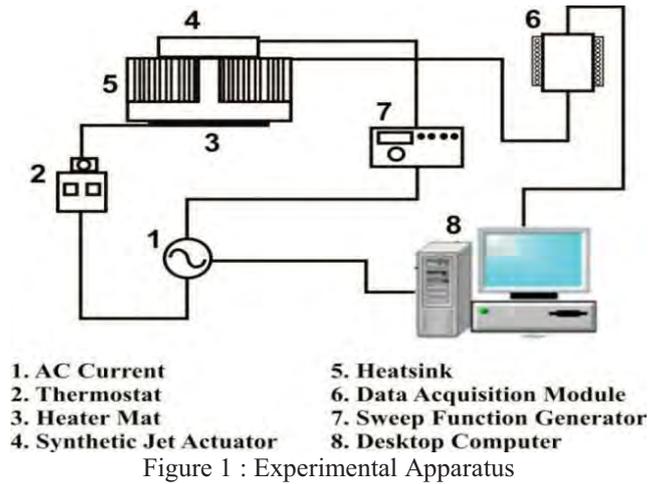

Figure 1 : Experimental Apparatus

Figure 1 shows the detail of the experimental apparatus used in this study which consisted of the thermostat, heater mat, impinging synthetic jet module, heat sink and DAQ (Data Acquisition). More detail for Synjet cooling apparatus was depicted in Figure 2.

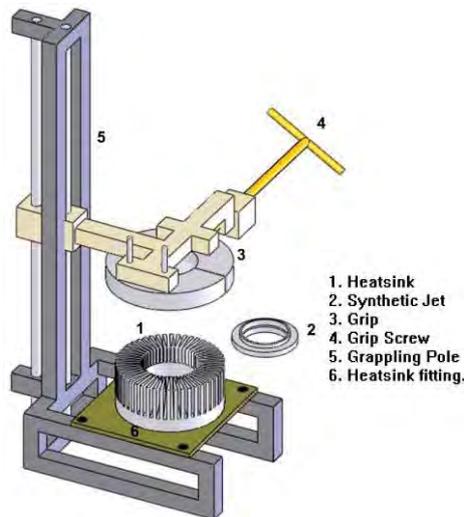

Figure 2 : Synthetic Jet Cooling Apparatus

### 3. RESULTS AND DISCUSSION

#### 3.1 Computational work

Figure 3 depicted static temperatur contour inside cavity, inside heatsink, and outer field outside the heatsink using circular orifice with 120 Hz of Sinusoidal wave function. Simulation was made for 1/16 condition with the assumption that suction phase and blowing phase was uniformly at every nozzle.

In Figure 3, it can be seen that heat flow moving up from cavity heatsink toward heatsink fins. At condition  $\frac{1}{4}$  cycle, heat that produced by heater mat starts to move up inside the heatsink. And then, at condition  $\frac{1}{2}$  cycle, it seems that heatflow is move toward heatsink fins. Furthermore, at condition  $\frac{3}{4}$  cycle, heatflow moves faster than before to go out from heatsink fin. And at 1 cycle, heatflow is released from heatsink to environment gradually.

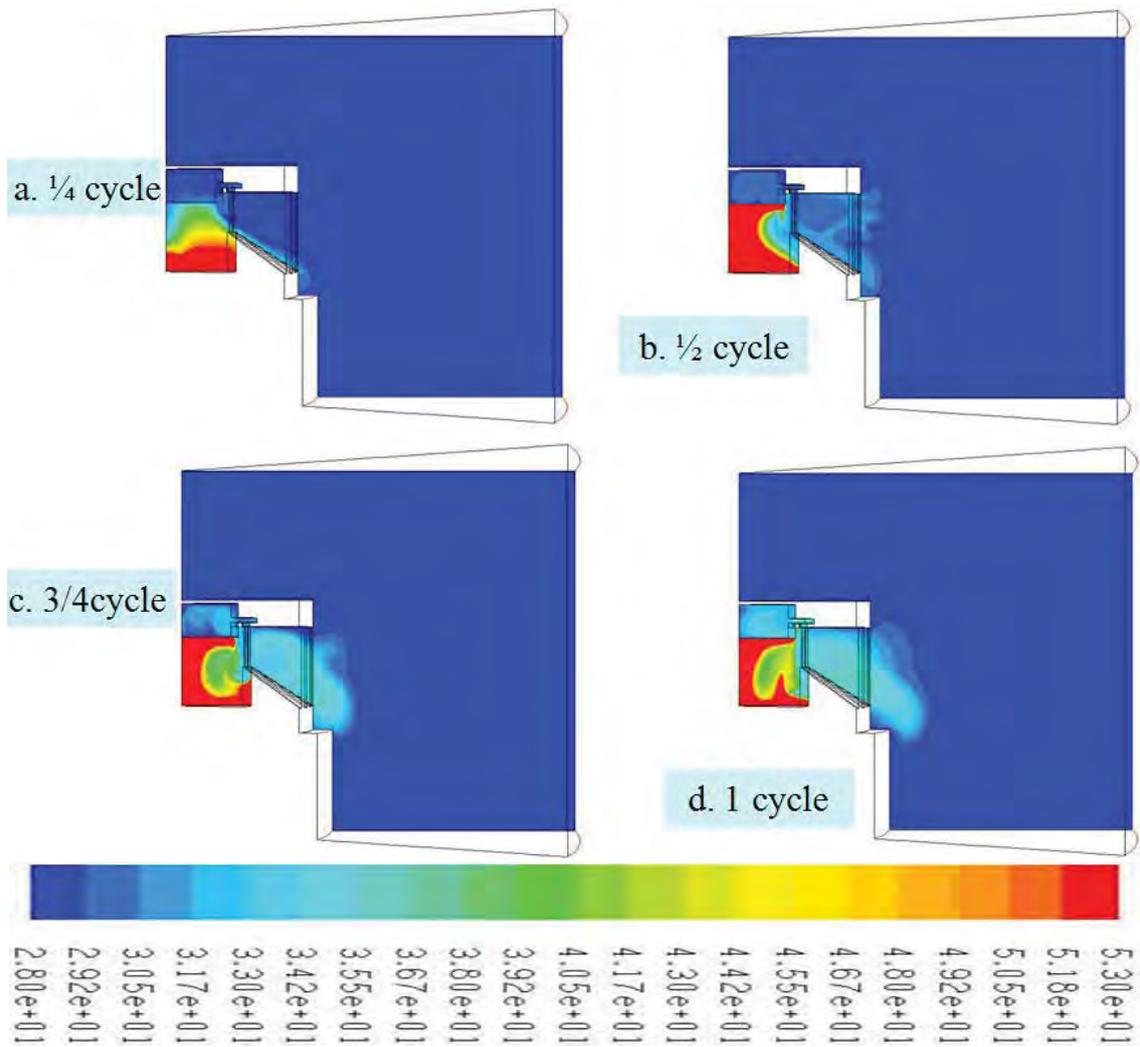

Figure 3 :Temperature Contour with Circular orifice (120 Hz of square Function).

Figure 4 shows static temperature contour inside cavity, inside heatsink, and outer field outside the heatsink using square orifice with 120 Hz of square wave function. Simulation was made for 1/16 condition with the assumption that suction phase and blowing phase was uniformly at every nozzle.

In Figure 4, seen that heat flow move up from cavity heatsink toward heatsink fins but faster if compared with sinusoidal wave function. At condition 1/4 cycle, 1/2 cycle, and 1 cycle was seems like using sinusoidal wave function but with faster moving fluid and contour of static temperature inside cavity, inside heatsink was more dominated with low temperature region if compare with sinusoidal driven membrane.

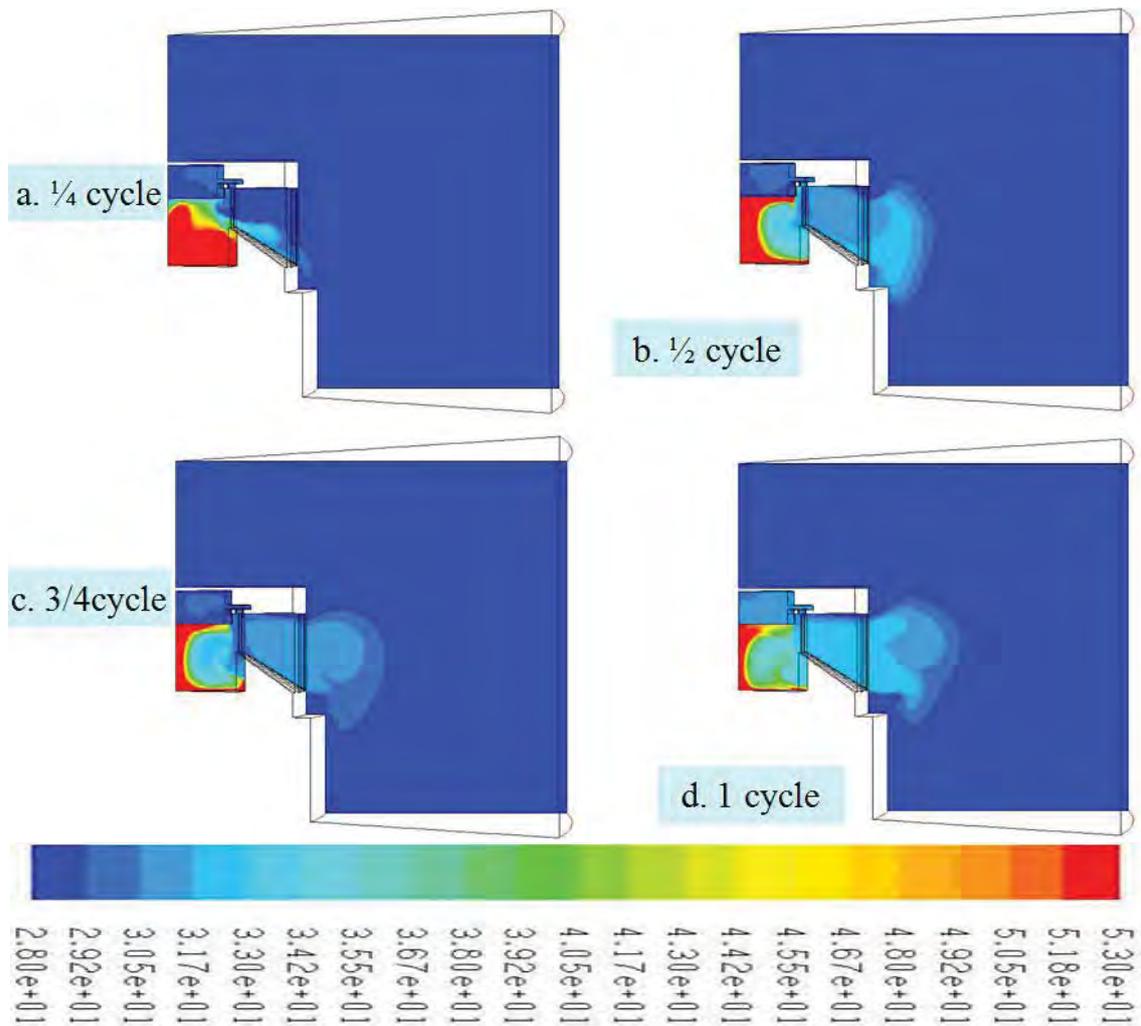

Figure 4. Temperature Contour with square orifice (120 Hz of square Function).

### 3.2 Experimental work

Figure 5 shows the temperature history for 3600 seconds experiment with variation of orifice shape at the same diameter using 120 Hz of square wave function. In that figure, it can be seen that at both of orifice shape, cooling performance become remarkable after 1000 seconds activation of synthetic jet. Apparatus with square orifice is decrease 2.8°C temperature during the experimental work while circular orifice at the same diameter decrease 1.5°C. Moreover, after 2500 seconds with circular orifice, the temperature of heatsink tend to rise, whereas with square orifice, temperature of heatsink still decrease although with lower temperature gradient. So it follows that 120Hz of square with square orifice has better cooling characteristics than circular orifice at the same condition. The tendency of temperature to rise as well as the cooling performance with lower gradient temperature at any given time indicate significant effects of recirculation due to confinement effect. Agrawal et al. [9] have explored that confinement effect can be decreased if we increase the impinging distance at a certain number. However, at larger axial distances, the jet velocity reduces due to entrainment of still ambient air, which again reduces the heat transfer coefficient. Gulati et al. [3] have discussed that besides recirculation, another possible reason and need to be investigated later for the higher cooling performance with square orifice at small distances is that the Nusselt number contours retain the shape of the orifice from which the flow emerges at lower axial distances. So that, a larger surface area is covered by the flow with a square orifice at smaller axial distances if compared to circular orifice with same radius. From the previous investigation by Grinstein and DeVore [10], the entrainment rate for the square orifice is significantly larger than those for circular orifice. Due to a large entrainment, square orifice attains a larger mass flux at the same distance from the orifice. The mass flux has a direct bearing on momentum and heat transport between jet and surrounding. This is a possible reason of square orifice synthetic jet outperforming its circular orifice counterpart.

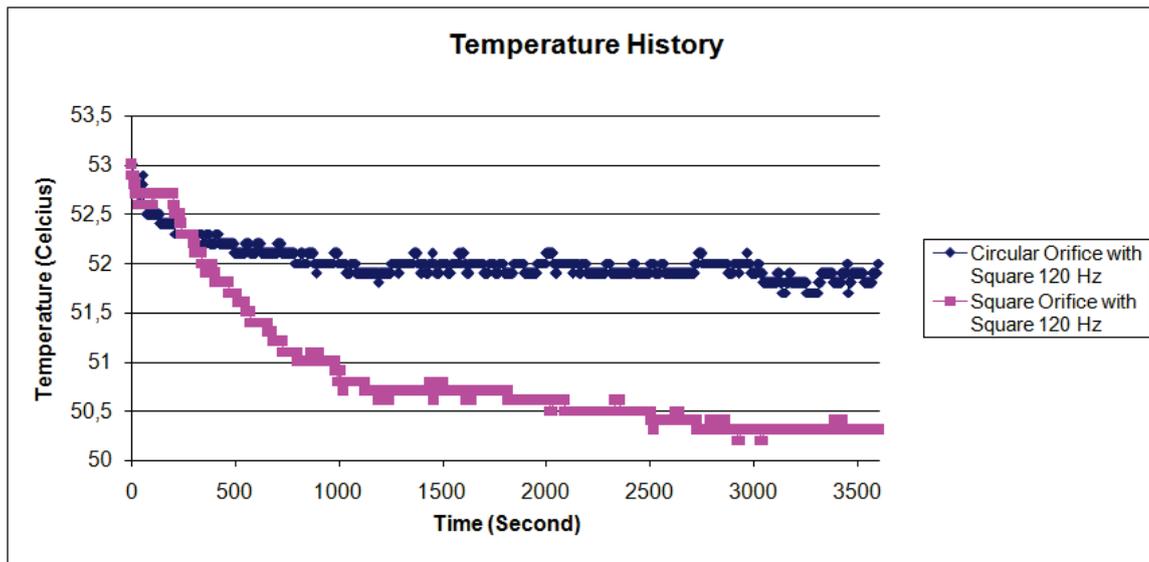

Figure 5 : Temperature History of Experiment with square and Circular orifice (120 Hz of square Function).

#### 4. CONCLUSION

The heat transfer experiments and CFD simulation are conducted using synthetic jet with various type and frequency of wave function and shape of orifice. From variation of sinusoidal and square 80 Hz, 120 Hz, and 160 Hz and orifice shape variation square and circular orifice, it is found that cooling effect for 60 minutes measurement was optimum with 120 Hz square function and square orifice. Both of experimental and computational results revealed that using shape orifice variation on same aspect ratio give significant effect to develop synthetic jet as new alternative cooling system of microelectronic components. Square orifice has larger covered area if compared to circular orifice at the same radius, thus resulting in larger entrainment rate that leading to an increase of heat transfer performance.

## ABSTRACT

Technology of Friction Stir Welding (FSW) as a technique for joining metal is relatively new. In some cases on Aluminum joining, FSW gives better results compared with the Arc Welding processes, including the quality of welds and less distortion. FSW can even use milling machine or drilling machine, by replacing the tools and the appropriate accessories. The purposes of this study was analysis the effect of process parameters on micro Friction Stir Lap Welding to the tensile load of welds, in this case using A1100 Aluminum material, with thickness of 0.4 mm. Tools material are HSS material, which are shaped with micro grinding process. Tool Shoulder diameter are 3 mm, while the diameter pin 2 mm and a length of pin 0.7 mm. The parameter variation used in this study were the variable of spindle speed (2300, 2600, and 2900 rpm), variable of tool tilt angle (0, 1, 2 degree) and a variable of Feed rate (50, 60, 70 mm/min). Where the variation of these parameters will affect to the mechanical properties of welds (as response) was the tensile load. Analysis and to find the optimum parameters of the correlation between the microFSLW parameters with the tensile load of welds, using a Response Surface Methods (RSM).

## 1. INTRODUCTION

Friction stir welding technology (FSW) is a metal joining technique is relatively new. FSW technology into the aluminum alternative joining process is relatively simple, even in some cases has advantages when compared with conventional joining process (e.g.: welding process, Riveting processes). FSW can even use milling machine or drilling machine, with replacing appropriate tools, jigs and fixtures.

The development of micro systems in the industrial community has been impressive in both their pace and diversity of new applications. The trend of more compact and sophisticated Microsystems requires miniaturized, high precision, and high quality mechanical means for device bonding, assembly and packaging [1]. Shoulder usually involves local heating, where heating sources derived. This technique requires contact with the electrodes, it is less favored in the application of micro-systems packaging. When laser welding is often used for a variety thin products such as biomedical tools, cigarette lighters, a search tool springs, laminated motor / transformer, battery cans and packages of hybrid circuits. As an alternative, FSW can be used in applications for thin metal connecting electronic, medical and micro equipment in order to limit damage from excessive heat [1]. Scialpi *et al.* [2] have successfully applied FSW on thin plastic. For joining a thin aluminum plate (<1mm) FSW technology and equipment needs special technology and devices. Thin plate and research related parameters called micro Friction Stir Welding.

Research of FSW process on thin material urgently needs to be done because of joining thin plate are often worked in the workshop. It is necessary to study the jig and joining techniques, the optimum parameters and their impact on the quality of welds, surface quality and stability of the welding results. The purpose of this study was to analyze the effect of welding parameters on the welds shear strength of Friction Stir Spot Welding connection (FSSW) on A1100 aluminum plate, with a thickness of 0.4 mm. The variation of the FSSW parameters used in this study were:

1. Tool rotation (spindle speed)
2. Plunge speed
3. Pin diameter

Further analysis of the interaction between the welds properties and Friction Stir welding process parameters to obtain the optimum response, carried out by applying *Response Surface Methodology* ((RSM)

## 2. BASIC THEORY

Friction Stir Welding (FSW) was invented at The Welding Institute (TWI) of the United Kingdom in 1991 as a solid-state joining technique and was initially applied to aluminum alloys. The basic concept of FSW is remarkably simple. A non-consumable rotating tool with a specially designed pin and shoulder is inserted into the abutting edges of sheets or plates to be joined and subsequently traversed along the joint line. Then, the material is heated and melted around the tool, causing plastic deformation and solid-state bonding occurs between the surfaces of the sheet up and down. FSW is a solid-state joining process in which the material being welded is not completely melted during the process, and this process is applied at the time we want to preserve the character of the beginning of the base material. Figure 1 illustrates process definitions for the tool and workpiece. Most definitions are self-explanatory, but advancing and retreating side definitions require a brief explanation. Advancing and retreating side orientations require knowledge of the tool rotation and travel directions. In Fig.1, the FSW tool rotates in the counterclockwise direction and travels into the page (or left to right). In Fig.1 the advancing side is on the right, where the tool rotation direction is the same as the tool travel direction (opposite the direction of metal flow), and the retreating side is on the left, where the tool rotation is opposite the tool travel direction (parallel to the direction of metal flow) [1].

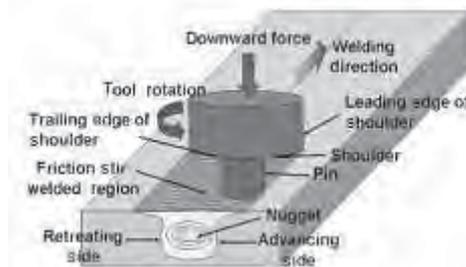

Figure 1: Schematic drawing of FSW [1]

There are two considerations the speed of tool to be done on FSW; how fast spindle speed and how fast travel speed. These two parameters have a great role and be selected carefully to ensure a success and efficient welding. The relationship between the speed of welding and heat input during welding is very complex. But in general, it can be said that the increase in rotational speed or lower traverse speed will result in a hotter weld. In order to produce a success weld it is necessary that material around tool is hot enough to enable the flow of plastic required and minimize forces acting on tool. If material is too cold will make the cavity or other defects can arise in slurry zones, and in extreme cases the tool may break off [3].

During the tool plunge, material displaced by the pin is fed into the cavity within the tool shoulder. This material serves as the start of a reservoir for the forging action of the shoulder. Forward movement of the tool forces new material into the cavity of the shoulder, pushing the existing material into the flow of the pin. Proper operation of this shoulder design requires tilting the tool  $2^\circ$  to  $4^\circ$  from the normal of the workpiece away from the direction of travel; this is necessary to maintain the material reservoir and to enable the trailing edge of the shoulder tool to produce a compressive forging force on the weld [1].

The Advantages of FSW process are:

- Improved safety due to the absence of toxic fumes or the spatter of molten material.
- No consumables — A threaded pin made of conventional tool steel, *e.g.*, hardened H13, can weld over 1000m of aluminum, and no filler or gas shield is required for aluminum.
- Easily automated on simple milling machines — lower setup costs and less training.
- Can operate in all positions (horizontal, vertical, *etc.*), as there is no weld pool.
- Generally good weld appearance and minimal thickness under/over-matching, thus reducing the need for expensive machining after welding.
- Low environmental impact.

Disadvantages of Friction Stir Welding process:

- Exit hole left when tool is withdrawn.
- Large down forces required with heavy-duty clamping necessary to hold the plates together.
- Less flexible than manual and arc welding processes (difficulties with thickness variations and non-linear welds).
- Often slower traverse rate than some fusion welding techniques, although this may be offset if fewer welding passes are required

This process is mostly used in large-sized aluminum material in which the material conditions are not easy for the Heat-treatment after welding to restore the initial properties. Kawasaki Heavy Industries (Japan) are using friction stir spot welding to attach stringers to roof panels. They developed a new aluminium car body shell, which is assembled by this method. Main

reason for Kawasaki Heavy Industries is the fact that it improves the fatness and visual appearance of the skin panels because of the low heat input [3].

Some researchers try to know the correlation of FSW parameters process. Rajakumar *et al.* [5] developed a mathematical model using the RSM to analyze the influence of process parameters and the parameters of FSW tools on the material tensile strength of aluminum AA7075. Lakshminarayanan and Balasubramanian [6] also studied the effect of FSW welding parameters on tensile strength of the connection handle is made of aluminum alloy AA7039 using Taguchi's parametric design approach. Rajakumar [7] investigated the mechanical properties of the empirical relationship to describe the tensile strength and hardness are the mechanical properties that are considered important. Scialpi [2], Wang [8] and Baskoro [9,10] studied FSW on thin plate (thickness < 1 mm)

Study the parameter effect of *micro Friction Stir Lap Welding* process to the shear strength of the weld, in this case using A1100 Aluminum material, with a thickness of 0.4 mm. Tools Material are made from material HSS, which is the pin shape processed with micro grinding. Tool Shoulder diameter are 3 mm, with a cylindrical pin of 0° angle, while the diameter pin 2 mm and a length of pin 0.7 mm. The parameter variations used in this study are the variable of spindle speed (2300, 2600, and 2900 rpm), variable of *tool tilt angle* (0°, 1°, 2°) and a variable of *Feed rate* (50, 60, 70 mm/min). The variation of these parameters will affect to the mechanical properties (as response), *i.e.* the tensile strength of welds joint. Analysis of the interaction between the welds and spot welding process parameters to obtain optimal weld strength, carried out by applying Response Surface Methods (RSM). Research Specimen were aluminum plate A1100 (Table 1) and cut in a size of 100 mm x 50 mm. At welding process, the specimens were stacked with a width of 40 mm overlap as shown in Fig. 2.

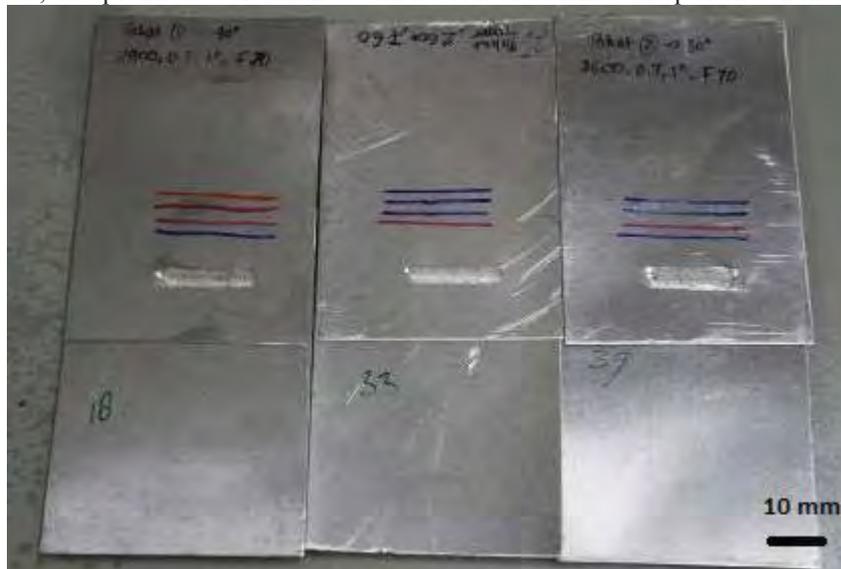

Figure 2: Specimens of micro FSLW

The machines that used in the FSW process was CNC Vertical Milling Machine, Model EMCO type VMC-200. The holder of the workpiece on the machine table used a fixture as shown in Fig. 3. To control the spindle speed of mini grinder used digital photo tachometer, and adjusted manually.

Table 1: Chemical composition of Aluminum A 1100

Composition	Percent
Cu	0-0.05 %
Mg	0-0.05 %
Si	0-0.25 %
Fe	0-0.40 %
Mn	0-0.05 %
Zn	0-0.07 %
Ti	0-0.05 %
Al	balance

*Weld* Specimens that have been processed, cut using wire cut, with a width of 25 mm, for tensile testing sample. The shear strength of the specimen tested using the tensile test Machine merk Galdabini and the maximum load that can be tested is 2500 N, with a withdrawal rate of 5 mm/min. The tensile test, used JIS standard (JIS.2201-1999) as shown in Fig. 4.

### Regression models

Researcher want to determine the value of the parameter input process in which the optimum response. Optimum can be either minimum or maximum specific functions in terms of input parameters. *Regression Models* is a collection of mathematical and statistical techniques useful for analyzing problems where several independent variables affect the dependent variable or response and the goal is to optimize the response [12]. In many experimental conditions, it is possible to represent an independent factor in quantitative form as given in equation (1). Then these factors can be considered as having a functional relationship or response as follows:

$$Y = \phi(x_1, x_2, \dots, x_k) + e_r \quad (1)$$

Between the response  $Y$  and  $x_1, x_2, \dots, x_k$  factors quantitative  $k$ , the function  $\Phi$  is called *the response surface* or *the response function*. residual  $Er$  measure experimental error. For the set of independent variables, response surface characteristics. When the mathematical form of  $\Phi$  is unknown, it can be expected in the experimental area with a polynomial. In this investigation, Regression Models applied to develop a mathematical model in the form of a multiple regression equation for the quantitative characteristics of aluminum alloy FSW. In applying Regression Models, the independent variable is seen as a mathematical model fitted surface. Represent the tensile strength of welds TS, the response is a function of tool rotation speed (N), the angle of the tool (A), and feed rate (F), can be expressed in Table 2.

The design of experiment uses a model of a three-level factorial design. Factorial designs are widely used in the experiment, when researchers need to evaluate the combined effect of several controllable factors in the response.  $3^q$  factorial design is factorial arrangement with  $q$  factors, each at three levels. Rate factor referred to as low, medium, and high, represented by a “-1” (low), “0” (intermediate), and “1” (high). When measuring the response variable contains all possible combinations of factor levels, type of experimental design is called a full factorial experiment (complete factorial experiment) [13].

### 3. RESULTS AND DISCUSSION

Designs of experiment for  $\mu$ FSSW and parameters process are showed in Table 2. Because of the difficulties to find the contact area, then the data used are *Tensile Load peak*.

Table 2: DoE and Shear strength of  $\mu$ FSLW

No	Tilt angle [°]	Feed rate [mm/ menit]	SpindleSpeed [rpm]	Code A [Tilt angle]	Code B [Feed rate]	Code C [Spindle Speed]	Load Peak [N]
1	0	50	2300	-1	-1	-1	120.5
2	0	50	2600	-1	-1	0	197.8
3	0	50	2900	-1	-1	1	142.9
4	0	60	2300	-1	0	-1	87.1
5	0	60	2600	-1	0	0	104.8
6	0	60	2900	-1	0	1	83.7
7	0	70	2300	-1	1	-1	246.6
8	0	70	2600	-1	1	0	169.3
9	0	70	2900	-1	1	1	170.8
10	1	50	2300	0	-1	-1	190.5
11	1	50	2600	0	-1	0	205.4
12	1	50	2900	0	-1	1	168.1
13	1	60	2300	0	0	-1	139.9
14	1	60	2600	0	0	0	177.6
15	1	60	2900	0	0	1	308.9
16	1	70	2300	0	1	-1	146.1
17	1	70	2600	0	1	0	150.3
18	1	70	2900	0	1	1	218.3
19	2	50	2300	1	-1	-1	254
20	2	50	2600	1	-1	0	56.5
21	2	50	2900	1	-1	1	121.5
22	2	60	2300	1	0	-1	172.2
23	2	60	2600	1	0	0	181.6
24	2	60	2900	1	0	1	430.2
25	2	70	2300	1	1	-1	280.9
26	2	70	2600	1	1	0	67.2
27	2	70	2900	1	1	1	196.4

The results of Response Surface Methods (RSM) analysis of tensile test data (tensile strength) produces equation (2), and plotted in Fig. 5.

$$Y_{ts} = 202.9 + 29.3.A + 11.3.B - 26.6.C + 3.1.A.B - 16.5.A.C - 14.2.B.C - 12.6.A^2 - 21.5.B^2 - 2.1.C^2 \quad (2)$$

Equation 2 gives the mathematical model of the FSSW parameters interaction on tensile load of welds, and Fig. 5 shows the 2 parameters correlation to tensile load. There are 2 parameters (A, B) that influence positively to response. Parameter C has negative effect to the response. It shows that Tilt angle (A) will increase the Tensile load. There are similarities between the results of FSW on thin plate and FSW on thick plate, which is tilt angle parameter has positive correlation with tensile load [10]. Otherwise, by the increases of Spindle speed (C) it will decrease the tensile load.

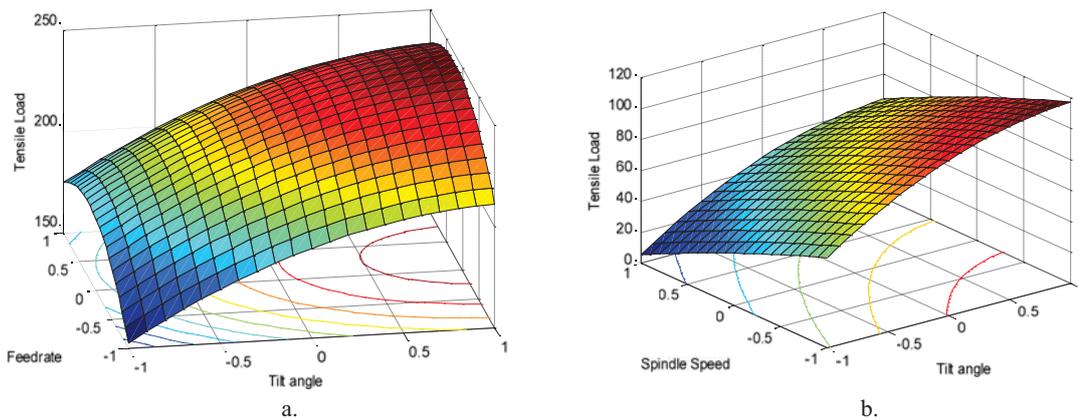

Figure 5: 2 parameters correlation to tensile load. a. Tilt angle-Feed rate to tensile load. b. Tilt angle-Spindle Speed to tensile load.

#### 4. CONCLUSION

From the experiment, it can be concluded that:

- a. The important welding parameter in Micro FSW Lap welding process is tilt angle.
- b. Research of FSW need to be done on a wider parameter range, and more variation of material.
- c. There are many potential applications in micro friction stir welding and its advantages of low temperature.
- d. FSW is a promising *green* technology.

## ABSTRACT

To improve production efficiency and quality in fiber boatyard many research have been done both through technology as well as management aspects. One of these developments is Vacuum Assisted Resin Transfer Molding (VARTM) which is claimed to have high strength and material efficiency. This method has not much been applied in Indonesian boatyards, most of them are still using conventional hand lay-up. The research is aimed to investigate the strength of the composite and the optimum amount of materials to obtain the required strength for its application on boat building. Experimental approach was conducted in the research using 800 biaxial and 900 unidirectional E-glass for reinforcement, and vinylester (RIPOXY R-802-EX-1) resin for the matrix. The ultimate tensile strength and Young's modulus of the composites are obtained through tensile and flexural test based on ASTM D 3039 and ASTM D 790 standards. The data obtained are used to determine the optimum number of layers and fiber content on certain locations of the boat hull structure in order to comply with the requirements of classification rules.

### Keyword:

Vacuum Assisted Resin Transfer Molding, boat, fiber content, strength

## 1. INTRODUCTION

### 1.1. Background

Composite technology has been developing very rapidly including its application on boatbuilding. Researches have been carried out to improve the production efficiency and quality of boatbuilding, including the application of materials and production processes. Vacuum Assisted Resin Transfer Molding (VARTM) is claimed could increase material efficiency and strength in many applications [1], but this method has not been widely applied in Indonesian boatyards, most of them still use conventional hand lay-up method [2]. It is expected that the claim would also applicable for boatbuilding.

### 1.2. Research objectives

The research is aimed to investigate the role of Vacuum Assisted Resin Transfer Molding (VARTM) in improving the efficiency and quality boat production, to obtain tensile and flexural strength data of the composite, to determine the optimum thickness and fiber content of the material to be applied in boatbuilding as required by the classification rules.

## 2. RESEARCH METHODOLOGY

Experimental and analytical approaches were conducted in the research using 800 biaxial and 900 unidirectional E-glass for reinforcement, and vinylester (RIPOXY R-802-EX-1) resin for the matrix. The ultimate tensile strength and Young's modulus of the composites are obtained through tensile and flexural test based on ASTM D 3039 and ASTM D 790 standards [3]. Ansys software was used to simulate the optimum thickness and fiber content of the material for its application on boatbuilding based on the data obtained from the experiment and the requirements of classification rules.

### 2.1. The materials

For reinforcement two types of E-glass were used in the experiment; unidirectional fabric 0° with specific density of 894.56 g/m<sup>2</sup>, the orientation was made 45° and 90°, and biaxial fabric +45°/-45° with specific density of 841.89 g/m<sup>2</sup>. Vinyl ester Ripoxy R-802 EX-1 was chosen for the matrix with the following specifications: specific density 1.12 gr/cm<sup>3</sup>, tensile strength 78 Mpa, Tensile modulus 3.38 Gpa, Flexural Strength 127 Mpa, Flexural modulus 2.75 Gpa, elongation 6 %, Heat distortion temperature 100°C. Vinyl ester was mixed with 10% monomer, 0.5% promoter, and 2% catalyst. Vinyl ester was chosen due to its high strength, hardness, and high resistance to heat and corrosion compared to polyester and epoxy [4].

## 2.2. Vacuum assisted resin transfer molding (VARTM) method

In Vacuum Assisted Resin Transfer Molding (VARTM) prior of its laminating process all the reinforcement fiber is laid on the mold, covered with plastic sheet and sealed to prevent the mold from leaking during the vacuum process, and the resin is prepared in a container and connected to the mold via plastic hose through a special entrance hole. Vacuum pressure was utilized to take the air out of the laminate. The pressure difference between the atmosphere and vacuum provides driving force for infusing the resin into the laminate and to compact the fiber reinforcement to prevent its orientation from shifting during curing process [5].

Figure 1 : Vacuum Assisted Resin Transfer Molding Process

## 2.3. Tensile and flexural strength

Tensile strength test was carried out based on ASTM D 3039 standard with the following specimen dimensions: length 250 mm, breadth 25.4 mm, two-layer biaxial E-glass thickness 1.33 mm and two-layer unidirectional E-glass thickness 1.5 mm, minimum tab length 38 mm. The test conditions standard were: room temperature  $23 \pm 1^{\circ}\text{C}$ , humidity  $50 \pm 10\%$ , tensional speed 16.7 m/s and 33.4 m/s.

Flexural strength test was carried out based on ASTM D 790 standard for thickness less than 1.6 mm the specimen dimensions are: length 50.8 mm, breadth 12.7 mm, minimum pointer radius 3.2 mm. The test conditions standard were: room temperature  $23 \pm 2^{\circ}\text{C}$ , humidity  $50 \pm 10\%$ .

Theoretically the tensile strength and modulus of the composite could be obtained from the following calculations, even though laboratory test is still needed to compare their accuracy:

$$\text{Tensile strength} = 1800 W_f^2 - 1400 W_f + 510 \text{ (N/mm}^2\text{)} \quad (1)$$

$$\text{Tensile modulus} = (130 W_f^2 - 104 W_f + 39) 10^3 \text{ (N/mm}^2\text{)} \quad (2)$$

Where:  $W_f$  is fiber content

The same approach is also applied for obtaining the flexural strength and modulus:

$$\text{Flexural strength} = 502 W_f^2 + 106.8 \text{ (N/mm}^2\text{)} \quad (3)$$

$$\text{Flexural modulus} = (33.4 W_f^2 + 2.2)10^3 \text{ (N/mm}^2\text{)} \quad (4)$$

## 2.4. Minimum hull thickness

There are some approaches available to determine the minimum composite thickness for boat hull include using scantling number [6], pressure forces to the boat parts from various directions [7], and other empirical formulas introduced by some classification societies such as American Bureau of Shipping (ABS) [8], Det Norske Veritas (DNV) [9], and Lloyd's Register of Shipping (LR) [10].

The minimum thickness is obtained from the sum of laminate layers that form the composite based on the required strength at the specific parts of the boat. The thickness of single laminate layer is obtained from the following formula:

$$t = m_f (S_f / W_f - (S_f - S_r)) / (1000 \cdot S_f \cdot S_r) \quad (5)$$

Where:  $m_f$  is fiber weight;  $S_f$  is density of the reinforcement; and  $S_r$  is the density of the matrix.

## 2.5. Fiber content

Fiber content is the amount of fiber reinforcement in the composite. In hand lay-up method the reinforcement usually consists of CSM (Chopped Strand Mat) and WR (Woven Roving), while in VARTM method multiaxial fiber is used for the reinforcement [11]. Following are fiber ratio of the reinforcement:

Table 1 Fiber Ratio of Reinforcement

Reinforcement Type	Glass Content
CSM (Hand Lay Up)	0.28
WR (Hand Lay Up)	0.35
Multiaxial (VARTM)	0.7

And therefore the weight of each laminate of the composite formed is obtained from the following formula:

$$\text{Weight per laminate} = (\text{fiber weight} \times \text{Fiber/Resin ratio}) + \text{fiber weight} \quad (6)$$

### 2.6. Optimum thickness and fiber content

The optimum thickness and fiber content of the composite to be applied in a specific boat using VARTM method are determined based on its tensile and flexural strength of the material that is required to withstand the forces work to a particular part of the boat such as bottom hull, side hull, and deck [12]. The tensile and flexural strength of E-glass 800 biaxial and 900 multi-axial used in the experiment are as follows:

Table 2 Tensile and Flexural Strength and Modulus of reinforcement

Material	Tensile Strength (N/mm <sup>2</sup> )	Tensile Modulus (N/mm <sup>2</sup> )	Flexural Strength (N/mm <sup>2</sup> )	Flexural Modulus (N/mm <sup>2</sup> )	Thickness per layer (mm)
800 Biaxial	412	29900	352.78	18566	0.61
900 Multi-axial	318	23400	288	14244	0.69

Since the strength of a composite is based on its reinforcement therefore the required fiber content in hand lay-up method is used as reference for the composite's strength, and the optimum thickness is derived based on this requirement.

### 3. CASE STUDY

To investigate the efficiency improvement by using VARTM compared to conventional hand lay-up a case study was carried out by applying both methods to a chosen boat design with the same material thickness required by certain classification society. The boat being chosen for the experiment is a patrol boat with the following main particular:

- Loa = 28 m
- Lwl = 26.9 m
- B = 5.4 m
- H = 3.42 m
- T = 2.95 m
- V = 30 knot

The results of analytical calculations of hand lay-up and VARTM methods for the bottom hull and side hull of the chosen boat are as follows:

Table 3 Analytical Calculation results

Hand lay-up							
Boat part	Thickness (mm)	Fiber content	Tension to break (N)	Tensile strength (Mpa)	Tensile Modulus (Gpa)	Flexural strength (Mpa)	Flexural Modulus (Gpa)
Side hull	15	8400	1673100	110	9.5	190.00	7.7
Bottom hull	26	14400	2944000	115	9.7	192.50	8
VARTM							
Side hull	15	18700	4682977	339	24.8	302.4	15.2
Bottom hull	26	33100	8188792	329	24.2	295.7	14.7
Efficiency Improvement							
Side hull		222.61%	180 %	308.18%	261.05%	159.16%	197.40%
Bottom hull		229.86%	178 %	286.08%	249.48%	153.61%	183.75%

Since the strength of the composite is in its reinforcement therefore the optimization of the composite thickness and fiber content is conducted by maintaining the value of hand lay-up's fiber content as reference of strength, which is around 45% of the VARTM method. For safety reason the thickness is multiplied by 1.5 as safety factor, and therefore for the chosen boat the proposed thickness of the side hull will be 10 mm, and the bottom hull will be 18 mm.

#### 4. CONCLUSION

The application of VARTM method in boat building has proven the improvement of efficiency both in using of material and production process, and increase the quality of the composite. By maintaining the fiber content as required by certain classification rules for hand lay-up the thickness of the composite could be optimized whereas the strength of the composite is still higher than hand lay-up method.

In the case study application on a 28 m patrol boat the composite thickness efficiency of the VARTM method could reach as high as 45% compare to hand lay-up method, and this will also affect the production cost of the boatyard.

### ABSTRACT

*Weight reduction and materials saving are one of the key priorities from a viewpoint of global environmental conservation. In the 1970s to 1980s, tube forming (TF) technology was in the second technological innovation for improving automotive fuel economy. In recent over one decade, TF technology, especially, tube hydroforming (THF) technology has become a popular method, in the automotive industry, for producing complex three-dimensional structural shapes because of its enormous advantages over the more traditional materials processes. Nowadays, global environmental issues are intensifying worldwide, and the further reduction of automotive weight and lightening of transport vehicles is one of the most urgent and key technological issues in the realization of a low-carbon society. The effect of reducing automotive weight is estimated to be, a reduction of about 17 to 20 kg of CO<sub>2</sub> emissions per kg of weight reduction over a vehicle's lifetime for every 10 percent reduction in automotive weight. This review article describes the state of the art in TH technologies mainly in Japan*

# Development And Testing of 5 kn Micro Forming Machine for Micro Part Manufacturing

Gandjar Kiswanto, Aida Mahmudah, Sugeng Supriadi

Dept. of Mechanical Engineering, Universitas Indonesia  
 gandjar\_kiswanto@eng.ui.ac.id

## ABSTRACT

Microforming machine is used to make micro-scale products. The development of this machine is necessary for microforming technology research. In this study, a microforming machine with a capacity of 5 kN is developed. The machine is driven by an electric motor that transfers to the ram using ball screw to change rotational into translational motion. Strength analysis of the machine structure is performed on a static and maximum loading condition since the operating condition is performing at a low speed and load. Machine performance was measured by analyzing geometrical tolerances of the machine, movement and stroke resolution, and verification using experiment to produce forming products of sheet metal made from aluminum, brass, copper, and steel. The result of this research shows that the 5 kN Micro Forming Machine with maximum loading is applicable to be implemented for micro forming process.

### Keywords

Micro forming, micro forming machine, sheet metal

## 1. INTRODUCTION

Micro-electro-mechanical systems (MEMS) technology receives great attention due to the increasing market and application fields in micro devices, such as electronic, medical care, biotechnology etc. The estimated rise in turnover from 15 to 35 billion US\$ in the last 7 years [1] shows a growing demand on micro technical products, which is mainly driven by a rising trend of miniaturization of products. However, this technology is faced with the enormous challenges to be implemented in the industry.

Currently, micro device was fabricated by using semiconductor process. There are several difficulties and limitations of fabrication MEMS parts using semiconductor process such as equipment expense is comparatively high, applicable materials are limited and production of 3D structural components is difficult. The manufacture of micro parts is very advanced in lithographic technologies, especially in LIGA-processes. Bulk production with high accuracy can be realized by these technologies, but costs are comparably high and the number of different materials is quite limited [2].

For a solution to these problems, the micro-metal-forming technology is introduced for producing sub-millimeter-scaled microparts. Nevertheless, the fundamental knowledge and technological data have not been satisfied. Therefore, the establishment of design manuals and codes for materials, machine, tools, and process conditions is crucial for realizing high-precision microforming process. In this study, development of micro forming machine was introduced.

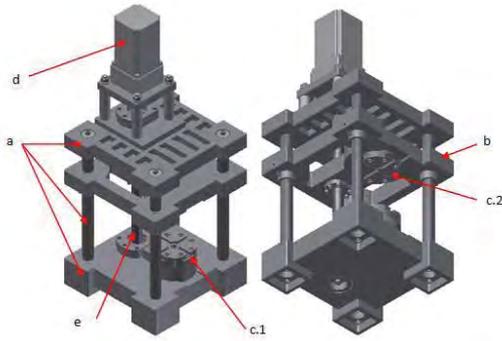

## 2. DEVELOPMENT OF 5 kN MICRO FORMING MACHINE

### Machine design

The design is conducted using VDI 2222 Design Method and Advanced Decision Matrix Method based on the Robust Decision Making [3]. The micro forming machine that consists of several sub-functions is assembled as shown in Fig. 1. The main components that construct micro forming machine are lower and upper base, guide pillar, upper and lower bolster, ram, motor spacer, ball screw, and stepper motor.

The working principle of this machine is driven by stepper motor (d) that transfers to rotating ball screw (e). The ball screw drive ram (b) to move up and down and control stroke motion. Movement is directed by guiding set (a). The tooling system (punch and dies) is mounted on the upper and lower bolster.

Part Name	Selected Material
-----------	-------------------

<b>Lower Base</b>	Low carbon steel: S45C
<b>Motor spacer</b>	
<b>Bolster_upper</b>	High carbon steel: SKD11
<b>Bolster_lower</b>	
<b>Ram</b>	
<b>Guide Pillar</b>	

Table 2. Result of Material Selections

Figure1 :Sub-Function of Micro Forming Machine; a). Guiding pillar , lower and upper base, b). Ram, c). Bolster,d).Stepper motor, e). Ball screw

**Material selection**

Material selection of micro forming machine components are selected by using Ashby method [4]. Table 2 shows material selection results for micro forming machine. Material properties of selected material is used for loading analysis to determine geometry of the parts.

**Loading analysis**

The analysis is conducted under maximum static loading. The loading scheme that occurs in the machine shown in the free body diagrams shown in Fig. 2. The loading force (F) is under maximum load capacity of the machine at 5 kN.

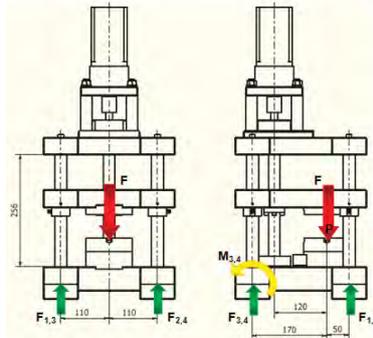

Figure2 : Free Body Diagram of Micro Forming Machine

By using static loading assumption, the force for each guide roll (F<sub>1</sub>, F<sub>2</sub>, F<sub>3</sub>, F<sub>4</sub>) were calculated as follows:

$$\sum F_y = 0 \tag{1}$$

$$F_1 = \frac{F}{4} \tag{2}$$

**Safety factor (FS)[19]**

The safety factor can be quickly estimated on the basis of estimated variations of the five measures previously discussed, i.e. material properties, stress, geometry, failure analysis, and desired reliability.

The simplest way to present this technique is to associate a value greater than 1 with each of the measures and define the factor of safety as the product of these five values:

$$FS = FS_{material} \cdot FS_{stress} \cdot FS_{geometry} \cdot FS_{failure\ analysis} \cdot FS_{reliability} \tag{3}$$

where,

$FS_{material} = 1,1$  because the material properties are known from a handbook or manufacturer's values.

$FS_{stress} = 1,3$  because the nature of the load is defined in an average manner, with overloads of 20–50%, and the stress analysis method may result in errors less than 50%.

$FS_{geometry} = 1,0$  because the manufacturing tolerances are tight and held well

$FS_{failure\ theory} = 1,1$  because the failure analysis to be used is derived for the state of stress, as for uniaxial or multiaxial static stresses

$FS_{reliability} = 1,3$  because the reliability is an average of 92–98%.

### Material strength

Material strength inspection is conducted to the components which are considered critical. For the material strength of lower base plate and ram, failure theory of Von Mises is used, since the materials are ductile. Von Mises equations used are as follows:

$$\left(\frac{\sigma_1}{\sigma_e}\right)^2 - \left(\frac{\sigma_1}{\sigma_e} \times \frac{\sigma_2}{\sigma_e}\right) + \left(\frac{\sigma_2}{\sigma_e}\right)^2 \leq 1 \quad (4)$$

With  $\sigma_e = \sigma_{yp}/FS$ , then

$$\left(\frac{\sigma_1}{\sigma_{yp}/2,5}\right)^2 - \left(\frac{\sigma_1}{\sigma_{yp}/2,5} \times \frac{\sigma_2}{\sigma_{yp}/2,5}\right) + \left(\frac{\sigma_2}{\sigma_{yp}/2,5}\right)^2 \leq 1 \quad (5)$$

Principle Stress:

$$\sigma_1 = \frac{\sigma_x + \sigma_y}{2} + \sqrt{\left(\frac{\sigma_x - \sigma_y}{2}\right)^2 + \tau_{xy}^2} \quad (6)$$

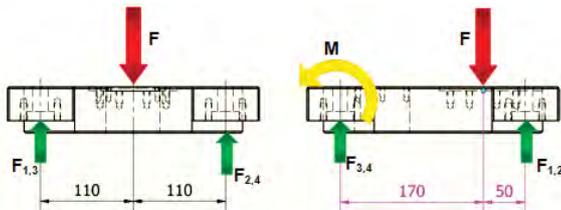

$$\sigma_2 = \frac{\sigma_x + \sigma_y}{2} - \sqrt{\left(\frac{\sigma_x - \sigma_y}{2}\right)^2 + \tau_{xy}^2}$$

Shear stress:      Normal stress:

$$\tau_{xy} = \frac{F}{A} \quad \sigma_y = \frac{Mc}{I} \quad (7)$$

#### 1. Lower base

The lower base serves as the base of press machine components at the bottom of the machine. Material used is S45C, with ultimate strength = 569 MPa and a yield strength = 343 MPa. Fig. 3 shows the free body diagram of the lower base. The result of stress analysis for lower base is shown in Fig. 4. In the figure shows that higher stress is lower than critical stress to induce failure.

$$F_1 = F_2 = F_3 = F_4 = 1,25 \text{ kN}$$

Figure 3 : Free Body Diagram of Lower Base

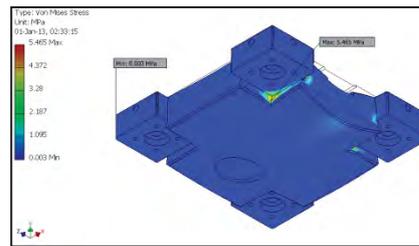

Figure 4 : Stress Distribution of Lower Base  
(continued)

#### 2. Ram

Ram serves as the base of moving components at press machine, and transmits the compressive force on the tool when pressing the workpiece. The material used is SKD11, with a yield strength = 1650 MPa. Fig. 5 shows the free body diagram of the ram. Fig. 6 shows stress distribution on the ram. Highest stress concentrations are located on the ball screw. Since ball screw is push and pull ram.

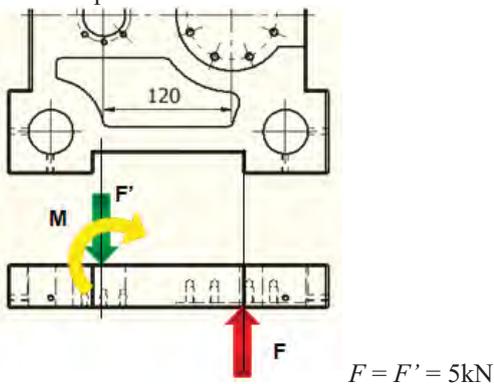

Figure 5 : Free Body Diagram of Ram

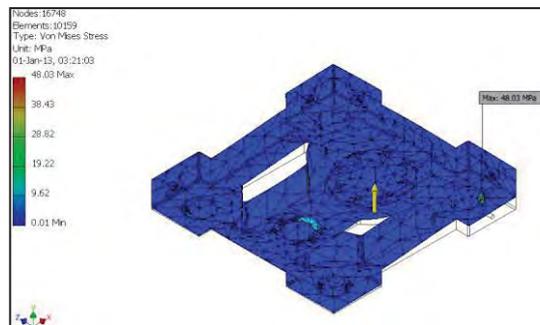

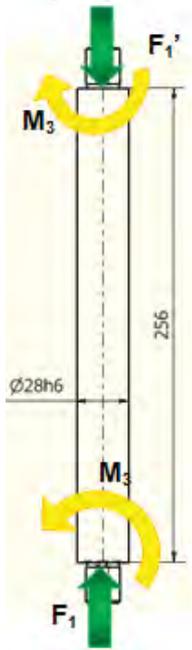

Figure 6 : Stress Distribution of Ram (continued)

#### 3. Guiding rod

Guiding rod is part of the guiding set that serves to direct the movement of the ram. The material used is SKD 11 with a yield strength = 1650 MPa. Fig. 23 shows the free body diagram of the guiding rod.

Because of the bending moment on the guiding rod, then the equations used to inspect the strength of guiding rod component are [5]:

From free body diagram that is shown in Fig 23:

$$F_1' = F_1$$

$$M_3' = M_3$$

Axial stress  $f_a$  dan permission axial stress [5]:

$$f_a = \frac{P}{A} = \frac{F_1}{\pi \times 14^2}$$

$$\text{So, } \frac{f_a}{F_a} + \frac{f_b}{F_b} \leq 1$$

can be used.

Bending stress  $f_b$  [16]:

$$f_b = \frac{Mc}{I} = \frac{M_3 \times r}{(\pi \times r^4)/4}$$

Permission bending stress  $F_b$  [16]:

$$F_b = \frac{83 \times 10^3 \times C_b}{(l \times d) / A_f}$$

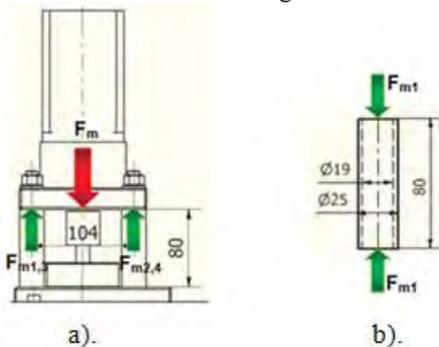

$$\frac{f_a}{F_a} + \frac{f_b}{F_b} \leq 1$$

So, the construction can resist the maximum loading.

Figure 7 :  
Free Body  
Diagram Guiding Rod

#### 4. Motor spacer

Motor spacer serves as a spacer between stepper motor bracket to the upper base. Material used is S45C with elastic modulus 205 GPa. Fig. 8 shows the free body diagram of the motor spacer. By calculate critical compressive force, the construction can resist the maximum loading.

$$F_m = (w_{motor} + w_{motor\ bracket}) \times g$$

$$F_{m1} = F_{m2} = F_{m3} = F_{m4} = \frac{F_m}{4}$$

$$I = \frac{\pi}{4} \times (r_o^4 - r_i^4)$$

Critical compressive force that can lead to buckling is:

$$P_{cr} = \frac{\pi^2 \times E \times I^9}{L^2}$$

$$P_{cr} > F_{m1}$$

Figure 8 : Free Body Diagram a). Motor; b). Spacer

#### Structure assembly of micro forming machine

Assembly structure is shown in Fig.9. In general, all the components are divided into fixed part (i.e., components that are not moving) and moving parts (i.e., the moving components).

#### Motion system

The selection of driven system is based on consideration for translational motion accuracy that required in micro forming process. The following driving components are used: Ball screw R25-5T3-FSI-500L, Stepping motor A140K – G599 – GB5, Driver MD5 - HF 28, Controller PMC – 1HS – USB. Fig. 9 shows a prototype micro forming machines that have been installed with moving controller.

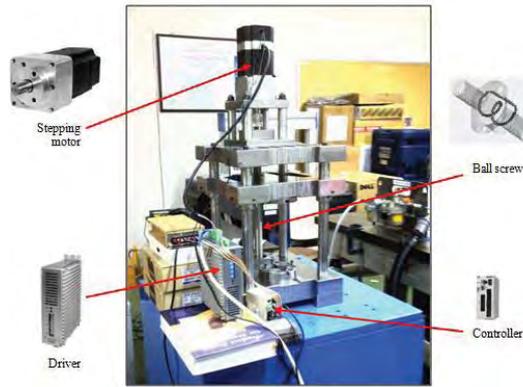

Figure 9.5kN Micro Forming Machine

### 3. EVALUATION OF MICRO FORMING MACHINE

The testing was consisting of geometric measurement, accuracy motion machine, and forming experiment to produce specific product. Geometric measurement is conducted based on Fig. 10. The experiment with predetermined product shape and dimension was performed to measure the performance of machine, as well as the handling for tools and material in the adequate working space with available supporting means. The concept of one piece loading was implemented for loading and unloading of material. The concept required workpiece was manually placed on the die one by one. Geometries of the assembled machine were verified using CMM Mitutoyo Crysta 544. The measurement results show good agreement with design.

#### Process experiment

Process experiment is carried out to determine whether the machine can function well in the forming process, ease of tool handling, loading and unloading of material with one piece loading method on the available working area. Therefore, the experiment required micro forming tool and sheet plate as raw material.

The experiment was conducted with scheme as shown in Fig. 10, and the detail drawing of the product is shown in Fig. 11. Then, based on the detail drawing of the product, it was made a micro forming tool with outer size 40x90x60, 5 mm. Micro forming tool was then mounted to the machine with a clamping unit provided. Material products to be made is aluminum, brass, copper and steel, with  $t = 0.1$  mm.

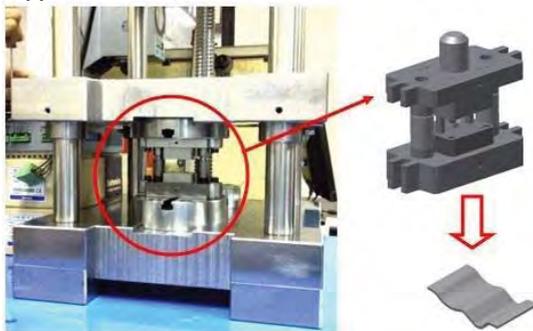

Figure 10 :Micro Forming Process Testing Scheme

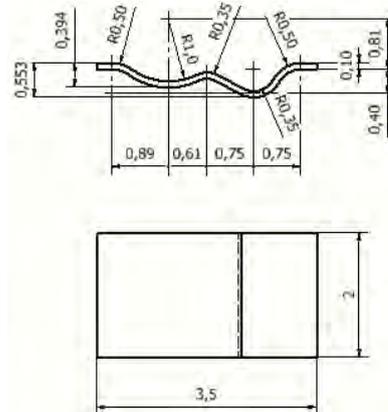

Figure 11: Detail Drawing of Product

At the time tool was placed in the machine (tool insertion), there was no difficulty. Difficulties arised when raw material was stored to the tool . This is due to the lack of locator height to place the raw material on the die. The locator height is 0.1 mm. In addition, the preparation of raw material to be formed was quite difficult because of its small size.

#### Operation position setting

The position of the operation consists of raw material loading position and forming process position (working position). The following is a description of each setting position:

##### 1. Raw Material Loading Position

The important considerations in this position are the area and the sufficient lighting for operators to store raw materials in the die. For that reason, it is determined the distance between the bottom surface of the ram with the top surface of the lower base

is 200.5 mm. So that the distance between the bottom surface of the bush on the micro tool with the shim ring is 100 mm. With a resolution position of  $2\mu\text{m}/\text{pulse}$ , the amount of transmitted pulse to reach this distance is:

In this experiment, stroke velocity was determined  $V = 50$  pps or  $V = 100 \mu\text{m}/\text{s}$ , and the holding time was 5 seconds. The results of this experiment have been observed using a contour measuring instrument detector with type COUNTERECCORD1710SD3 (ACCURETECH). Then, the results of measurement are processed by image processing (Fig. 34) to get the dimensions of the actual product. Fig.12 shows the comparison of the actual contours with the designed contour, and in table 4 is shown a summary of the radius measurement products.

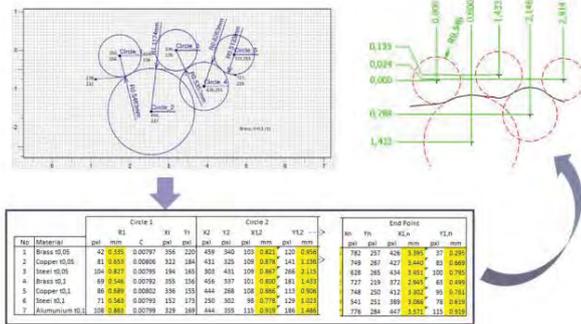

Figure 12 : Image Processing

Table 4. Summary of Radius Products Measurement

		Average Radius Deviation			
		Aluminium	Copper	Steel	Brass
		$t = 0,1$			
Radius of Designed Produk (*)	R1 0.4	0.13	0.29	0.16	0.11
	%	32.6%	72.3%	40.8%	28.3%
	R2 0.45	0.18	0.11	0.27	0.18
	%	39.2%	25.1%	61.0%	39.2%
	R3 0.25	0.12	0.17	0.21	0.29
	%	47.5%	66.2%	85.7%	114.3%
	R4 1.1	0.27	0.14	0.41	0.02
	%	24.5%	12.5%	37.6%	1.6%
	R5 0.4	0.30	0.18	0.39	0.15
	%	73.9%	44.0%	97.6%	36.6%
Deviation Average		43.5%	44.0%	64.6%	44.0%

From figure 35 and table 4, it can be concluded that Material brass, copper, and aluminum, resulting product contours nearing the expected designed product, while the steel materials produce different contours. Since the steel yield strength of the material is the biggest (1646 MPa). In addition, the sizes of the radius product were not sharp and did not consider the effect of material spring back. So that none of the material dimensions meet to the designed products. The smaller the radius, the larger deviation of the size that occurred. This can be seen in the size of the radius at  $R_3 = 0.25$ , deviation was very large, and almost happens on every material.

The results of the forming experiment were also observed using an electron microscope, and then the actual product shape was compared with the designed product as shown in Fig. 13. From these pictures, it can be seen that the product came closest to the desired shape was the product from aluminum. While the product contour from steel was the most different from the designed product. The results of these observations showed the same results with measurements using a contour measuring instrument detector.

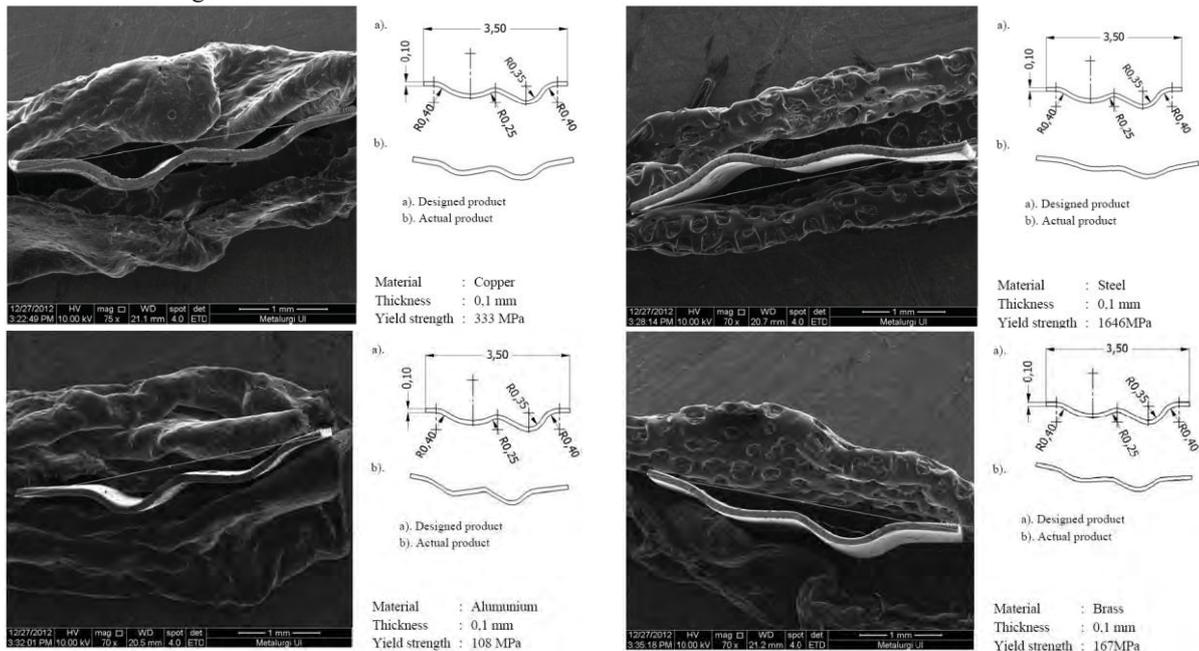

Figure 13: Brass  $t=0,1$  mm

#### 4. CONCLUSIONS AND SUGGESTIONS FOR FURTHER RESEARCH

##### Conclusion

From the research conducted it can be concluded some of the following result. The 5kN Micro Forming Machine has been produced successfully. Evaluation of the machine was carried out to produce a specific product with radius ranging from 0.25 mm - 1.1 mm. Working area meet the needs of an insertion tool. Preparation and loading of raw materials was difficult, because of its small size and lack of the locator height. Therefore several improvement activities are needed to improve machine performance such as; the additional components to be attached on the seat of bolster on lower base and ram, the addition of counter weight to compensate the ram weight and advanced control systems that meets the needs of micro-forming process.

 Andalas University, Kampus Limau Manis Padang 25163  
 E-mail : jhonmalta@ft.unand.ac.id

## ABSTRACT

*This research deals with a modification of anisotropic rotor model in order to approach the experimental results of the dynamic responses of anisotropic rotor. The prototype of an anisotropic rotor with two disks is supported by four quasi-rigid bearings. In the experimental studies, the dynamic responses of disks are recorded in horizontal and vertical directions at constant angular speed from 1 to 80 Hz with an incremental speed of 1 Hz. In the numerical studies, two mathematical models are developed by using a minimal number of discrete elements. The dynamic responses of the models are solved by using the Runge-Kutta method of fourth order. In the first model, the mass of shaft is negligible. In the second model, the mass of shaft is taken into account. Comparing the numerical and the experimental results, the natural frequencies of the numerical results of the first model is rather higher than the experimental results. The better results which closed to the experimental results are obtained in the second rotor model, whereas the mass of shaft contributes to reduce the natural frequencies. In the other results, the dynamic responses of the rotor both in simulation and in experiment show the instability area in a wide range.*

## Keywords

*Anisotropic rotor, shaft orientation, Runge-Kutta method*

## 1. INTRODUCTION

Many rotor models have been developed in order to investigate the real rotors in industry fields [1]-[7]. For a simple real rotor, a Jeffcott rotor model can be used to approach the rotor, but for a more complicated rotor system, it must be modeled by a more complicated rotor model too. In case of an anisotropic rotor, the directions of principal axes of shaft cross sections can be different along the shaft. Especially in case of a twisted anisotropic rotor, the directions of principal axes of cross sections change along the shaft. In this case, the rotor model must be modeled by discrete elements [8]. Actually, some existing methods e.g. finite element method can be used to develop the mathematical rotor model [9]-[11]. However, those methods should be modified due to the existing of the different element orientations along the shaft. In this paper, an alternative method is developed by using strain energy method for asymmetric bending of a beam in order to obtain the minimum number of shaft elements of rotor model.

An anisotropic rotor can be modeled in fixed or rotating reference frame. In fixed reference frame, the shaft stiffness of rotor model varies with time. In the rotating reference frame, the differential equations are speed-dependent. In dynamic analysis, the time-variant system is more complicated than the speed-dependent system. However, in the speed-dependent rotor system, the dynamic analysis should be simulated step by step at each frequency. The dynamic responses of the rotor model are solved by using the Runge-Kutta method. Further, the amplitudes of the dynamic responses of the rotor model are benchmarked by the experimental results.

## 2. DESCRIPTION OF THE ROTOR

### 2.1 Prototype of the rotor

In this research, the dynamic behavior of the rotor is investigated both in experimental and numerical simulation analyses. In the experimental studies, a prototype of the anisotropic rotor has been designed and manufactured as depicted in figure 1. The main rotor consists of a steel shaft (X90CrMoV18) with a diameter 8 mm and a total length of 626 mm. Nevertheless, the effective shaft length is assumed 540 mm that is the shaft length between the first bearing and the fourth bearing. The shaft is divided into three sections, in which each section has a 180 mm of shaft length. Along 166 mm of the shaft section the thickness of the cross section is 5 mm. The three sections of anisotropic shaft have different orientations of shaft with the orientation of each section is defined to be  $\beta_1=0^\circ$ ,  $\beta_2=30^\circ$ , and  $\beta_3=60^\circ$ , respectively. Two rigid disks are attached on the shaft. Each disk has 1.153 kg of mass. The ratios of mass moment of inertia are  $\Theta_{p1}=\Theta_{p2}=1.90$ . Near of each disk, an external damper is attached on the shaft. The main rotor is supported by four quasi-rigid bearings. The type of bearings is self-aligning ball bearing. The dynamic responses of the rotor are recorded by using two eddy current displacement sensors at each disk, in which the V-position of two sensors spans an angle of  $90^\circ$ . The displacement of disk in horizontal and vertical direction can be measured by using a rotary transformation of  $45^\circ$ .

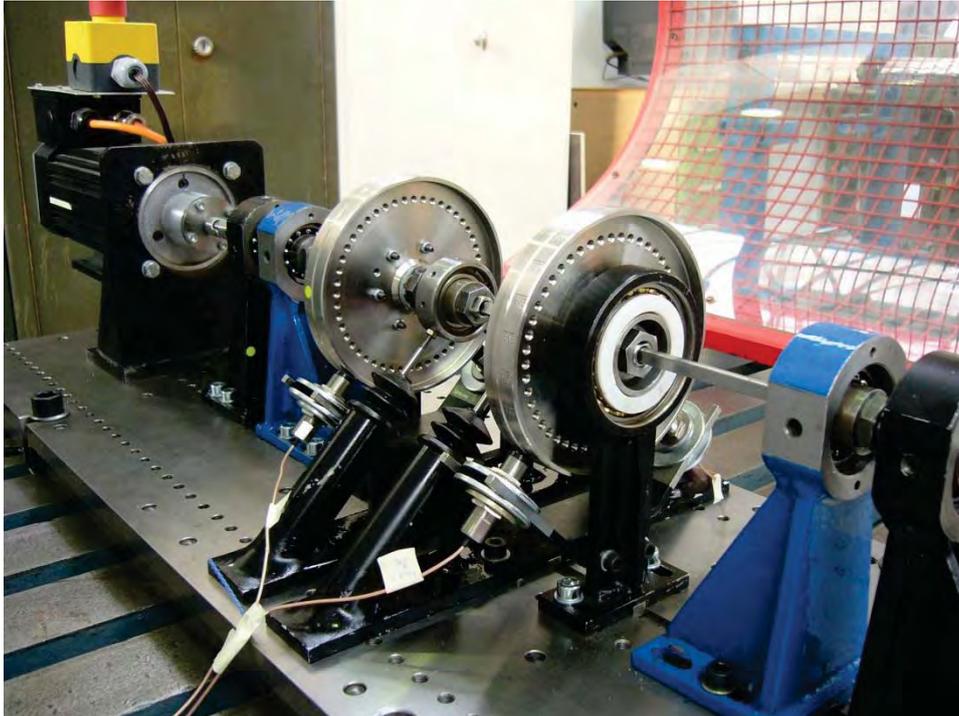

Figure 1: Prototype of anisotropic rotor supported by four quasi-rigid bearings

The rotor is operated at constant angular speed from 1 Hz until 80 Hz with an incremental speed of 1 Hz. The signals of the four displacement sensors are acquired by using the dSpace hardware type DS1103. The MATLAB software is used to control the dSpace and to process the signal data. The signals are filtered by a fourth order lo-pass butterworth filter in MATLAB with a cut off frequency at 100 Hz. The experimental data in time domain are transformed into the frequency domain by using Fast Fourier Transform (FFT).

## 2.1 Mathematical models of the rotor

Generally, the differential equations of rotor motion can be derived both in a fixed and rotating reference frame. If the rotor is modeled in a rotating reference frame, where the coordinate system follows the rotation of the shaft, then the differential equations of the system become speed-dependent. Hence, at constant rotational speed, the dynamic parameters of the rotor can be considered constant.

Furthermore, based on the experimental test-rig, whereas the two disks rotor system is supported by four quasi-rigid bearings must be modeled by multi degrees of freedom of rotor model. By using the minimal number of discrete shaft elements, for the first mathematical rotor model, the shaft is divided into five discrete elements as shown in figure 2. The parameters of the rotor model 1 are listed in table 1. The mass of shaft is negligible. The shaft orientations of the shaft element 1 and 2 are  $\beta_1 = \beta_2 = 0^\circ$ . Further, the shaft orientations of the shaft elements 3, 4, and 5 are  $\beta_3 = 30^\circ$ ,  $\beta_4 = \beta_5 = 60^\circ$ , respectively. For external damper, an approach of proportional damping due to absolute velocity of disk can be used. In the rotor model 1, the coefficients of the proportional external damping and internal damping are assumed  $d_a = 0.18$  and  $d_i = 0.001$ , respectively. Furthermore, the differential equations of the rotor motion can be arranged as in [12]-[13] as

$$[[M_T] + [M_G]]\{\ddot{q}_w\} + [[D_T] + [D_G] + [D_a] + [D_i]]\{\dot{q}_w\} + [[K_T] + [K_G] + [K_a] + [K_w]]\{q_w\} = \{\{p_T\} + \{p_a\} + \{p_g\}\} \quad (1)$$

or in a simple form, the eq.1 is written as

$$[M]\{\ddot{q}_w\} + [D]\{\dot{q}_w\} + [K]\{q_w\} = \{p\}, \quad (2)$$

where  $[M]$ ,  $[D]$ , and  $[K]$  are mass, damping, and stiffness matrices, respectively. These matrices are  $4N \times 4N$  of matrix size, with  $N$  is the number of disk. The  $\{q_w\}$  is the column matrix of displacement of disks and the  $\{p\}$  is the force column matrix. The subscript T and G are to define the derivation matrices of translatory inertia and rotary inertia, respectively. Further, the  $[D_a]$ ,  $[D_i]$ , and  $[K_a]$  are the external damping, internal damping, and proportional stiffness matrix of derivation of external damping matrix, respectively.

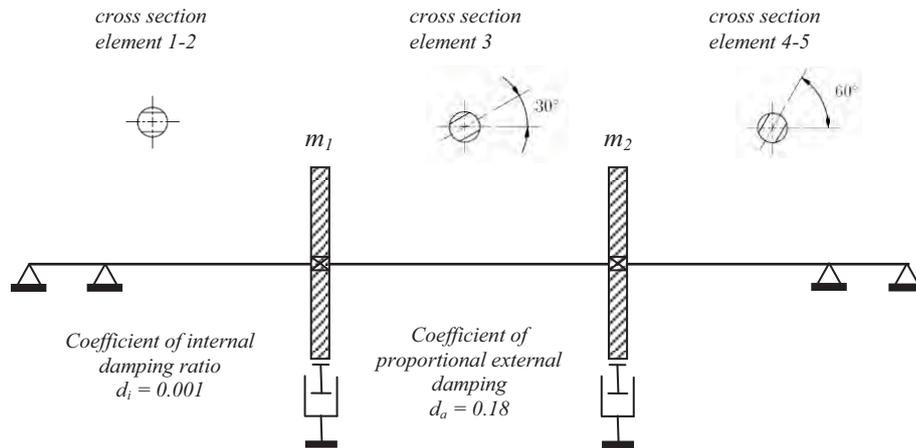

Figure 2: Mathematical model 1 of the rotor (mass of shaft is negligible)

Table 1: Parameter of discrete shaft element (model 1).

No. element	Length of element [m]	Modulus of elasticity [MPa]	Orientation of shaft element [degree]	Mass of disk/shaft element [kg]	Polar mass moment of inertia, $\Theta_p$ [ $\text{kgm}^2$ ]	Axial mass moment of inertia, $\Theta_a$ [ $\text{kgm}^2$ ]
1	0.050	210E+9	0	-	-	-
2	0.130	210E+9	0	-	-	-
-	-	-	-	$m_1 = 1.153$	0.002572	0.001356
3	0.180	210E+9	30	-	-	-
-	-	-	-	$m_2 = 1.153$	0.002572	0.001356
4	0.130	210E+9	60	-	-	-
5	0.050	210E+9	60	-	-	-

Furthermore, the stiffness matrix  $[K_W]$  can be arranged based on the Strain-Energy method [14]. The mathematical model in figure 2 is solved to obtain the reaction forces of all supports and the distribution of bending moment for each force or external bending moment acting at node.

For the second mathematical rotor model, the mass of shaft is taken into account. The mass of each discrete shaft element in the rotor model 1 is assumed as small and very thick disk as shown in figure 3 and the parameter of these shaft elements in table 2. Because a disk must be attached at a node, thus a point of mass of shaft element is placed in the center of each discrete shaft element; therefore, in the rotor model 2 a discrete shaft element as in the model 1 is divided into two discrete shaft elements. The other parameters in the rotor model 1 are the same with the parameters in the model 2.

### 3.RESULTS AND DISCUSSION

In this presented work, the natural frequencies and the dynamic responses of the rotor will be analyzed. In the experimental results, the natural frequencies of the rotor are obtained from the free vibrations of the rotor at rest excited by an impact force at disk 2 in z-direction. In the numerical results, the natural frequencies are obtained by solving the eigenvalues of the homogenous linear equation of the rotor in eq.1. Comparing the natural frequencies of the rotor as presented in table 3, the four lower natural frequencies of the rotor in the numerical result in the rotor model 1 are rather higher than the experimental result. Note that, for simplification in comparison of the natural frequencies, the third and the fourth natural frequencies both in the experimental result and the numerical result of the rotor model 1 are listed as the fifth and the sixth natural frequencies in table 3. In the numerical result of the rotor model 2, the six lower natural frequencies of the rotor are slightly lower than the natural frequencies of the rotor model 1, because the mass of shaft elements is taken into account and this mass contributes to reduce the natural frequencies. An alternative way in modeling of anisotropic rotor, whereas there is no change of the number of degrees of freedom of the rotor model and the number of discrete shaft elements: the mass of shaft is added in the mass of disk of the rotor, directly. The result of the first natural frequency of the modified rotor model 1 is only slightly higher than the first natural frequency of the rotor model 2. The second natural frequency of the modified rotor model 1 is only slightly decreased. However, the third and the fourth natural frequencies of the modified rotor model 1 (i.e. listed at the fifth and the sixth natural frequencies in table 3) tend to close to the experimental results.

Table 3: Comparison of natural frequencies

Natural frequency	Experimental [Hz]	Numerical (model 1) [Hz]	Numerical (model 2) [Hz]	Numerical (modified model 1) [Hz]
1	21	25.3	24.3	24.5
2	26	33.5	25.7	32.5
3	-	-	33.5	-
4	-	-	38.6	-
5	55	55.7	55.4	53.9
6	68	72.8	72.5	70.6

Furthermore, the dynamic responses of the rotor especially in the experimental results only the displacement of the disk 2 will be analyzed, because the responses of the disk 2 shows the better signal than the signal at disk 1. This may be caused by two possibilities. First, it may be caused by the coupling (see figure 1) which holds the free motion of the shaft end. Therefore, a bending moment occurs in the bearing which reduces the displacement near this bearing. For the disk 2, this effect is small because of the larger distance to the bearing. Second, it may be caused by a misalignment or bowing at the shaft center line. In the dynamic responses analyses, the signal in time domain is transformed into frequency domain by using Fast Fourier Transform (FFT) in the MATLAB software. At each rotating speed of the rotor from 1 Hz to 80 Hz with an incremental speed of 1 Hz, the  $\Omega$  and  $2\Omega$  components of the signal are separated. At each frequency of the  $\Omega$  and  $2\Omega$  signal components, the maximum amplitudes are recorded and presented as shown in figure 4. In this figure, the dynamic responses of the rotor model 2 cannot be reached, because the difference between the biggest and the smallest of mass components in the mass matrix is too high, therefore the time interval  $\Delta t$  in the numerical simulation should be very small. The problem occurs in a calculation accuracy and in a computational time.

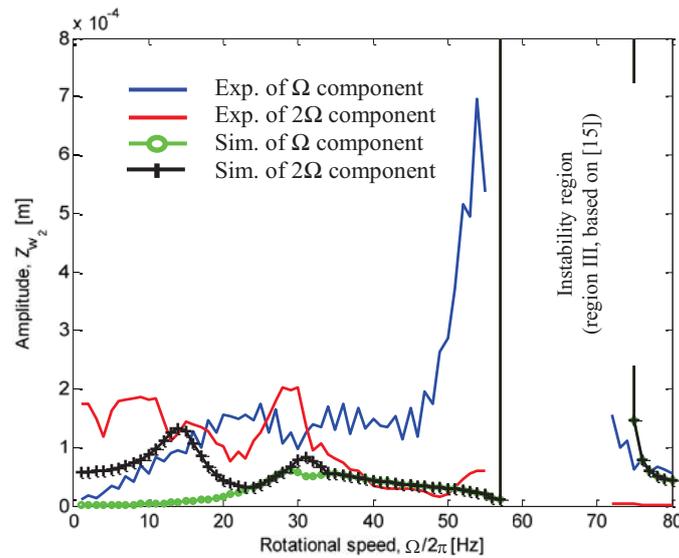

Figure 4: Comparison of the experimental and numerical simulation results (model 1) of the dynamic responses of the disk 2 ( $Z_{w2}$ )

The responses of the disk 2 in figure 4 tend to similar results which have three separated regions of instability as shown for the rotor cases in [15]. The first region of instability corresponds to the region between the first and the second natural frequency and the third instability region to the third and the fourth natural frequency with a shift to higher frequencies. However, the response amplitudes in the first region (18-27 Hz) as listed in table 4 and the second region (34-38 Hz) do not show unstable responses. It was verified experimentally in figure 4 that the rotor may be influenced by higher damping coefficient especially by the external dampers. The instability region of the experimental results occur only in the third region at frequencies 56-71 Hz, whereas in the numerical results of the rotor model 1 at frequencies 58-74 Hz and in the modified rotor model 1 at frequencies 55-72 Hz. Here, the third instability interval of the experimental result is narrower than the one of the numerical results.

Furthermore, the comparison of the regions with the relatively higher amplitudes or instability regions based on the  $\Omega$  component of the responses in the disk 2 is listed in table 4. The responses in the experimental results at rotational speeds around 18-27 Hz and around 34-38 Hz occur with the moderately higher amplitudes, whereas the moderately higher amplitudes in the numerical results occur at rotational speed around 27-28 Hz and 33-35 Hz in the rotor model 1 and 24-26 Hz and 33-35 Hz in the modified rotor model 1. Generally, the numerical results of the modified rotor model 1 tend to similar to the result of the rotor model 1.

Table 4: Comparison of the relatively higher amplitudes or the instability regions based on the  $\Omega$  component of the responses at disk 2

Region	Experimenta 1 [Hz]	Numerical (model 1) [Hz]	Numerical (model 2) [Hz]	Numerical (modified model 1) [Hz]
1	18-27 <sup>(*)</sup>	27-28 <sup>(*)</sup>	n.a.	24-26 <sup>(*)</sup>
2	34-38 <sup>(*)</sup>	33-35 <sup>(*)</sup>	n.a.	33-35 <sup>(*)</sup>
3	56-71	58-74	n.a.	55-72

<sup>(\*)</sup> the response amplitude in this region is moderately high only (not unstable)

Finally, the  $2\Omega$  component of the experimental results is compared to the numerical results. In the experimental results, the peaks of the  $2\Omega$  component occur at frequencies 15 Hz and 30 Hz, whereas in the numerical results at frequencies 14.6 Hz and 30.8 Hz. This comparison is listed in table 5. At lower rotational speeds (i.e. rotational speeds from  $\Omega=0$  to 12 Hz), the  $2\Omega$  components of the experimental result in figure 4 show the higher amplitudes compared to the numerical result. In the numerical result, the deflections of the rotor at lower rotational speeds are caused by the anisotropy of the shaft, whereas the greater deflections in the experimental results are caused not only by the anisotropy of the shaft but also by the misalignment or bowing in the shaft. Therefore, measured data up to 12 Hz were neglected in the following analysis.

Table 5: Comparison of the peaks of the  $2\Omega$  component of the responses at the disk 2

Peak	Experimenta 1 [Hz]	Numerical (model 1) [Hz]	Numerical (model 2) [Hz]	Numerical (modified model 1) [Hz]
1	15	14.6	n.a.	13.5
2	30	30.8	n.a.	30.0

#### 4. CONCLUSION

Based on the experimental and numerical simulation results, generally, the dynamic responses of the anisotropic rotor are dominated by  $\Omega$  and  $2\Omega$  components of the rotating disk speeds. Because of anisotropy of the rotor the instabilities occur in the wide range with the sharp boundary of the rotating disk speeds. Comparing the numerical and the experimental results, the natural frequencies of the numerical results of the first model is rather higher than the experimental results. The better results which closed to the experimental results are obtained in the second rotor model, where the mass of shaft is taken into account, therefore, they contribute to reduce the natural frequencies. However, the rotor model, in which the mass of element is distributed into mass of discrete shaft element, therefore the number of discrete shaft element and the degrees of freedom of the rotor system increase, thus the computational time will increase significantly. Besides, the numerical problem will occur in the simulation of the dynamic responses if the mass of disk and the mass of shaft is too different each other. A better alternative way in modeling of anisotropic rotor, where there is no change of the number of degrees of freedom of the rotor model and the number of discrete shaft elements: the mass of shaft is added in the mass of disk of the rotor, directly.

#### ACKNOWLEDGMENT

## ABSTRACT

Dieless bellows forming using local heating technique is an advanced flexible forming technology to produce bellows from straight tube without the use of dies. The deformation is induced by applying continuous compression, and local heating. Advantages of these processes are the absence of dies, applicability for various materials, suitability for flexible forming process including low batch production, flexibility on workpiece sizes and output geometries. However, the implementation of these processes is still low owing to the low quality, reproducibility, and production speed. The limitation of these dieless forming processes using local heating is caused by the absence of dies required to form the desired profile. Therefore deformation depends on temperature, length of heating zone, processing speed, speed ratio of feeding to fabrication speeds. In order to enhance the product quality in these dieless forming with local heating, real-time monitoring are necessary to identify deformation progress. Machine vision based on image processing technique was selected to monitor deformation behavior on dieless bellows forming process. The present paper describes real-time monitoring using image processing approach to monitor dimensional profile and temperature distribution during the process. The results show that machine vision is effective and efficient to monitor dynamic deformation of dieless bellows forming process and able to identify abnormal process condition.

## Keywords

Dieless bellows forming, machine vision, real-time monitoring.

## 1. INTRODUCTION

Dieless bellows forming is novel process to produce metal bellows without die materials. This process is able to produce metal bellows with various geometry without changing the tools. However there is a technical challenge of increasing dimensional accuracy and reliability[1-3]. Since the process is conducted at high temperature, non-contact sensing technique is necessary. Laser micrometer was applied to monitor metal forming process at high temperature such as dieless drawing process[4]. However this technique is less effective since sensing position is not in deformation zone. When unstable deformation occurs, it is difficult to recognize the deformation immediately[5]. In other hand, temperature distribution as one of key point to control deformation behavior depends on selected processing condition[3, 6]. Therefore real time monitoring on dimension and temperature distribution is essential to achieve real-time control system. Machine vision based on image processing technique offers an alternative technique to monitor dimensional and thermal behavior on deformation zone of dieless drawing process simultaneously. Since machine vision can be used in limited space and wide covered area. This paper describes the utilization of machine vision technique to maintain dimensional bellows profile and temperature distribution.

## 2. DIELESS BELLOWS FORMING PROCESS

Dieless bellows forming is a heat assisted forming technique without using die material to make metal bellows from straight tube as shown in Figure 1. Bellows is series of convolution on the pipe. Formation of the local convolution on the heating area is produced by applying compression speed ( $v_1$ ) from back side faster than feeding speed ( $v_2$ ) on front side. Height of bellows convolution depends on compression speed ratio which is ratio of  $v_1 / v_2$ . Dieless bellows forming is very sensitive temperature disturbance. Therefore stable bellows convolution is difficult to obtain. Therefore real-time bellows formation is necessary to get early information of unstable bellows formation. In this work is presented utilization of machine vision technique to monitor deformation progress in dieless bellows forming process.

## 3. MACHINE VISION

Semi-dieless bellows forming has two main characteristics, a wide deformation zone and a complex deformation mechanism. Therefore the deformation process is difficult to observe using a narrow measuring scope. The semi-dieless bellows forming

apparatus has limited spaced for equipping a sensor, which must be flexibly attached in the semi-dieless bellows forming apparatus. A vision-based sensing system is a suitable sensing technique that deals with those measuring conditions for tool inspection and hot forging, [7-9]. Dworkin and Nye (2006) developed a machine vision system using an infrared filter to monitor a hot forging process. An infrared-pass filter is used to improve the visibility of the fluorescent workpiece through elevated temperature. The machine vision algorithm is the same as that used in our previous study to monitor dieless tube drawing process [10, 11]. The components of the vision-based monitoring are image acquisition, image processing, data processing, and measurement accuracy of machine vision.

#### 4. EXPERIMENTAL PROCEDURE

##### 4.1 Image acquisition

Since the initial deformation occurs under the heating coil and it is not directly visible, the camera must be tilted up to  $10^\circ$  from the perpendicular direction, as the optimum position considering the visibility and accuracy, to obtain the representative image in Figure 1. In this study, the image was captured without using an infrared-pass filter. A high contrast image of the workpiece was obtained by decreasing the exposure level on the camera.

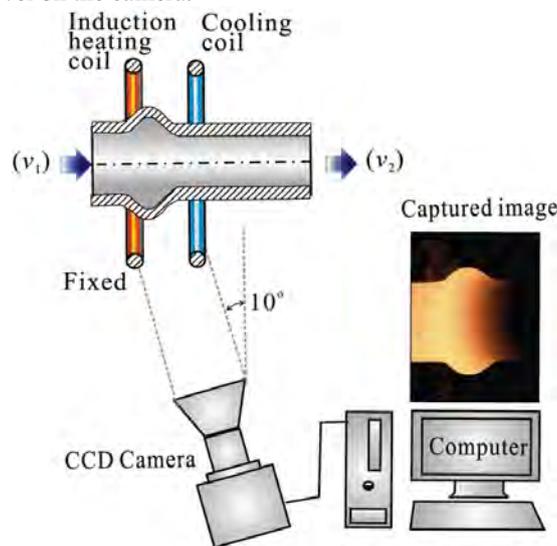

Figure 1: Camera positioning for monitoring the local deformation of the tube during semi-dieless bellows forming.

##### 4.2 Image processing

After images captured, image processing technique is applied to measure bellows height through convert to gray follow by edge detection. Bellows height is obtained by measuring outer diameter then multiply with pixel ratio to metric unit. It is obtained by comparing real part dimension.

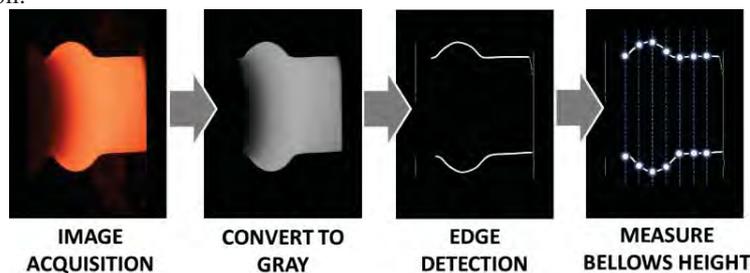

Figure 2 : Image processing to measure bellows height.

The image processing to measure the bellows height is conducted by edge detection of the workpiece outline. The convolution height is measured by calculating the distance between the workpiece edge outline, as shown in Figure3. The measuring region was set up as 16 sections, as shown in Figure 4. The measured output from image processing is the number of pixels. The desired measured value is in metric units. Therefore, a pixel ratio is used to convert the pixel number into metric. The pixel unit is obtained by comparing the image processing result and the actual dimension.

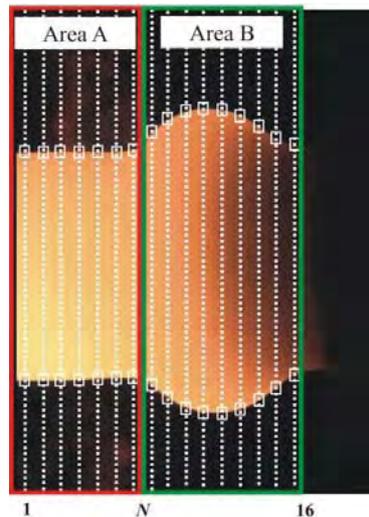

Figure3: Multi-sectional measurement in the deformation part for semi-dieless bellows forming process.

## 5. RESULT AND DISCUSSION

### 5.1 Measurement result using machine vision

Every section shows a different diameter, as shown in Figure 4. The measuring area is divided into two: areas A and B. The initiation of bellows convolution takes place in “area A” encompassing the 1<sup>st</sup> section up to section *N*. The convolution height increases to the maximum value in “area B”, which is from section *N* up to section 16. In semi-dieless bellows forming, after the first bellows is formed, the next convolution is initiated.

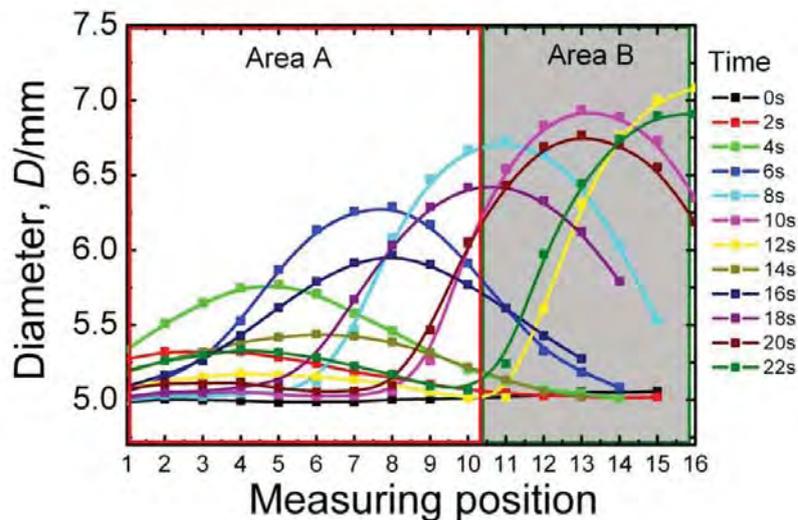

Figure 4: Deformation process in semi-dieless bellows forming at different measuring positions.

### 5.1 Data processing

In semi-dieless bellows forming, the important property for controlling the process is the bellows height. Since the maximum height of the bellows moves from one section to another section, an additional program is necessary to select the appropriate bellows height data. An additional data processing algorithm is necessary. Therefore, the measurement area is divided into two observation areas. Figure5 shows the algorithm used to manipulate measurement data from 16 sections to the deformation point during semi-dieless bellows forming. The monitoring of bellows height should enable us to monitor the current bellows deformation.

The first step is to find the maximum diameter  $D(t)$  among all the measurement sections. The position of the maximum diameter is

section  $M$ . After the first convolution reaches its maximum height, which is indicated by the derivative of  $D(t)$  being equal to or less than zero ( $dD/dt \leq 0$ ), the analysis shifts to the next convolution, which occurs in area A. Section  $N$  must be decided in order to determine area A. Section  $N$  has the minimum diameter from among section 4 to section  $M$ . After a boundary of area A is obtained (the  $N$  value), the next convolution height is the maximum diameter in area A. The process is repeated until the semi-dieless bellows forming process is finished. Figure 6 (a) shows the original measurement data in time series for 16 sections before the measurement value was selected and after using the algorithm to acquire bellows height data (Figure 6 (b)). The convolution height is the maximum value for every peak point. Therefore, the monitoring of every convolution can be conducted. The time period between measurement peaks indicates the pitch distance after multiplication with feeding speed ( $v_2$ ).

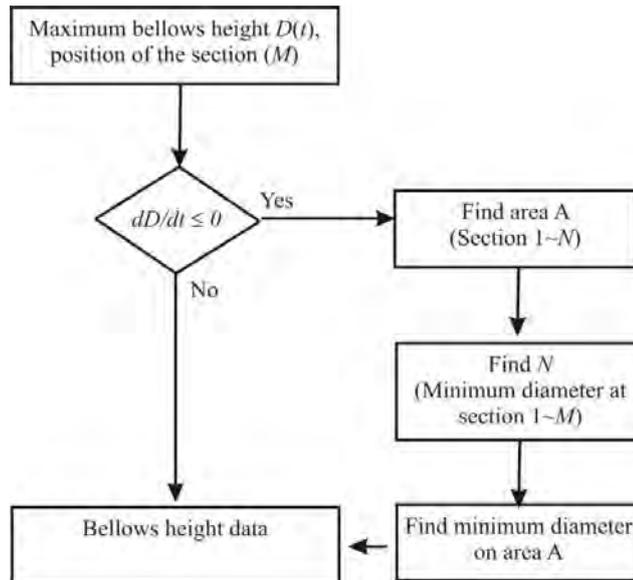

Figure5 Algorithm to determine the required bellows height from multi-sectional measurements.

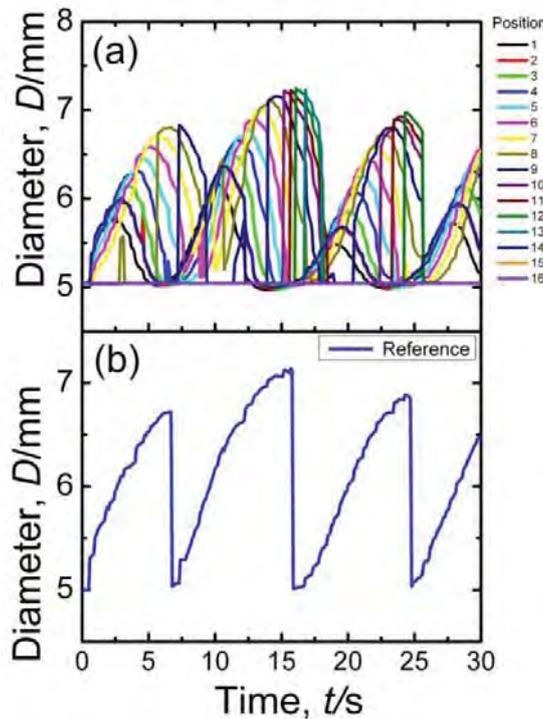

Figure 6: (a) Bellows profile measurement data sensed from 16 sections, (b) Profile height data in time series after data

processing

### 5.2 Measurement the accuracy of machine vision

The accuracy of the machine vision technique was evaluated by optical microscope measurement. The convolution height determined using the machine vision result shows a good agreement with the optical microscope result. Figure7 shows the accuracy of machine vision result for pitch. The average pitch value obtained from machine vision is smaller than that measured with the microscope. In machine vision, the pitch distance is calculated by multiplying the time interval between the peak of convolution and moving speed of the convolution. Measurement error of pitch from the machine vision might be caused by improper assumption of moving speed of the formed convolution. In this paper assume that the moving speed of the convolution is equal with feeding speed. In the actual condition, the formed convolution (deformation area) is a transitional speed area from compression speed into feeding speed. Therefore, the moving speed is higher than feeding speed.

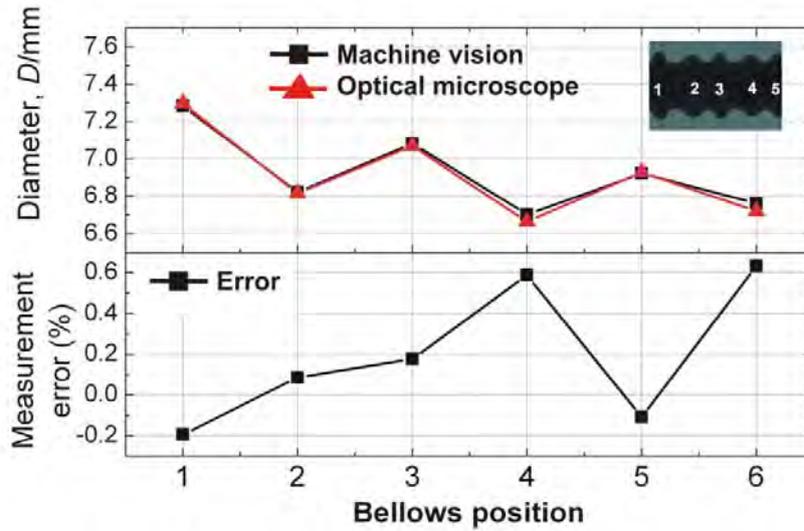

Figure7 :Measurement accuracy of bellows height obtained by machine vision.

### 5.3 Measurement abnormality of dieless bellows forming process

By analyzing bright intensity, machine vision can estimate temperature [10, 11]. In our previous work was verified this. When this technique is applied to monitor maximum bellows processing temperature, there are correlation between variation of maximum bellows forming temperature and variation of bellows height. As shown in Figure 8 history of maximum bellows forming process is vary depends on bellows formation progress. When convolution is produced temperature increased, while when temperature is decreased is new convolution is initiated. At low bellows forming temperature produce lower convolution height, while at high processing temperature shows high convolution height. By analyzing variation of temperature can be used to identify stability of bellows formation.

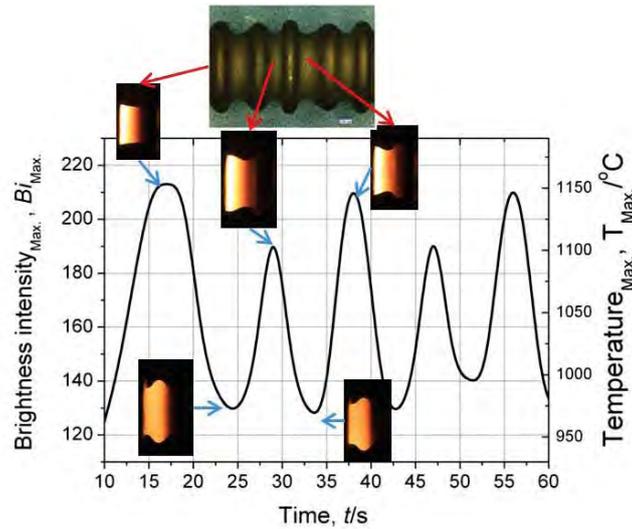

Figure 8: Unstable bellows height can be detected by variation of brightness intensity that correlate with temperature.

When unstable processing temperature of bellows occurs in radial direction, axymetric bellows shape will obtained. Table. 1 shows the example of balanced brightness intensity and unbalance brightness intensity between upper side and bottom side. When gap of upper and bottom side inceases aximetric bellows will occurs.

Table. 1 Comparison of Brightness profile to examine axymetricity.

Time	1) Balanced brightness intensity	2) Unbalanced brightness intensity	Difference brightness intensity $\Delta Bi = Bi_1 - Bi_2$

36s			

## 6. CONCLUSIONS

In this paper described real-time monitoring system using vision based image processing to monitor deformation of bellows formation. That performs flexibility to monitor deformation in limited access in dieless bellows forming machine. The results of machine vision has been validated that shows good agreement with other measuring device. The proposed technique also able to monitor temperature different that promote unstable deformation and asymmetric bellows shape. Therefore unstable deformation can be easily detect to anticipate further product defect. Therefore vision-based monitoring system is effective and efficient to sense deformation progress for dieless bellows forming process.

### ABSTRACT

The structure and construction of the ship is made of aluminum alloy, generally are of wrought aluminum alloys, when experiencing fatigue failure caused by a cracked vessel structure, is a serious problem. Reviewing of 'weakness' of wrought aluminum alloys for the ship, then in this study tries to provide material alternative for ship building is composite material based on aluminum casting AlSi10Mg (b) and reinforcing material silicon carbide (SiC), which has been in-treatment with the optimum composition 15%. Analysis of numerical computation with the help of ANSYS software version 2.00 to be made numerical modeling ship to ship aluminum EN AC-AlSi10Mg (b) and ship composite EN AC-AlSi10Mg (b)+SiC\*/ 15p whether the material can be applied to building ship for see the distribution of stress . The results of the stress distribution in both of model numerical of ship, its value does not exceed the stress permits ( $\sigma$  0.2) and have a factor of safety above the minimum allowable limit, so it is safe to use. The overall, in numerical modeling, the ship material aluminum and ship composite materials can be used as an alternative material for ship building, however is still needed comprehensive testing in the field.

## ABSTRACT

Fishing boat technology has grown up rapidly, both the fishing equipment and the boat itself. The weaknesses of monohull fishing boat, particularly in relation with ship stability, have been anticipated by the introduction of catamaran fishing vessel. In addition, the scarcity of fossil fuels hence causes the fishermen cannot afford to buy it, and many fishing boats are grounded, but now faces promising hopes by the introduction of hybrid/electric boat together with the use of conventional engine and its fuel.

The current paper describes engineering review and economic viability of the use of hybrid/electric catamaran fishing vessel. Comparative analysis with other published data is carried out in order to support the findings of the current research.

### Keywords:

## 1. INTRODUCTION

Catamaran type of vessel has been widely used since the last 30 years for many purposes: passenger carrier, oceanographic research vessel and sailing yacht [1]. The use of catamaran for fishing vessel was reported in [2]. A new layout arrangement on main deck was proposed and compared with the monohull type. It was discovered that the catamaran of the same displacement has wider deck area hence better deck arrangement may be applied. This consequently provides wider space to put fishing equipment on deck as well as to store the catching fishes.

That fishing vessel was developed with the use of conventional engine together with the use fossil fuel. It is found to be not economical in term of fuel spending and environmental issues. The money spent by fishermen to purchase fuel has increased significantly hence becomes un-affordable to the most of them. In other side, there is an increase on green-house gases (GHG) such as NO<sub>2</sub>, SO<sub>2</sub> and CO<sub>2</sub> to the atmosphere hence the concept is not environmentally friendly.

Many attempts to minimize the use of fuel and GHG effect have been carried out worldwide. The use of alternative energy to complement the fossil fuel and if possible, to replace the use of it is actively conducted around the globe. Some of the ideas include the use of sail, solar cells and wave power mechanism [3]. The combination of engine and sail, later known as sail assisted engine, has been applied in many places in Indonesia for many years especially by fishermen. It has been found to cut the use of fuel of about 15% as reported in [4]. The hybrid use of solar powered and wave power mechanism is another possible answer [3].

Recent analysis in [5] indicates the conflicting of energy against the economic consequences of the use of hybrid system. The use of hybrid system, in one hand, may reduce the cost of energy spending but in other hand, it causes the delay of cargoes delivery to customers hence become less attractive to them. Other issues to consider including the cost of installing the hybrid system, which is normally rather expensive and stability evaluation especially with the use of sails may cause some problems. The use of sails may increase the metacenter and hence affect the ship stability. Accordingly, this may cause the boat become less comfortable.

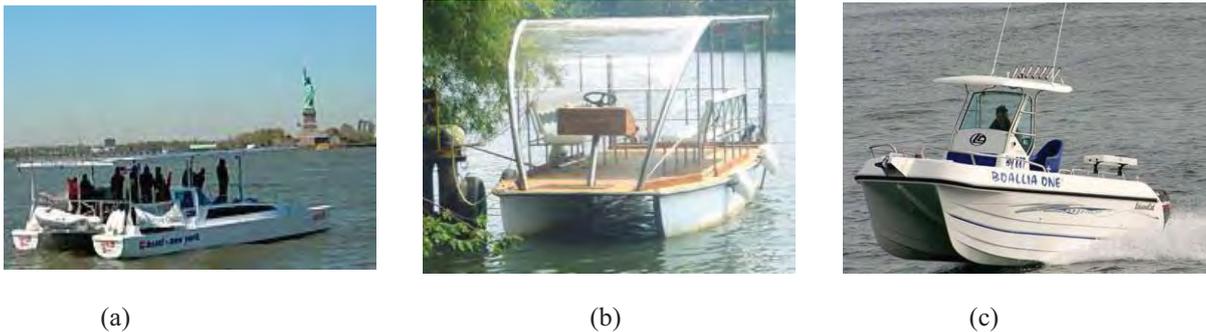

Furthermore, the emissions from ships produce GHG such as NO<sub>2</sub>, SO<sub>2</sub> and CO<sub>2</sub>. CO<sub>2</sub> emissions have a global climate impact and concentrated effort is being made worldwide towards their reduction. In order to monitor and quantify CO<sub>2</sub> emissions, the International Maritime Organization (IMO) introduces an Energy Efficiency Design Index (EEDI) [6], [7].

## 2. ENGINEERING REVIEW

### 2.1 Solar power boat

The idea of developing solar power boat coming from electric power boat, where the energy captured from sun-rays is stored into battery. The energy is then used to power the engine to move the boat into certain distance at certain speed. The first practical electric boat, powered by solar energy, was constructed in 1975 in England [9]. It was later followed by some countries, such as Switzerland, which has developed the biggest solar powered vessel so-far with length up to 31m and sailed around the world successfully. Planet-Solar, the Swiss solar catamaran has travelled a journey of about 60,000 kilometers across the ocean. With 537 m<sup>2</sup> of solar panels, the Planet-Solar has ever produced up to 600 kWh in good weather to cause the boat to go up to 300 km when the battery is charged up to 100%. Every thing on board is powered by the sun: the engine to computers through the water heating. In 2008, Japanese already launched the 200 m length “Auriga Leader” cargo ship solar power. The ship with displacement of about 60, 000 tonnes capable to carry about 6400 cars. The ship was produced by a joint venture of Nippon Yusen K K shipyard and Nippon Oil Corp [8].

Furthermore, Figures 1(a) to 1(c) portaits the development of adequately small solar power boat around the world.

**Figure 1: Examples development of solar power boat**

Figure 1 (a) shows a 14-meter boat (Sun 21 New York) which produces about 2,000 kWh of solar energy at constant speed of 5-6 knots (10-12 km/h) [9]. She enjoyed her first journey in the Rhine in October 2006. Figure 1(b) shows a 9-seat tourism boat developed in India and she can run at service speed about 6.5 knots [9]. Figure 1(c) shows a leisure boat of 6.88m length (Islander 6000) which is designed for fishermen along with walk-around decks and including two forward platforms for fly-fishing [10].

### 2.3 Emission factor

International Maritime Organization (IMO) adopted a new chapter to MARPOL annex VI in order to reduce GHG emission from international shipping by improving the energy efficiency for ships. The hull design, propulsion techniques and operational practices are expected technology that can be improved in order to increase the energy efficiency for ships. The Marine Environment Protection Committee (MEPC) approved the interim guidelines on the method of calculation of Energy Efficiency Design Index (EEDI) towards determining minimum energy efficiency level for new ships. It is mandatory to all merchant ships of 400 GT and above regardless the nationality of the owners [11]. However, it is considered in the near future to apply to other type of vessels using fossil fuels.

Furthermore, the EEDI formula provides a specific figure for an individual ship design, as proposed by IMO [6], [7], as given in Equation (1):

$$EEDI = \frac{P \times sfc \times C_F}{C \times V} \text{ gm CO}_2/\text{tonne mile} \quad (1)$$

Where  $P$  is power (kW),  $sfc$  is specific fuel consumption (gm/kW.hr),  $C_F$  is a CO<sub>2</sub> conversion (tonne CO<sub>2</sub>/tonne fuel),  $C$  is the capacity of the ship (DWT or GT) and  $V$  the speed (knots). As such, EEDI can be seen as a measure of a ship's CO<sub>2</sub> efficiency.

When considering the overall form of EEDI, it is clear that in order to reduce the index for a given ship at a given speed, a decrease in propulsive power must be achieved and/or improvements made in engine efficiency with a reduction in  $sfc$ . The EEDI formula can later be simplified to Equation (2):

$$EEDI = \text{CO}_2 \text{ emission} / \text{transport work} \quad (2)$$

The CO<sub>2</sub> emission represents total CO<sub>2</sub> emission from combustion of fuel at design stage, including propulsion and auxiliary engines, taking into account the carbon content of the fuels in question. If shaft generators or innovative mechanical or

electrical energy efficient technologies are incorporated on board a ship, these effects are deducted from the total CO<sub>2</sub> emission. If wind or solar energy is used to board a ship, the energy saved by such measures will also be deducted from the total CO<sub>2</sub> emissions, based on the actual efficiency of the system. The transport work is calculated by multiplying the ship's capacity as designed (DWT for cargo ships and GT for passenger vessels) with the ship's design speed measured at the maximum design load condition and at 75% of the rated installed shaft power. Speed is the most essential factor in the formula and may be reduced to achieve the required index.

### 3. ECONOMIC REVIEW

Solar power boats obtain their energy from the sun. Using electric motors and storage batteries charged by solar panels and photovoltaic cells, solar power boats can significantly reduce the use of fossil fuels. Solar boats are uniquely suited to transform light energy (from the sun) to movement. Environmentally friendly solar energy is an energy efficient way to power commercial oceangoing vessels and leisure boats [9]. This later found to be very worthwhile if installed into fishing vessels.

The high cost of fossil fuels hence causes the fishermen unable to buy it, can be overcome by the introduction of solar power boat. The high cost of solar panel can be anticipated by the combination use of conventional diesel engine and the solar panels. In this case, the size of engine may be reduced and hence the fuel consumption. The high cost of solar panels is purely a crucial problem at the beginning (for the fishermen), but they will spend less money to buy fuels in the future as long as they maintain the solar panels properly [13].

### 4. EXAMPLE OF APPLICATION AND DISCUSSION

#### 4.1. The practical electric boat

A small and practical solar powered catamaran was developed and reported in [12]. The principle particulars of the boat are: L<sub>BP</sub> = 9.765 m, B = 3.5 m, T = 0.9 m and block coefficient (C<sub>B</sub>) = 0.68. The resistance calculation was made based on Insel and Molland approach [14]; the complete formulation is given in Equations (3 and 4). The service speed of the boat is 6.25 knots (Fr = 0.33) hence its total resistance is 0.95 kN.

The most widely used estimation of catamaran resistance is the method proposed by Insel and Molland [14]. In this case, catamaran hull consists of 2 isolated demihulls and creates wave and viscous resistance interference and formulated as follows:

$$C_T = (1 + \phi k) \sigma C_F + \tau C_W \quad (3)$$

Where:

C<sub>T</sub> is total resistance coefficient,

C<sub>F</sub> is frictional resistance coefficient and obtained from ITTC-1957 correlation line,

C<sub>W</sub> is wave resistance coefficient of isolated demihull,

(1+k) is form factor value of isolated demihull,

ϕ is used to estimate the change of pressure around demihull,

σ represents additional velocity between demihulls and calculated from the summation of local frictional resistance around wetted surface area.

In fact, the factors of ϕ and σ are difficult to measure hence for the practical purposes, the two factors can be combined to form viscous resistance interference factor β where (1 + ϕ k)σ = (1 + β k) hence:

$$C_T = (1 + \beta k) C_F + \tau C_W \quad (4)$$

Where for monohull or demihull at isolation the value of β=1 and τ=1.

Furthermore, the effective power of the boat is calculated using Equation (5) and giving the effective power (PE) about 3.04 kW. However, since the boat is a catamaran and using two engines and propellers hence the capacity of each engine is 1.52 kW. The thrust power is calculated using Equation (5) and giving thrust power (T) of about 3.053 kW.

$$P_E = R_T V \quad (5)$$

Furthermore, Ref [12] concluded that the boat required 10 solar panels in which each panel can produce energy about 100 WP (watt-peak). The charged battery can power the boat, solely supported by 10 solar panels, for about 5 hours.

#### 4.2. Possible Cost Saving

The Indian boat (Sun 21) as shown in Figure 1 (b) is a 45.9-foot-long specially built solar powered boat known as a catamaran [9]. It is installed 48 silicon photovoltaic cells on its canopy like roof, which can collect energy from sunlight and transmit it to a device in one of her cabins. The device transmits the energy to the 3,600 lbs of storage batteries placed below the deck. The 11-ton solar boat was powered on the energy needed to light 10 100-watt light bulbs. The typical speed was 3.5 knots and together with two engines so that the boat can go up to 107 nautical miles a day in good weather. Her fuel consumption is about 17 Liter/hour (MCR), hence, ignoring the cost of the system, the solar boat can save 17 liter/hour x 24 hours x IDR 4,500 that is IDR 1,836,000 per day.

Meanwhile, other work conducted in Indonesia and reported in [13], the cost to built a solar boat of 4.30 m LOA, 3.80 m LWL, 2.50 m breadth moulded (B), 0.30 m draught (T) and 1.39 ton displacement was approximately IDR 105 millions. In term of investment value, the cost of the boat is somehow more expensive than the same boat powered by conventional engine. The boat can save about IDR 1.4 million for 20 operational days. This is, indeed a very small saving of money, but the operational cost could be cheaper in long term since the boat does not need fuel and the battery (if well maintained) can be used up to about 10 years.

Furthermore, refers to the work report in [9] and [11], the use of solar cells can reduce energy index (EEDI) of those two boats. Further details of the calculation is still being carried out at ITS.

## 5. CONCLUSION

The current work clearly portrays the study into the development of solar powered boat in order to reduce the use of fossil fuels. It has been found (through case example) that the use of solar panel in combination with the operation of electric engine was to be very useful.

Economic review indicates the potency of cost saving if the solar power is applied to small boat such as fishing vessels. In term of energy index, the system can reduce the emission of green houses gases. There is shown a good promise that can lead to significant savings in fuel consumption and hence reduce emission of greenhouse gases. However, in reacting to the increase pressure from the environmental viewpoints and with the possibility of future introduction of emissions trading schemes, reduction in power and emissions might be achieved with design changes and fuel saving devices but this may not be the best economic solution.

### ABSTRACT

The risk assessment commonly is performed by assessing the risk of accident from the point of probability of historical accident. Since sometimes it is quite difficult to get the historical data, the instrument to assess safety risk for ferry is developed through AHP and fuzzy approach. The instrument is based on the shiphandling difficulty level for ferry and later it is named with SHDMF. This paper presents how the SHDMF could be validated through experiment in shiphandling simulator. The shiphandling simulator NAVI TRAINER 5000 Transas is used. The experiment is performed by using 13 groups on ferry passenger with 7 scenarios which constitute of berthing, unberthing and crossing activities at Madura Strait, Indonesia. The result is compared to the SHDMF calculation.

### Keywords

*Shiphandling simulator, risk assessment, AHP and fuzzy approach*

## 1. INTRODUCTION

The risk assessment is an activity to assess level of risk concerned from one activity. Risk assessment approach generally uses historical data as an input to predict the outcome of process. Yet, this historical data sometimes is quite difficult to be acquired. Therefore, the development of analytic model could be an alternative approach to be used as an instrument of risk assessment. The analytic model validation needs to be performed in relation with real world. The types of validation consist of two types which are internal validation and external validation. The internal validation relates to the model validation itself and it could be performed according to its approach. Meanwhile, the external validation is performed based on the design of model itself. It may use real experiment, simulated experiment or even by case study. In this paper, to validate the AHP Fuzzy shiphandling difficulty model for ferry (SHDMF), shiphandling simulator experiment is carried out. The shiphandling simulator experiment is conducted by placing some experienced officers through some scenarios and the results are compared to the SHDMF. This experiment will be used as a justification step whether such simulator experiment approach could be employed for validating SHDMF. The description of SHDMF, shiphandling simulator and the result of experiments are described in this paper.

## 2. REFERENCES REVIEW

In this section, shiphandling difficulty model for ferry (SHDMF) and simulator overview are presented. The SHDMF reference review is based on the previous research which was conducted by the writers. In this paper, we do not discuss in detail about SHDMF construction such as AHP formulation and fuzzy member development, because this paper is a continuation of previous research and it focuses on the part of external validation.

### 2.1 Shiphandling difficulty model for ferry (SHDMF)

Shiphandling difficulty model (SHDMF) for ferry is developed through analytic hierarchy process (AHP) and fuzzy logic approach [1]. The first approach is performed to determine hierarchy among factors which consider as complex and inconstant toward shiphandling operation. The output of AHP is used to formulate fuzzy logic. The end output of this model is the level of shiphandling difficulty which further is used as a tool of making decision in risk accident assessment. The layout of SHDM is illustrated in figure 1.

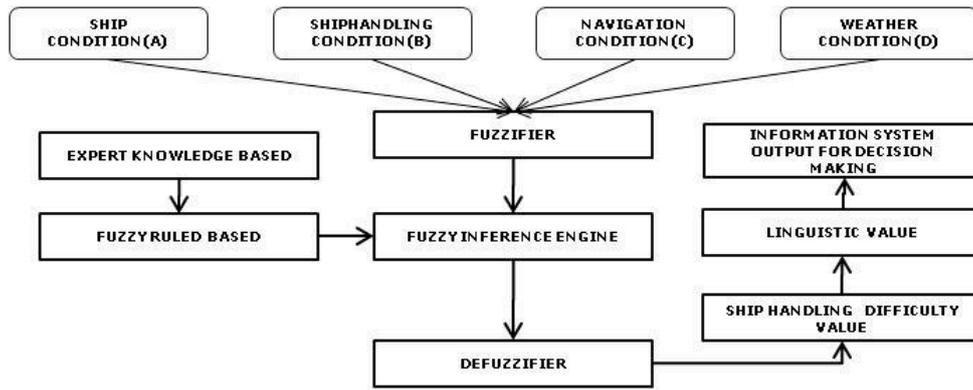

Figure 1 SHDMF overview

There are four variables which are processed into fuzzifier such as ship condition (A), Shiphandling facility condition (B), Navigation condition (C) and Weather condition (D). Each variable consists of sub variables which was arranged and formed in accordance with AHP. The ship condition (A) consists of tonnage (A1), ship draft (A2), ship type (A3), ship age (A4), bridge location (A5) and ship trim (A6). The shiphandling facility condition (B) covers main engine type (B1), propeller number (B2), the type of propeller (B3), ship rudder type (B4) and side thruster (B5). Then navigation condition (C) considers sub variables such as ship speed (C1), the depth of water (C2), ship position (C3), navigation status (C4) and traffic situation (C5). The last variable, weather condition (D) consists of wave (D1), wind (D2), current (D3), visibility (D4), swell (D5) and day/time situation (D6).

The fuzzy Mamdani Min- Max method is selected as methodology approach. In this method, the rule composition is developed based on the method of minimum. The fuzzy crisp solution is generated by taking the maximum value of the rule, then it is used to modify fuzzy area and it is applied to the output area with union (And) operation. If the entire preposition has been evaluated then the output will consist of fuzzy crisp which reflects the contribution of each preposition. It can be written as:

$$\mu_{fs}(x) = \text{Max}(\mu_{fs}(x), \mu_{fc}(x)) \quad (1)$$

Where:

$\mu_{fs}(x)$ =value of membership fuzzy solution until rule-x

$\mu_{fc}(x)$ =value of membership fuzzy consequence until rule-x

Based on the algorithm (1), for the purpose of this research, the algorithm is modified to accommodate 4 inputs and 1 consequence. The operator MIN is used for finding the consequence for each rule toward the inputs and the operator MAX is used for finding the aggregation among the consequences rules. The algorithm can be presented as:

$$\mu_{SHD}(z) = \max^i [\min[\mu_{WS}(i), \mu_{WF}(i), \mu_{WN}(i), \mu_{WW}(i)]] \quad (2)$$

Where,

$\mu_{WS}(i)$  : membership degree of ship condition for rule i.

$\mu_{WF}(i)$  : membership degree of shiphandling facility condition for rule i.

$\mu_{WN}(i)$  : membership degree of navigation condition for rule i.

$\mu_{WW}(i)$  : membership degree of weather condition for rule i.

min : operator for consequence

max<sup>i</sup> : operator for aggregation

$\mu_{SHD}(z)$  : membership degree of shiphandling difficulty/fuzzy solution.

Finally, formulation of the implication of fuzzy solution as a crisp value based on the Centroid method could be written as:

$$SHD(z) = \frac{\int_z \mu_{SHD}(z) \cdot z \, dz}{\int_z \mu_{SHD}(z) \, dz} \quad (3)$$

Where, SHD (z) : crisp value of shiphandling difficulty

$\mu_{SHD}(z)$  : membership degree of shiphandling difficulty.

## 2.2 Simulator Overview

This sub section present references study of simulator but this is not an exhaustive list of review study. The references studies use a simulator on road transport and maritime transport as a keyword to start with. The advantage of using simulator in some research can be explained that simulator provides interactivity process, record function and multiple measurements [2]. The interactivity process is quite important to see the behavior of respondent as well as the behavior of simulator. Therefore, the behavior aspects become the main purpose of using simulator. The behavior characteristic in detail can be analyzed such in waterway design [3]. Further, the availability record function will make a simple task for reviewing precisely. The most important, multiple measurements at same time could be performed at simulator. The measurement of respondent by simulator can be conducted in the term of internal measurement such as respondent property and external measurement such as speed and time [4]. Other purpose of using simulator is to perform hazard measurement related activities. For instance, simulators had been used for hazard anticipation [5, 6], risky situation as well as control strategic and decision making [7], dangerous territory and attention demand [8] as the considerations of safe and controllable environment become a main issue.

However, among the advantages of shiphhandling simulator, some disadvantages need to be notice. Generally, simulator does not present all visual cues but it provides necessary visual cues for designed scenario. Moreover, simulator may not represent visual complexity of real world because it may cause high cost of simulator and it may not necessarily to be shown. Respondents need to try simulator as they may need to familiarize and to adapt before they may feel fine to use it [9]. Here, the adaptation process is quite important to get the better result of experiment as it may be performed through practice session based on time, distance or scenario [6, 9].

The fidelity of simulator is the most important consideration before a simulator is used for a designed research. The term fidelity refers to the appearance and functionality simulator as it is experienced by expert which may consist of familiar pilot with designed scenario [3]. The appearance of simulator may be justified on screen to eye distance, the field of view, color and texture, resolution and update rate. The functionality of simulator may be verified by bridge control equipment and instrument display. Therefore, the mock up of bridge as similar as real ship will enhance fidelity of simulator.

The method of using simulator generally discusses on profile and number of respondents, the design of experiment, the use of apparatus and procedure. The profile and number of respondents will much depend on the purpose of simulator experiment. For instance, three pilots had been used to evaluate the ship collision risk monitoring system [10]. The most important is the expertise level of respondent which may be based on license level and experience. The design of experiment can be prepared based on the purpose of research, therefore different research objective may need different design. The design of experiments may be formed in form of scenarios. The use of apparatus depends also on the objective of research. The apparatus may consist of equipment inside simulator and it may also necessary to use the different type of simulator. The procedure of experiment will ensure the validity and reliability process of research.

## 3. PROCEDURE

The procedure of experiment consists of several steps such as the assignment of respondent, the creation of scenario, the familiarization of shiphhandling simulator, actual experiment and result analysis. The respondent of simulator was selected based on the level of experience and competency. The scenario is developed at Madura Strait in Indonesia between ferry port of Ujung and ferry port of Kamal. Before the experiment is performed, the familiarization of using simulator was conducted based on the scenario which will be used. The familiarization consists of two parts. The first part, the explanation of bridge equipment and scenario overview are given. Secondly, they try all equipment and scenario until the end of scenario for twice. Then, the actual experiment is conducted and at the end the result is analyzed.

Respondents are divided into 13 groups which each of group consists of two or three members. One member of each group is assigned as a master and the rest are acted as an officer on duty or as a wheel man. Each group will be examined through same scenario and bridge. For collecting data purpose, they are provided with questionnaire paper. Through radio communication, they are asked to fill up questionnaire after the completion of each scenario.

Scenario is arranged according to the input of SHDMF, so comparison result as a benchmark can be obtained. The scenarios consider variables as developed in the SHDMF. They consist of ship condition, shiphhandling facility condition, navigation condition and weather condition. The experiment uses a shiphhandling simulator TRANSAS NAVI Trainer 5000. This simulator has capability for performing shiphhandling and navigation activity as well as for recording parameter during experiment. The experiment is performed on ferry passenger with 974 gross tonnages. The ferry has length 58,6 meter , engine power 2x637 kW. Some restrictions of inputs are given such as the age of ship, the type of rudder which is not mentioned in the simulator. The example of extracted scenario is illustrated in Table 1.

Table 1 extracted form of scenario

A	SHIP CONDITION	VALUE	B	SHIP HD. FAC. COND.	VALUE
1	Ship Tonnage/DWT	974 t	1	Main Engine Type	Diesel
2	Ship Draft	2,4 m	2	Propeller number	2
3	Ship Type	Full super structure	3	Propeller type	Fixed
4	Age of Ship	Less than 10 years	4	Number of Rudder	2
5	Bridge Location	Forward	5	Rudder type	Simple/unbalanced
6	Ship Trim	By stern	6	Side thruster	Yes
C	NAVIGATION COND	VALUE	D	WEATHER COND	VALUE
1	Ship speed	Max 13 knots	1	Wave	000/ 0 meter
2	Water depth	Min 4 m	2	Wind	000/ 0 knots
3	Communication	Yes	3	Current	000/ 0 knots
4	Ship position	Various	4	Visibility	6 nm
5	Navigation status	Underway	5	Swell	000/ 0 meter
6	Traffic situation	Various	6	Day/Night	Day

Shiphandling difficulty experiment (SIMEXP) is conducted through seven scenarios. The scenario 1 until scenario 5 examines the shiphandling difficulty in approaching jetty during berthing and unberthing activities. The scenario 6 and 7 examine the shiphandling difficulty during crossing the strait. Each scenario is modified on some input parameters, particularly on the weather condition. The scenario is commenced from condition without any disturbance on the weather and at the end, the 2 meter wave, 2 meter swell, 2 knots of sea current and 20 knots of wind speed are given. Therefore, it is assumed that the difficulty level of shiphandling will increase gradually. The lay out screenshot of scenario as a sample is illustrated in figure 2.

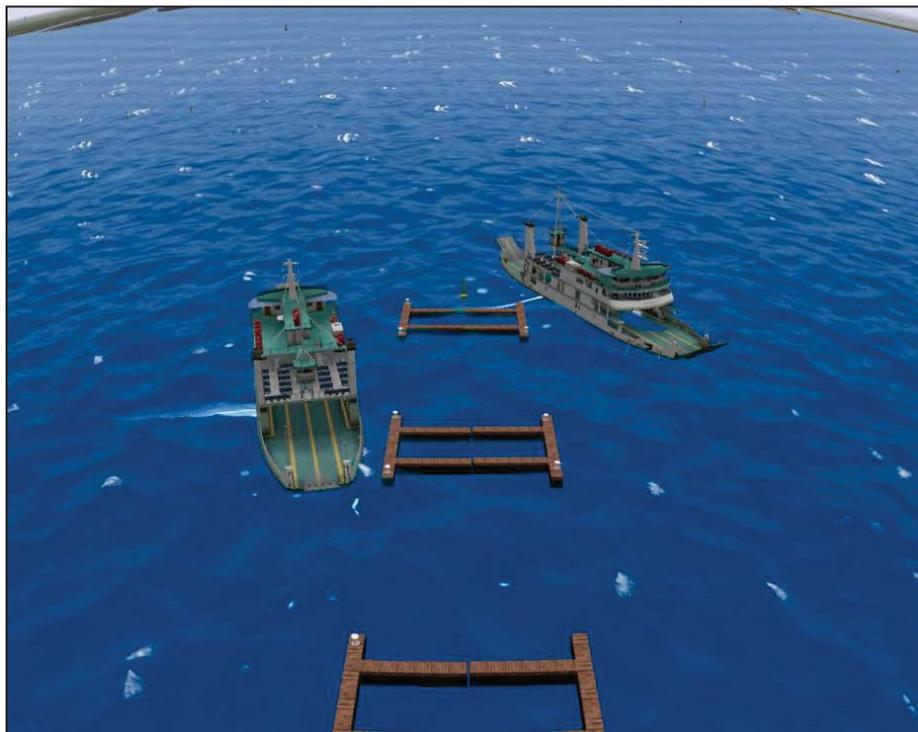

Figure 2 layout sample of scenario

The result of SIMEXP in the form of average score for all groups is converted into linguistic scale. Then the linguistic scale for SIMEXP is compared with the linguistic scale for SHDMF in term of linguistic difficulty for further analysis. The linguistic scale table is presented in table 2.

Table 2 Linguistic scale for SHDMF

SHDMF LINGUISTIC LEVEL	SCORE	DIFFICULTY RANK	SHDMF SCORE	ACCEPTANCE CRITERIA
Extremely Safe	125	NEGLIGENCE	100	ACCEPTABLE
Fairly Safe	200			
Somewhat safe	275			
Neither Safe/Dangerous	350	MARGINAL	250	
Somewhat dangerous	430	CRITICAL	400	
Fairly dangerous	480	CATASTROPIC	440	UNACCEPTABLE
Extremely dangerous			500	

#### 4. RESULT AND DISCUSSION

The measurement of this experiment consists of two measurements which are internal and external measurements. The Internal measurement relates to the respondent profile. The respondent profile describes several parameters such as age, competency certificate and sea experience. Among 13 groups, the mean of respondent age is 34 years old with standard deviation of 6 years old. In average, they have 10 years sea experience with 5 years standard deviation. Regarding certificate competency, 6 groups hold class 3 certificate and 7 groups hold class 4 certificate. The decision about which class of certificate competency used for this experiment is based on the field observation, most officers in charge of navigational watch and some master of ferry at some ferry routes in Indonesia hold class 4 certificate. Therefore, justification of respondent with the minimum of class 4 certificate is taken.

Based on the Gross tonnage of ship, individually as a member of group, 9 respondents on ship with  $GT < 500$ , 10 respondents with  $500 \leq GT < 3000$ , 13 respondents with  $3000 \leq GT < 10000$ , and 4 respondents with  $GT \geq 10000$ . They had experience on ship length as 5 respondents on ship with  $7m \leq LOA < 24m$ , 14 respondents with  $24m \leq LOA < 100m$ , 9 respondents with  $100 \leq LOA < 200m$  and 9 respondents with  $LOA \geq 200m$ . Most respondents had experience on more than 2 meter of ship draft. Regarding bridge location, 12 respondents had experience on forward bridge, 4 respondents on mid bridge and 19 respondents on aft bridge. Most of respondent had experience on main engine with more than 750 HP. Moreover, they are also asked for their experience on ship rudder, ship propeller, bow thruster and others related questions.

Meanwhile, the external measurement relates to performance measurement which is accomplished by subjective measurement through shiphandling difficulty questionnaire for each scenario. The external measurement is decided by each group after having discussion with their member to state their subjective level of shiphandling difficulty.

The result of simulator experiment (SIMEXP) is analyzed through 5 steps. The first step, the average score of shiphandling difficulty for each scenario is accounted. The average score consisted of 13 groups of experiments. For instance, for the unberthing scenario 1, the average score is 11, 54 while the average score for the unberthing scenario 2 is 21,79 (see table 3 ). The second step is the translation of average score into linguistic level. The linguistic level is created in the previous section. For instance, the mentioned average score for the unberthing scenario 1 is "fairly safe". The detail table of linguistic level can be consulted again in the table 2.

The third step is placing the input data used in the SIMEXP into shiphandling difficulty model for ferry (SHDMF). Then, the result in the form of score is averaged. The fourth step is similar with the second step which the translation of SHDMF score into linguistic level is executed. The last step, step 5, comparison both linguistic level of SIMEXP and SHDMF is conducted. The comparison is grouped into unberthing scenario, berthing scenario and crossing strait scenario. Table 3 shows the result of comparison between SIMEXP and SHDMF for unberthing scenario. It is shown that the SIMEXP linguistic level for scenario 1, 2 and 3 have a one level lower than SHDMF linguistic level, whereas for scenario 4 and 5 is on the same linguistic level.

Table 3 comparison result for unberthing scenario

Scenario	Scenario 1	Scenario 2	Scenario 3	Scenario 4	Scenario 5
<b>SIMEXP Score</b>	11,54	21,79	25,64	53,85	51,28
<b>SIMEXP Linguistic</b>	Fairly Safe	Fairly Safe	Somewhat Safe	Neither Safe/Danger	Neither Safe/Danger
<b>SHDMF Score</b>	25,82	41,09	44,46	45,47	45,78
<b>SHDMF Linguistic</b>	Somewhat Safe	Somewhat Safe	Neither Safe/Danger	Neither Safe/Danger	Neither Safe/Danger

For the berthing scenario, same analogy is assigned. The result of comparison between SIMEXP and SHDMF is presented in table 4. We may see also that that linguistic level of SIMEXP for scenario 1,2 and 3 have one level lower than SHDMF linguistic level.

Table 4 comparison result for berthing scenario

Scenario	Scenario 1	Scenario 2	Scenario 3	Scenario 4	Scenario 5
<b>SIMEXP Score</b>	12,82	24,36	26,92	55,13	56,41
<b>SIMEXP Linguistic</b>	Fairly Safe	Somewhat Safe	Somewhat Safe	Neither Safe/Danger	Neither Safe/Danger
<b>SHDMF Score</b>	25,82	41,09	44,46	45,47	45,78
<b>SHDMF Linguistic</b>	Somewhat Safe	Somewhat Safe	Neither Safe/Danger	Neither Safe/Danger	Neither Safe/Danger

For the crossing scenario, same analogy is assigned. The result of comparison between SIMEXP and SHDMF is presented in table 5. We may see that there is no different linguistic between SIMEXP and SHDMF.

Table 5 comparison result for crossing strait scenario

Scenario	Scenario 6A	Scenario 6B	Scenario 7A	Scenario 7B
<b>SIMEXP Score</b>	19,23	23,08	33,33	34,62
<b>SIMEXP Linguistic</b>	Fairly Safe	Fairly Safe	Somewhat Safe	Somewhat Safe
<b>SHDMF Score</b>	25,94	39,01	43,16	43,36
<b>SHDMF Linguistic</b>	Somewhat Safe	Somewhat Safe	Somewhat Safe	Somewhat Safe

Based on the comparison result, we may see that SIMEXP has lower linguistic level in certain scenario than SHDMF. It may be also stated that SHDMF for all cases has one linguistic level higher than SIMEXP. As a conclusion, the SHDMF in all cases of experiment has one linguistic level higher than SIMEXP. It could be argued that SHDMF could be used for higher standard of safety assessment related to the shiphandling difficulty level. Meanwhile, the result of experiment is based on the subjective judgment by questionnaire. It is necessary in the future, the result of SIMEXP could be justified through objective analysis therefore the experiment will give more precisely result. Finally, the simulator experiment (SIMEXP) approach is an alternative approach which could be used to justify the external validation of SHDMF.

## ABSTRACT

The use of multi-hull vessels, particularly of catamaran type, is very popular since the last 3 decades. It has been widely used as passenger and cargo carriers, oceanographic research vessels and fast patrol boats. The reasons behind this success are attributed to better transverse stability; wider deck space area and possible lower drag hence lower power of engine produced by the multi-hull vessels.

The paper explains the investigation of resistance/powering and seakeeping of mono- and multi-hull vessels which is operated within archipelagic waters such as Moluccas islands. Studies are conducted on medium size of passenger vessels in order to identify and illustrate potential levels of savings in propulsive power at the design stage. Performance of ships at sea (seakeeping) evaluation is included since typical of Moluccas waters consist of narrow straits or restricted waters and open sea waters which is completely two different situations in term of sea conditions.

## Keywords

*resistance, powering, mono-hull, multi-hull, seakeeping.*

## 1. INTRODUCTION

The need for sea transportation sea system according to geography, weather, climate and waves condition become a crucial problem particularly to archipelagic countries such as Indonesia and the Philippines. The need for various types of ship has increased in the last thirty years, where many ship types been developed to satisfy the engineering and economic criteria. Among other, multihull concept (such as catamaran and trimaran) has received considerable attention due to their stability characteristics and freedom in arranging deck layouts. The multihulls have been built as passenger vessel, sporting craft, oceanographic research vessel and fishing vessel [1].

There are plenty work conducted world-wide in order to explore the benefits of multihull ships. [2] developed a preliminary design method to provide accurate solution of catamaran passenger vessel. Meanwhile, trimaran hull form or vessel with three hulls has received considerable attention because it can provide even bigger deck area and shallower-draft [3, 4]. The form of trimaran, at the beginning, is popularly used as warships because of its high quality of stability [5].

The calculation of power required by the catamarans and trimaran needs an investigation into the resistance characteristics entirely in order to obtain the most by ship design [6]. The resistance of catamaran and trimaran can provide complex phenomena to ship designers particularly with the appearance of interaction between the demihull of catamaran or between the main-hull and side-hull of trimaran. Therefore, it has been a basic need to obtain the breakdown and understanding of correct ship resistance components in order to obtain accurate calculation based on scaling transformation from model to the real ship.

Furthermore, during its voyage on the water, a ship experiences 6 degree of freedom (DOF) of movement [3] Among others, three DOF (heave, pitch, roll) relates to ship performance at sea (seakeeping) and this connects to the comfortability of the vessel. Seakeeping characteristics can be estimated or calculated using tank test or tested in an MOB, numerically using computational fluid dynamics (CFD) approach, and using commercial design softwares such as Maxsurf [7].

## 2. MODEL DESCRIPTION AND TEST SET-UP

The models (mono, catamaran and trimaran) were produced according to a scale of 1:9. Their principal dimensions and mass properties are shown in Table 1. The model was statically and dynamically balanced to adjust the position of centre of gravity and radii of gyration as specified. Figure 1 to 3 showed the setting of monohull, catamaran and trimaran in the towing tank, respectively.

A series of model tests was conducted at the towing tank of Indonesian Hydrodynamics Laboratory (IHL) [7]. In this model tests, the resistance tests were carried out where the model was towed by the carriage. The model was connected to the load cell transducer at a point located amidships and vertically at 0.45T above base line, allowing the model to move freely in the vertical plane.

Table 1. Principal data of monohull, catamaran and trimaran

Dimension	Mono	Catamaran		Trimaran	
		Twin	Demi	Main	Side
LWL (m)	13.8	14.5	14.5	14.5	12.0
B (m)	2.88	7.66	1.86	2.00	1.15
D (m)	0.65	0.65	0.65	0.72	0.52
H(m)	1.30	1.30	1.30	1.44	1.24
Cb	0.50	0.38	0.382	0.384	0.39
DISP (tons)	11.8	11.8	5.90	6.96	2.42
TOTAL DISP (tons)	11.8	11.8		11.8	

Figure 1: Monohull model

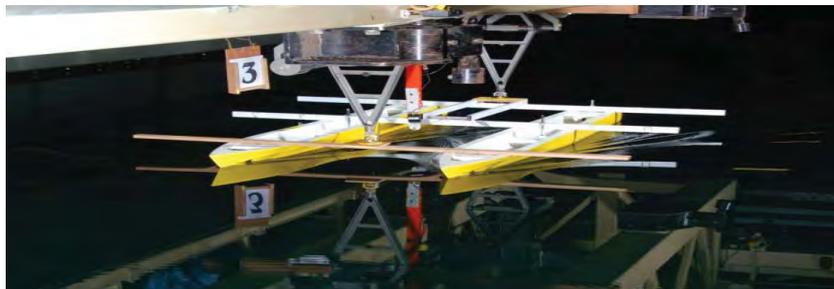

Figure 2: Catamaran model

Figure 3: Trimaran model

### 3. EXPERIMENTAL AND NUMERICAL RESULTS

The wider space area for activities on main deck is the main concern for the commercial sea transportation now. The space area on main deck for catamaran is mostly related to the separation length ratio ( $S/L$ ). Therefore, this ratio need to be investigated and discussed into the resistance performance to estimate the ship power and seakeeping qualities.

### 3.1. Resistance/ Powering

The most widely used estimation of catamaran resistance is the method proposed by [8]. In this case, catamaran hull consists of 2 isolated demihulls and creates wave and viscous resistance interference and formulated as follows:

$$C_T = (1 + \phi k) \sigma C_F + \tau C_W \tag{1}$$

Where:

$C_T$  is total resistance coefficient,

$C_F$  is frictional resistance coefficient and obtained from ITTC-1957 correlation line,

$C_W$  is wave resistance coefficient of isolated demihull,

$(1+k)$  is form factor value of isolated demihull,

$\phi$  is used to estimate the change of pressure around demihull,

$\sigma$  represents additional velocity between demihulls and calculated from the summation of local frictional resistance around wetted surface area.

In fact, the factors of  $\phi$  and  $\sigma$  are difficult to measure hence for the practical purposes, the two factors can be combined to form viscous resistance interference factor  $\beta$  where  $(1 + \phi k) \sigma = (1 + \beta k)$  hence:

$$C_T = (1 + \beta k) C_F + \tau C_W \tag{2}$$

Where for monohull or demihull at isolation the value of  $\beta=1$  and  $\tau=1$ .

Empirical formulation to estimate the total resistance of trimaran, however, is so far not known and depends highly on the experimental results [9]. This is attributed to the minimum publications of trimaran resistance Yet, there is no standard design or model test for trimaran. Results of the experimental work were tabulated in Table 2, which described the correlation of resistance against speeds of ship.

Furthermore, the results from Maxsurf were shown in Table 2. Despite the software does not take resistance interaction between the hulls, the numerical study was taken at  $S/L=0.3$  when there is presumably no significant interaction between demihulls [4, 8]

### 3.2. Seakeeping

The requested random wave condition was adjusted prior to the actual model. This condition was done by measuring wave height at the neutral position of the model. The wave elevation was measured by means of a resistance wire type wave probe. The irregular waves were adjusted such that the spectral density distribution compares with the required theoretical energy distribution

When there is a linear relation between wave elevation and motions, accelerations or forces, this relation can be presented in the frequency domain with response functions or Response Amplitude Operators (RAOs). These RAOs give the ratio between the input wave amplitude and the output signal for each wave frequency and can be calculated using the spectral densities of the calibrated wave and the output signals according to :

$$H_u = \frac{u_a(\omega_e)}{\zeta_a(\omega_e)} = \sqrt{\frac{S_{uu}(\omega_e)}{S_{\zeta\zeta}(\omega_e)}} \quad (3)$$

In which:

- $H_u$  = response function of a signal u
- $U_a(\omega_e)$  = amplitude of frequency  $\omega_e$  of signal u
- $\zeta_a(\omega_e)$  = amplitude of frequency  $\omega_e$  of wave elevation  $\zeta$
- $S_{uu}(\omega_e)$  = spectral density of signal u
- $S_{\zeta\zeta}(\omega_e)$  = spectral density of wave elevation  $\zeta$

Beaufort provides data on wave height where the sea state 3 wave height between 0.6 m – 1 m high and sea state 5 waves between 2 m - 3 m, seakeeping analysis with Maxsurf Program for both sea conditions

#### 4. DISCUSSION

Experimental results shown in Table 3 and the Maxsurf results in Table 2 described the relation between speed and resistance at various configurations. However, Maxsurf shows a little increase compared to the experimental result and this also occurs at catamaran and trimaran configurations. This is attributed to the exclusion of resistance interference and wave breaking phenomenon by Maxsurf. The last term occurs at higher speed or Froude numbers and further discussion about this can be found in Hogben and Standing [10,11]. Similar phenomena are also shown by catamaran with clearance  $S/L=0.3$  (see Figure 2) and trimaran with clearance  $S/L=0.3$  (see Figure 8) configurations. The catamaran form (Figure 2) shows lower resistance and the trimaran mode (Figure 3) indicates even lower resistance than the monohull mode of similar displacement. The reason for this, despite similar displacement, is because the catamaran and trimaran modes have slenderer hull-form than the monohull one. Thus, this has caused the resistance interaction and hence total resistance to decrease. By the use of Maxsurf, however, there is no indication of resistance decrease since the software or code does not take both resistance interaction and wave breaking phenomenon into consideration.

Among the catamaran and trimaran modes, it is clear that the total resistance decreases as the separation to length (S/L) ratio increases and this is caused by the decrease of resistance interaction following the increase of S/L ratios. This is in a good agreement with Utama [8, 12].

#### Curve Response Amplitude Operator (RAO) influence on Wave Encountered

Figure 4: Sea state 3 Wave height 0.6 m conditions of monohull heading 90 deg and 180 deg

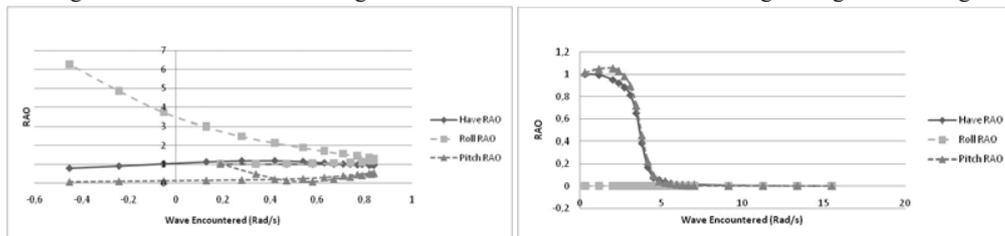

Figure 5: Sea state 3 Wave height 0.6 m conditions of catamaran heading 90 deg and 180 deg

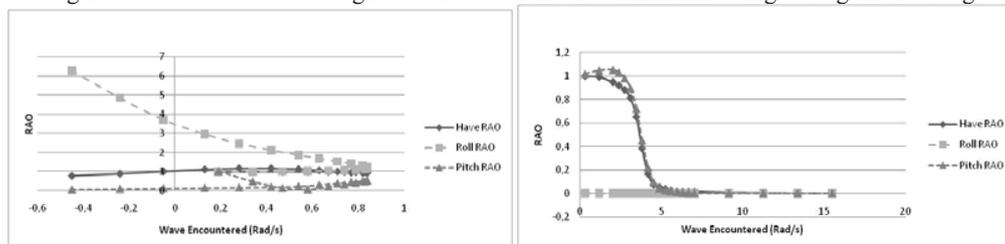

Figure 6: Sea state 3 Wave height 0.6 m conditions of trimaran heading 90 deg and 180 deg

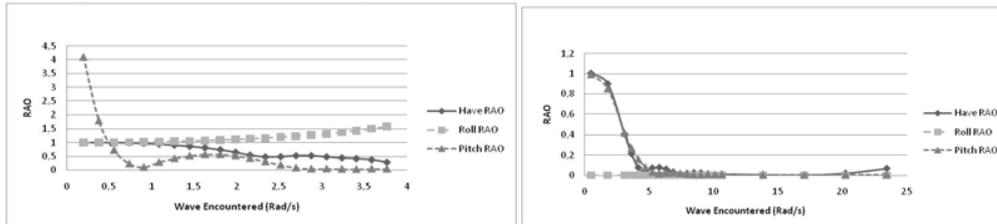

Figure 7: Sea state 5 Wave height 2.0 m conditions of monohull heading 90 deg and 180 deg

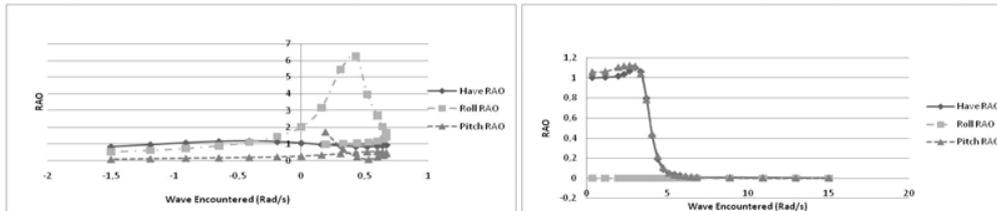

Figure 8: Sea state 5 Wave height 2.0 m conditions of catamaran heading 90 deg and 180 deg

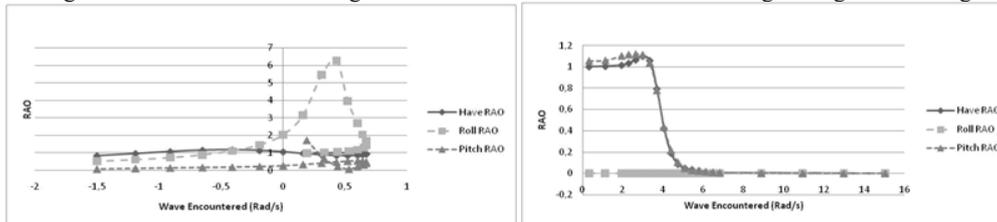

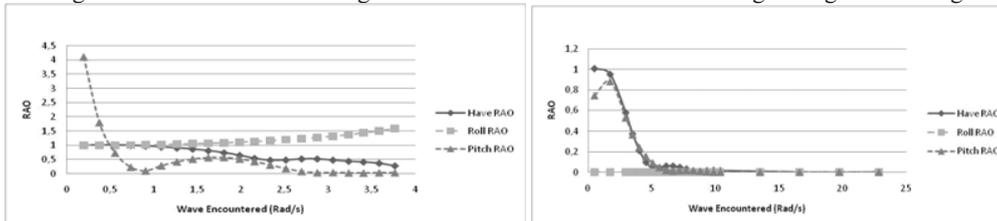

Figure 9: Sea state 5 Wave height 2.0 m conditions of trimaran heading 90 deg and 180 deg

In addition, among the multihulls, the catamaran mode demonstrates slightly smaller heave and pitch responses compared to the trimaran. Conversely, the trimaran showed smaller roll response to the catamaran. This is because of the number of hulls, in which trimaran has more hulls and hence the total ship breadth. This further cause better or lower roll response, but higher heave and pitch responses, and this corresponds well with [ 8].

## 5. CONCLUSION

View of the experimental and numerical model analyses undertaken in research work, the following conclusion can be drawn:

The catamaran and trimaran configurations provide lower total resistance than monohull one with equal displacement. The main and most significant factor is the geometry of ship hull and arrangement of ship wetted surface area.

The trimaran mode demonstrates higher resistance or power effective at lower separation ratio ( $S/L=0.2$  and  $0.3$ ). This is because the main hull of trimaran is bluff enough to cause higher flow interaction between the hulls hence causes higher resistance and power effective. In addition, the trimaran possesses three hulls, whilst the catamaran does have only two hence resistance and resistance interaction of the trimaran are consequently higher than those of the catamaran. However, at  $S/L=0.4$  the interaction decreases significantly hence total resistance and power effective become much smaller.

The multihull modes show almost similar motion characteristics as compared to the monohull. This is an indication (up to sea state 3), that catamaran and trimaran are as comfortable as the monohull. Furthermore, the effect of wave direction on ship motion is clear. Heave and pitch motions of both multihulls are more excessive under following sea condition, whilst roll motion is more extreme under quartering and beam sea conditions.

## Vane-Turbine as an Energy Conversion in the Propeller Slipstream of Single Screw Ship

S Leksono<sup>a</sup>, IKAP Utama<sup>a</sup>, MA Djoni<sup>b</sup>, WD Aryawan<sup>a</sup>

<sup>a</sup>Department of Naval Architecture and Shipbuilding Engineering, ITS, Surabaya, Indonesia

<sup>b</sup>Department of Mechanical Engineering, ITS, Surabaya, Indonesia

### ABSTRACT

The screw propeller of a ship generates thrust to make it moving. As a propeller rotates, it draws fluid into itself from the surrounding area (slipstream). The propeller produces two types of flow behind it, accelerated flow and circulating flow. Some of the energy from the ship engine is lost in the accelerated flow behind ship as a jet wash. The kinetic energy losses in the slipstream propeller will be captured by a Turbine and then called the propeller-turbine system. This composed of screw propeller of a vessel (called the main propeller) and a vane turbine that is the area of vanes located inside the wake of the main propeller. It recovers the energy generated by the main propeller pushing water back out (which would be otherwise wasted behind the main propeller) and hopefully enhancing the efficiency of the main propeller.

The influence of vane turbine on the performance breakdown of single screw ships were analyzed by using 5 (five) ships. Ship powering was calculated by using DESPC (DESP Code 10) software and the performance of vane turbine by applying actuator disc theory for calculating thrust and power generated. Although the vane turbine affected speed loss of the ship, the power efficiency gained to be found always positive. Vane turbine is suitable as an energy saving device of the single screw ship.

## ABSTRACT

Shipbuilding market is booming in Indonesia due to dramatic increase of national merchant shipping fleet since the implementation of cabotage principle in 2005. In order to fulfill the demand of shipping market and to renew the old fleet it is predicted that at least one million GT new buildings are on demand every year. Unfortunately the capacity of the national shipbuilding industry is not sufficient to cater the growing market due to its low productivity, high building cost, and slow delivery time. Integrated shipbuilding cluster has just been introduced to the Indonesian shipbuilding industry in attempt to increase their capacity and productivity. In conjunction with this research is being carried out to apply Multi-yard ship construction method to the shipyards involved in the clusters as complementary to the integrated shipbuilding cluster with the objective to increase the productivity and quality of the shipyards and to reduce the delivery time of ships being built so that the existing market could be grasped. Three shipyards in Jakarta are chosen for the research and the ship being built is investigated as pilot project. Beside all the committed industries in the cluster i.e. core industry, pulling industry, supporting industry, supplying industry and supporting services, the shipyards are assigned to build certain parts of ships in accordance to their individual characteristics, then the ship parts or blocks are joined together in one of the collaborating shipyards. Ship structural components are defined and the processing tasks are distributed to the shipyards in accordance to their typical expertise, the coordination and production processes including the man-hours needed are simulated using available production soft-wares. Since the shipyards are located in the same area transporting of the ship blocks will not be any problem, each individual yard will only concentrate to build certain parts of the ships so that their learning process will be shortened, and the construction process of the ships can be carried out simultaneously by the collaborating shipyards, thus the ships can be built faster and hence will increase the productivity of the shipyards involved. Good coordination among the shipyards and application of same ship production standards are the key components for the successful implementation of the method. It is assumed that 30% of shipyards productivity could be achieved

## 1. INTRODUCTION

### 1.1. Background

Since the implementation of Cabotage principle in 2005 and the establishment of Shipping Law No. 17/2008 the national shipbuilding market has increased dramatically due to obligation of using national flagged ships for local shipping, even though part of the demand is fulfilled by importing used ships from aboard, but the used ships need to be renewed in less than 5 years because many of them are considered very old. According to INSA (Indonesian National Shipowners Association) it is predicted that at least 1 million GT of ships are on demand every year [1]. Unfortunately this market booming could not be catered by national shipbuilding industry due to lack of building capacity, low productivity, high building cost, and slow delivery time. In attempt to increase the building capacity of the national shipbuilding industry and to improve its productivity shipbuilding industry cluster has been introduced in Surabaya in 2006 known as KIKAS (Klaster Industri Perkapalan Surabaya), in Jakarta in 2007 known as KIKAJA (Klaster Industri Perkapalan Jakarta) [2], and recently in 2012 has just been proposed in Lampung Province [3].

### 1.2. Shipbuilding Industry Cluster

Industrial cluster is defined as a group of inter-related industries that drive wealth creation in a region, primarily through export of goods and services. It represents the entire value chain of a broadly defined industry from suppliers to end products, including supporting services and specialized infrastructure. Cluster industries are geographically concentrated and inter-connected by the flow of goods and services [4].

In the case of shipbuilding cluster there are 4 industries that inter-related with shipbuilding industry as the core, they are: pulling industry, supplying industry, supporting industry, and supporting services [5], which can be illustrated as follows:

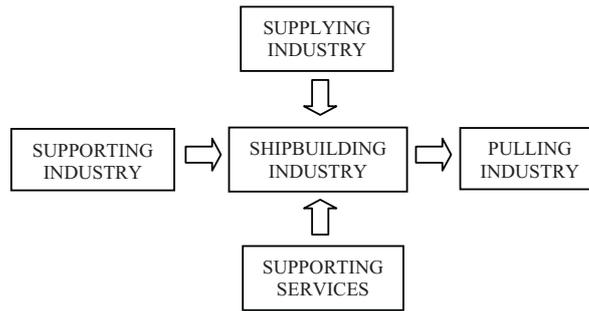

Figure 1: Shipbuilding Industry Cluster

Shipbuilding industry is the core of the cluster that will create wealth in the region with all its prospective opportunities, shipping industry is the pulling industry that provide market for the shipbuilding industry, supporting industry is the industry that produces main materials and components for shipbuilding that need further fabrication or work by the shipyards such as steel plates and sections and other hull materials, fabrication industry, and consumables industries such as water, gas and electricity etc., supplying industry is those that supply all kind of machineries and equipment for the ship that only need to be installed or applied by the shipyards including paint, chains, zinc anodes etc., and supporting services are institutions that provide services both directly and indirectly to the shipbuilding industry such as classification societies, design and surveying firms, educational institutions, financial institutions etc. All the inter-related industries should commit themselves to foster the development of the shipbuilding cluster.

### 1.3. Multi-yard Ship Construction Method

Multi-yard ship construction method is a ship production approach for building a ship by more than one shipyard [6]. The shipyards in the group should be complementing each other with their particular facilities, shipbuilding experience, and capacity. Each shipyard is assigned to build certain blocks of the ship in accordance with their respective specialty, upon their completion the blocks are transported to one of the group's building dock to be erected and joined to each other to form a complete ship. By implementing this method the ship can be built much faster than if it is built by a single shipyard; smaller shipyards still have opportunity to build ships larger than their capacity; the shipyards can take advantage out of their differences; competition is changed into collaboration, and every yard gets benefit from it. On the other hand some requirements are needed to be considered such as: the location of the collaborating shipyards has to be in the neighbouring area; the approach is more suitable for ship series project; good coordination system is needed; every shipyard in the group must implement the same production standards, and high commitment from the collaborating yards.

### 1.4. Objectives of the Research

The objective of the research is to explore the role of multi-yard ship construction method in assisting to achieve the successful implementation of shipbuilding industry cluster.

## 2. THE ROLE OF MULTI-YARD SHIP CONSTRUCTION

### 2.1. Why Multi-yard Ship Construction

Refer to the definition of shipbuilding industry cluster where a number of shipyards and other inter-related industries exist in a certain region and the industries commit to support each other to drive wealth creation in the region it is very appropriate to implement Muti-yard Ship Construction method to the industries in the cluster to the shipyards in particular. The neighboring shipyards will complement each other instead of unhealthy competition; less obstacles in coordination and transportation of ship's components; related industries to the shipyards will benefit from continuous jobs and orders created by series of ships built in the collaborating yards; and hence the efficiency and productivity of the cluster will increase too.

### 2.2. Stages of Implementation

To implement the method to shipbuilding industry cluster the "plan-do-check-act cycle" principle introduced by W Edwards Deming in quality management [7] are proposed in the form of the following stages:

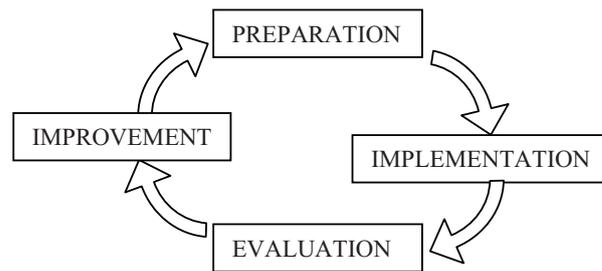

Figure 2 Implementation Stages

### 2.2.1. Preparation stage

In the preparation stage the activities started with introduction of the method to the involving shipyards and industries to ensure their understanding of and commitment to the system, then followed by identification of individual yard's specialty and capability as the basis for the assignment of construction tasks, the ship structural design is then broken-down into blocks and smaller parts design followed by ship parts definition, which will be used to calculate the work content and to arrange the work processing schedule.

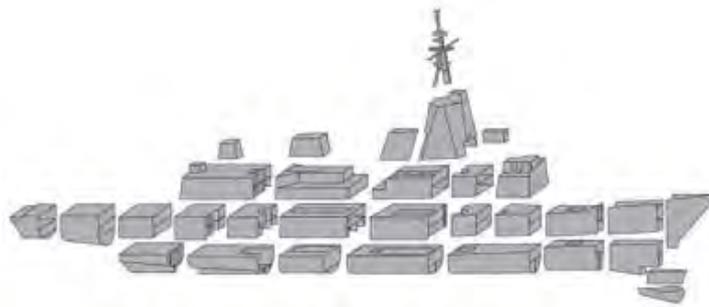

Figure 3 Ship Blocks Break-down Structure

### 2.2.2. Implementation stage

Upon completion of the preparation stage the method is ready to be implemented. Raw materials such as plates and sections and ship equipment are procured by the coordinating yard on behalf of the "consortium". It is suggested that the materials are not directly sent to individual yard but to one of the supporting industry to be fabricated into ship parts. These ship parts are then distributed to each individual yard to be assembled into panels, modules and blocks in accordance to the tasks assigned to them. In carrying out the tasks each yard is given production drawings and work instruction, and the time schedule on when the blocks and modules should be completed and shipped to the block joining yard. The blocks and modules are shipped using barge towed by tugboats, at the joining yard they are lifted to the buffer area to wait for their turn to be erected to the building dock to be joined to the other blocks. Blocks joining schedule and production schedule are arranged based on the work content and standard man-hour applied in the collaborating yards. When the blocks and modules have been joined on the building dock the rest of the activities are as applied in the ordinary shipbuilding process.

### 2.2.3. Evaluation stage

Every work being undertaken in the collaborating yards should be monitored and its results should be recorded along the implementation of the system so that future analysis and evaluation could be carried out well at certain agreed milestones in order to continuously improve the benefit of the method. To accomplish it regular coordination meeting should be carried out in various levels according to the needs, so that every target and achievement could be analyzed and lessons learn could be drawn.

### 2.2.4. Improvement stage

Data recorded from the production processes are used for analyzing and evaluating the achievements of the method, and lessons learn from the evaluation are used as input and recommendations for the following implementation of the system so that continuous improvement could be applied.

### 2.3. Tasks Assignment

Capability and specialty of each collaborating yard should be identified before the production tasks could be assigned to them in order to have complementary between the yards. Refer to Product Work Breakdown Structure (PWBS) [8] of the ship being built work contents of each block of the ship could be identified and matched to the specialty and capability of the collaborating yards. Based on these findings the tasks are then assigned to each individual yard.

Combined with man-hour standards applied in the consortium the work contents are also used for arranging the production schedule including blocks erection schedule. Using backward calculation based on the blocks erection schedule the starting time of each construction work in each individual yard could be decided. It is assumed that if everything is going in accordance to the planning the ship could be completed on time.

#### **2.4. The Coordination**

Coordination is the key element of the Multi-yard Ship Construction method. Complementary between the collaborating yards, good efficiency and productivity can only be achieved through good coordination therefore how the system would be coordinated should be decided in advance among the inter-related industries. The coordination should cover at least the following subjects:

##### **2.4.1. Product Work Breakdown Structure and ship-part definitions**

The task would include the breakdown of construction design into blocks and modules, and defining of every ship-part including its details and work instructions as basis for defining the work contents and construction schedules.

##### **2.4.2. Role of individual shipyard**

Based on the product work breakdown structure and ship-part definitions the role of individual yard are appointed in accordance with its capability and specialty so that the collaborating yards could complement each other in achieving the objective of the system.

##### **2.4.3. Application of standards**

Consistency in using the standards will minimize unnecessary reworks and confusions during the construction process therefore application of same standards is very important in determining the successful implementation of multi-yard ship construction method. The standards applied in multi-yard ship construction method would include: measurement standard, parts definition standard, production standard, man-hour standard etc.

##### **2.4.4. Scheduling**

Schedule is part of the planning therefore it should be realistically arranged based on past experience and agreed standards. The schedule is arranged based on product work breakdown structure and parts definition combined with agreed man-hour standard which can be divided into blocks joining schedule and production schedule. The two schedules are dependent on each other and should be agreed by all collaborating yards.

### **3. BENEFITS OF MULTI-YARD SHIP CONSTRUCTION TO SHIPBUILDING CLUSTER**

The implementation of multi-yard ship construction is in line with the concept of shipbuilding industry cluster because it fosters the complementary and collaboration of the neighboring yards and other related industries. Each individual yard does not have to invest for all kind of production facilities and machineries as in the ordinary yard but only facilities and machineries needed for the tasks assigned to it so that will optimize the investment cost, for example the fabrication of plates and sections is not carried out by the shipyards but by one of the supporting industry therefore fabrication machineries are not needed in the shipyards. Each individual yard only constructs the blocks or modules assigned to it so that many works could be carried out simultaneously, and if the ships are built in series the learning process could be accomplished much faster and hence the ships could be built faster too and in good quality.

### **4. THE PILOT PROJECT**

The pilot project was undertaken on the proposed shipbuilding industry cluster in Tanggamus Regency, Lampung. There are four shipyards existed in this cluster which consist of: 1 large repair and new building yard with capacity up to 150,000 DWT; 1 middle size repair and new building yard with capacity up to 50,000 DWT; and 2 small size repair and new building yards with capacity up to 15,000 DWT, and other related industries such as fabrication firms, ship equipment manufacturers, steel mill, classification societies etc. [9].

For the purpose of this pilot project and for familiarization of multi-yard ship construction method the ship to be built is an aluminum catamaran 59.50 m search and rescue boat with the following main particulars:

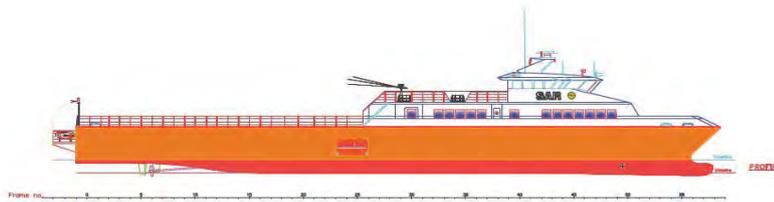

Figure 4 Aluminum Catamaran 59.50 m SAR Boat

▪ Length Over All (Loa)	59.50 m
▪ Length Waterline (LWL)	55.60 m
▪ Breadth (B max)	16.00 m
▪ Height (H amidships)	4.50 m
▪ Design Draft	1.50 m
▪ Maximum Speed	28 knots
▪ Displacement	320 tons
▪ Crews	25 persons
▪ Fuel Tank Capacity	42.5 tons
▪ Fresh Water Tank Capacity	10 tons
▪ Main Engine (High Duty)	2 x min 1342Kw (1800HP)
▪ Generator	2 x min 150 kVA

The ship was broken-down into seven main blocks with their estimated individual assembly time as follows: 1 Navigation Bridge (24 days), 1 accommodation block (72 days), 1 main deck with helipad (18 days), 2 engine room blocks (30 days each), 2 forward below deck blocks (18 days each). It was assumed that the procurement of materials and equipment was well planned and they all arrived in accordance with the schedule. Fabrication of the ship parts was assigned to a fabrication shop in the cluster, and the parts arrived in the yards on schedule.

Since the ship is relatively small therefore only three shipyards were involved in the pilot project i.e. two small yards and one middle size yard. The tasks assignments to the yards are as follows: Small yard I was assigned to build engine room blocks, Small yard II was assigned to build forward below deck blocks and navigation bridge, the Middle size yard would build accommodation block and main deck. The construction sequences were simulated including the blocks joining processes and on block outfitting works. It was assumed that the fabrication of ship parts was started one week before the first assembly work was commenced in the yard, time needed for transporting each block to the slipway is one day, and joining process were between two to three days. It was concluded that the construction work of the ship would accomplish in 83 days, and the ship was ready for launching.

Using the conventional method the ship would be ready for launching in about six months, thus the proposed method would save about 50% of the time for construction. The results would be more significant if a series of ships were built.

## 5. CONCLUSION

Multi-yard ship construction method is properly suit in shipbuilding industry cluster because the collaborating yards are located in the same area so that coordination and transport of ship parts from fabrication shop to the yards and blocks from constructing yards to building dock effectively. The overall production processes could be achieved faster compared to the conventional method, which means the productivity of the shipyards is increased.

## ACKNOWLEDGMENT

Special thanks are addressed to National Search and Rescue Agency for allowing its boat for the simulation of the project, and IPERINDO (Association of Indonesia's shipbuilding and offshore industry) for providing information on shipbuilding practices.

## ABSTRACT

Research and development of biofuel and bioenergy prime mover has been active recently. Micro gas turbine (MGT) is one of prime mover and has been projected as a prospective prime mover; technically, dimension, cost, environmentally, and has a high tolerance to many kind of fuels. The aim of this research is to analyze the performance of Proto X-2 Bioenergy Micro Gas Turbine that has been developed which consist of one stage radial compressor and turbine, and a combustion system. The Proto X-2 then tested with biofuel; Diesel-bioethanol blended. The fuel blends were varied to 100% Diesel (D100), 2.5% bioethanol (DBE2.5), 5% bioethanol (DBE5), 7.5% bioethanol (DBE7.5), and 10% bioethanol (DBE10). The nozzle was 0.75 GPH with 45 degree spray angle. CFD simulation is also done with CFDSOF<sup>®</sup> and the results are utilized to verify the experimental data. The analysis then focused on combustion temperature since it's dominant effect on the system performance. DBE2.5 yield the optimum result with 1000 rpm increasing the shaft speed, 2.2% in pressure ratio, 2°C lower TIT, and increased AFR compared to D100. Combustion temperature contours was only slightly difference to experimental data with maximum deviation 7.4%. Optimal biofuel use on the Proto X-2 can increase it's performance and more suitable to use in Zero Energy Building.

## 1. INTRODUCTION

Research and development of biofuel and bioenergy prime mover has been active in recent years. Micro gas turbine (MGT) is one of prime mover has been projected as a prospective; technically, dimension, cost, environmentally with power up to 200kW [1]. High power to weight ratio and wide range of application; as a power source for electricity and other application. This characteristic has lead to development of Proto X-2 Bioenergi Micro Gas Turbine which has been developed in past few years. It's high exhaust gas temperature also can be used for other application; such as a hot inlet gas for shell & tube heat exchanger [2-5]. High tolerance to many kind of fuel also another advantage of gas turbine system, from gas to liquid; LPG, CH<sub>4</sub> domestic oil, alcohol family (methanol, ethanol) and include biofuel, such as biogas, sunflower oil [6-8]. Furthermore, the global issue about decreasing fossil fuel, environment, and political views has stimulate the research and development of renewable fuel and it's application [9,10]. This condition also lead the development of biofuel and bioenergy power system, including in Indonesia. Ministry of Energy and Mineral Resources (KESDM) has supporting the development of new and renewable fuel in Indonesia and planning that new and re-newable energy could be at least 25% part of national energy use in 2025. This policy also known as "VISI 25/25" [11]. Main strategy of "VISI 25/25" are stated as below:

- Development of sustainable energy village (Desa Mandiri Energi – DME)
- Bioenergy application for industrial sector
- Bioenergy application for other sector; power source and domestic application

Renewable energy resource is undoubtedly available in Indonesia, such as biogas, jatropha oil, bioethanol, etc. Bioethanol is one of available biofuel which has been used widely, especially to blend with Diesel fuel. Among others biofuel, fuel-grade bioethanol has several advantages and the most compatible for fossil fuel; biodegradable, low toxicity, renewable properties (from biomass or plant), can be directly blend to diesel fuel, thus can reduce the use of fossil fuel, and it's high oxygen concentration in bioethanol will make the combustion leaner, increase the combustion performance and give lower emission compared to diesel fuel [10], [12,13]. Recent research of prototype Proto X-2 MGT discover availability with the use of biofuels; Diesel fuel (fossil fuel), bioethanol (biofuel), and jatropha oil (biofuel) [14-16]. Aside of it's advantages compare to

diesel fuel, bioethanol as fuel also has circumstances; which are the mixture homogeneity with Diesel fuel is doubtful and alcohol contained need special pump rather than ordinary fuel pump.

This research aim is to analyze the combustion performance of Proto X-2 MGT with the use of Diesel-bioethanol blends. The blends were varied into several fraction to 100% Diesel (D100), 2.5% bioethanol (DBE2.5), 5% bioethanol (DBE5), 7.5% bioethanol (DBE7.5), and 10% bioethanol (DBE10). This blendsfuel then directly injected to combustion system of Proto X-2 Bioenergy Micro gas Turbine and ignited. Among its components, combustion system is one of the three main component on micro gas turbine which can be represent the performance of the system, beside compressor and turbine. The combustion system consist of swirl unit a incorporating spray nozzle and a combustion chamber. Swirler use to give a better mixture fuel-air which a turbulent flow [7]. Combustion process took place in three zone; primary, secondary, and tertiary zone, where the fuel entered the combustion chamber via nozzle at primary zone and enter the turbine with high temperature, which also known as TIT (Turbine Inlet Temperature). Overall system performance oftenly represented by this characteristic parameter since the TIT is affected by the fuel flow rate, air flow rate, and pressure ratio. This combustion chamber and modeled with CFD method to predict the combustion process since the Diesel-bioethanol blended gave a different combustion characteristic. Both of this experimental and CFD simulation (CFDSOF) result will be used to develop the prototype. Optimal biofuel application on the Proto X-2 and sustainable research in bioenergy can increase it's performance and make it suitable to use in Zero Energy Building, as shown in research road-map in figure 1.

Figure 1: Research road map

## 2. EXPERIMENTAL SET-UP

The research methodology consist of two parts: (a) Experiment on Proto X-2 Bioenergy micro gas turbine and (b) CFD simulation.

### 2.1 Experiment

Experiment done to prototype of Proto X-2 Bioenergy Micro Gas Turbine and use two kind of fuel; Diesel fuel and Diesel-bioethanol blends. The fuel blends was varied to 100% Diesel (D100), 2.5% bioethanol (DBE2.5), 5% bioethanol (DBE5), 7.5% bioethanol (DBE7.5), and 10% bioethanol (DBE10). Ethanol is a oxygenate fuel and consist of up to 35% oxygen [10], where the bioethanol used in this research is E-75. The experimental set-up of prototype is shown on figure 2 below and resulting parameter and characteristics parameter [2]: (a) shaft speed, (b) compressor pressure ratio, (c) Turbine inlet temperature, (d) fuel flow rate, (e) Air flow rate. (f) AFR. The Proto X-2 Bioenergy Micro gas Turbine consist of single stage compressor and turbine, and the combustion system. The compressor and turbine were radial type and the combustion system consist of swirl unit a incorporating spray nozzle and a combustion chamber [17], as seen on figure 3. The nozzle use was liquid fuel nozzle, capacity of 0.75 GPH and 45° spray angle. The combustion chamber consist of flame swirler and

combustion liner. The ignited flame was run through the primary, secondary, and the tertiary zone of the combustion chamber. Fuel pressure was 20 bar. The fuel leave the nozzle and entered the burner swirler so that the swirling flame can occurred. The experimental data shown in figure 6-figure 10.

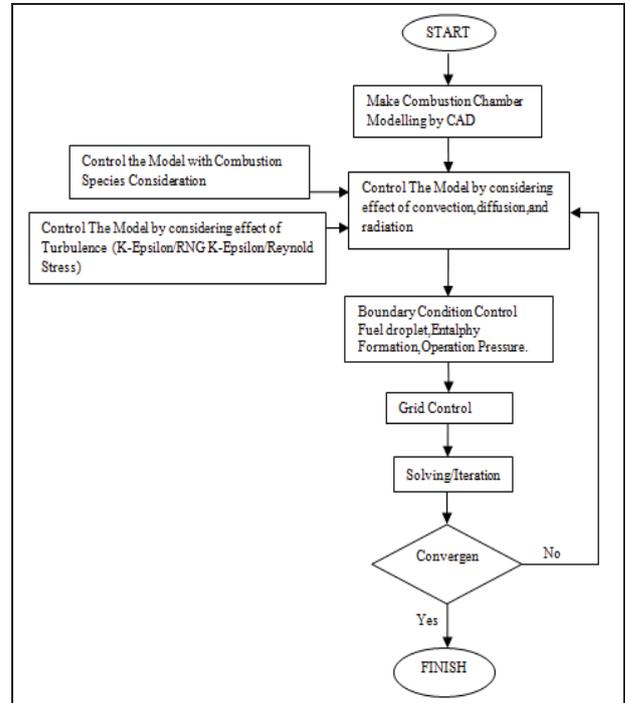

Figure 4: CFD simulation flow chart

## 2.2 CFD Simulation

CFD simulation done to D100, DBE2.5, DBE5, DBE7.5 with CFDSOF<sup>®</sup> software. The result thus compared with CFD simulation result of combustion chamber from experimental data. The model was simplified into 2D, the grid was 300 x 30, 250 mm in length, 25 mm in width as shown in figure 4. The Model Control using the *k-ε* model of turbulence and combustion air velocity entered the chamber was assumed 1m/s and consist of 21% oxygen. The result of CFD simulation shown in figure 10-figure 14.

## 3. RESULT AND DISCUSSION

### 3.1. Experimental Data

Figure 5-figure 9 showed the experimental data of Proto X-2 bioenergy MGT. The parameters were shaft speed (N), pressure ratio, AFR, and turbine inlet temperature (TIT). DBE2.5 yield the optimum result. The shaft speed was increased from 35864 rpm (D100) to 36921 rpm in figure 5. DBE5 has increased the shaft speed on high fuel flow rate, while others not. The similiar result also yield in pressure ratio, DBE2.5 increased the pressure ratio of 2.2% compared to D100 on average while other fraction tend to decrease the pressure ratio. Oxygenate of ethanol [9,10] at DBE2.5 has the possibility resulting a leaner combustion and more complete combustion, while higher water contained in others blends tends to act as cooling agent rather than react with fuel. As the speed increased, the TIT increased due to higher combustion energy at higher fuel flow rate. From figure 6, turbine inlet temperature (TIT) by fuel flow rate reuslting from DBE2.5 was slightly lower to D100 but with higher shaft speed and higher pressure ratio. DBE2.5 yield from maximum tested fuel flow rate with TIT of 515°C at 0.893 g/s compared to D100 which yield 517°C at 0.924 g/s. AFR tend to decreased as the fuel flow rate increased. This phenomenon occur in all varied fuel fraction which means the increasing shaft speed not yet provide enough air flow rate. DBE2.5 yield highest AFR at 124 of 0.65 g/s fuel flow rate compared to D100 with AFR of 119 at fuel flow rate of 0.68 g/s. At maximum tested fuel flow rate, AFR of DBE2.5 was 93 compared to D100 with AFR of 91.8. Those phenomenon clearly presentated on figure 9 (a) that DBE2.5 yield shaft speed higher than other bioethanol fraction, although 280 rpm lower than D100. But compared with average fuel flow rate on figure 9 (b) which DBE 2.5 yield 2.6% lower than D100 and other characteristic

parameter, this value is acceptable. Blends homogeneity has to be a factor to concern on since this two kind of fuel has different characteristics. To avoid unmixedness between Diesel fuel-bioethanol, Arifin Nur et.al [10] have added *Sorbitan Methyl Ester* (SPAN 80) as surfactant to increase the chemical bonds stability. Unmixedness fuel blends was occur at higher bioethanol fraction also will decrease the fuel pump performance for long-term use.

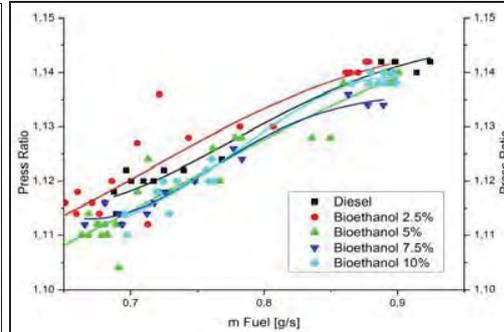

Figure 6: Pressure ratio –fuel flow rate

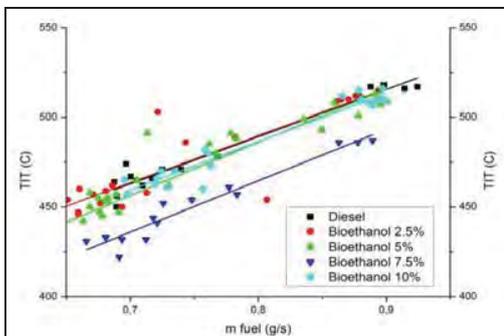

Figure 7: TIT – ful flow rate

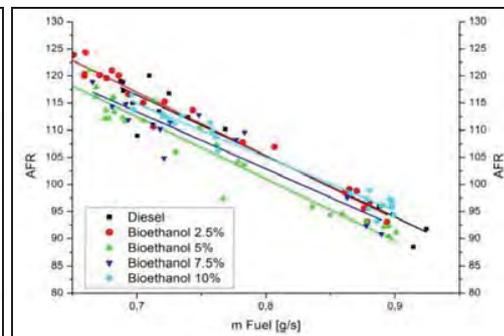

Figure 8: AFR – fuel flow rate

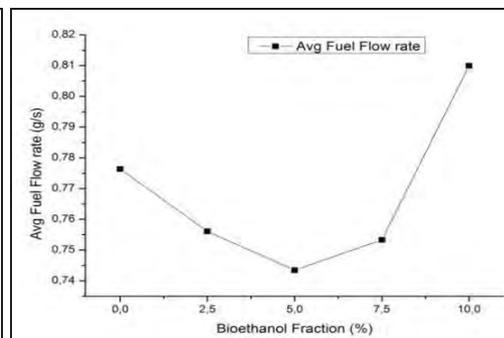

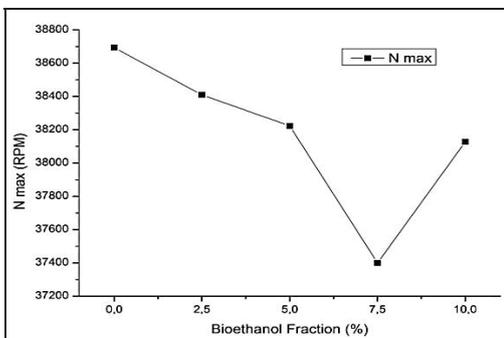

Figure 9: Shaft speed (a) and fuel flow rate (b).

### 3.2. CFD Simulation Result

The result of CFD simulation on Proto X-2 combustion temperature shown on figure 10-figure 14 with the use of Diesel-bioethanol blended fuel. On figure 10, temperature contour of prototype combustor running on 100 % Diesel Fuel (D100). Maximum combustion temperature achieved at 909,2 K (636,05 °C) occur at the center of the flame, line with fuel droplet out of the nozzle. With inlet fuel flow rate for CFD simulation 0.7 g/s, the combustion gas left the combustion chamber and entered the turbine at 550°C while experimental data on D100 is 517°C or 6.38% lower. Combustion temperature contour of DBE2.5 showed on figure 11. The CFD simulation showed that the combustion temperature at combustion chamber outlet is 537°C while the experimental data is 515°C, or 4.27%. The maximum combustion temperature occurred at flame centre line, 631°C. As seen on figure 13, the combustion outlet temperature of DBE5 is 540°C, while experimental data showed 509°C, or 6% difference. The maximum flame temperature was 625°C. Combustion temperature contour of DBE7.5 shown on figure 13. The CFD simulation showed that the combustion temperature at combustion chamber outlet is 523°C while the experimental data was 487°C, or 7.39% lower. The maximum combustion temperature occurred at flame centre line, 627°C. Combustion

temperature contour of DBE7.5 shown on figure 14. The CFD simulation showed that the combustion temperature at combustion chamber outlet was 519°C while the experimental data is 509°C, or 1.9% lower. The maximum combustion temperature occurred at flame centre line, 614°C. CFD simulation to MGT combustion chamber shows that the combustion chamber outlet temperature tend to lower at higher bioethanol fraction in Diesel-bioethanol blends. As the distance flame to flame tube became smaller, the temperature decreased. Leaner combustion occurred with secondary air from secondary air holes and the sirler which provide good mixing between fuel and oxydator and leaner combustion so the combustion was more complete and may reduce the NO<sub>x</sub> production [18,19]. Similiar trends also showed by experimental data, except on DBE10. This phenomenon may caused by homogeneity of fuel blends at high bioethanol fraction or poor mixing that could induce combustion instabilities [19]. In Diesel-bioethanol blends, the bioethanol tend to form coagulant and the temperature tend to increase as on D100. The difference location in measurement point was suspected to caused the temperature difference between experimental data and CFD simulation.

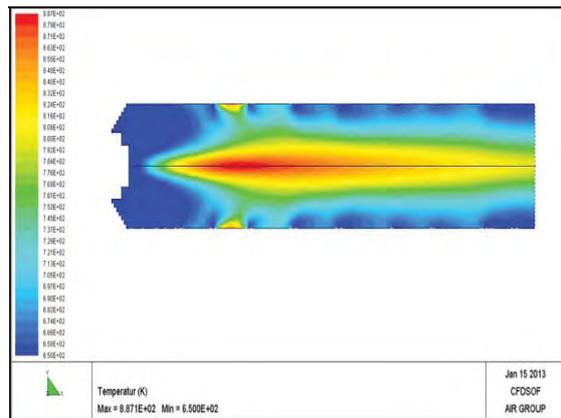

Figure 14: Temperature Contour for DBE 10

#### 4. Conclusion

The optimum combustion characteristic of Proto X-2 Bioenergy Micro gas Turbine is achieved by using 2.5% bioethanol in Diesel-bioethanol blends (DBE2.5) in overall. DBE2.5 increased the shaft speed from 35864 rpm (D100) to 36921 rpm. The compressor pressure ratio increased by 2.2% while other blend decreased the pressure ratio. With lower fuel flow rate, DBE2.5 decreased the TIT to 515°C. The result of CFD simulation was slightly difference to the experimental data which the TIT tends to lower at higher bioethanol fraction. Overall, CFD simulation resulting 7.38% lower (maximum) than experimental data.

## ABSTRACT

The aims of the research work described in this paper is a part were to use computational fluid dynamics (CFD) to investigate the effect of downdraught mass flow rate generated and the uniformity of the velocity and temperature profiles downstream of the multi-array nozzles. This involved a study to define the optimum number, and the most effective arrangement of spray nozzles in a multi-nozzle array. Two basic arrangements of the nozzles were investigated; one in which a constant radius of 0.75 metres was maintained for the nozzle pitch circle as nozzles were added, and another, in which a constant separation distance or spacing of 0.75 metres was maintained between all nozzles. A second simulation was set up using the configuration with constant spacing, with a single central nozzle added. A final simulation was carried out to determine if further optimization of the nozzle configuration could be obtained by altering the constant nozzle spacing in the range 0.35 to 0.85 metres. Based on these simulations, that constant spacing provided much more even cooling with fewer nozzles than the configurations with constant radius. The arrangement with 11 nozzles gave the best overall performance with nozzle spacing to 0.65 metres.

## 1. INTRODUCTION

The passive downdraught evaporative cooling system might be fully-equipped with a wetted pad mode or water spray mode using atomizer [1], but excess water is still remain a not easy problem to manage. In a multi-nozzle array of identical nozzles at the same driving pressure, the spray water mass flow will be directly proportional to the number of nozzles used. However, the number of nozzles and their relative positions will affect thermal energy and momentum transfer due to the increasing interference between the individual spray cones when additional nozzles are added. It was expected that eventually, the inclusion of additional nozzles would offer no advantage, and that an optimum configuration could be identified.

A possible alternative approach which might offer some advantages would be to add additional nozzles while keeping the total spray water mass flow constant. While this approach would be possible theoretically, the subdivision of the constant total spray water flow each time an additional nozzle was added, would require the use of different nozzles of progressively smaller orifice diameter at each stage, and might also require a change in the driving pressure. Also, the droplet size distribution generated by the nozzles would change at each stage. This alternative approach was not investigated and further investigation in this paper used the same mass flow rate in each stage.

Modelling and testing of a CFD model of a single spray nozzle in a vertical cylinder in the interest of verification of appropriate software has been carried out [2]. The model, which simulated both the water mist evaporation process and the thermal energy and momentum transfer between the droplets and the surrounding air, was developed with the objective of validating the basic spray modelling methodology used in the present work by reproducing the results for a single spray nozzle model produced by Gant at the UK Health and Safety Laboratory, (HSL), Buxton [3]. The result of the simulation then be compared with the experimental data of single spray model carried out by St. George and Bucklin [4], resulting good agreement though velocity at the centre downstream to the nozzles slightly lower. Further development work on the model to incorporate two commercially-available nozzles, (BETE PJ32 and TF6) [5], and calculations to ensure that the results were theoretically and physically sensible are also described [2]. Results from recent experiments [6], which were carried out specifically to check the validity of the droplet evaporation model in CFX were also as a motivation in this work.

## 2. MODELLING OF MULTI-NOZZLE ARRAY OF IDENTICAL NOZZLES

The flow domain for these studies was created with overall length and diameter as a vertical cylinder at  $D = 4$  metres and  $L_0 = 3$  metres respectively.

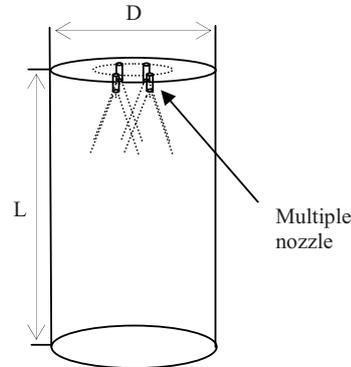

Figure 1: Flow Domain dimensions for multiple nozzle simulations

The evaporation modelling and droplet size distribution were set up with a single downward-facing nozzle at the centre of the upper circular face. The nozzle was modelled as a cylinder of diameter  $d_0 = 0.00625$  metres and length 0.05 metres, as shown on top in Figure 1. Within CFX [7] in the present work, a droplet diameter distribution was specified as a series of mass and number fractions in discrete diameter bands. This approach was adopted corresponding to the TF6 nozzles used with a water droplet mass flow rate of 0.096 kg/s and a spray velocity of 21.57 m/s, for a water temperature of 10°C, and a CFX input data set use 1500 representative particles to represent the droplet population, and was created from information based on mass and number fraction data sets summed to unity exactly, that at least one representative particle was present in each diameter band, and data was given in references [8] at a driving pressure of 3.33 bar:

Droplet diameter bands ( $\mu\text{m}$ )

27, 55, 82, 106, 121, 136, 152, 171, 193, 230, 256, 282, 307, 339, 381, 425

0.0029,0.0100,0.0217,0.0387,0.0550,0.0745,0.0963,0.1136,0.1195,0.1119,0.0959,0.0800,0.0652,0.0502,0.0371,0.0273

Number fraction per band

0.3438,0.1379,0.0915,0.0758,0.0727,0.0686,0.0641,0.0529,0.0389,0.0214,0.0133,0.0083,0.0053,0.0030,0.0016,0.0008

In setting up the flow physics a reference temperature of 25°C, a reference pressure of 1 atmosphere, and a reference air density of 1.2 kg/m<sup>3</sup> were used. The boundary condition on both the upper and the lower circular faces of the flow domain was set as an opening, which permitted both inflow and outflow from the flow domain, and a free-slip adiabatic wall condition was specified at the cylinder surface. Buoyancy effects were modelled using the standard density difference model within CFX combined with an acceleration of -9.81 m/s<sup>2</sup> in the Y direction.

Within the flow domain, a variable composition gas mixture of air and water vapour was set up, with the water droplet being set up as a dispersed liquid phase. Drag forces on the liquid droplet were modelled by the Schiller Naumann equation. This drag model is based on the assumptions that the fluid droplets within the spray were sufficiently small to be considered spherical and that the volume fraction of the droplets was small. These assumptions were considered to be reasonable. Interphase thermal energy transfer was modelled using the Ranz Marshall (Nusselt number based) correlation, (ANSYS CFX 13-Solver theory guide 2010) [7]. Droplet evaporation was modelled using the standard evaporation model within CFX, in which the saturated vapour pressure is correlated as a function of temperature through the Antoine equation:

$$p_{sat} = \exp\left(A - \frac{B}{T + C}\right) \quad (\text{bar}) \quad (1)$$

where  $T$  is the temperature in kelvin and the constants  $A$ ,  $B$  and  $C$  are 5.11564ln(10), 1687.54ln(10) and -42.92 respectively.

For turbulence modelling, both the shear stress transport (SST) and k-epsilon models were used with automatic wall functions. In both cases, the inlet turbulence intensity level was set to 5%. However, only k-epsilon turbulence model were discussed.

At the spray inlet, the droplet injection region was specified using the standard cone injection method within CFX. Since the Lagrangian model does not accurately simulate primary droplet break-up, the injection centre was placed 0.01 metres below the nozzle outlet plane. The cone angle  $\theta$  was specified as 90° with full cone injection. Using a larger number of droplets gave a smoother distribution of results, but also increased the computing time and memory needed.

### 3. INVESTIGATION OF MULTIPLE NOZZLE CONFIGURATIONS

Two basic arrangements of the nozzles were investigated; a configuration, (Figure 2(a)), in which a constant radius,  $r = 0.75$  metres was maintained for the nozzle pitch circle as nozzles were added, and a configuration, (Figure 2(b)), in which a constant separation distance  $d = 0.75$  metres was maintained between all nozzles.

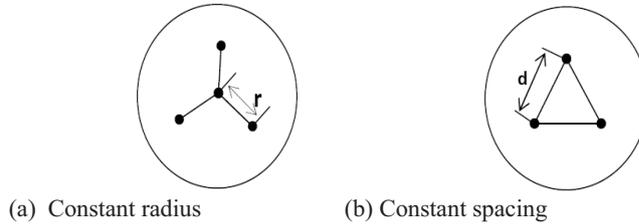

Figure 2: Basic nozzle arrangements

A range of constant radius configurations using from 3 to 20 nozzles was simulated. The configurations with 4, 11 and 18 nozzles are shown in Figure 3.

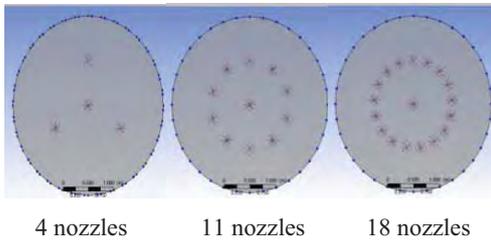

Figure 3: Constant radius configurations

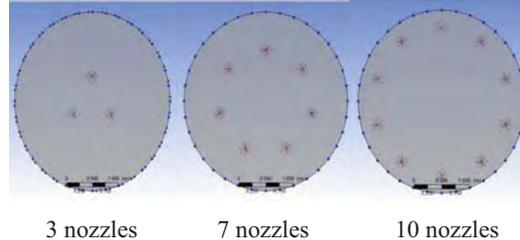

Figure 4: Configurations with constant spacing

A range of configurations with constant spacing using from 3 to 12 nozzles was simulated, also. The configurations with 3, 7 and 10 nozzles are shown in Figure 4.

The surface and volume meshes were created using minimum and maximum face spacings of 0.002 metres and 0.02 metres, with an angular resolution of  $30^\circ$ , and a body spacing of 0.02 metres. These settings produced approximately 1,455,000 tetrahedral elements for the simulations using 3 nozzles, and 3,655,000 tetrahedral elements for the simulation using 20 nozzles. The inlet boundary condition at the upper circular face was specified as an opening with an incoming air temperature of  $30^\circ\text{C}$  and 0% relative humidity. The boundary condition at the lower circular face was specified as an outlet at atmospheric pressure. A free-slip adiabatic wall condition was set on the cylinder surface. Steady-state simulations were carried out using a physical time scale control 0.05s with a residual target of  $1e-6$  and using the k-epsilon turbulence model with the inlet turbulence level set to 5%.

The variations in average outlet temperature and in total mass flow rate for all configurations are shown in Figure 5

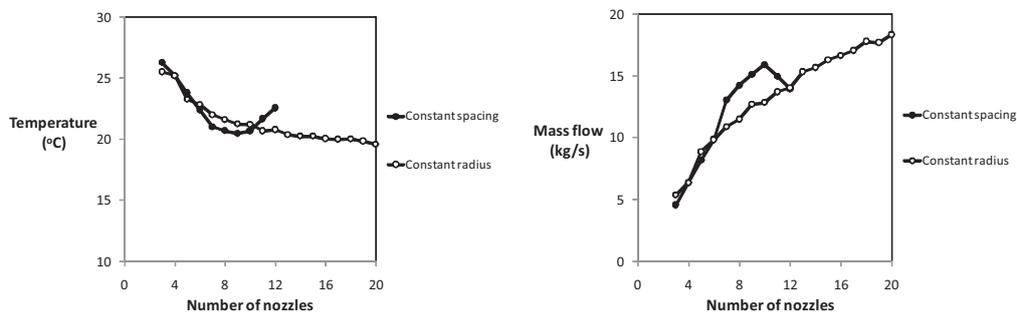

Figure 5: Variation in outlet temperature and mass flow with nozzle configuration

It can be seen from Figure 5 that the constant radius configuration produced the lowest overall temperature and the highest mass flow rate, but used more nozzles to produce these effects than the configuration with constant spacing. In particular, for numbers of nozzles between 6 and 11 the configuration with constant spacing was more effective at both reducing the average outlet temperature and entraining the air flow. The best cooling performance was obtained with 9 nozzles and the highest entrainment rate with 10 nozzles.

Based on these results a second series of simulations was set up using the configuration with constant spacing to investigate the effect of adding a central nozzle for the 8 to 12 nozzles including central nozzle.

#### 4. CONSTANT SPACING CONFIGURATION WITH CENTRAL NOZZLE

A second series of simulations was set up using the configuration with constant spacing, with a single central nozzle added. The configurations investigated used 8 to 12 nozzles. In all cases a constant nozzle spacing of  $d = 0.75$  metres was maintained. Contour plots showing the outlet temperature distributions range of 283.1 - 303.1 K obtained are shown in Figure 6.

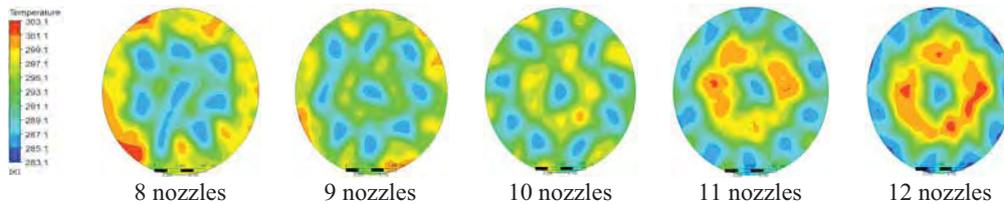

Figure 6- Outlet temperature distributions, configurations with constant spacing and a single central nozzle

By comparing the image for the case with 11 nozzles in Figure 6 with the result for the case with 10 nozzles without central nozzle, a significant improvement in cooling in the central region was observed. The variations in average outlet temperature and in total mass flow rate obtained for all configurations are shown in Figure 7 together with the previous results shown in Figures 5 for comparison.

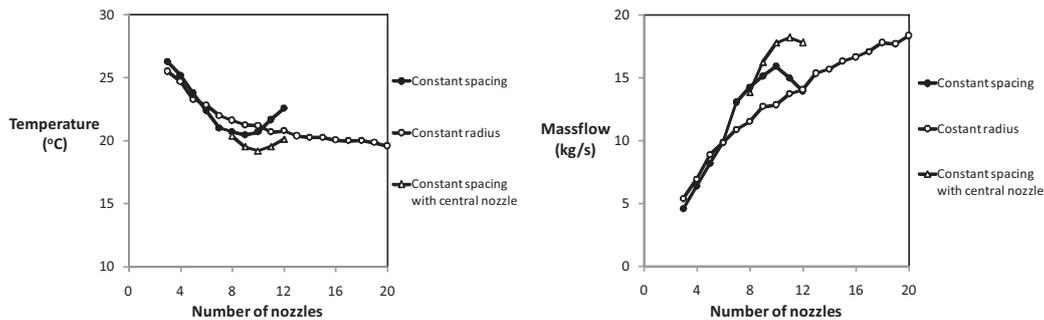

Figure 7: Variation in average outlet temperature and mass flow, (showing additional configurations with constant spacing and single central nozzle)

It can be seen from Figure 7 that the configurations with the additional central nozzle produced both lower average outlet temperatures and higher entrained mass flow rate in all cases. The best cooling performance was obtained with 10 nozzles and the highest entrainment rate with 11 nozzles.

Based on these results a third series of simulations was carried out to investigate if further optimization of the nozzle configuration could be obtained by altering the constant nozzle spacing. The configuration selected for these further studies was the 11-nozzle configuration. This configuration was selected because it produced the highest entrainment rate.

#### 5. OPTIMIZATION OF NOZZLE SEPARATION

These simulations were carried out for constant nozzle spacings  $d$  ranging from 0.35 to 0.85 metres in 0.1 metres steps. The simulations were carried out using an incoming air temperature of 30°C and 0% relative humidity and spray water temperature of 10°C.

The variations in average outlet temperature and mass flow rate with nozzle spacing are shown in Figure 8.

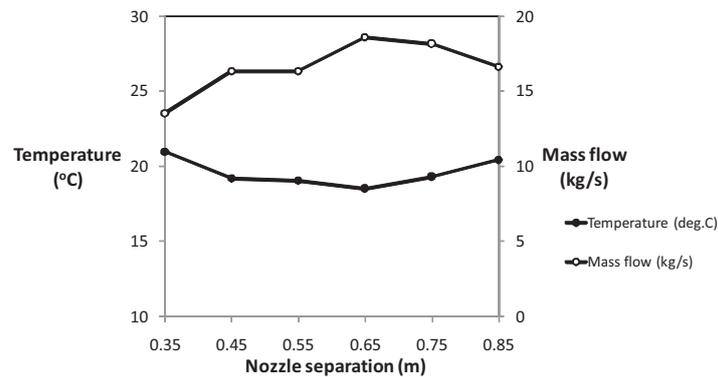

Figure 8: Variation in average outlet temperature and mass flow with nozzle spacing for 11-nozzle configuration with central nozzle

It can be seen from Figure 8 that the configuration with the 0.65 metres nozzle spacing produced both the lowest average outlet temperature and the highest entrained mass flow rate. Based on these results this nozzle spacing of 0.65 was selected for use in all future studies.

## 6. COOLING POWER FOR OPTIMUM NOZZLE CONFIGURATION

For evaporative cooling the sensible cooling power can be estimated from the induced mass flow rate and temperature reduction of the air flow. This calculation was carried out for the optimum arrangement of 11 nozzles and the result is discussed in a separately study. Certainly, it is possible when more detailed simulations using the optimum nozzle arrangement conducted and discussed.

## 7. CONCLUSIONS

CFD simulations were carried out to define the optimum number, and the most effective arrangement of spray nozzles in a multi-nozzle array. Two basic arrangements of the nozzles were investigated; one in which a constant radius of 0.75 metres was maintained for the nozzle pitch circle as nozzles were added, and another, in which a constant separation distance or spacing of 0.75 metres was maintained between all nozzles. Based on these simulations it was concluded that the configurations with constant spacing provided much more even cooling with fewer nozzles than the configurations with constant radius.

A second series of simulations was set up using the configuration with constant spacing, with a single central nozzle added. It was concluded that this arrangement produced both lower average outlet temperatures and higher entrained mass flow rates in all cases and that the arrangement with 11 nozzles gave the best overall performance.

A final series of simulation was carried out to determine if further optimization of the nozzle configuration could be obtained by altering the constant nozzle spacing in the range 0.35 to 0.85 metres. It was concluded that a further improvement in performance could be achieved by setting the nozzle spacing to 0.65 metres and this configuration would be selected for use in all future studies.

## ACKNOWLEDGMENT

My first thank must go to Dr George Simpson at Kingston University London (ex) for helpful discussion in preparing the work. Also, I would like to thank to Dr Yufeng Yao for his support and good collaboration. The support obtained from Muhammadiyah University of Surakarta is also gratefully acknowledged.

## ABSTRACT

Absorption Chiller is a refrigeration system for generating chilled water that makes use thermal energy (heat) to evaporate water refrigerant from LiBr Solution in a heat exchanger called generator. The water vapor is then condensed and the condensate is sent to evaporator as refrigerant. There is a component named absorber that has the functions of absorbing exhaust water vapor from evaporator and transferring the absorbed water to separation process in generator. The cooling performance of evaporator is determined by evaporation water temperature which depends on the absorption process performance. In this paper, the study of spray nozzle modification on 10 kW Chiller model to improve the cooling performance would be presented. The results give that evaporation temperature could reach until 4 degree Celcius and COP at instantaneous load is better than previous type of absorbent spray droplets.

## Keywords

*Absorption chiller, refrigerant, evaporation, absorption, cooling performance*

## 1. INTRODUCTION

Absorption chiller is a refrigeration system for generating chilled water by utilizing a heat source and an absorption process of the refrigerant by a particular solution. Although this type of chiller has lower coefficient of performance but it provides advantages over vapor compression system by reducing electrical energy consumption and using environmentally friendly refrigerants. It is therefore important for the absorption chiller to be developed to assist the national program of energy security and environmental sustainability.

Basically, the process of absorption refrigeration cycle is similar to that of vapor compression system. The most common absorption chiller systems are water-lithium bromide and ammonia-water, with water and ammonia respectively the refrigerant for each system. In the absorption refrigeration cycle, the compression step is accomplished by the use of absorber, pump, and generator. Exhaust vapor from evaporator is absorbed by LiBr solution in absorber. The diluted solution is then pumped from lower pressure chamber (absorber) to higher pressure chamber (generator). The water is then partly separated from LiBr solution by applying heat in the generator. The heat source can be derived from steam, hot water or the residual heat of combustion with low temperatures ranging from 80 °C. Refrigerant vapor from generator is then cooled in condenser to provide condensate of liquid refrigerant which can be re-circulated to the evaporator.

Thermodynamic cycle of the absorption refrigeration process is shown through pressure, temperature and concentration diagram, known as Duhring Plot [3]. In the diagram, there is a crystallization line or saturation line, which should be considered in the design process so that concentration does not exceed the saturated condition. Working temperature and concentration determine the operating pressure of refrigerant evaporation (desorption) in the generator and condensation in the condenser. To increase overall system efficiency, the heat of hot strong LiBr solution from generator is transferred to cold weak solution from absorber in a heat exchanger. Thus the heating load of the generator and cooling load of the absorber can be reduced simultaneously.

(a) PTX Solution Properties Diagram [Wang SK.,2000]

(b) Thermodynamics Cycle[Wang X. et.al, 2009]

Based on the validation studies on 10 kW absorption chiller model in BTMP [1,2], it has been concluded that modification on the model is required to improve the absorption process in absorber and refrigerant distribution in evaporator. Heat and mass transfer between refrigerant and absorbent occurs through direct contact mechanism on the droplet surface circulated [2]. Furthermore, in this study, chiller performance will be assessed by modifying the spray nozzle that can provide extensive contacts in the absorber and better refrigerant distribution in the evaporator.

## 2. METHODOLOGY

### 2.1. Overview Design and Validation Test [1,2]

Absorption chiller 10 kW cooling capacity system model has modular design consisting of 4 main equipments i.e. generator, condenser, evaporator, and absorber. The unit model is equipped with supporting facilities for testing which include heating fluid supply simulator, cooling water supply and dummy cooling load.

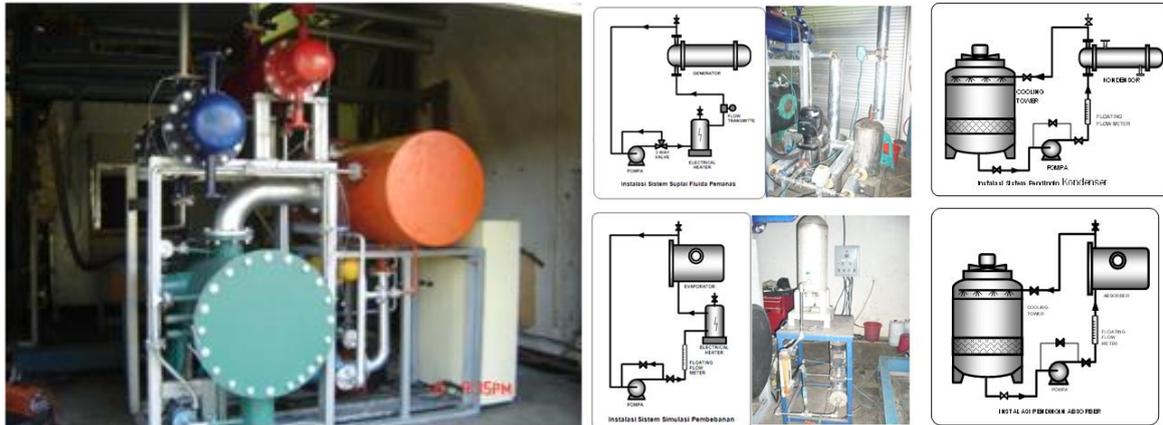

Figure 4. Unit and Supporting Facilities of Chiller Absorption Model 10 kW  
 (a) Model Unit (b) Utility Facilities for Heat Source, Cooling Water & Dummy Load

## 2.2. Modification Spray Nozzle at Absorber and Evaporator

The process of heat and mass transfer in the absorber occurs through direct contact mechanism between refrigerant vapor and LiBr solution droplets. Dimensions and distribution of droplets largely determine the effectiveness of the absorption process of the vapor to the liquid phase. Thus to optimize the process, the chiller model was modified with a spray nozzle system that has the ability to produce smaller particle size and more widely spread.

The previous design of the evaporator had poor distribution of refrigerant spray on the tube bundle. The use of spray nozzle provide better distribution, however smaller particle size can cause a problem of refrigerant spraying droplet evaporation. The vapor will add the absorption load that must be handled by the absorber.

## 2.3. Cooling Performance Evaluation

The effect of the nozzle spray modification will be studied by conducting test run on absorption chiller model. The test results will be compared to that of previous spray system. The parameters to be validated are temperature chilled water out evaporator before and after the modification at the same cooling loads.

## 3. RESULT & DISCUSSION

### 3.1. Study Design and Results Validation [1,2]

Absorption Chiller 10 kW Model is a single effect type of small-scale absorption chiller which has modular component configuration and requires a solution of lithium bromide-water (LiBr) with a concentration of 51-55% (mass fraction). Operating pressures for generator is around 7.721 kPa (related to saturated water temperature at 39.9 °C), while in the

evaporator pressure evaporation at 0.872 kPa (related to saturated liquid water temperature at 5 °C). The 10 kW cooling capacity is planned to be able to cool the incoming water temperature from 12 °C to 8 °C.

The test run on model before modification results in performance of lowest achieved chilled water temperature of 11.49 °C averaged without cooling load while the average evaporation temperature is reached only by 7 °C. Based on that results and visual observation in connection with spray setting during test run, the validation study has concluded that the model needs modification to reduce droplet dimension of LiBr-solution sprays in absorber and to improve refrigerant spray pattern in evaporator.

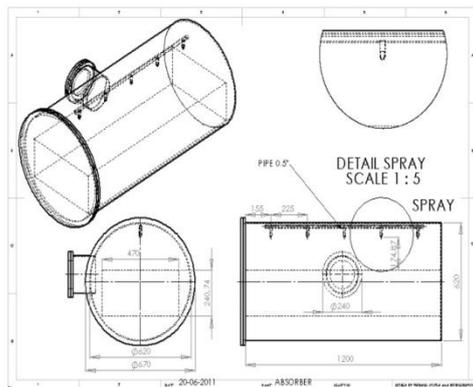

### 3.2. Modification and Functional Test Spray Nozzle

Heat and mass transfer processes in absorber occur on the surface of the LiBr-solution droplets. When the droplets in contact with refrigerant vapor, then the solution will absorb the water vapor to make the absorbent diluted. Although the vapor temperature is lower than droplets temperature, the heat brought by the vapor makes dilute solution temperature will increase. Therefore for continuous operation, the heat must be removed from the absorber by cooling system.

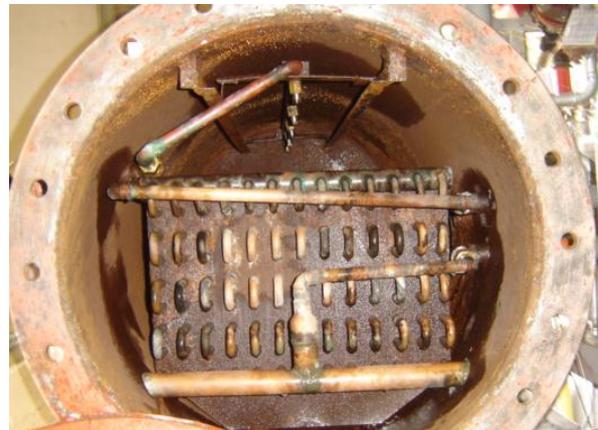

The transfer processes between vapor and absorbent droplets are affected by several parameters including LiBr concentration in the droplets, droplets temperature, and contact surface area between the two phases. The higher LiBr concentration the stronger the absorption power is. However, the concentration must be controlled so that it does not exceed its saturation point. Since the process is exothermic then the lower droplet temperature is better. However, the cooling water temperature will limit this parameter. The transfer processes occur on the droplets surface. The larger the area, the probability of the absorption process will increase. Since, total contact surface area depends on the average droplet diameter for a particular flowrate, the increasing contact surface area can be achieved by application of spraying nozzle that can give smaller droplets diameter.

The problem of previous configuration of the evaporator is that the distribution of spray does not spread evenly. This brings partly unwetted tube bundle so that no heat transfer occurs on that part. Improving method being chosen in this case is the use of spray nozzle. For that reason, full cone and wide spread angle spray nozzle was installed to replace previous spraying system in evaporator.

Commercial nozzle spray is specified by its spray pattern, spray angle, volumetric flowrate at a particular pressure drop available, connection diameter. Since, the use of spray nozzle is a part of modification of the existing unit, their requirements is limited by tube bundle size, maximum available distance between nozzle and tube bundle, and estimated fluid flowrate. Therefore, nozzle configuration used is a full cone type with a diameter of 2.4 and 3.2 mm, spray angle of 80° and 75°, ¼ in and 3/8 in connection for evaporator and absorber respectively. The number of spray nozzle required is 5 units for the absorber and 4 units for the evaporator.

 Figure 6. Evaporator after Modification Technical Drawing (a) Spraying Nozzle Configuration (b) [5]

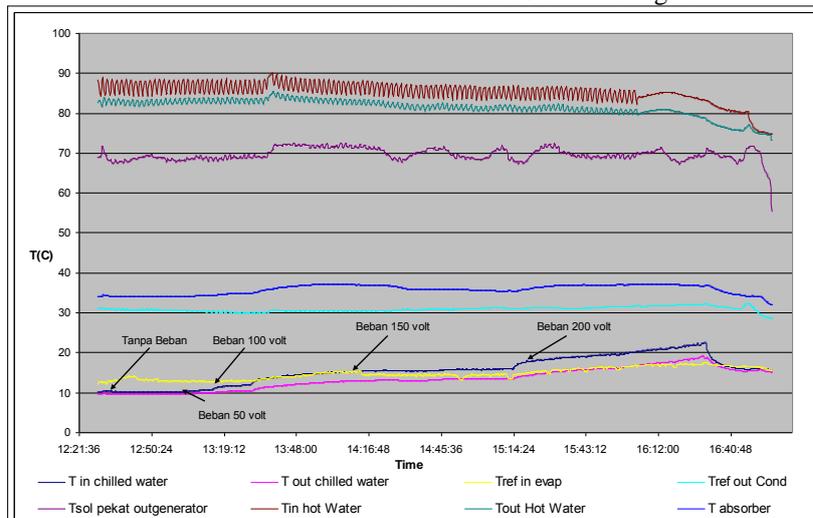

Before performing the test run of the modified chiller unit, spray nozzles are functionally tested to observe the size of the droplets and spray distribution capabilities. The results are shown in the following figure, and the spray nozzle configuration was able to produce granular and extensively better contact.

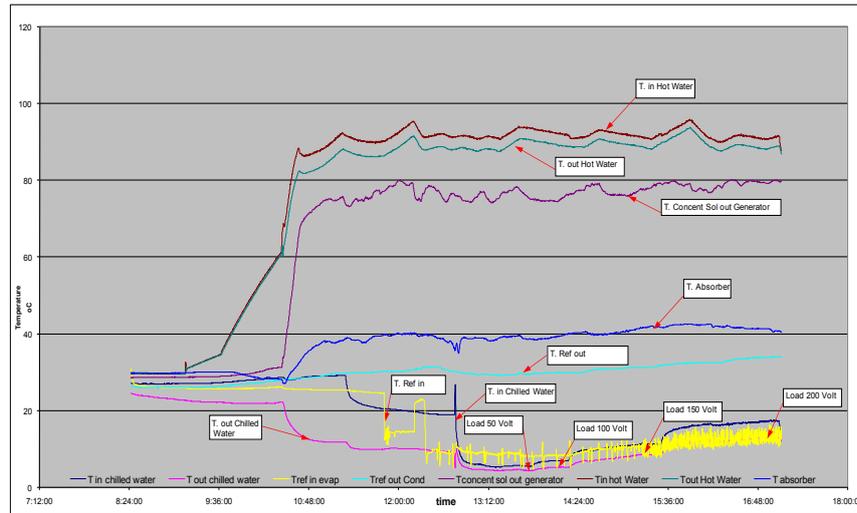

(a) (b)  
 Figure 7. Functional Test Nozzle Spraying in Absorber (a) and in Evaporator (b) [6]

### 3.3. Cooling Performance Evaluation

To evaluate chiller modification, test runs are conducted on 10 kW absorption chiller models by measuring the temperature of chilled water out. Based on the results obtained in the previous test run before chiller modification, the temperature of the chilled water out only reached 11.49 °C without load (design point 8 °C) [1,2]. After modification, the temperature of the chilled water out could have reached 4.32 °C at 2.28 kW cooling load.

**4. CONCLUSION**

There is a significant difference in the temperature of chilled water out after extensive modifications to the spraying system in absorber and evaporator of the 10 kW absorption chiller model unit. Modified spray nozzle can increase the cooling capacity with the temperature of chilled water out can reaches until 4.32 °C in conditions amounting to 2.28 kW cooling load. The modification to increase contact surface area in the absorber and to distribute the refrigerant spray evenly in the evaporator has improved overall chiller performance.

## ABSTRACT

The ratio of the liquid-vapor flow rate through the swirling nozzle with a swirl's chamber volume variation is investigated experimentally. The application of swirling nozzle is to vaporized liquid state of Liquefied Petroleum Gas (LPG) in order to prevent the liquid flow into regulator or gas stove which potentially become explosive (BLEVE). The results show that there is a significant relationship between the swirl volume with the liquid-vapor mass flow rate ratio of LPG through the swirling nozzle. By increasing the swirl's chamber volume intend to increase the liquid-vapor mass flow rate ratio of LPG. To increase the percentage of the vapor flow rate through the swirling nozzle, by adjusting swirling nozzle to the smallest swirl's chamber volume, 13 022 mm<sup>3</sup>. The phase of LPG before entry to swirling nozzle is 100 % liquid when the bottle of LPG turned until 90° to the horizontal, and the estimation results of the percentage vapor flow rate after swirling nozzle can be achieved by 50 % to 72.63 % if the flow rate of LPG regulated 0.016 liter /s to 0.025 liters / s.

## Keywords

Ratio of liquid-vapor LPG flow rate, Swirling nozzle, Swirling chamber.

## 1. INTRODUCTION

Accidents caused by fire is a terrible disaster which so often made headlines in the media because it caused a lot of material loss and even death. For example, in Jakarta, electric and stove fires is a major cause for the household. Over the past 10 years there have been over 800 fires each year, or about 2 to 3 times per day fires, with casualties reached 27 people died and losses directly reaches a value of Rp 250 billion each year [1].

Related with the number of explosion cases, especially in the use of LPG gas stoves, some efforts to reduce the risk of explosion or increase security for users of gas (LPG) has been carried out, such as: the socialization of the use of gas stove at the time of the distribution of 3 Kg LPG cylinders and gas stoves to the community and the issuance of Indonesian National Standard (SNI) to ensure the quality of hardware and software: Steel Bottle (ISO 1452-2007), Valve of Bottle (ISO 1591-2008), Rubber seals (ISO 7655-2010), Low Pressure Regulator (SNI 7369 -2008), High pressure regulators (ISO 7618-2010), Rubber Hose (SNI 06-7213-2006), fuel LPG gas stove with a fireplace lighter mechanical systems (ISO 7368-2007).

Practically in field shows that efforts to reduce the risk of explosion and ensure the safety of users of LPG gas stove is still far from expectations. Until now, still an accident by the explosion of LPG as a result of low gas stove users' understanding of the design, construction, operation and maintenance of system hardware burner LPG (cylinder, regulator, hose and stove) and of the hardware and the software itself is apparently not able to ensure the safety of LPG explosion risk. It is shown from the results of field surveys and investigations conducted by the Indonesian Consumers Foundation (YLKI) delivered by the Chairman (YLKI) Sincere Eternal that states, 70% of cases of LPG gas explosion from a gas stove accessories that do not meet the standards and 30% due to consumer behavior [2].

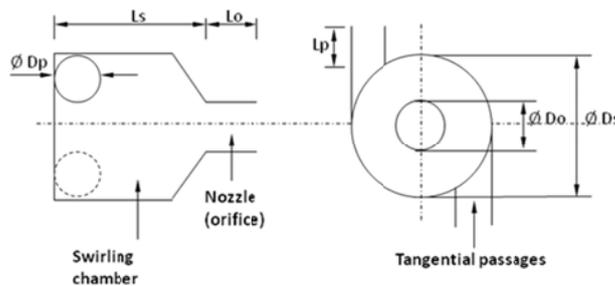

In the initial experiments in this study found that when 3 kg LPG tank toppled or tilted position more than 60 degrees from the upright / vertical and in a state of flow of LPG there will be started a flow of liquid phase's LPG to the Regulator. LPG liquid flow resulted in increased pressure on regulators thus causing the Lock Up (steel ball at the outlet of the regulator lock/close the flow of LPG). This causes the flame at the burner goes out, while the LPG liquid trapped inside the channel entrance and the room beneath the membrane on the regulator, so it may not exit and re-entry again into the tube. This phenomenon is rarely recognized by the users of LPG gas stove so that when the regulator is opened or removed from the valve tank, there will be a blast of liquid LPG from the inlet regulator that is potentially cause an explosion (cloud vapor explosion) if there is a heat source nearby. In the schematic, the sequence of explosion due to the potential overthrow of LPG tank can be described as follows:

**Figure 1.** The occurrence of sequence Potential Explosion Due to the slope of LPG > 60°

Potential for explosion due to the flow and trapping of liquid LPG in LPG regulators when cylinder rolled or tilted not recognized by the public users LPG gas stoves. Therefore, it is necessary to do an experimental study in order to prevent the LPG liquid's flow through regulator. Efforts to prevent the flow of liquid LPG can be done by changing the flow phase's of LPG liquid into a vapor phase's of LPG using a swirling nozzle as an atomizer. This study aims to determine the ratio of liquid-vapor flow rate through the nozzle if a swirling chamber volume variations

Often referred to as the swirling Nozzle Pressure or Pressure Swirl Nozzle atomizer serves to break the liquid into droplets form (small droplets). Nozzle swirling commonly found in many engineering applications such as in burning, drying or agriculture [3]. Figure 4. shows the basic scheme swirling Nozzle. The liquid is fed into the swirling chamber through a tangential line to give liquids with a high angular velocity, and formed a layer of fluid with the internal surface of free-floating in the swirling chamber, giving rise to the vortex core. The liquid is then removed from the nozzle in the form of a hollow conical sheet which breaks up into droplets (small droplets) [4].

**Figure 2.** Basic Scheme of Swirling Nozzle

Ls : min 0.5 mm, Lp : 0.34 mm, Lo : 0.6 mm Ds:5.76 mm, Dp : 0.51 mm, Do:1 mm

Research related to the thickness of the coating fluid produced swirling nozzle has been done by Han, Allocca, Aziz and Ali, and Khoo and Hargrave which showed that the liquid layer thickness decreases with increasing injection pressure, nozzle hole diameter shrink, adding to the length of the orifice, enlarging the diameter swirling chamber and shorten the length of swirling chamber [5].

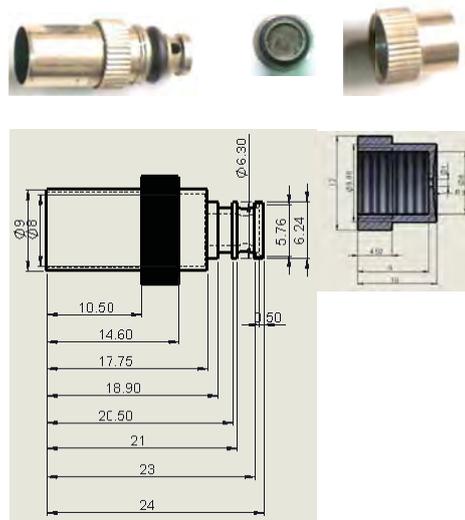

## 2. EXPERIMENTAL METHOD

The research based an experimental method and Research was done at Thermodynamic Laboratory conducted the Flame & Combustion Group at Department of Mechanical Engineering Universitas Indonesia. Experimental study of fluid mass flow rate ratio of LPG through the swirling nozzle atomizer with a swirling chamber volume variation is done with a slope angle

from the vertical bottle of LPG 90° to get 100 % liquid's phase of LPG out from the bottle of LPG. The experiment consisted of 4 stages:

- Measurement of mass flow rate ratio of LPG liquid-vapor through a nozzle with a swirling chamber volume of 13.022 mm<sup>3</sup>, variations in flow rate of LPG (0016, 0018, 0022 and 0025 Liter / second)
- Measurement of mass flow rate ratio of LPG liquid-vapor through a nozzle with a swirling chamber volume of 13.465 mm<sup>3</sup>, variations in flow rate of LPG (0016, 0018, 0022 and 0025 Liter / second)
- Measurement of mass flow rate ratio of LPG liquid-vapor through a nozzle with a swirling chamber volume of 13.882 mm<sup>3</sup>, variations in flow rate of LPG (0016, 0018, 0022 and 0025 Liter / second)
- Measurement of mass flow rate ratio of LPG liquid-vapor through a nozzle with a swirling chamber volume of 14.324 mm<sup>3</sup>, variations in flow rate of LPG (0016, 0018, 0022 and 0025 Liter / sec).

The dimensions of swirling nozzles which used in this study can be seen in figure 3 below:

**Figure 3.** Swirling Nozzle dimesion

Swirling chamber volume of swirling nozzle which used in this study can be varied by adjusting the length of swirling chamber.

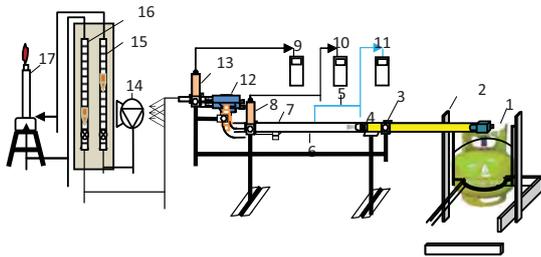

Figure 4. Installation Testing Scheme

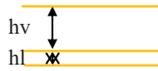

Installation testing scheme can be described as follows:

- a. Measurement of liquid-vapor mass flow rate ratio of LPG through a swirling nozzle with a swirling chamber volume 13.022 mm<sup>3</sup>
    - 1) Valve / valve on the fuel and air rotameter fully closed, while the stop valve is opened fully.
    - 2) In the LPG cylinders upright position (0° tilt from vertical position), LPG vapor flowed into the acrylic tube and pressure transducer.
    - 3) In the waiting about 15 minutes until the steam pressure readings on vapor pressure meters and temperature on the thermometer and record the results are stable
    - 4) Valves / fuel valve on the rotameter was opened just enough to drain the LPG to the burner and the flame ignited by lighters.
    - 5) The flow rate of LPG is set on a scale of 1 cm or equal to 0.016 liter / sec.
    - 6) The valve / air valve on the rotameter is set to obtain a stable flame.
    - 7) tank rotated so that the exact slope at position 90° of upright/vertical in its holder
    - 8) The height of the liquid LPG in the acrylic pipe was measured with a ruler and recorded in the first minute and the fifth to take an average.
    - 9) Play the LPG back to an upright position
    - 10) Close the stop valve and wait until the LPG in the acrylic pipe and fire up the burner goes out.
  - 10) Step 1) to 10) is repeated (with changes in flow rate of LPG in step 5)) respectively for 3 times repetition in accordance with the variation of the flow rate of LPG in step 5) (0018, 0022 and 0025 Liter / s)
  - b. Measurement of liquid-vapor mass flow rate ratio of LPG through a swirling nozzle next to the swirling chamber volume 13.465 mm<sup>3</sup>, 13.882 mm<sup>3</sup> and 14.324 mm<sup>3</sup>, performed with the same steps as above (step 1 to 11)
- The liquid-vapor mass flow rate ratio of LPG through the swirling nozzle which is calculated from the ratio of the volume of the liquid-vapor flows in the acrylic pipe installed after swirling nozzle.

$$= \frac{\text{Volume of LPG Liquid in Pipe}}{\text{Volume of LPG Vapor in Pipe}}$$

The volume of liquid and vapor LPG in the acrylic pipe can be calculated from the results of measurements of the radius of the pipe and high liquid LPG in the acrylic pipe. The formula for calculating the volume of liquid LPG in the acrylic pipe can be described as follows:

hv = height of vapor  
 hl = height of liquid

Figure 5. Image of height of LPG liquid and vapor in Acrylic Pipe

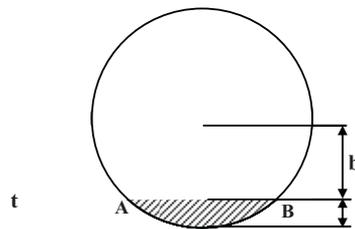

Figure 6. In Cross Section Pipes Acrylic

Description:

- $\alpha$  = angle pie
- r = radius of pipe
- t = height of liquid LPG

And then the volume of LPG liquid in the acrylic pipe can be calculated .

To calculate the cross-sectional area of fluid or shaded area in the cross-sectional images of the acrylic pipe with a height above the liquid is less than or equal to the radius of the pipe, earthenware widely used formula as follows [6]:

= Pie Area AOB - Triangle Area AOB

$$= \left( \frac{\alpha}{360^\circ} \pi r^2 \right) - \left( \frac{1}{2} \sin(\alpha) r^2 \right)$$

pie angle ( $\alpha$ ) is calculated using the following formula:

$$\alpha = 2 \arcsin \frac{r-t}{r}$$

Meanwhile, to calculate the cross-sectional area of fluid with a high fluid greater than the radius of the pipe, use the formula:

= cross-section area of pipe – vapor cross-section area

Vapor sectional area calculated by the formula above potsherd, with a value of t is a high vapor (pipe diameter – high of liquid).

The volume of LPG vapor in the pipe is calculated by the formula:

= Pipe volume – LPG liquid volume in the pipe

Percentage of LPG vapor in the pipe is calculated by the formula:

$$= \frac{\text{pipe volume} - \text{LPG liquid volume in the pipe}}{\text{pipe volume}} \times 100\%$$

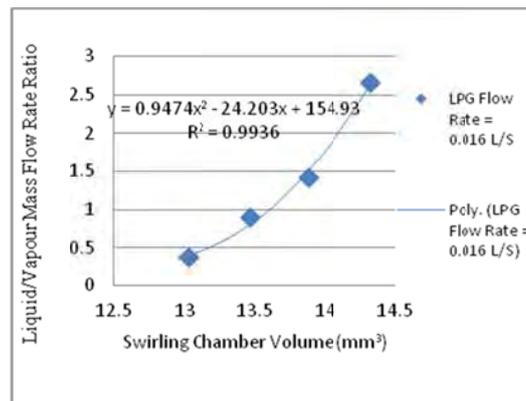

### 3. Result and Discussion

The measurement results can be seen in the following table:

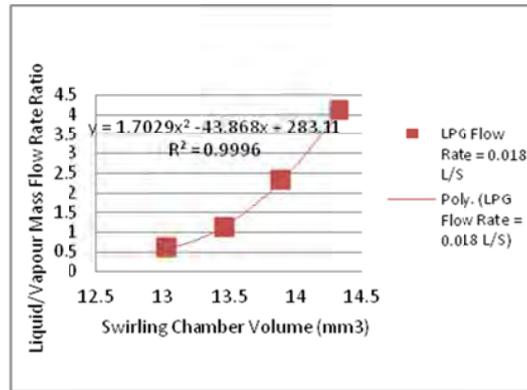

**Tabel.1**  
 Measurement result

LPG Flow Rate(L/s)	Swirling Chamber Volume(mm <sup>3</sup> )	Liquid-Vapor Rasio	Vapor Volume (%)
0.016	13.022	0.377	72.634
	13.465	0.891	52.893
	13.882	1.419	41.344
	14.324	2.654	27.366
0.018	13.022	0.626	61.514
	13.465	1.123	47.107
	13.882	2.324	30.086
	14.324	4.117	19.543
0.022	13.022	0.793	55.781
	13.465	1.598	38.486
	13.882	3.528	22.086
	14.324	5.805	14.695
0.025	13.022	1	50
	13.465	2.044	32.851
	13.882	4.856	17.076
	14.324	7.058	12.411

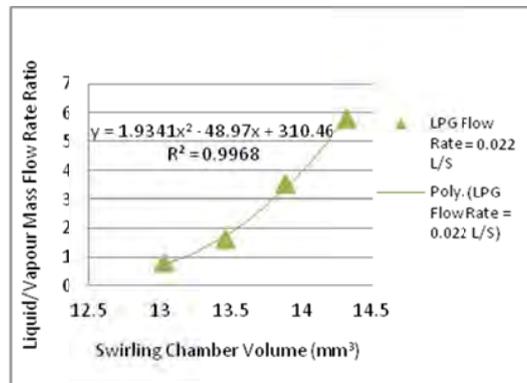

Relationship between swirling chamber volume variation with the liquid-vapor mass flow rate of LPG can be seen in the following graph:

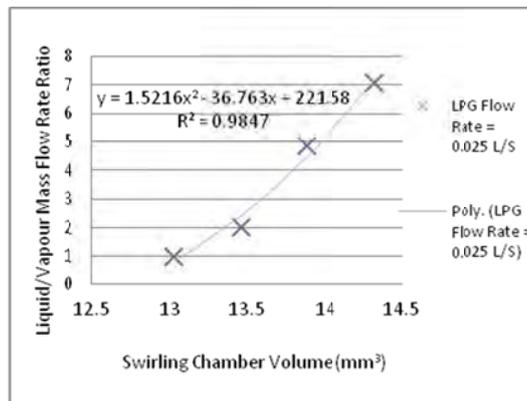

**Figure 7.** Relationship Between Swirling Chamber Volume with Liquid-Vapor Mass Flow Rate Ratio of LPG in 0.016 Liter / second

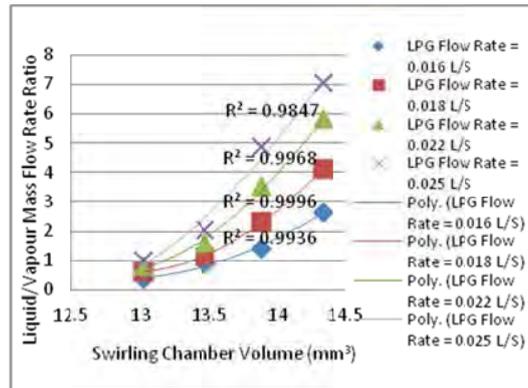

**Figure 8.** Relationship Between Swirling Chamber Volume with Liquid-Vapor Mass Flow Rate Ratio of LPG in 0.018 Liter / second

**Figure 9.** Relationship Between Swirling Chamber Volume with Liquid-Vapor Mass Flow Rate Ratio of LPG in 0.022 Liter / second

**Figure 10.** Relationship Between Swirling Chamber Volume with Liquid-Vapor Mass Flow Rate Ratio of LPG in 0.025 Liter / second

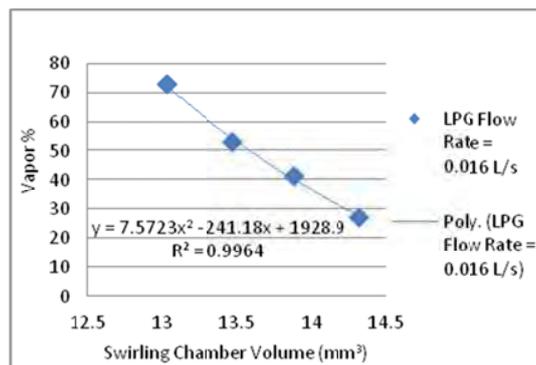

**Figure 11.** Relationship Between Swirling Chamber Volume with Liquid-Vapor Mass Flow Rate Ratio of LPG in 0.016, 0.018, 0.022 dan 0.025 Liter / second

From the graph above can be seen that, at a flow rate of LPG 0016 liters / second, the relationship between the swirling chamber volume with the liquid-Vapor mass flow rate ratio of LPG formed rank 2 polynomial regression equation:  $y = 0.9474x^2 - 154.9324.203x$  the value of  $R^2 = 0.9936$  or the correlation coefficient  $R = 0.9968$ . At LPG flow rate 0.018 liters / sec, the relationship between the swirling chamber volume with the liquid-Vapor mass flow rate ratio of LPG formed rank 2 polynomial regression equation:  $y = 1.7029x^2 - 43.868x + 283.11$  with  $R^2 = 0.9996$  value or correlation coefficient  $R = 0.999$ . At LPG flow rate 0.022 liters / sec, the relationship between the swirling chamber volume with the liquid-Vapor mass flow rate ratio of LPG formed rank 2 polynomial regression equation:  $y = 1.9341x^2 - 48.97x + 310.46$  with  $R^2 = 0.9968$  value or correlation coefficient  $R = 0.998$ . At LPG flow rate 0.025 liters / sec, the relationship between the swirling chamber volume with the liquid-Vapor mass flow rate ratio of LPG formed rank 2 polynomial regression equation:  $y = 1.5216x^2 - 36.763x + 221.58$  with  $R^2 = 0.9847$  value or correlation coefficient  $R = 0.992$ .

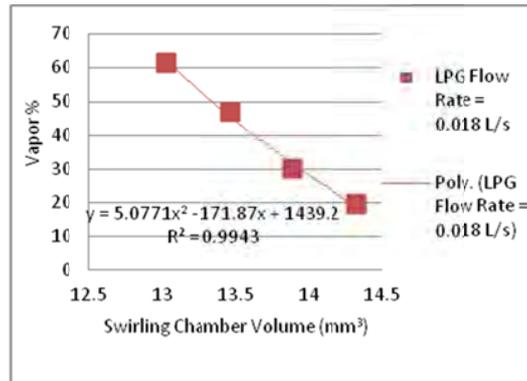

The value of correlation coefficient R on the graph the relationship between the swirling chamber volume with the liquid-Vapor mass flow rate ratio of 4 variations LPG flow rate (0.016, 0.018, 0.022 and 0.025 liters / sec) are all larger than the R product moment correlation table with significance level 5% and 1% respectively for 0.950 and 0.990 [15]. Thus it can be said that there is a significant relationship between the swirling chamber volume with the liquid-Vapor mass flow rate ratio of 4 variation of LPG flow rate (0.016, 0.018, 0.022 and 0.025 liters/sec). The greater the volume of swirling chamber, then the ratio of liquid-Vapor mass flow rate of LPG are also getting bigger. Conversely, the smaller the volume of swirling chamber, then the liquid-Vapor mass flow rate ratio of LPG are also getting smaller.

Meanwhile, the relationship between variations in the percentage volume of swirling chamber with Vapor flow rate of LPG can be seen in the following graph:

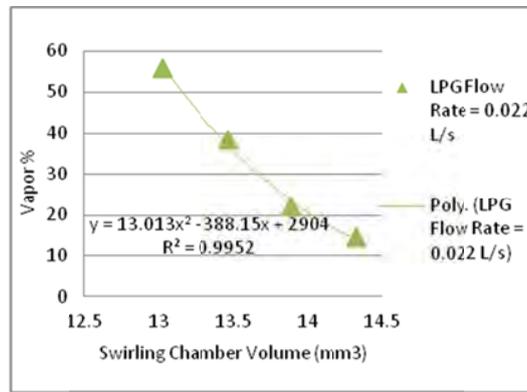

**Figure 12.** Relationship Between Swirling Chamber Volume with Vapor Flow Rate Percentage at Flow Rate of LPG 0016 L /

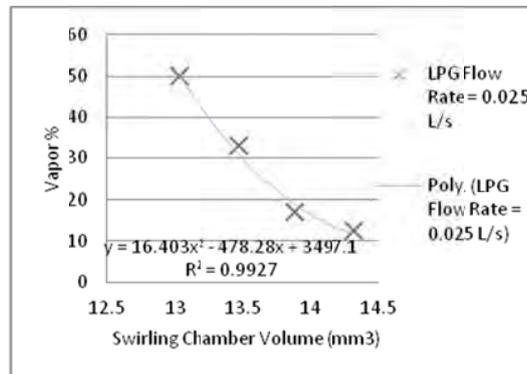

s

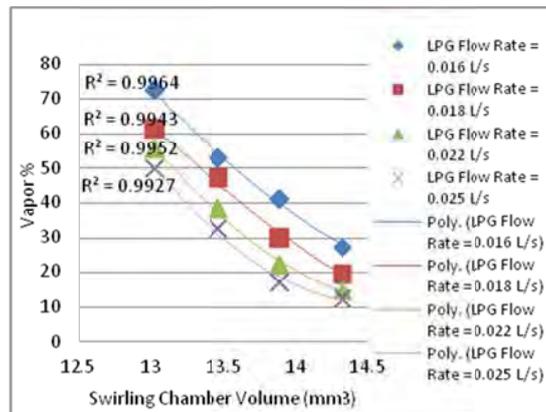

**Figure 13.** Relationship Between Swirling Chamber Volume with Vapor Flow Rate Percentage at Flow Rate of LPG 0.018 L/s

**Figure 14.** Relationship Between Swirling Chamber Volume with Vapor Flow Rate Percentage at Flow Rate of LPG 0.022 L/s

**Figure 15.** Relationship Between Swirling Chamber Volume with Vapor Flow Rate Percentage at Flow Rate of LPG 0.025 L/s

**Figure 16.** Relationship Between Swirling Chamber Volume with Vapor Flow Rate Percentage at Flow Rate of LPG 0.016, 0.018, 0.022 dan 0.025 L/s

From the graph above can be seen that, at a flow rate of LPG 0.016 liters / second, the relationship between the swirling chamber volume with percentage of LPG Vapor flow rate to form rank 2 polynomial regression equation:  $y = 7.5723x^2 - 241.18x + 1928.9$  with  $R^2 = 0.9964$  value or coefficient correlation  $R = 0.9982$ . At LPG flow rate 0.018 liters / sec, the relationship between the swirling chamber volume with percentage of LPG Vapor flow rate to form rank 2 polynomial regression equation:  $y = 5.0771x^2 - 171.87x + 1439.2$  with  $R^2 = 0.9943$  value or correlation coefficient  $R = 0.9971$ . In 0.022 LPG flow rate liters / sec, the relationship between the swirling chamber volume with percentage of LPG Vapor flow rate to form rank 2 polynomial regression equation:  $y = 13.013x^2 - 388.15x + 2904$  with a value of  $R^2 = 0.9952$  or correlation coefficient  $R = 0.9976$ . At LPG flow rate 0.025 liters / sec, the relationship between the swirling chamber volume with percentage of LPG Vapor flow rate to form rank 2 polynomial regression equation:  $y = 16.403x^2 - 478.28x + 3497.1$  with  $R^2 = 0.9927$  value or correlation coefficient  $R = 0.9963$ .

The value of correlation coefficient R on the figure/graph the relationship between the swirling chamber volume with percentage of LPG Vapor flow rate of 4 variations of LPG flow rate (0.016, 0.018, 0.022 and 0.025 liters/s) are all larger than the R product moment correlation table with a significance level of 5% and 1% respectively for 0950 and 0990 [7]. Thus it can be said that there is a significant relationship between swirling chamber volume and inversely proportional to the percentage of vapor flow rate at 4 variation of LPG flow rate (0.016, 0.018, 0.022 and 0.025 L/s). The larger the swirling chamber volume, the percentage of LPG vapor flow rate gets smaller. Conversely, the smaller the volume of swirling chamber, then the percentage of LPG vapor flow rate will be even greater.

#### 4. CONCLUSION

- There is a significant relationship between the volume ratio of swirling chamber with the liquid-Vapor flow rate at 4 variation of LPG flow rate (0.016, 0.018, 0.022 and 0.025 liters / sec). The greater the volume of swirling chamber, the bigger the ratio of liquid-Vapor flow rate of LPG through the regulator. Conversely, the smaller of the swirling chamber volume, the smaller the ratio of liquid-Vapor flow rate or better atomizing.
- There is a significant relationship between the percentage of vapor flow rate to the swirling volume chamber and the variations of flow rate LPG flow rate (0.016, 0.018, 0.022 and 0.025 liters / sec). The larger the swirling chamber volume, the percentage of LPG Vapor flow rate gets smaller. Conversely, the smaller the volume of swirling chamber, then the percentage of LPG Vapor flow rate will be even greater.
- The process of evaporation of a liquid to a Vapor of LPG due to swirling nozzle effect quite effective, where the minimum volume of swirling chamber, vapor quality can be achieved about 50% to 72.6%. Thus preventing the release of liquid LPG to the atmosphere or room air can be minimized in an effort to prevent fires and explosions caused by Vapor Cloud Explosion.

### ABSTRACT

Savonius windmill having advantages very high starting torque and simple construction is applicable for Indonesia as a developing country with annual average wind speed 4,5 – 5,0 m/s. The purpose of the experiment is to identify characteristics of an electric machine used for low speed electric generator. The electric machine for the experiment is a permanent magnet electric motor usually used for electric bicycle. The electric motor is tested as an electric generator and rotated with variations of speed. Outputs of the generator are torque, voltage and current with 1) variation of lamps-load, 2) constant voltage-load for 12 volt and 24 volt battery charging and 3) combination of 12 volt battery charging and variation of lamps-load. The average efficiency of the generator is 59,8% and 65,4% for 12 volt and 24 volt battery charging. Battery charging starts at 95 rpm and maximum electric generating current is 20 Ampere at generator speed about 175 rpm.

## ABSTRACT

The energy performance of Tandem Blade Savonius (TBS) rotor was studied by CFD simulation within comparing pressure gap between upstream and downstream. These were three types of TBS: Overlap (Type I), symmetrically (Type II) and Convergence (Type III). Through a comprehensive study of pressure distribution in and around of rotor blade, it is possible to identify the power generation for each model, and to show that the optimum energy conversion is produced by convergence type of TBS (Type III). Furthermore, the convergence of TBS performance can be optimized by using Response Surface Method (RSM) through improved their partition space between blade and tandem. By using radius tandem blade (RTB) as variable of optimization, we obtain the optimum design of TBS geometrically which have good performance of new Savonius Rotor model

## Keywords

Optimization, RSM, CFD Simulation, Tandem Blade, Savonius.

## 1. INTRODUCTION

The effect of fast growing application of computational fluid dynamics (CFD) within the last two decades is the significance of numerical flow simulations in the design of hydraulic machinery that has grown to a considerable extent. At present, CFD simulations can often replace elaborate experiments due to the fact that even complex geometries and entire machines can be modeled. Separate numerical investigations for single turbo-machinery components has been common practice, yet these simulations are not referenced for interactions between the additional components which have strong influence on the operational behavior of the entire machine.

Many researches were conducted to demonstrate the influence of modified Savonius rotor blade geometry parameters such as twist blade, overlap ratio, amount of blade, multi-stage, sweep area, none circular blade, and additional guide blade on the aerodynamic performance of the rotor blade. However, the influence of geometrical design variables and their interactions on the rotor aerodynamic performance was not examined in detail in these works. From this point of view, the present research is focused on suggesting a rotor blade shape design using the numerical optimization method coupled with the statistical approach. Response surface method (RSM) is a collection of statistical and mathematical techniques useful for developing and improving the optimization process, which uses collectively design of experiment, regression analysis, and analysis of variance [1].

The Savonius hydrokinetic turbine is simple geometry and its construction is low-cost to manufacture. It starts rotating at lower speeds as compared to its counterpart hydraulic turbines, having a high starting torque. It produces low noise and can make use of the water river flowing in any horizontal direction to its rotation. However, in spite of these advantages, this turbine faces one main disadvantage of having low efficiency. The preliminary research has been done to choose the best design rotor tandem blade of savonius (TBS). By using the result CFD simulation of the three models i.e.: (a) Overlap TBS, (b) Symmetrically TBS and (c) Convergent TBS as shown in Fig. 1, one of the best choice to be deeply studied is obtained. The optimum turbine power generation predicted by taking into calculation maximum pressure gap ( $\Delta p$ ) between upstream and downstream is Type Convergent TBS [2].

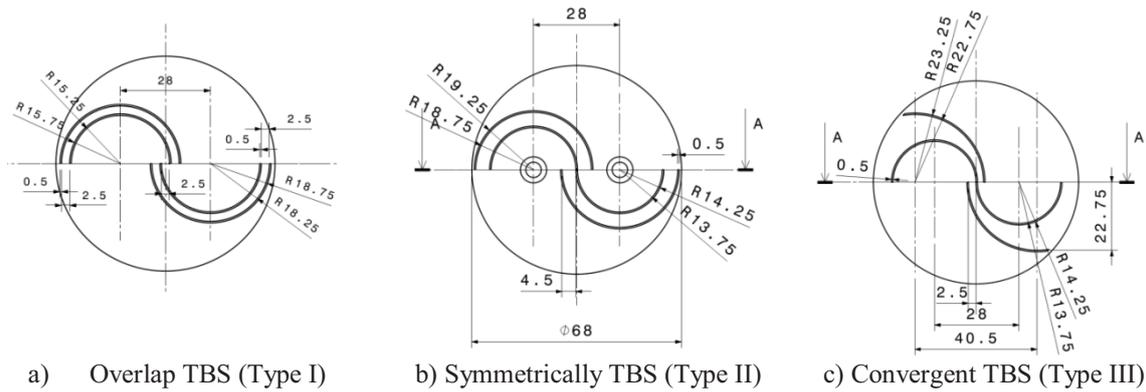

Figure 1: Three models and dimension of Tandem Blade of Savonius (TBS) Design [2].

The Savonius conventional has two pairs of cylindrical blade that look like a letter S which not connected to the middle or with gaps (overlapping) on both ends of the blade that serves as the entry of outflow from the first blade (thrust) to the second blade (return). As shown in Fig. 2, the first blade (advancing blade) got a drag force from the main flow (free flow) while the second blade (returning blade) got a returned force from the opposite direction outflow through the gap (overlap) resulting in a pair off couple force that is able to generate torque and power.

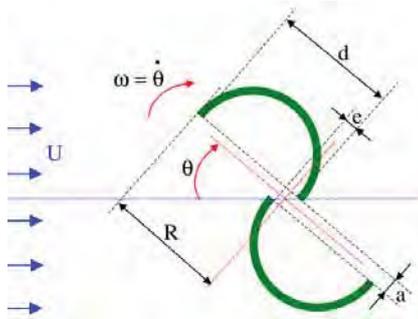

Figure 2: Original Savonius Rotor

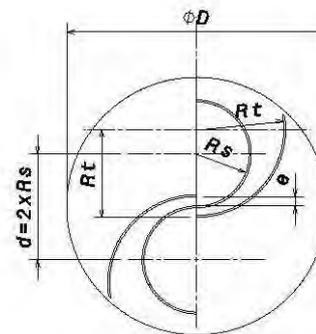

Figure 3: Convergent Tandem Blade Savonius

This paper focuses on optimization using RSM for designing geometry of Convergent TBS as shown in Fig.3 above. Objective of this study is to determine the value of the independent variables that cause the value of maximum pressure gap between upstream and downstream to be optimal. In these experiments, the response variable pressure gap (y) is affected by two independent variables: Radius Tandem Blade “ $R_t$ ” or ( $x_1$ ) and Clearance Blade “ $e$ ” or ( $x_2$ ). By using an appropriate model formulation, the value of independent variables ( $x_1, x_2$ ) which causes maximum pressure gap designation optimal can be obtained.

## 2. RESPONSE SURFACE METHOD

To understand how far the optimum process is influenced by number of variables, it is often necessary for experimental data to be large and takes a long time, which automatically also cost a huge amount. Several statistical and mathematical techniques are often used to make an approach to gain understanding of the optimum conditions of the process or design without requiring too much data. Among the commonly used method is the response surface method (RSM).

RSM is a set of mathematical and statistical techniques that are useful for analyzing problems where several independent variables affect the response variable and the ultimate goal is to optimize the response. The basic idea of this method is the use of statistical experimental design assisted to find the optimal value of the response. This method was first proposed in 1951 and has been used extensively in both the research and industrial applications until today. For example, by constructing a mathematical model, researchers can determine the value of the independent variables that lead to an optimal value of the response variable.

The first step of the RSM is to find a relationship between the response variable y with  $x_i$  independent through a first order polynomial equation (model order I). Independent variables denoted by  $x_1, x_2, \dots, x_k$ . These variables are assumed to be controlled by the researcher and the influence response variable y is assumed as a random variable. If the response is well modeled by a linear function of the independent variables  $x_i$ , the function approximation of the model order I are:

$$y = \beta_0 + \sum_{i=1}^k \beta_i x_i + \varepsilon \quad (1)$$

with,  $y$  : dependent variable (response)

$x_i$  : factors that influence response variables,  $i = 1, 2, \dots, k$

$\varepsilon$  : residual component (error) which is random and distributed identical and independent (Independent Identically Distributed-IID) Normal distribution with the average value of 0 and variance  $\sigma^2$ . In mathematically expressed by  $\varepsilon \approx \text{IID Normal}(0, \sigma^2)$ .

Furthermore, at the condition near the response, the second order model (order II) or more normally required to approximate the response due to the curvature in the surface. In many cases, the model order II two expressed in equation (2) is considered sufficient.

$$\hat{y} = \beta_0 + \sum_{i=1}^k \beta_i x_i + \sum_{i=1}^k \beta_{ii} x_i^2 + \sum_i \sum_j \beta_{ij} x_i x_j, i < j \quad (2)$$

Analysis of the response surface fitting Order II is often referred as the canonical analysis [1]. Least squares method is used to estimate parameters on the approximation functions. The subsequent RSM analysis can be used for surface fitting. If the surface fitting is a good approximation of a function of the response, surface fitting analysis would be equivalent with the actual analysis systems.

Analysis of variance and regression analysis are the statistical techniques to estimate regression coefficients in the quadratic polynomial model and also yield a measure of uncertainty in the coefficients. One of the important statistical parameters is the coefficient of determination,  $R^2$  which provides the summary statistic that measures how well the regression equation fits the data. It is given as:

$$R^2 = \frac{SSR}{SSTO} = 1 - \frac{SSE}{SSTO} \quad (3)$$

where SSTO is the total sum of squares, SSR is the regression sum of squares, and SSE is the error sum of squares. From the inspection of Equation (3), it is found that  $0 \leq R^2 \leq 1$ . However, a large value of  $R^2$  does not necessarily imply that the regression model is a good one. Adding a variable to the model always increases  $R^2$ , regardless of whether the additional variable is statistically significant or not. Thus, it is possible for the models that have large values of  $R^2$  to yield the poor predictions of new observations or estimates of the mean response. Because  $R^2$  always increases as we add terms to the model, the adjusted  $R^2$  statistic parameter,  $R^2_{adj}$  defined below is frequently used.

$$R^2_{adj} = 1 - \frac{SSE/(n_s - n_{rc})}{SSTO/(n_s - 1)} = 1 - \left( \frac{n_s - 1}{n_s - n_{rc}} \right) (1 - R^2) \quad (4)$$

In general, the adjusted- $R^2$  statistic does not always increase as variables are added to the model. In fact, if unnecessary terms are added, the value of  $R^2_{adj}$  often decreases.

It is important to determine the value of each regression variable in the regression model, because the model may be effective with the inclusion of additional variables or with the deletion of the variables already in the model. The test statistic (t-statistic) for testing the significance of any individual regression coefficient is

$$t = \frac{c_j}{\sqrt{\sigma^2 C_{jj}}}, \quad j = i, \dots, n_{rc} \quad (5)$$

Where  $\sigma^2$  is the estimation of variance and  $C_{jj}$  is the diagonal element of  $(X^T X)^{-1}$  corresponding to  $c_j$ .

### 3. DEVELOPMENT OF SAVONIUS ROTOR

Currently, the Savonius turbine has been developed with various modifications with the purpose of improving their performances. Cesar Humberto [3] combined the simulation and optimization method using genetic algorithm (GA) to design modified savonius rotor. Browsing point of optimization by using Polar Coordinate system for changing the shape of original rotor savonius combining with Banesh rotor produce a new shape of rotor savonius which is more efficient.

Menet, et.al.[4] has modified the savonius rotor which only changes the position of an off-set the second pair of rotor blades, now has three geometric parameters, namely: (1) primary overlap ( $e$ ), secondary overlap ( $e'$ ), and the angle between the axis blades ( $\beta$ ). The result is relatively expected s new rotor induces maximum value of static torque is much higher than those obtained with the conventional rotor. However, they found low values and negative torque when an angle  $\beta$  has large variations. Overall, the average value of the torque increased to  $C_m = 0.48$  or 60% more than the conventional rotor.

Fujisawa [5] has published a study comparing experimental results with a numerical study also using the discrete vortex method. He concluded that the numerical calculations were adequate to “predict the basic features of the variation in flow fields with rotor angle”. Nevertheless, the procreation of the flow field around a stationary rotor was poor, and Fujisawa supposed that it was due to false assumptions used in the calculations. Sometimes, some visualizations of the flow in and around the rotor are proposed, but with a poor description of the physical phenomena. Fujisawa [6] also presented an exclusive description of the Visualization study of the flow in and around a of the conventional Savonius rotor, they conclude that the overall pressure coefficient decreased due to the effect of the circulation generated by rotor rotation. This is a phenomenon of circulation persists in revolving condition compared with stationary rotor, where the flow through the overlap is reduced due to backflow. The flow is expected to reduce the effect of pressure recovery on the back side of blade behind because of the pressure distribution near the overlap.

Kamoji et al. [7] improved the coefficient of power and obtained uniform coefficient of static torque. To achieve these objectives, the rotors are being studied with and without central shaft between the end plates. Experimental tests in a closed jet wind tunnel on modified form of the conventional Savonius rotor with the central shaft have the value of  $C_p = 0.32$ . They studied the effect of geometrical parameters on the performance of the rotors in terms of coefficient of static torque, coefficient of torque and coefficient of power. The parameters studied are overlap ratio, blade arc angle, aspect ratio, and Reynolds number.

Performance of Savonius hydro-kinetic turbine has dependence with the principle to generate drag forces is formulated by  $F = p \cdot A = \frac{1}{2} \cdot \rho \cdot A \cdot U^2$ , thus optimizing torque and power turbine formation is highly dependent on the blades swept area (A) and velocity of fluid (U). Therefore, this paper introduced a new concept design of Savonius rotor by broadening swept area of tandem blade that can increase drag force production on the blade as shown as Fig. 3. To achieve the maximum power generation using convergent TBS rotor design, we use CFD simulation and RSM to realize optimum Radius Tandem Blade (Rt) and Clearance Blade (e) as independence variable.

#### 4. CFD SIMULATION

By adapting the law of Navier-Stokes model of rotation frame, the equations governing the behavior Savonius hydrokinetics turbines will be used in this study. The equations rule the behavior of fluid flow including conservation of mass (eq. 6) and momentum equations (eq. 7). Two types of acceleration in the momentum equation representing two Savonius hydrokinetics turbine rotation are the Coriolis acceleration,  $(2 \tilde{\omega} \times \bar{v}_r)$  and the centripetal acceleration  $(\tilde{\omega} \times \tilde{\omega} \times \hat{r})$ .

$$\frac{\partial \rho}{\partial t} + \nabla \cdot \rho \bar{v}_r = 0 \quad (6)$$

$$\frac{\partial}{\partial t} (\rho \bar{v}_r) + \nabla \cdot (\rho \bar{v}_r \cdot \bar{v}_r) + \rho (2 \tilde{\omega} \times \bar{v}_r + \tilde{\omega} \times \tilde{\omega} \times \hat{r}) = -\nabla p + \nabla \tau + F \quad (7)$$

In this equation,  $\hat{r}$  is the radial position of the rotating domain forms,  $\tilde{\omega}$  domain is the angular velocity of the rotor,  $\bar{v}_r$  is the relative velocity,  $p$  is the static pressure,  $\tau$  is the stress tensor and  $F$  represents the external body force. Adopting a combined formulation in cylindrical coordinates and Cartesian, in order to simulate two separate regions of the domain, i.e. inflows rotate the rotor-stator and external. Standard K- $\epsilon$  model, Eq. (8) and (9), is used to simulate the turbulence in the flow field [8]. They are coupled to the Navier-Stokes equations although included in the convection zone. It is a widely used and provides sufficient accuracy and worthy to represent the various types of flow. K- $\epsilon$  model is a two-equation models involving turbulent kinetic energy,  $k$ , and the dissipation rate,  $\epsilon$ , as follows,

$$\frac{\partial}{\partial t} (\rho k) + \frac{\partial}{\partial x_i} (\rho k u_i) = \frac{\partial}{\partial x_j} \left[ \left( \mu + \frac{\mu_t}{\sigma_k} \right) \frac{\partial k}{\partial x_j} \right] + G_k + G_b - \rho \epsilon - Y_M + S_k \quad (8)$$

$$\frac{\partial}{\partial t} (\rho \epsilon) + \frac{\partial}{\partial x_i} (\rho \epsilon u_i) = \frac{\partial}{\partial x_j} \left[ \left( \mu + \frac{\mu_t}{\sigma_\epsilon} \right) \frac{\partial \epsilon}{\partial x_j} \right] + C_{1\epsilon} \frac{\epsilon}{k} (G_K + C_{3\epsilon} G_b) - C_{2\epsilon} \rho \frac{\epsilon^2}{k} + S_\epsilon \quad (9)$$

$$\mu_t = \rho C_\mu \frac{k^2}{\epsilon} \quad (10)$$

In this model,  $G_k$  represents the generation of turbulence kinetic energy due to the velocity gradient, whereas  $G_b$  describe the generation of turbulence kinetic energy due to buoyancy, and  $Y_M$  is the contribution of the fluctuating dilatation to the overall dissipation rate. Variable  $\sigma_k$  and  $\sigma_\epsilon$  are Prandtl numbers for the turbulent with value of  $k = 1.0$  and  $\epsilon = 1.3$ . Constants  $C_{1\epsilon} = 1.44$  and  $C_{2\epsilon} = 1.92$ . Turbulent viscosity (or Eddy current),  $\mu_t$  is computed by combining  $k$  and  $\epsilon$  as shown in Eq. 10, where  $C_\mu = 0.09$ .

This equation will be used to predict fluid flow through a turbine that will improve its performance.

By using simulation software ANSYS Release 14.0 it's the following boundary conditions that have been applied. The stationary domain has a free stream velocity. The hydrodynamic pressure conditions are applied and the initialization is done. Inlet and Outlet are default boundary conditions in simulation software. Inlet requires the speed of inlet velocity of water and the outlet requires the relative pressure,  $1.0132 \times 10^5$  [Pa], at the initial conditions. The blade surfaces are enabled a "wall"

condition. This condition enables the calculation of properties such as force, torque on the surface. Once the domains have been specified, a default fluid-fluid interface is detected between the rotating and stationary domain.

A two-dimensional view of the rotor model was considered. It is because the rotor blades rotate in the same plane as the approaching water flow stream. The computational domain was discretized using two-dimensional unstructured mesh (triangular mesh). The left boundary had Velocity Inlet condition while the right boundary had Outflow condition. The top and bottom boundaries for the open channel sidewalls had symmetry conditions. The moving wall condition was employed for the rotor model to study the effect of fluid motion in and around the rotating Savonius rotor. The dimensions of the computational domain were 500 mm in length and 75,5 [mm] in width, which were also similar to the experimental conditions. For the various model conditions, the geometry of the rotor was changed and accordingly different meshes were generated for each condition.

Steps in the simulation solutions consist of:

1. Solver (Pressure Based, Steady, 2D)
2. Viscous Model: Standard k-epsilon (k-ε) / Near-Wall Treatment: Standard Wall Functions
3. Material: Water ( $\mu= 1.002 \times 10^{-3}$  [kg/m-s],  $\rho= 1.000$  [kg/m<sup>3</sup>])
4. Operating conditions: Atmospheric Pressure (1.0132 [bar])
5. Boundary Conditions:
  - Inlet: Velocity Inlet
  - Sides: No slip wall
  - Blades: Stationary Wall
  - Outlet: Outlet
6. Solution controls:
  - Pressure Velocity Coupling: SIMPLE
  - Discretization: fluids
7. Pressure (Standard) / Inlet Velocity: 1 [m/s]

## 5. RESULT AND DISCUSSION

In the contour plots as shown at Figure 5, the blade on the left hand side is the returning blade and that on the right hand side is the advancing blade. The contour plots predict the variations in velocity and pressure in various regions near the blades within the flow domain. It can be observed from the pressure contour plots that pressure gap occur across the rotor from upstream to downstream side. This pressure gap indicates power extracted by the rotor causing its rotation [5]. The static pressure on the convex side of both the blades can be observed to be lower than those on the concave side of the blades; in fact, a region of negative pressure exists on the convex side of the blades. This occurs due to the high flow velocity over the convex side of the blades. As a result, a pressure difference acts across the concave and convex side of the blades, which provide the necessary torque for causing rotation of the blades.

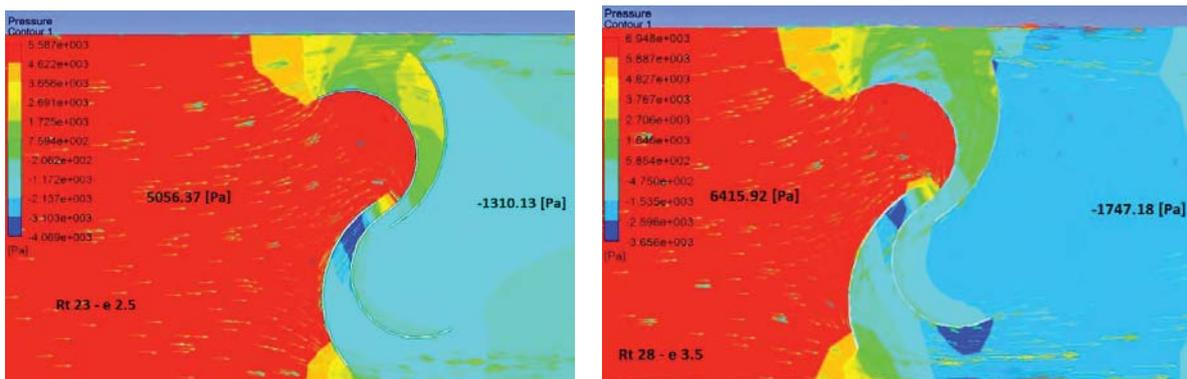

Figure 5: CFD simulation demonstrate the effect of Radius Tandem (Rt) and Clearance (e) caused pressure drop ( $\Delta P$ ).

To discuss the results of RSM optimization, as shown in Table 1 presented the CFD simulation data of rotor convergent TBS model using variable tandem radius (Rt) and Blade Clearance (e) with the lowest value of 23 mm - 2.5 mm and the highest 28 mm - 3.5 mm, both pressure gap indicates that each  $\Delta p = 6366.5$  (Pa) and  $\Delta p = 8163.1$  (Pa). The two independent variables were considered as variables that affect maximize pressure gap (y), i.e., Radius ( $x_1$ ) and Clearance ( $x_2$ ). Experimental design used in the DoE is three-level factorial design (3k) using the Central Composite Design (CCD) which is presented in Table 2.

The first step has been tested using a linear regression equation (Order I) with obtained R-square is only 54% and a P-value > 0.05 so it does not show any significance of the model. Furthermore, similar test attempted to Order II model equations (linear + square) obtained a significant regression coefficient. To check the significance of the second-order model, it can be seen that p-value = 0.000 is less than the significance level  $\alpha = 5\%$ , see also that the independent variables  $x_1$  made a significant contribution in the model, but  $x_2$  is not significant. But, overall this model it is able to demonstrate the high value of R-square = 94.7 % in Table 3, which means that the regression equation model is consistent with the real condition of the model studied. The model regression equation is expressed in the form:

$$\Delta P = 8951.2 + 1376 (Rt) - 238.9 (e) - 1166.7 (Rt)^2 - 241.5 (e)^2 + \varepsilon$$

After the optimization model has determined, the next step is to determine the conditions optimum of significant factors. From the contour plot of the image below, it can be concluded that the image does not have a stationary point. Consequently that calculation of the stationary point and surface characteristics of the response is not necessary. The result of response ( $\Delta P$ ) optimization will be obtained after value of (Rt) and (e) which substituted into the model equation above with constant value of Rt = 27 [mm] and variable e = 2.5 [mm] ÷ 3.5 [mm]. By using Minitab Software, it is more simple to obtain the result of peak

point in the curvature as shown in Fig. 7 which show optimal value of  $R_t = 27$  [mm] and  $e = 2.75$  [mm] with response of maximum  $\Delta P = 9415.91$  [Pa].

## 6. CONCLUSION

Finally, with applied CFD simulation and optimization using RSM, we are able to assist design engineering of the critical part of convergent tandem blade of Savonius rotor that capable to generate maximum power on hydrokinetic turbine model. The result of design optimization of Savonius tandem blade is showed in Fig. 8 below with  $R_t = 27$  [mm] and  $e = 2.75$  [mm].

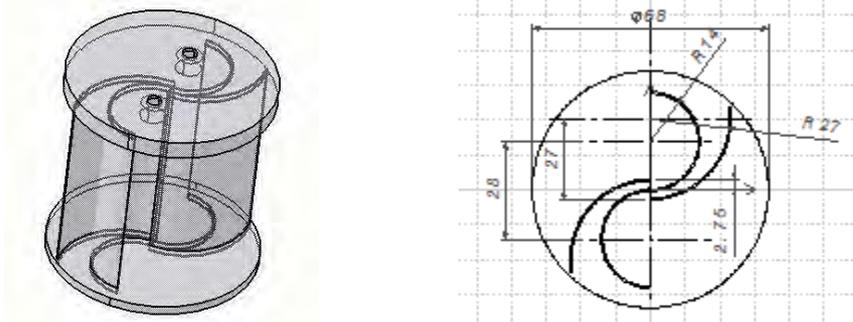

Figure 8: The result design of convergent tandem blade of Savonius Rotor

## ACKNOWLEDGMENT

The authors acknowledge with thanks the assistance rendered by Dr. Eng. Agus Choiron, (Lecturer) and Tri Handoko (Assistant Lecturer), Manufacture and Engineering Design Laboratory Department of Mechanical Engineering, Brawijaya University of Malang - Indonesia), for providing crucial insights during the course of the research work.

## ABSTRACT

This paper presents a study of the combustion of mineral diesel and biodiesel in a direct injection diesel engine. For this, a numerical simulation using the CFD code *OpenFoam*, the simulation of injection, evaporation and combustion process were carried out. The comparison was made in terms of combustion characteristics such as the pressure and temperature in the combustion chamber between the mineral diesel, biodiesel and its blend. These combustion characteristics can then be used for calculating the heat release and combustion efficiency. It was found that the calculated pressure and temperature in the combustion chamber tend to be similar with which the experimental data. The results demonstrate the benefits and the ability of the open source CFD software for analysis and optimization of the combustion in diesel engines.

## Keywords

*Combustion, CFD, Biodiesel, temperature, combustion*

## 1. INTRODUCTION

This study aims to develop a calculation method using open source-based software package (*OpenFoam*) for combustion parameters in diesel engine. The method developed is expected to perform the calculations that are comparable with of commercial softwares such as *FLUENT*, *AVL-FIRE* and *STAR-CD*. For the visualization of the simulation results, the other open-source code is also used, the so called *ParaView*. This study is design to support the Indonesian National Research Agenda [1] and the topic of this study related to the design and optimization of combustion process of the alternative fuels such as biodiesel, bi-oil and biogas according to recent studies though biodiesel has been implemented in Indonesia in the transport sector, but there are still many problems found regarding the performance of the engine (deposit formation). Therefore, a numerical study is needed on the effects of mixtures of biodiesel on the mechanism of combustion in diesel engines [2].

## 2. METHOD

### 2.1 Generating Drawing and Mesh for Combustion Chamber

To simulate the combustion process in diesel engine, drawing of the combustion chamber is required, consisting of a space that is confined by top piston with bowl at the bottom, cylinder liner as the wall and cylinder head at the top. Furthermore the drawing of the combustion chamber is generated using an open source software (for example: *OpenOffice Draw*) or generated first using the popular package such as *AutoCad* and then transferred to *OpenFoam* format with *OpenOfficeDraw*.

The space of combustion chamber should then be divided into mesh consisting of many tiny compartments where it will represent the unique parameters of combustion process (temperature, pressure, concentration etc.). *OpenFoam* has a procedure for generating the mesh, so called *blockMesh*.

### 2.2 Setting Parameters before Simulation (Pre-processing)

A package in the *OpenFoam* for simulating the combustion in diesel engine (Solver) is the *dieselEngineFoam* [3], [4], [5]. Solver *dieselEngineFoam* can simulate the dynamic combustion process in the diesel engine by giving the output in the form of profiles of combustion parameters as a function of crank angle (crank angle). Before starting with the simulation, the following setting or adjustment are needed:

#### Setting of initial and boundary conditions [4], [5], [6]

Setting of initial and boundary conditions include the condition of the fuel injector, fuel flow profile, type of injector, the parameters associated with composition of incoming air ( $O_2$ ,  $N_2$ ) and the physical-chemical properties such as pressure, temperature, concentration of exhaust gas emission. Boundary conditions include the position and direction injection injector, nozzle diameter, temperature, mass flow rate profile of the injected fuel etc. In addition, the fuel injector used in this study is **unitInjector**. Furthermore the model for fuel atomization can be selected from a variety of options (contained in the file **constant / sprayProperties**). The initial conditions in the simulation can be edited in the directory (**/ 0**).

#### Determination of Physical Properties [4], [5]

Before running the simulation, there are some files in the OpenFoam that should be edited, relating to the physical-chemical properties: **chemistryProperties**, **environmentalProperties**, **combustionProperties** and **thermophysicalProperties**. **chemistryProperties** includes definition of chemical reactions, **environmentalProperties** includes gravity and **combustionProperties** includes setting combustion calculations with or without ignition, timing and duration of ignition. **thermophysicalProperties** includes the setting and type of reaction scheme to be used in the simulation.

#### 2.3 Running Solver [4], [5]

For running the simulation, the following multiple procedures are used:

- Open the case that we will run in the file / 0
- Determine the reaction and ignition
- Generate the drawing and mesh of the combustion chamber
- Running the dieselEngineFoam

#### 2.4 Post-Processing

The simulation results can then be processed using the open source software ParaView. Processing of the simulation results will provide the temperature and pressure distribution profile, diameter of fuel droplets, and exhaust emission concentration before/after combustion. Figure 1 is an example of the results of processing using ParaView.

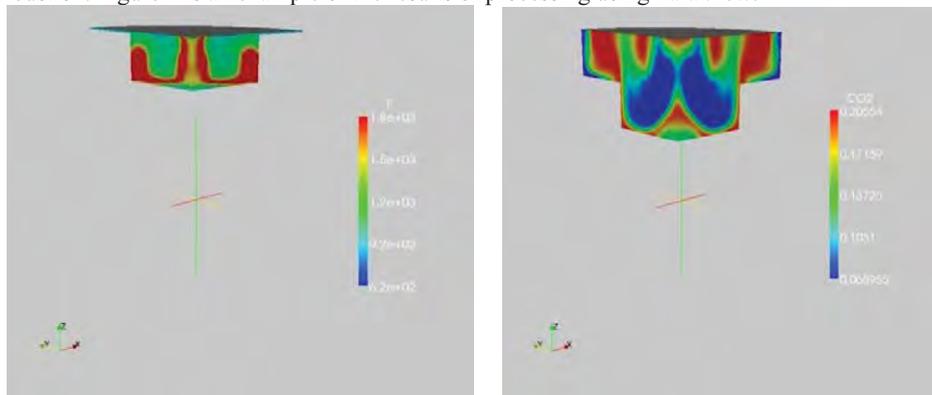

Figure 1: Temperature and CO<sub>2</sub> distribution in combustion chamber after combustion

### 3. RESULTS AND DISCUSSION

The dynamics simulations are performed on a cylindrical combustion chamber with the following sizes:

- Stroke (Conrod Length): 0.22 meters
- Bore: 0.104 meters
- Stroke: 0.115 meters
- Clearance: 0.0005 meters

Dynamics simulation are performed during the movement of piston (up and down) with the rotational speed of 1500 RPM. Figure 2 shows the piston head used in the simulation and fitted valley

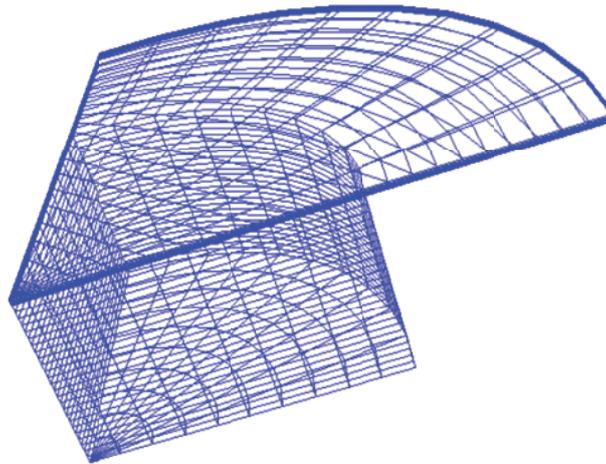

Figure 2: Top piston geometry for dynamic simulation

The parameters and conditions used in the simulation are shown in Table 1. The simulation for combustion is applied for two types of fuels namely mineral diesel fuel and biodiesel-mineral diesel fuel blend (w/w-50%, B50)

Table 1: Simulation parameter in combustion chamber for two different condition

Simulation Parameter	Values	
	Condition 1	Condition 2
Speed (RPM)	1500 RPM	1500 RPM
Injected Fuel Mass	0,00003 Kg	0,00003 Kg
Start of Injection	-20 °CA	-24°CA
End of Injection	-2 °CA	-6°CA

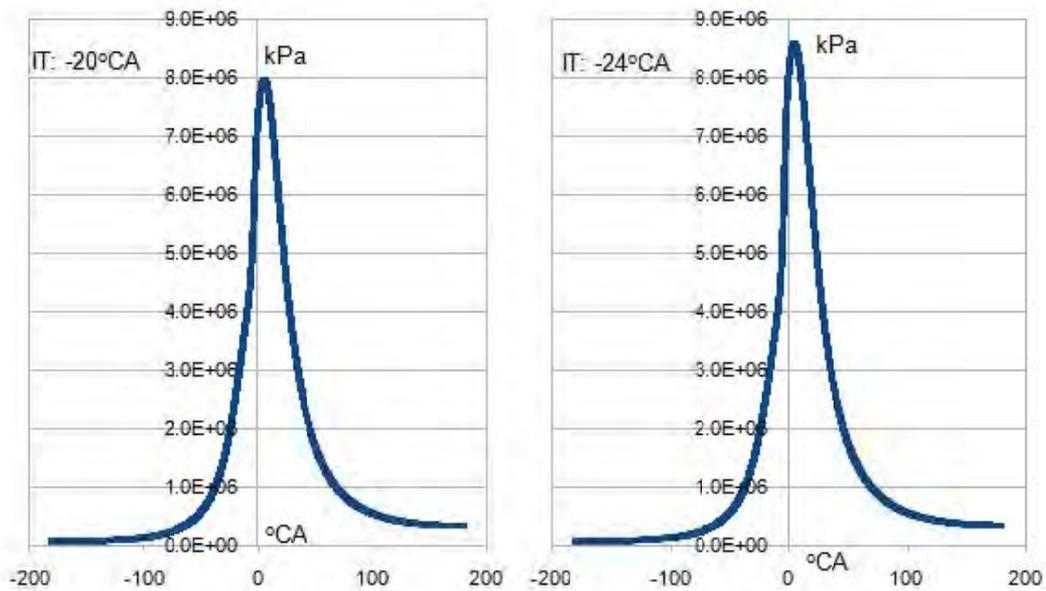

Figure 3: Pressure profile in combustion chamber at injection timing of -20 and -24°CA for mineral diesel fuel

The simulations are performed at two different injection times, the first injection time is started at -20°CA and ended at -2°CA. While the second injection time is started at -24°CA and ended at -6°CA. Their results of dynamics simulation for pressure and temperature in the combustion chamber can be seen in Figure 3 to 6. Results in Figure 3 shows the pressure profile in the combustion chamber when mineral diesel fuel is burned at two different injection time. It appears that at the time after the combustion pressures begin to rise until it reaches a peak at between 4-5°CA, the pressure then goes down after burning of the mineral diesel fuel finish. The peak pressure at injection time of -20°CA is about  $8.10^6$  kPa (80 bar) and the value at

injection time of  $-24^{\circ}\text{CA}$  is higher ( $8,5 \cdot 10^6$  kPa).

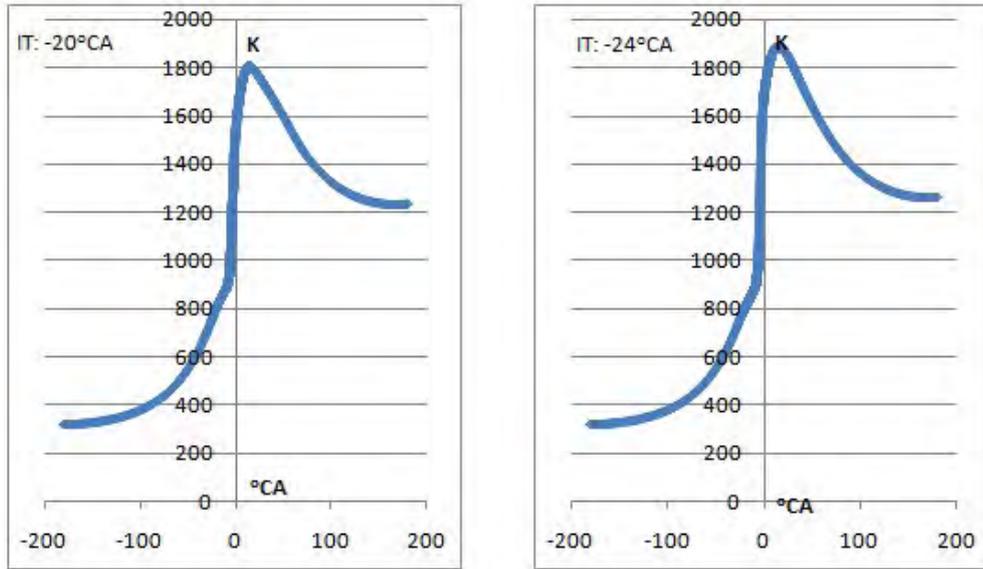

Figure 4: Temperature profile in combustion chamber at injection timing of  $-20^{\circ}$  and  $-24^{\circ}\text{CA}$  for mineral diesel fuel

The results in Figure 4 shows the temperature profile in the combustion chamber at injection time of  $-20^{\circ}$  and  $-24^{\circ}\text{CA}$ . It appears that at the time after the the injection, when the combustion of mineral diesel fuel starts, the temperature profile began to rise suddenly until it reaches a peak value at about  $11-12^{\circ}\text{CA}$ , then decreased drastically at stage of exhaust stroke.

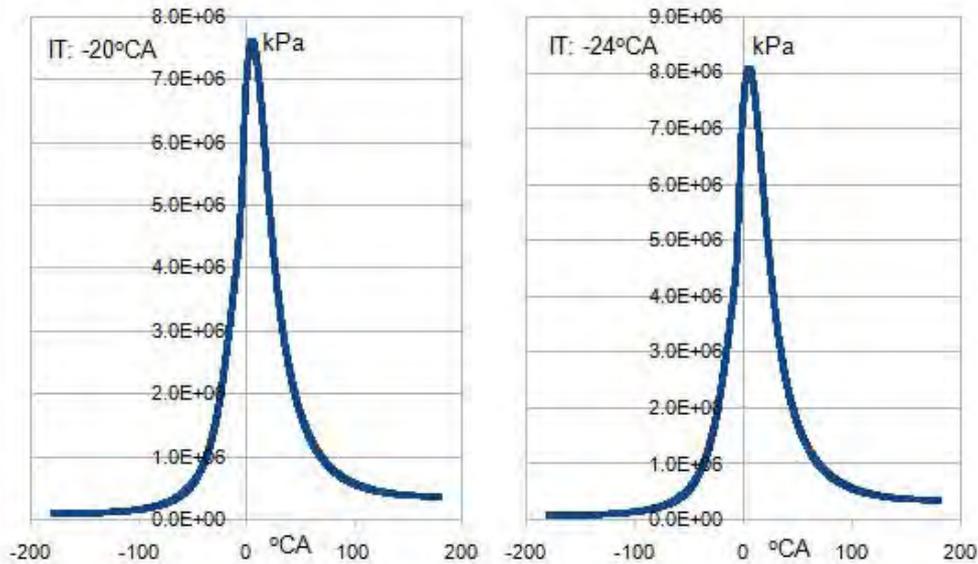

Figure 5: Pressure profile in combustion chamber at injection timing of  $-20$  and  $-24^{\circ}\text{CA}$  for biodiesel blend (B50)

The results in Figure 5 shows the dynamic pressure profile in the combustion chamber of the biodiesel blend (B50) at injection timing of  $-20$  and  $-24^{\circ}\text{CA}$ . It is shown that the peak pressure of combustion at injection time of  $-24^{\circ}\text{CA}$  is higher than that of  $-20^{\circ}\text{CA}$ . This phenomenon is similar to the combustion of mineral diesel, if the fuel is injected earlier then the relting peak pressure will be higher. It also appears the pressure reaches the peak value at  $5-6^{\circ}\text{CA}$  for both values of injection timing.

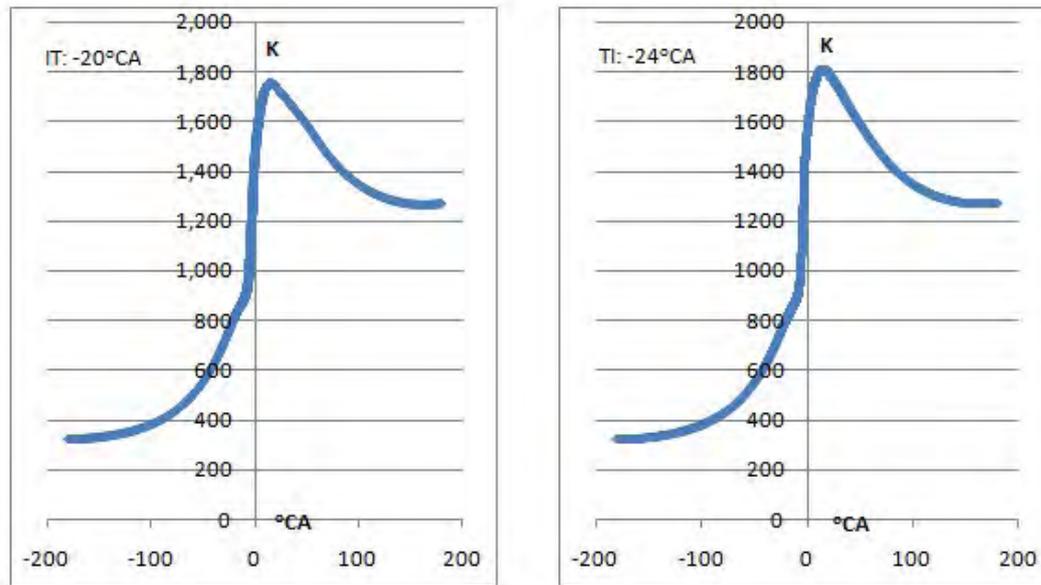

Figure 6: Temperature profile in combustion chamber at injection timing of -20 and -24°CA for biodiesel blend (B50)  
 Figure 6 shows the temperature profile in the combustion chamber for at injection timing of -20 and -24°CA. The trend in peak temperature for both mineral diesel fuel and B50 are similar. The peak temperature for combustion of B50 at injection timing of -24°CA is about 1800 K and this is higher than that of injection timing of -20°CA (1750 K). The values of the peak pressure and peak temperature for the combustion both mineral diesel fuel and B50 are summarized in Table 2. The results show that the peak pressure and temperature of combustion with mineral diesel are higher than that of B50 at injection timing of -20 as well as of -24°CA. This corresponds to the value of the calorie content of the mineral diesel which is higher than that of B50. Thus, the combustion of mineral diesel will produce and release higher heat and also the peak pressure and temperature.

Table 2: The values of the peak pressure and temperature for the combustion of mineral diesel and B50

Combustion Characteristics	Mineral Diesel		B50	
	-20°CA	-24°CA	-20°CA	-24°CA
Peak Pressure (10 <sup>5</sup> kPa)	80	86	76	81
Peak Temperature (K)	1805	1880	1750	1800

#### 4. CONCLUSION AND RECOMMENDATION

The conclusion that can be derived from the results of the dynamic simulation of a diesel engine combustion chamber is as follows:

- Simulation using CFD software opensource (OpenFoam) can be done easily using the solver dieselEngineFoam and is relatively fast
- The simulation results of the pressure and temperature profile has shown a correlation with the physical properties of the fuel (mineral diesel and B50), especially with the calorie content.

Recommendations that can be given for the next study are as follows:

- Need further simulation with more variations in injection pressure injection, biodiesel blends (fuel properties) and engine design parameter (injection angle, bowl design, load etc).
- Need validation of the simulation results by comparing with experimental data or secondary data from the literature

This study is still ongoing with calculation and visualization of emission profiles (CO, NOx and unburned hydrocarbon) using opensource software ParaView, and will be reported soon.

#### ACKNOWLEDGMENT

This project is financially supported by University of Indonesia through the RUUI 2012 research project. The assistance of Mr. Himawan Sutrianto from BTMP BPP Teknologi in conducting the numerical study using OpenFoam is also highly appreciated.

### ABSTRACT

There has been some success story in the formulating models for different flow regimes, and a number of corresponding flow maps for horizontal has been developed. Furthermore, most of the maps were generated based on visual observations and are, therefore, subjective in nature. Meanwhile, slugging phenomenon that can be defined as initiation of a water hammer is a very interesting topic because it has a strategic impact on safety factor of the equipment in piping systems i.e. pressurized water reactor (PWR), heat exchanger, steam or gas transportation in chemical industry, air conditioning, etc. The objective of the present research was to investigate the slugging as an initiating water hammer phenomena through non directly contact steam condensing in a horizontal pipe to develop the flow pattern map of steam-condensate flow in a horizontal double pipe. The experimental apparatus used in the present experimental study consisted of an inner annulus pipe made of copper ( $d_{in} = 17.2$  mm,  $d_o = 19$  mm) with a length of 1.8 m. The outer pipe annulus was a galvanized iron pipe ( $d_{in} = 108.3$  mm,  $d_o = 114.3$  mm) with a length of 1.6 m. The liquid being tested was water. The experiments were conducted at a static pressure of  $P_s = 108.825$  kPa and the temperature of  $T = 119.7$  °C. The pressure drop in axial direction of the test was directly measured by using a differential pressure transducer (validyne, accuracy of  $\pm 0.25\%$ ) with a sampling rate of 7.353 kHz. The obtained experimental data of temperature and differential pressure fluctuations during the steam condensation in a horizontal pipe was analyzed using a statistical analysis. It was found that: 1) the flow pattern map of non slugging (stratified and wavy flow), transition (wavy-slug flow), and slugging (slug and large-slug), were determined, here the transition flow pattern of slug and large-slug is defined as a initiating of water hammer, 2) transition area range of wavy-slug flow pattern are from  $\dot{m}_{co} = 1 \times 10^{-1}$  kg/s to  $\dot{m}_{co} = 6 \times 10^{-1}$  kg/s for  $\dot{m}_{st} = 6 \times 10^{-3}$  kg/s to  $\dot{m}_{st} = 7.5 \times 10^{-3}$  kg/s, and  $\dot{m}_{co} < 3 \times 10^{-1}$  kg/s for  $\dot{m}_{st} = 8 \times 10^{-3}$  kg/s to  $\dot{m}_{st} = 9 \times 10^{-3}$  kg/s. These obtained data are very important in order to develop a database for input in a safe early warning system design of two-phase flow piping installation system during the steam condensation.

### Keywords

Flow pattern map, slugging, steam-condensate, horizontal double pipe, water hammer

### 1. INTRODUCTION

Research in relation to the condensation heat transfer coefficient on a vertical pipe. The test section consisted of a vertical, double-pipe cylinder made of stainless steel SUS304 has been conducted by Nagae T, Murase M, Wu T, Vierow K. [1]. The inner tube was the heat transfer tube with inside diameter of 19.3 mm, wall thickness of 3.04 mm and height of 1.8 m. The mixture of steam and air flowed into the tube from the bottom inlet. The coolant water flows along the outer surface of the heat transfer tube. The temperature distribution in the axial direction under pressure of 0.1 MPa, at an inlet steam flow rate of 1.23g/s is found. Since the steam condenses and its partial pressure drops as it flows downstream, steam-air mixture temperature decreases accordingly. While the enthalpy of the steam is higher near the inlet, and thus the temperature decrease rate is low, the enthalpy decreases with the temperature decrease and the temperature decrease rate tends to grow higher.

More than five decades there have been studies efforts toward better understanding the mechanism of two-phase flow. Meanwhile because of the complex nature of two-phase flow, a complete understanding has not yet been achieved. Many investigations have postulated that the mechanisms are different for each flow regimes or pattern. Accordingly, there has been some success story in the formulating models for different flow regimes, and a number of corresponding flow maps for horizontal has been developed. A well known flow pattern map was proposed by Mandane et al. [2]. Furthermore, many of the maps are the product of visual observations and are, therefore, subjective in nature. By far the most commonly used methods to discriminate flow regimes, particularly in early years, were application of visual and high speed cameras. More modern methods use analysis of the time series on experimental data from X-ray, conductance probes, pressure transducers in attempt to classify the pattern objectively. Matsui [3,4] used differential pressure transducers, Tutu [5] used absolute pressure transducers, Brauner D., O. Shaham, and Y. Taitel [6] used conductance probes, Jones and Zuber [7] used an X-ray void measurement system for the vertical upflow in a tube. Elkow and Rezkallah [8] used a capacitance sensor to measure void fluctuation. In most

cases the analysis of the power spectrum density (PSD) function are usually employed to extract the periodic feature of a signal. Matsui [4] calculated the PSD and probability density function (PDF) of the transient pressure drop signal to identify flow pattern of two-phase flow in a vertical pipe. Franca F., Acikgoz M., Lahey R.T. Jr., Clause A. [9] and Cai, Y., Wambsgans M.W., Jendrzeczyk J.A. [10] employed PSD and other fractal techniques for flow pattern identification as well. Wang [11, 12] used Nonlinear analysis to analyze differential pressure fluctuations of two phase flow through a T-junction with the aim to make clear the two-phase flow behavior splitting at a T-junction. These results may be significant for better understanding the flow structure and also for establishing valid models different from conventional viewpoints.

Based on the above description, an investigation of steam condensation and two phase flow is very wide-ranging. Many things can still be explored to explain the phenomena of two phase flow, especially related to condensation, both in the geometry, orientation or position of the pipe, and condensation process. From those facts, the objectives of this research are to study the two-phase flow pattern map of steam-condensate flow in a horizontal double pipe.

## 2. METHODOLOGY

The experiment apparatus used in present experimental study is shown in Fig. 1 and the detail of the test pipe is in Fig. 2.

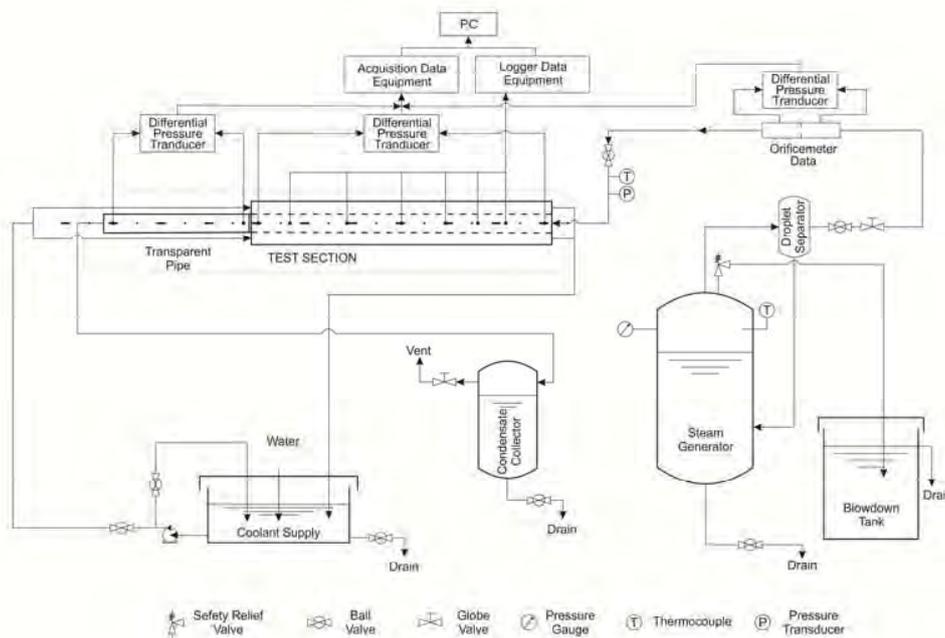

Figure 1: Experiment apparatus used in the present study

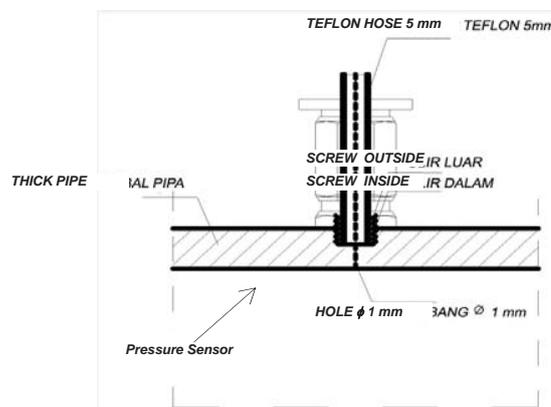

Figure 2: The detail installation of the differential pressure sensor

The Tested liquid was water. The experiment apparatus consisted of the inner annulus pipe made from copper ( $d_{in} = 17.2$  mm,  $d_o = 19$  mm) with a length of 1.8 m. The outer pipe annulus is a galvanized iron pipe ( $d_{in} = 108.3$  mm,  $d_o = 114.3$  mm) with a length of 1.6 m. In the present experimental study, the water was heated using a boiler to generate steam which was then flowed and condensed inside the annulus pipe to form a steam-condensate two-phase flow in horizontal pipe. The experiments were conducted at a static pressure of  $P_s = 108.825$  kPa dan the temperature of  $T = 119.7$  °C. The water was used as a coolant in the outer of annulus pipe. The pressure drop in the axial direction of the test was directly measured by using a differential pressure transducer with a sampling rate of 7.353 kHz.

### 3. RESULTS AND DISCUSSION

Flow pattern transition region map between non-slugging and slugging can be seen in Fig. 3. This map are derived from statistical analysis of pressure difference fluctuation data with the frequency domain (power spectra density) and time domain (root mean square, standard deviation, Skewness, Kurtosis and normal distribution). Based on the results of statistical analysis it can be concluded that at different cooling water mass flow rate ranging from  $\dot{m}_{co} = 1.24 \times 10^{-1}$  kg/s to  $\dot{m}_{co} = 5.78 \times 10^{-1}$  kg/s for steam mass flow rate less than  $\dot{m}_{st} = 6 \times 10^{-3}$  kg/s, the flow pattern is stratified or wavy flow that categorized as non-slugging. In the same range of cooling water mass flow rate, for steam mass flow rate  $\dot{m}_{st} = 6 \times 10^{-3}$  kg/s to  $\dot{m}_{st} = 7.5 \times 10^{-3}$  kg/s, the flow pattern is Wavy-slug that then classified as transitional. Furthermore, for the small cooling water mass flow rate (less than  $\dot{m}_{co} = 3 \times 10^{-1}$  kg/s) and for high steam mass flow rate ( $\dot{m}_{st} = 8 \times 10^{-3}$  kg/s to  $\dot{m}_{st} = 9 \times 10^{-3}$  kg/s) re-establish the wavy-slug flow pattern (transition) and stratified (non-slugging). However, for the large cooling water mass flow rate ( $\dot{m}_{co} = 4 \times 10^{-1}$  kg/s to  $\dot{m}_{co} = 6 \times 10^{-1}$  kg/s) and the steam mass flow rate ( $\dot{m}_{st} = 8 \times 10^{-3}$  kg/s to  $\dot{m}_{st} = 9 \times 10^{-3}$  kg/s), the flow patterns occurred slug or large-slug.

Next, for the small cooling water mass flow rate (less than  $\dot{m}_{co} = 2 \times 10^{-1}$  kg/s) and steam mass flow rates between  $\dot{m}_{st} = 7 \times 10^{-3}$  kg/s to  $\dot{m}_{st} = 8 \times 10^{-3}$  kg/s is also slug flow pattern occurred. Based on the above description, it can be concluded that the flow pattern that occurs is the start from stratified and Wavy (non-slugging), Wavy-slug (transitions) and slug or large slug (slugging). These data are very important to complete the database that can be used as an input in early warning system design for plant safety piping system. Next, visualization of flow pattern in a horizontal transparent pipe ( $d_i = 17$  mm, *plexiglass*) is shown in Fig. 4. Position of the transparent pipe is after the condenser pipe.

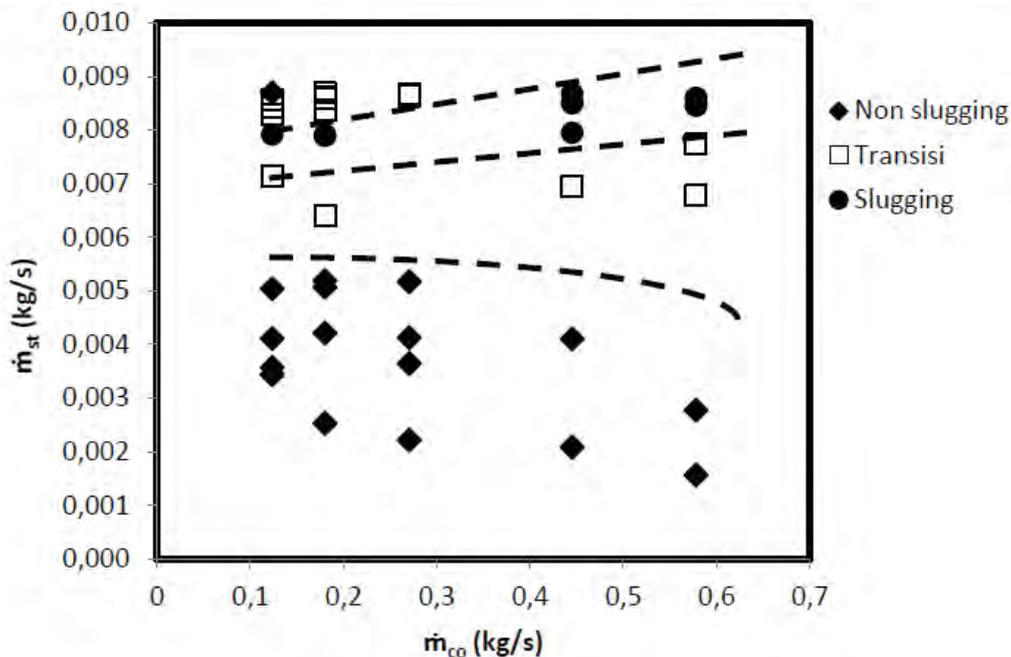

Figure 3: Flow pattern map of slugging and non slugging

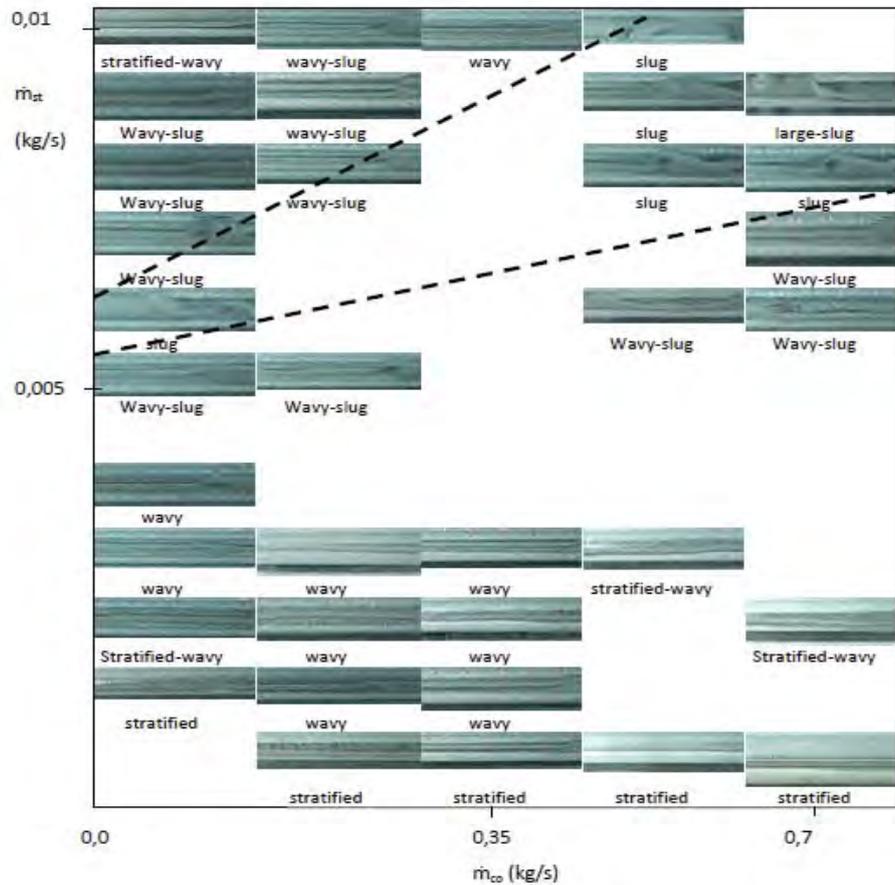

Figure 4: Visualization of flow pattern map

From this figure, it can be shown that the stratified, stratified-wavy dan wavy flow were obtained for the lowest of  $\dot{m}_{st}$  and the lowest to highest of  $\dot{m}_{co}$ . Meanwhile, for the highest of  $\dot{m}_{st}$  with the lowest of  $\dot{m}_{co}$ , the stratified-wavy dan wavy-slug were obtained. While, for the highest of  $\dot{m}_{st}$  and  $\dot{m}_{co}$ , the slug dan large-slug flow pattern were obtained. In addition, the wavy-slug flow pattern as transition from non-slugging to slugging flow pattern were obtained also for the medium of  $\dot{m}_{st}$  and lowest to highest of  $\dot{m}_{co}$ . Based on the analysis, it can be concluded that the flow pattern are stratified, stratified-wavy dan wavy (non slugging), wavy-slug (transition), slug and large-slug (slugging). These data are important for completing the database as input of early warning system design in two phase flow piping installation safety i.e. in the hotleg of pressurized water reactor (PWR), steam transportation, etc.

#### 4. CONCLUSION

As a result it was found as : 1) the flow pattern area of non slugging (stratified and wavy flow), transition (wavy-slug flow), and slugging (slug and large-slug), were determined, here the transition flow pattern of slug and large-slug is defined as a initiating of water hammer, 2) transition area range of wavy-slug flow pattern are from  $\dot{m}_{co}=1 \times 10^{-1}$  kg/s to  $\dot{m}_{co}= 6 \times 10^{-1}$  kg/s for  $\dot{m}_{st}=6 \times 10^{-3}$  kg/s to  $\dot{m}_{st}=7.5 \times 10^{-3}$  kg/s, and  $\dot{m}_{co} < 3 \times 10^{-1}$  kg/s for  $\dot{m}_{st}=8 \times 10^{-3}$  kg/s to  $\dot{m}_{st}=9 \times 10^{-3}$  kg/s. These obtained data are very important in order to develop the database for input the early warning system design in a safety of two-phase flow installation piping system during the steam condensation.

## ABSTRACT

Absorption chillers use thermal energy as driving source, and have a feature of being capable of saving electricity. Meanwhile, the global warming issue has worsened markedly in recent years, which causes us to be confronted with the urgent task of realization of low-carbon society. Under these situations, we developed single-double effect combined absorption chillers for "Solar air-conditioning system". This chiller is composed of a highly-efficient gas absorption chiller/heater with COP1.3 (gross calorific value) as a main machine. It enables low temp. solar hot water at 75degreeC under operation at the cooling rating (load factor: 100%, cooling water temp: 32degreeC). We constructed the demonstration plant in Japan. Cooling capacity is 738kW, and evacuated glass tube type solar energy collectors supply 75-90degreeC hot water to the absorption chiller. In summer, fuel gas reduction by 10% could be achieved and the results as estimated were obtained.

## Keywords

*Absorption chiller, Solar heat, Solar air-conditioning system, solar collector, Demonstration plant.*

## 1. INTRODUCTION

Absorption chillers are units to supply chilled water using gas and oil as fuel. In Japan, absorption chillers have been widely used for industrial and commercial central air-conditioning because they contribute to electric-load leveling in summer because of capable of cooling using little power, and use water having zero ozone depletion potential (ODP) as refrigerant.

Meanwhile, the global warming issue has worsened markedly in recent years, which causes us to be confronted with the urgent task of realization of low-carbon society. In Japan, power for air-conditioning accounts for 43% of total power consumption used for office buildings and absorption chillers are also strongly required saving-energy.

Under these situations, a solar cooling system which performs cooling by introducing hot water obtained from solar heat into absorption chillers using thermal energy as driving source has received increasing attention and undergone promotion of development toward practical use recently. This is because this cooling system is capable of using solar heat whose reserve amount is much abundant and whose energy conversion efficiency is higher among renewable energy for air-conditioning application with high power consumption rate in industrial and commercial fields.

We has developed a single-double effect combined absorption chiller exclusively designed for the solar cooling system and launched in June 2010. The aspect is shown in Figure 1.

We constructed the demonstration plant of this system in Japan. we report the outline and the performance of the chillers and demonstration plant.

Figure 1: Aspect of Solar Absorption Chiller

## 2. SOLAR ABSORPTION CHILLERS (SINGLE-DOUBLE EFFECT COMB-INED)

## 2.1 Use and Problem of Solar Heat

Among renewable energy, solar energy is rich in reserve, which undergoes promotion of application, however, it is almost applicable to solar battery (photovoltaic energy) but solar energy has been not picked up as the method for using as heat source so much. However, as shown in Figure 2, photovoltaic energy generation is as low as approx. 10% in generating efficiency and in case that solar energy is picked up as hot water at approx. 90°C, the energy conversion efficiency is as high as 40% and the high-end evacuated tubular type reaches 50%. The system using solar hot water as driving source is applicable only to absorption chillers practically. The conventional air-conditioning system is shown in Figure 3.

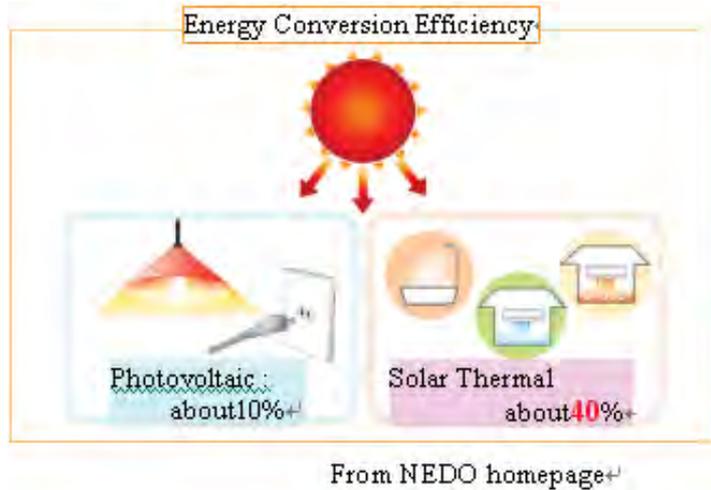

Figure 2: Solar energy conversion efficiency

However, solar heat is unstable heat source which is easily influenced by weather and it is difficult to use it according to fluctuating air-conditioning loads. Solar thermal air-conditioning system has been tried to be diffused since 1980's, however, they have been familiarized fully. The reasons are shown as follows:

- (1) As shown in Figure 3, in the solar thermal air-conditioning system, in addition to the absorption chiller, the backup boiler and accompanying machines are required, which causes the system composition to be complicated and the investment efficiency using renewable energy is not expected.
- (2) It is necessary to control the solar hot water and backup system according to fluctuations in solar heat and air-conditioning loads, however, it is difficult to control and establish an optimal control system to use solar heat efficiently, and it is necessary to familiarize local operators to learn as well.
- (3) The double-effect type which is mainly used as an absorption chiller, which requires heat at 120°C or more as driving source. In case that solar heat at approx. 90°C is used, only the single-effect system functions. In case that the backup system functions, even if fuel is used, the efficiency is low because of single effect system, the effect of introduction by renewable energy is not expected so much.

## 2.2 Improvement from Conventional System

In consideration with the problems in the above-mentioned solar thermal air conditioning, we developed single-double effect combined absorption chillers for using solar hot water preferentially in combination with backup heat source such as gas, oil, etc. (hereinafter referred to as the Solar Absorption Chillers). The improved system using them is shown in Figure 4.

Figure 3 ventional Solar Thermal Air-Conditioning System

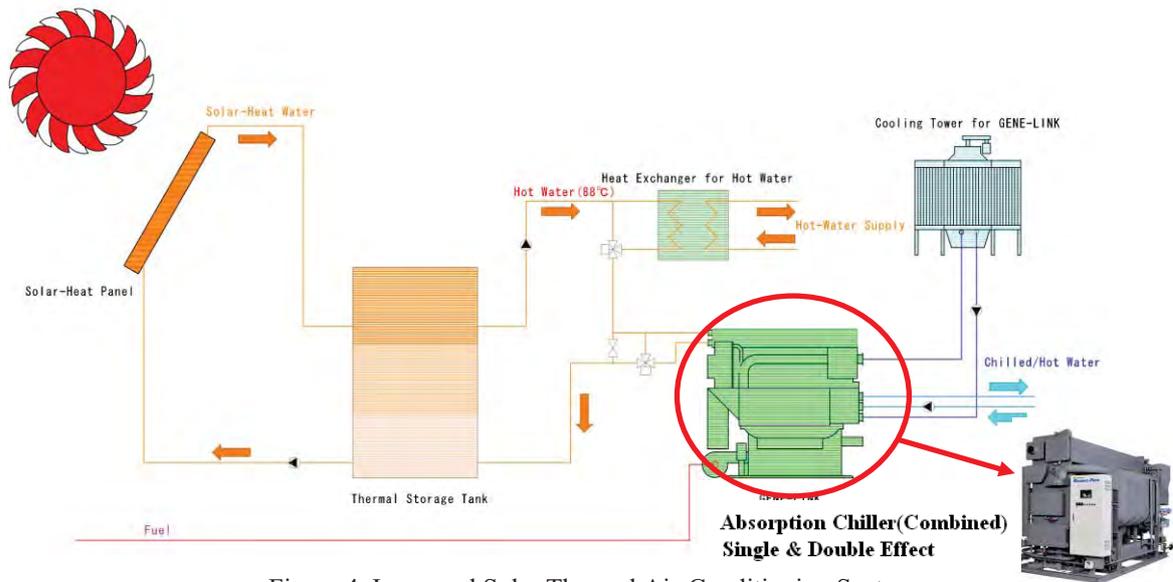

Figure 4. Improved Solar Thermal Air-Conditioning System

The features are shown as follows:

- (1) Since these solar absorption chillers are equipped with generators driven by solar hot water based on direct-fired absorption chillers, a backup system are unnecessary to be prepared, No. of composition elements are reduced, which simplifies the air-conditioning system
- (2) These solar absorption chillers control so as to use solar hot water preferentially based on driving by fuel such as gas, oil, etc. In addition, control of loading is performed according to fluctuations in air-conditioning loading.
- (3) When driving by fuel, double-effect operation is performed, the same efficiency as absorption chillers which are currently diffused is obtained, which allows saving energy operation because renewable energy is used.

### 2.3 Outline of Solar Absorption Chillers

Solar Absorption Chillers are composed of highly-efficient gas absorption chillers with COP1.3 (gross calorific value) as main machines which are equipped with a solar heat recovery unit comprising a heat recovery heat exchanger and special condenser.

As shown in the cycle-flow diagram in Figure 5, solar heat hot water is used for heating and regenerating absorbing solution at the heat recovery heat exchanger. Using refrigerant generated during this regeneration process for cooling enables the amount of fuel used for the high temp. generator to be reduced.

Generally, solar energy collectors have characteristics in which the smaller the difference in temperature between the collection temperature and outside air temperature is, the higher the collection efficiency is, therefore, it is necessary to allow solar absorption chillers to use even low temp. hot water to increase the efficiency of the overall system.

As chillers which are capable of reducing fuel consumption by introducing hot water, exhaust heat introduction absorption chillers (Gene-Link) can be considered, however, Gene-Links are products designed to use exhaust heat hot water at stably high temperature (83 to 90°C) obtained by cogeneration systems, etc. and cannot use low temp. hot water.

The reason is that Gene-Links are composed as shown in the principle drawing in Figure 6, in which refrigerant vapor generated at the heat recovery heat exchanger and refrigerant vapor generated at the low temp. regenerator are condensed in the condenser of the base absorption chillers. Therefore, the saturated temperature of the heat recovery heat exchanger is restricted by the saturated temperature of the condenser of this absorption chiller body, which prevents the log-mean temperature difference to collect low temp. hot water from being maintained.

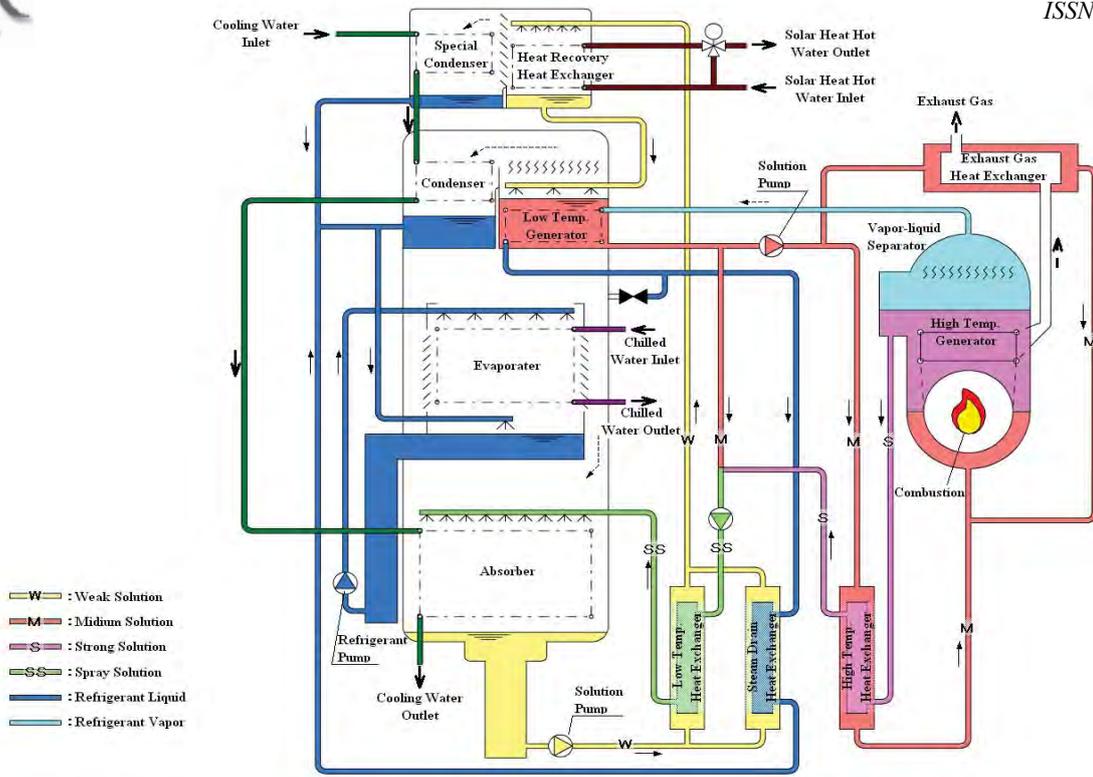

Figure 5: Cycle flow-diagram of Solar Absorption Chiller

Consequently, as shown in the principle drawing in Figure 7, in Solar Absorption Chillers, a condenser exclusive for the heat recovery heat exchanger is newly provided to separate the heat recovery unit and the base absorption chiller and a structure to initially introduce cooling water to the special condenser is employed, which reduces the pressure in the heat recovery unit and maintains the log-mean temperature difference to collect low temp. hot water.

As shown in Figure 8, these chillers enable low temp. hot water at 75°C under operation at the cooling rating (load factor: 100%, cooling water temp: 32 °C) or even lower temp. hot water depending on loading conditions and cooling water conditions to be used

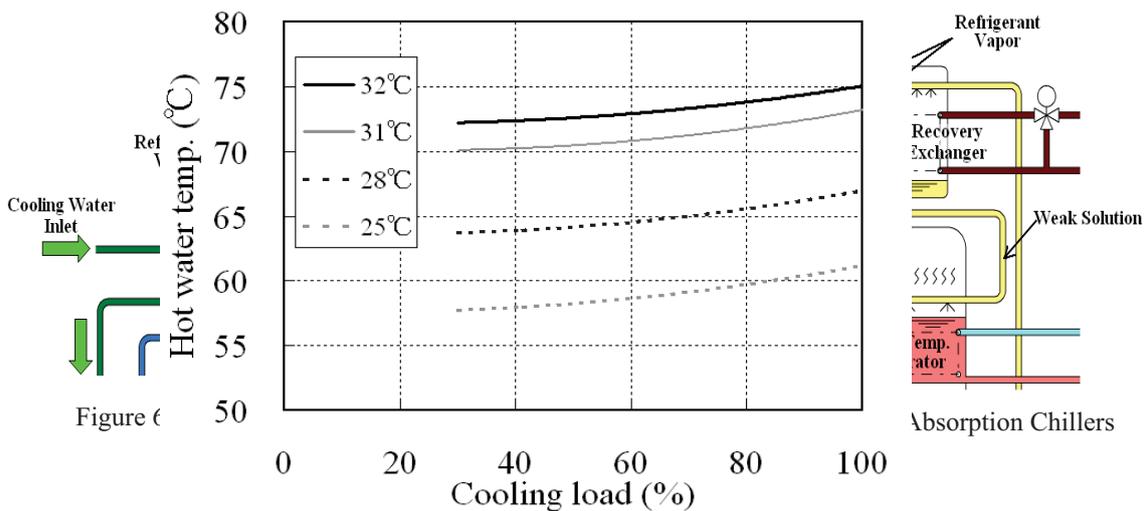

Figure 8: Hot water temperature for which Solar-Driven Hybrid Chiller can be used

### 3. SOLAR COOLING SYSTEM

#### 3.1 Outline of Solar Cooling System

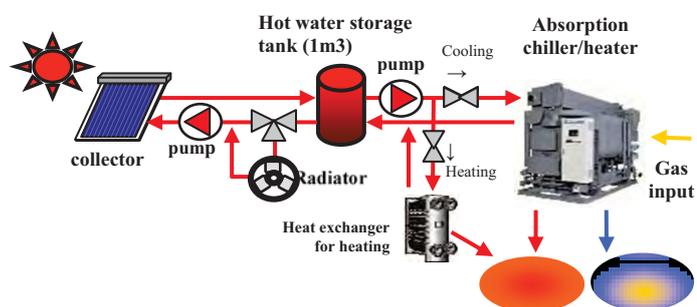

Figure 9: Schematic diagram of system

The demonstration plants are installed in our factory located in Kusatsu City of Shiga Prefecture, Japan. This system was completed in Dec. 2010 and started to undergo full-sized verification test in Feb. 2011. The flow diagram of this system is shown in Figure 9.

Solar heat (hot water at 75°C to 90°C) is introduced into the Solar Absorption Chiller. In addition, if solar heat is insufficient, the backup system to compensate for the energy through gas is available.

Evacuated glass tube type solar energy collectors which are highly efficient in a high-temp area at 75°C to 90°C is used for the solar energy collector. 160 sheets of collectors (260m<sup>2</sup>) which satisfy the exhaust heat recovery amount (0.6kW/RT, 126kW \*cooling water at 31°C) during rated operation in case of solar heat hot water of Solar Absorption Chiller at 75°C were installed on the roof of the office.

The hot water storage tank is provided to absorb the difference of flow rate between the solar energy collector and Solar Absorption Chiller and serves as a temporal cushion if solar radiation fluctuates suddenly.

The radiator is provided to prevent hot water from boiling by excessive heat collection by operating when collected solar heat cannot be used on holidays, etc.

Figure 10: Aspect of Collector

### 3.2 Feature of Solar cooling system

#### 3.2.1 Lowering the temperature of solar heat usable area

Collector	<evacuated tube> 1.62m <sup>2</sup> ×160 sets	total area: 260m <sup>2</sup> (aperture area: 213m <sup>2</sup> ) conductor: water tilt angle: 8° azimuth angle: SSE35° output(Max): 128kW
absorption chiller	cooling capacity 738 [kW](210RT)	

Generally, solar energy collectors have characteristics in which the smaller the difference in temperature between the collection temperature and outside air temperature is, the higher the collection efficiency is, therefore, it is necessary to allow solar absorption chillers to use even low temp. hot water to increase the efficiency of the overall system.

As section 2 already described, in the Solar Absorption Chiller in this system, solar heat at 75°C (rated) and approx. 60 °C (under partial loading) can be used by employing a hot water heat exchanger optimized for use of solar heat and improving the flow of cooling water.

#### 3.2.2 Simplifying and downsizing the solar system

The auxiliaries (Figure 11) such as pumps, etc. to supply hot water obtained from the solar energy collector to the Solar Absorption Chiller are required, however, those items are simplified as much as possible while considering packaging with the Solar Absorption Chiller.

Packaging after reflecting these verification results can reduce the details of work at site and costs for building up the system as one of targets.

#### 3.2.3 Controlling and Monitoring System

When introducing the solar cooling system, it was necessary to specially build up the control functions such as starting/stopping the heat collecting facility and excessive solar heat collection of the solar energy collector, however, these control functions are assembled into the Solar Absorption Chiller in this system and control of the overall system is enabled.

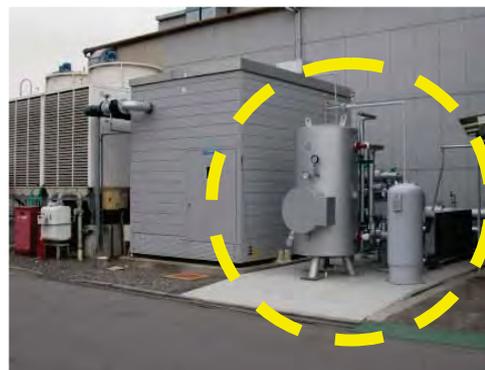

Figure 11: Collection of heat facility

Assembling the control functions into the Solar Absorption Chiller maximizes the saving energy effect based on the use of solar heat by strengthening the linkage with the control functions of the Solar

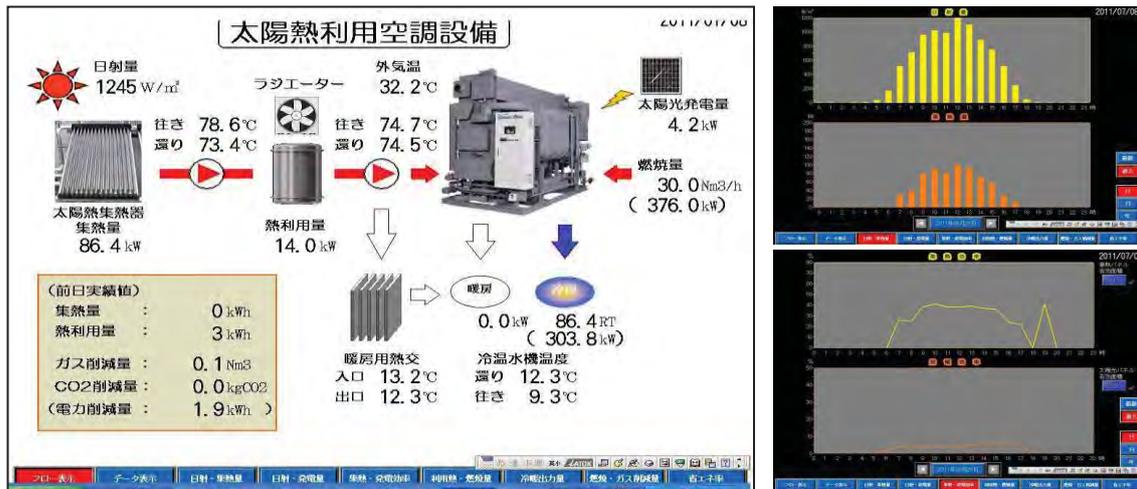

Figure.12: Monitoring System

Absorption Chiller in addition to eliminating the needs of the special control equipment.

Some examples of linkage control with the Solar Absorption Chiller added to this system are shown as follows:

- (1) Backup linkage at the Solar Absorption Chiller
- (2) Interlocking control in response to change in the temperature setting

Further, the system is equipped also with the information collection function to monitor the system operation status and energy-saving effect.

Figure 12 shows a part of the monitor system to display the collection data. The monitor system enables daily and hourly collection amount and efficiency to be displayed, which contributes to the grasping of operation conditions and review for improvement of system.

As mentioned above, when building up the solar cooling system, cost reduction is a big issue. Assembling the control system and monitor system into the Solar Absorption Chiller greatly serves to reduce the cost for building up the system.

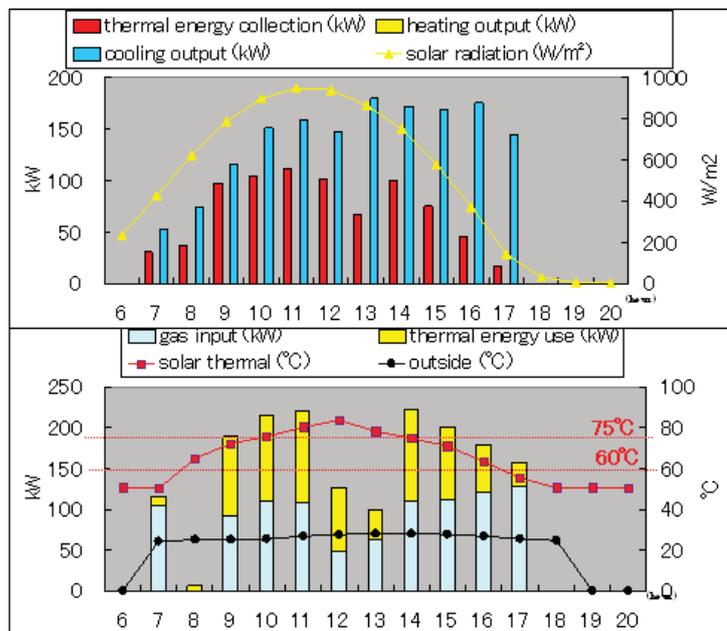

Figure 13: Operation data of cooling (20th May)

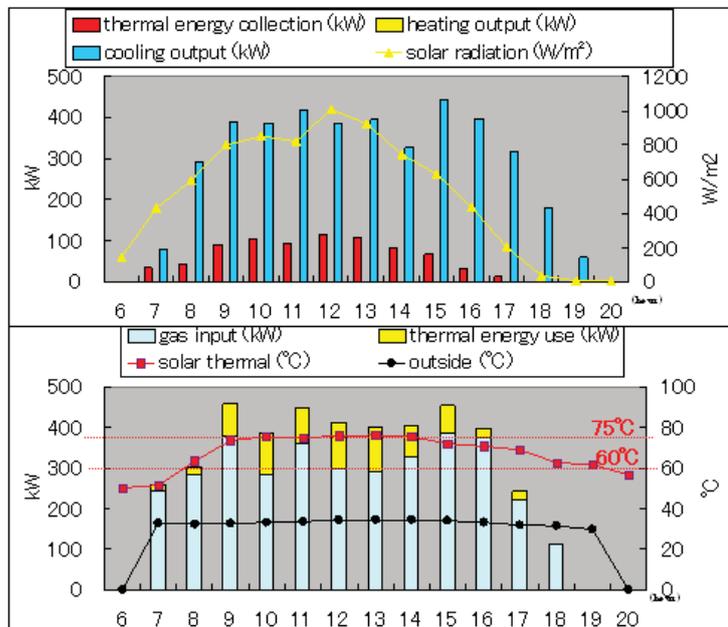

Figure 14: Operation data of cooling (28th July)

### 3.3 Evaluation status and results

#### 3.3.1 Operation conditions

Figure 13 shows the operation data on May 20 and Figure 14 shows the operation data on June 28. From the data, it was confirmed that the solar heat priority usage function and gas-based backup function operate properly and overall system functions normally.

Because of operations with comparatively-low loads on the conditions where the maximum temperature was 28.4°C and the air-conditioning loading factor was 23% on May 20, the gas amount could be reduced by 25%. Meanwhile, the maximum temperature was 34.5 °C and the air-conditioning loading factor was as high as 60% on June 28, however, the gas amount could be reduced by 11%.

Cooling operation starts in late May, therefore, the monthly reduction rate shows the data only in June, however, reduction by 10% could be achieved and the results as estimated were obtained.

#### 3.3.2 Effect of Solar Absorption Chiller

It was confirmed that hot water obtained from the solar energy collector is constantly used at 75°C or less and can be used even at approx. 60 °C during low-load operations.

In the actual system, the effect could not be quantified because fluctuation in solar radiation and load should be considered, however, use of Solar Absorption Chiller developed exclusively for use of solar heat can reduce the hot water temperature from the solar energy collector more than use of conventional exhaust heat introduction type absorption chiller (Gene-Link) , therefore, it was confirmed that this system increased the collection efficiency of the solar energy collector and improves the efficiency of overall system.

#### 3.3.3 Improvement points

When changing to the low-load operation mode where the refrigerant pump of the chiller activates the start/stop control, introduction of hot water is turned on and off interlinking with start/stop of the refrigerant pump, however, even in operable load only by solar heat hot water, it is confirmed that the pick-up temperature increases due to output delay when turning on and backup control by combustion activates. We plan to review the control to minimize the delay and add it to the system.

## 4. CONCLUSION

- (1) The Combination of the heat recovery exchanger and special condenser of Solar Absorption Chiller enables the machine to be operable even if the temperature decreases up to 75°C and does not require the backup by combustion gas in an area with 30% or less of load factor
- (2) In case where the temperature of hot water is 90 °C, the reduction rate of combustion gas at 100% load factor becomes 32%, therefore, the performance increased in comparison with 26% of the conventional Gene-Link. In addition, the cooling load area operable only by hot water was expanded to approx. 57%.
- (3) From the verification of the demonstration plant of solar cooling system, the usefulness of the Solar Absorption Chiller developed exclusively for use of solar heat was confirmed.
- (4) Further, we make sure that our built-up system is useful to make it easier to introduce a solar cooling system. By commercializing the system into which improvement points during verification were fed back in the future, we aim to make the solar cooling system to be recognized as a useful solution tool for global warming problem and promote them..

## ABSTRACT

The comparison between computer fluid dynamic (CFD) simulation and experimental heat transfer coefficient of natural refrigerants in minichannel was investigated in this studied. The experimental data were conducted in the horizontal circular small tubes of 1.5 and 3.0 mm inner diameter, the length of 1000 and 2000 mm, the conditions of experiment were described as following: the mass flux range from 200 – 650 kg/m<sup>2</sup>s, the heat flux varied from 5 to 40 kW/m<sup>2</sup> and saturation temperature changed from 0 to 10°C. The boiling heat transfer coefficient of natural refrigerant was evaluated and compared to CFD predictions. The results showed that the simulation were able to reproduce the general features acquired in the experiments.

**Keywords:** Heat transfer coefficient; Correlation; CFD simulation; natural refrigerant; minichannel.

## 1. INTRODUCTION

During the development of the refrigeration and air conditioning industry, refrigerants have gone to the 4<sup>th</sup> generation (James M. Calm, 2008). Due to the implement of Global warming and the Ozone depletion, the future refrigerants should meet the demand of the environmental criterions, such as: low global warming and Ozone depletion potential. In addition, the future ones also might to be compatible with new technology, market as well as passing the safety policy.

In improvement process of the next refrigerant generation, natural refrigerant; that has been used widely in refrigerant industry such as CO<sub>2</sub> and ammoniac, paid the considerable attentions to researchers. Many studies have been evaluating their fluid flow and heat transfer through the experimental and numerical methods recently.

Pettersen et al. (2004), Yun et al. (2005), Choi et al. (2007), Hihara et al. (2009) and Wu et al. (2011) investigated the heat transfer and pressure drop of CO<sub>2</sub> experimentally. Pamitran et al. (2011) estimated the evaporative heat transfer of three natural refrigerants include CO<sub>2</sub>, NH<sub>3</sub> and C<sub>3</sub>H<sub>8</sub>. The results were compared to many existing correlation and the modified correlation of heat transfer coefficient of three refrigerants also were developed.

He et al. (2005) and Masoud (2009) investigated numerically the convective heat transfer of CO<sub>2</sub> in a porous tube. Masoud used FLUENT code 6.1 to simulate the single phase flow and the force convective heat transfer of CO<sub>2</sub> at the supercritical pressure.

In this study, the comparison between CFD simulation and experimental heat transfer coefficient of two natural refrigerants CO<sub>2</sub> and NH<sub>3</sub> was presented. The effects of mass flux, heat flux, saturation temperature and inner diameter on the heat transfer coefficient were analyzed. The results of CFD simulation show a good agreement with experimental ones.

## 2. EXPERIMENTAL SETUP

### 2.1 Experimental facility

The experimental apparatus is comprised of a refrigerant loop, three water loops, and a data acquisition system. A schematic diagram of the refrigerant loop was shown in Figure 1. The refrigerant flow system consists of a condensing unit, receiver, refrigerant pump, mass flow meter, and pre-heater. Vapor phase refrigerant from the evaporative test

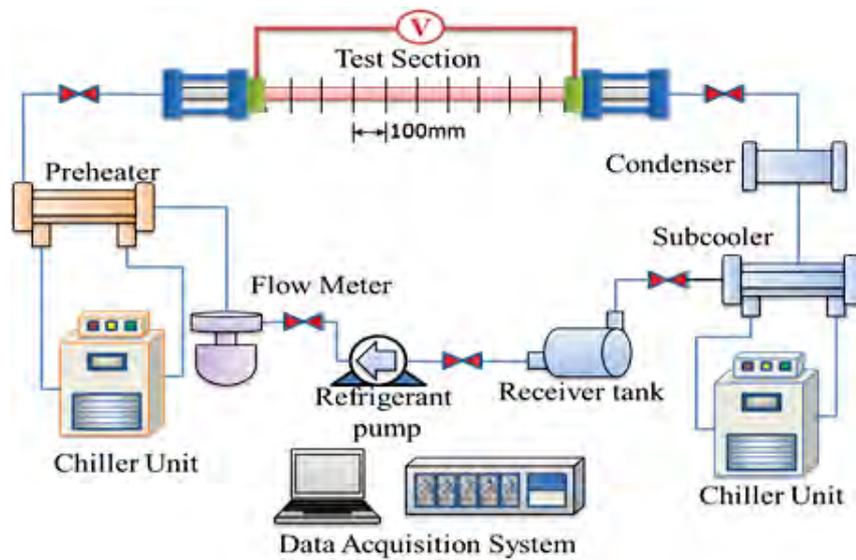

Figure1. Schematic of experimental apparatus

section was condensed into the liquid phase in the condensing unit. The condensed refrigerant was then supplied to the receiver and pumped by the refrigerant pump, which is connected to an electric motor controller used to control the flow rate of the refrigerant. A Coriolis-type mass flow meter was used to measure the refrigerant flow rate. The mass vapor quality at the inlet of the test section was controlled using a pre-heater. Temperatures of condenser, sub-cooler and pre-heater were adjusted by three individual water loops.

The test sections were made of circular stainless steel smooth tubes with inner diameters of 1.5 and 3.0 mm, a heated lengths of 1000 and 2000mm in the horizontal orientation. For evaporation at the test section, power was supplied from an electric transformer to the test section. The input electric voltage and current were adjusted to control the input power. The test section was well insulated with rubber and foam. The outside tube wall temperatures at the top and bottom side were measured at every 100 mm axial intervals of the heated length using thermocouples at each measured site. The local saturation pressure, which was used to determine the saturation temperature, was measured using Bourdon tube-type pressure gauges at the inlet and the outlet of the test section, as shown in Figure 1. A pressure transducer was installed to measure the pressure gradient of the refrigerant flowing along from the inlet to outlet of the test section. Sight glasses with the same inner diameter as the test section and a length of 200 mm were installed to visualize the flow and to enhance the flow stability of the fluid when entering the test section.

The physical properties of the refrigerant were obtained from REFPROP 8. The temperature and flow rate data were recorded using data acquisition and flow meter, respectively. Table 1 gives a summary of the estimated uncertainty associated with all the parameters at a 95% confidence interval. The uncertainties were obtained using both random and systematic errors, and these changed values according to the flow conditions, so their minimum to maximum ranges were shown.

## 2.2 Experimental data reduction

The local heat transfer coefficients at position  $z$  along the length of the test section were defined as follow, with  $q$  is heat flux and  $T$  is temperature.

$$h = \frac{q}{T_{wi} - T_{sat}} \quad (1)$$

The inside tube wall temperature,  $T_{wi}$  was the average temperature of the top, left sides, and the bottom wall temperatures, and was determined based on the steady-state one-dimensional radial conduction heat transfer through the wall with internal heat generation. The vapor quality,  $x$ , at the measurement locations,  $z$ , were determined based on the thermodynamic properties.

$$x = \frac{i - i_l}{i_{lv}} \quad (2)$$

Table1 Summary of the estimated uncertainty

Parameter	Uncertainty
$T_{wi}$ (%)	$\pm 0.18$ to $\pm 5.58$
$P$ (kPa)	$\pm 2.5$
$G$ (%)	$\pm 1.85$ to $\pm 9.78$
$q$ (%)	$\pm 1.67$ to $\pm 3.58$
$x$ (%)	$\pm 1.79$ to $\pm 9.89$
$h$	$\pm 1.78$ to $\pm 27.6$

The refrigerant flow at the inlet of the test section was not completely saturated. The subcooled length was calculated using the following equation to determine the initial point of saturation.

$$z_{sc} = L \frac{i_l - i_{li}}{\Delta i} = L \frac{i_l - i_{li}}{\left(\frac{q}{W}\right)} \quad (3)$$

In eq. (2) and (3),  $i_{li}$  is enthalpy and  $L$  is tube length.

### 3. NUMERICAL SETUP

In this study, the ANSYS FLUENT v14 was used to simulate force convective boiling heat transfer of the natural refrigerants in the minichannel. The Eulerian multiphase and the RGN  $k-\epsilon$  model for each phase were applied. A computer with Intel E3-Xeon 1230V2 (8Mb cache, 3.3 GHz) with 16 GB ram was used in this simulation.

#### 3.1 Computational grid

The geometry was created in ANSYS WORKBENCH 14 and meshed later in ANSYS MESH ICEM. In this simulation, both the pipe and the fluid control volume were modeled. The meshing of domains was shown in Figure 2. The inflation with 5 layers was used at the fluid region near tube wall. The interior of fluid and pipe was meshed by sweep method. The grid was composed of 97497 nodes and 90022 elements. The maximum and minimum skewness values were reported at 0.53 and  $2.7 \times 10^{-2}$ , respectively. This meshing solution was selected after comparing to some further refinements.

#### 3.2 Wall boiling models

In this study, the two-phase flow convective boiling of the mini tube was carried out in five conditions of CO<sub>2</sub>. The solver was set up in steady state, pressure base type with an absolute velocity formulation. The properties of materials obtained in REFPROP 8 were set up in piecewise-linear mode for each phase. To model multiphase flow, the Eulerian model was used with boiling parameter. The wall boiling in nucleate boiling regime was modified from the model of Kurul and Podowski. To resolve for departed nucleate boiling regime, its formulation extended by Lavieville et al was used. The total wall heat flux was defined as following equation:

$$q_w = (q_c + q_Q + q_E) f(\alpha_l) + (1 - f(\alpha_l)) q_v + q_G \quad (4)$$

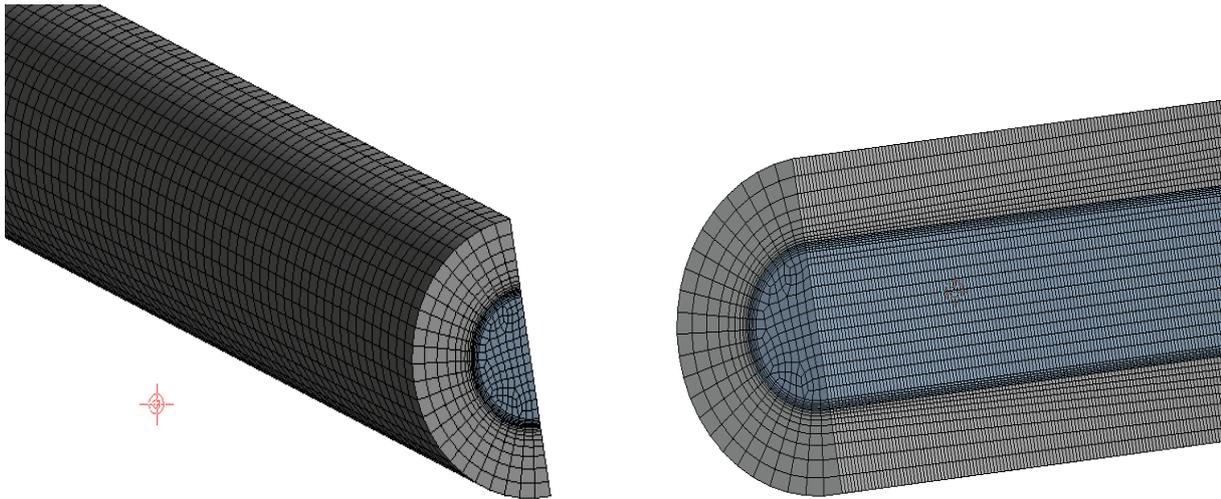

Where  $q_c$ ,  $q_Q$ ,  $q_E$  are convective heat, quenching heat flux, evaporative heat flux in the single phase, respectively.  $q_c$  models the heat flux transferred to the near wall liquid phase outside of nucleating bubbles influence area  $A_b$ .  $q_c$  was expressed as:

$$q_c = h_c (T_w - T_l) (1 - A_b) \quad (5)$$

Here,  $h_c$  is single phase heat transfer coefficient.  $T_w$  and  $T_l$  are the temperatures of wall and liquid phase near the wall, respectively.

The quenching heat flux  $q_Q$  in Eq. (4) models the cyclic averaged transient energy transfer related to liquid filling the wall vicinity after bubble detachment defined by equation:

$$q_Q = \frac{2k_l}{\sqrt{\pi \lambda_l T}} (T_w - T_l) \quad (6)$$

**Figure 2** The grid of test section

Because the velocity and temperature profiles in the bubbly boundary layer deviate from single-phase counterparts, the quenching model correction was used with the  $y^+$  value fixed to 250 as default. The evaporative flux  $q_E$  is determined as:

$$q_E = V_d N_w \rho_v i_{lv} f \quad (7)$$

In the Eq. (4),  $q_v$  and  $q_G$  present the convective heat flux of vapor phase and any others possible gas phase in a system, respectively. These parameters can be derived as:

$$q_V = h_V (T_W - T_V) \quad (8)$$

$$q_G = h_G (T_W - T_G) \quad (9)$$

The function  $f(\alpha_l)$  was proposed by Lavieville et al. (2005). That value could depend on the local liquid volume fraction  $\alpha_l$  with similar limiting values  $\alpha_{l,crit}$  as the the liquid volume fraction. The critical value for the liquid and vapor volume fraction is 0.2 and 0.8, respectively.

$$f(\alpha_l) = \begin{cases} 1 - \frac{1}{2} e^{-20(\alpha_l - \alpha_{l,crit})} & \alpha_l \geq \alpha_{l,crit} \\ \frac{1}{2} \left(\frac{\alpha_l}{\alpha_{l,crit}}\right)^{20\alpha_{l,crit}} & \alpha_l < \alpha_{l,crit} \end{cases} \quad (10)$$

The area of bubbles influence is defined as

$$A_b = \min \left( 1, K \frac{N_w \pi D_w^2}{4} \right) \quad (11)$$

The size of the bubble influence area around the nucleation site on the heated wall  $K$  is defined based on the Del Valle and Kenning's study. According to his study,  $K$  varies between 1.8 and 5:

$$K = 4.8 e^{\left(-\frac{Ja_{sub}}{50}\right)} \quad (12)$$

Here,  $Ja_{sub}$  is the subcooled Jacob number and defined as

$$Ja_{sub} = \frac{\rho_l c_{pl} (T_{sat} - T_l)}{\rho_v i_{lv}} \quad (13)$$

The nucleate site density  $N_w$  is presented by a correlation based on the wall superheat. In Lemmert and Chawla's study, the empirical parameters  $n$  and  $C$  were set equal 1.805 and 210, respectively

$$N_w = C^n (T_w - T_{sat})^n \quad (14)$$

In Eq. (11),  $D_w$  is the bubble departure diameter. It is defined by the model of Tolubinski as:

$$D_w = \min \left( 0.0014, 0.0006 e^{-\frac{Ja_{sub}}{45}} \right) (\text{mm}) \quad (15)$$

The frequency of bubble departure is denoted by  $f$  parameter based on Cole study.

$$f = \frac{1}{T} = \sqrt{\frac{4g(\rho_l - \rho_v)}{3\rho_l D_w}} \quad (16)$$

### 3.3 Interfacial area

The interaction between two-phase is modeled with the interfacial forces including drag force  $\vec{F}_D$ , lift force  $\vec{F}_L$  and turbulence drift forces,  $\vec{F}_{iv}^{TD}$ . The drag force was denoted as:

$$\vec{F}_D = \frac{3}{4} \frac{C_D}{d_b} \alpha_g \rho_i |\vec{u}_g - \vec{u}_i| (\vec{u}_g - \vec{u}_i) \quad (17)$$

Where  $d_b$  is the Sauter men bubble diameter from the interfacial area transport equation and  $C_D$  is the drag coefficient. In this study, the drag force of Ishii and Zuber correlation was used. The lift force can be calculated as

$$F_{iv}^L = -F_{iv}^L = -C_L \alpha_v \rho_i (\vec{u}_v - \vec{u}_i) \times (\nabla \times \vec{u}_i) \quad (18)$$

The lift coefficient  $C_L$  was determined via correlation of Tomiyama et al. It combines the action of classical aero dynamic lift force and the interaction between the bubble and the vortices shed by the bubble wake. The equation is described as:

$$C_{Lift} = C_{LF} + C_{WK} \quad (19)$$

The turbulence drift force in ANSYS FLUENT Eulerian multiphase model is based on the correlation of Simonin. It was modified from Rhee and Chow correlation to stable the volume flux calculation. This study used the default turbulent drift force model:

$$\vec{F}_{iv}^{TD} = -\vec{F}_{vi}^{TD} = -C_{TD} \rho_1 k \nabla \alpha_v \quad (20)$$

Here, the turbulent dispersion coefficient  $C_{TD}$  is set to 1.0 as default value.

## 4. RESULTS AND DISCUSSION

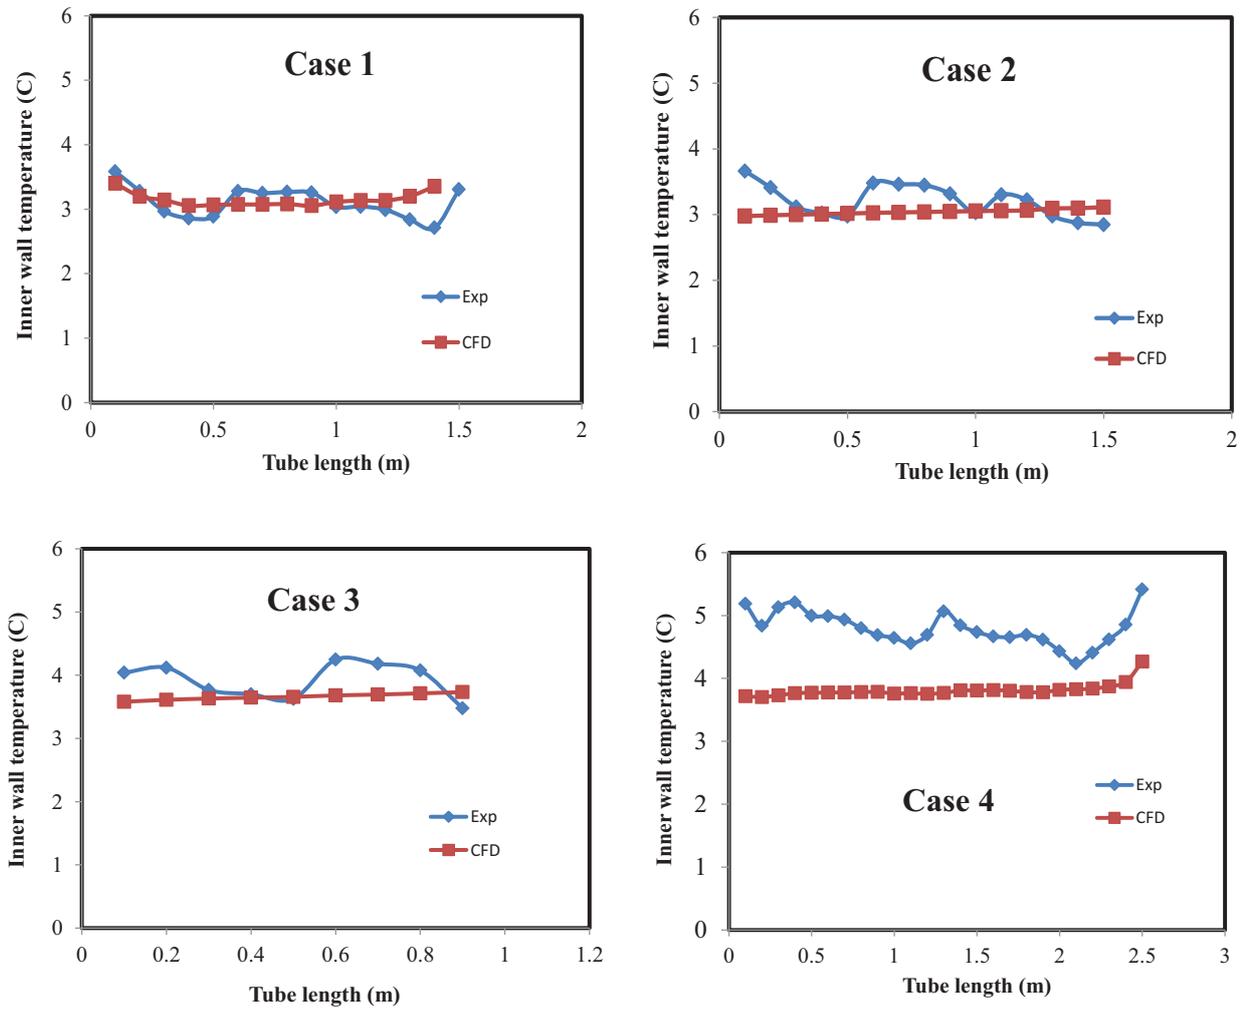

According to the explanation above, four experimental testing results of CO<sub>2</sub> analyzed in the discussion were simulated in ANSYS FLUENT for a comparison. The details of testing conditions were shown in the table 2.

Figure 3 illustrated the comparison of inner tube surface temperatures between the experimental test and CFD simulation. Both the temperatures of experimental test and CFD are average values taken at the top, mid and bottom of the test section. The results showed a good prediction of CFD simulation exception of case 4. This experimental temperature of case 4 is higher than the simulated one.

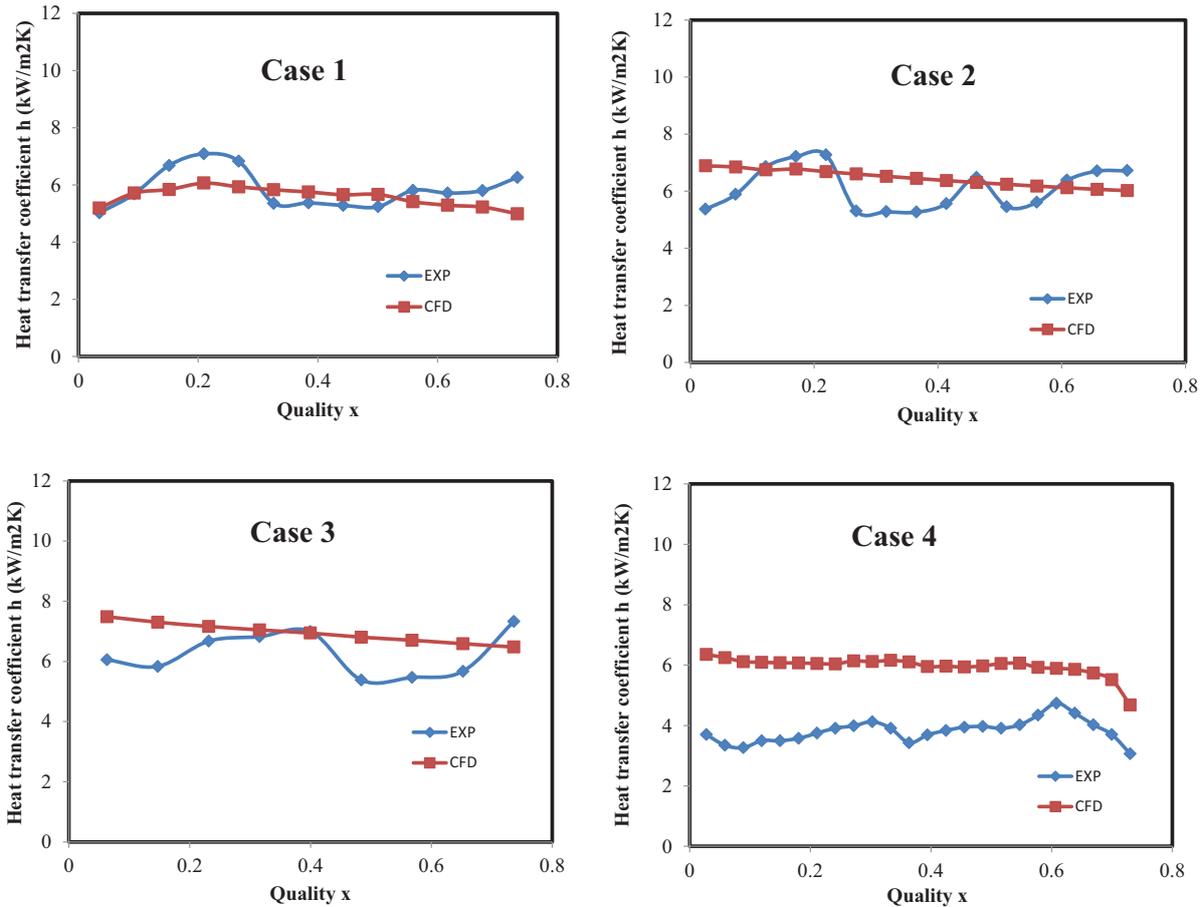

The comparison of heat transfer coefficient between the experimental test and the CFD simulation was depicted in Figure 4. The heat transfer coefficient in simulation results showed the closed values to the experimental ones.

**Table 2.** Experimental conditions

Case	Refrigerant	Diameter(mm)	Tsat (°C)	q (kW/m <sup>2</sup> )	G (kg/m <sup>2</sup> s)	T inlet (°C)
1	CO <sub>2</sub>	1.5	0	10	400	3.58
2		1.5	0	10	500	3.66
3		1.5	0	15	400	4.04
4		3.0	0	10	400	5.18

**Figure 3** Comparison of inner wall surface temperature between experimental test and CFD simulation in four cases (table 2).

**Figure 4** Comparison of heat transfer coefficient between the experimental results and CFD simulation in four cases (Table 2)

## 5. CONCLUSIONS

In this study, the convective heat transfer coefficient of two natural refrigerants CO<sub>2</sub> and NH<sub>3</sub> were carried out through experimental test and CFD simulation. The effect of mass flux, heat flux, inner tube diameter and the saturation temperature were analyzed. The results presented that the heat transfer coefficient increased with the increasing of mass flux, heat flux, saturation temperature and the decreasing of inner tube diameter. The Eulerian model in FLUENT was used to simulation the convective boiling heat transfer. The prediction shows a good result comparing to the one of experimental test.

## ABSTRACT

The flame flashback of premixed Air/LPG in acrylics tube tubes of Bunsen burner is investigated experimentally with a variation of tube's diameters (10 mm; 15 mm and 20 mm). The quantitative numerical results for the flame depth of penetrations and the flame propagation velocity are presented in this paper were calculated based on the predictions using empirical formulas of non dimensional factors, such :  $X_p/d_b$  ;  $S_p/U$  ; dilution coefficient,  $\phi$  ; Froude numbers,  $Fr$  ; and Lewis numbers,  $Le$  . In previous experiments, it has been known that fuel air mixture getting lean have an influence that the flame penetration distance,  $X_p$ , will be smaller. However, the flame propagation velocity,  $S_p$ , will be higher. The visualization of the flame's based position which is not attach anymore to the burner tip, rather move down and tilted flame tip stabilized in vertical tube were captured the imaging of flame using digital camera Canon EOS 60 Da, with image stabilizer ultrasonic EF 28-135 mm f/3.5 – 5.6 IS USM lenses, and the result is presented also in this paper.

## Keywords

Flame flashback, Premix Air/LPG flame propagation , Empirical formulas.

## Nomenclature

$X_p$	flame penetration distance [mm]
$S_p$	flame propagation velocity [mm/s]
$d_b$	diameter of tube [mm]
$U$	unburned gas velocity [mm/s]
$\phi$	dilution coefficient
$Fr$	<i>Froud</i> number
$Le$	<i>Lewis</i> number
$Da$	<i>Damkohler</i> number

## 1. INTRODUCTION

Liquefied Petroleum Gas or LPG is one of fuel which widely used for many different applications such as household needs, motor vehicle and industries [1]. Indonesia's government also has policy about conversion kerosene to LPG for household need or cooking [2]. LPG consists of propane and butane which is stored in liquid form by pressurization. Liquefied petroleum gas, or LP gas, is one of the most common alternative fuels used in the world today. In fact, in many places, it isn't an alternative fuel at all. Beside of alternative fuel, future combustion also concern about lean premixed at which this issue brings to fuel variability and reduce pollution. However, lean premixed burners require the flammable mixture to be prepared upstream the combustion chamber or flashback.

Flashback is a combustion condition at which the flame propagates upstream against the gas stream into the burner tube [3-4]. This phenomena is a critical issue for premixed combustor designs because causes serious hardware damage. Flashback may occur due to (i) boundary layer flame propagation (critical velocity gradient), (ii) turbulent flame propagation in core flow, (iii) combustion instabilities and (iv) upstream flame propagation induced by combustion induced vortex breakdown. Flashback due to mechanism has been studied for pure fuels [3], hydrogen blended [5-6], *synthetic gas* [7]. Those researches related to

composition, gas velocity and burner variation (swirl burner). Numerical simulation on flashback phenomena also has been investigated [8-10]. However, combustion with LPG fuel on flashback propensity is largely unknown.

In previous experiments, it has been known that fuel air mixture of LPG flame flashback getting lean have an influence that the flame penetration distance will be smaller and caused the flame propagation velocity will be higher [11-12]. Motivated by previous study, the following study presents flame flashback of premixed air-LPG on Pyrex tube with variation of ratio air-LPG and tube's diameter particularly for flame flashback limit. Upstream velocity and depth of penetration of flame will be also discussed.

## 2. EXPERIMENTAL METHOD

The burner is a vertical Pyrex tube 0.5 m long, and having variation of inner diameter 10 mm, 15 mm and 20 mm. The mixture of air-LPG is injected through the base of the tube. Mixture is assumed fill all of the tube.

Canon EOS 60 Da 18 megapixels is used to record flame flashback on LPG combustion. This camera has CMOS sensor with *digit 4* processor. *Canon EF 28-125 IS USM* is used as lens connected to the camera. The camera is placed in front of the tube to visualize any phenomena. The shutter speed is set to 1/60s with ISO 6400.

The experiments conducted by supplying mixture air-LPG into the burner. Flow rate of air and LPG are appropriate themselves by *rotameter* for air and *Dwyer RMA-2" flowmeter* for LPG. *Rotameter* is connected to *Bunsen burner Flame Propagation and Stability Unit P.A. Hilton Ltd C551* directly. Air and gas enter to Bunsen burner and then burn as shown in Pyrex tube. Flashback is occurred when the flow rate is gradually reduced and this critical flow rate cause the flame enters the tube and propagates along the wall. The flame movement can be stopped at any vertical location along the tube by rapidly increasing the flow rate to a value above critical. This procedure can observe a stationary inclined flame stabilized on the wall in a velocity gradient. Setup experiment and scheme of experiment are shown in Fig. 1 and Fig.2.

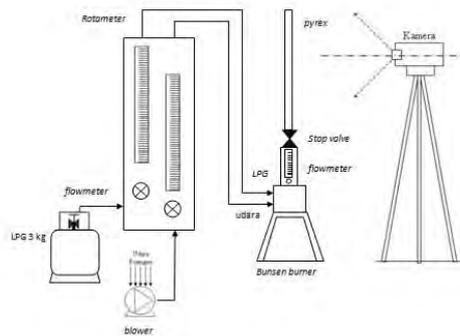

Fig. 1 Setup experiment

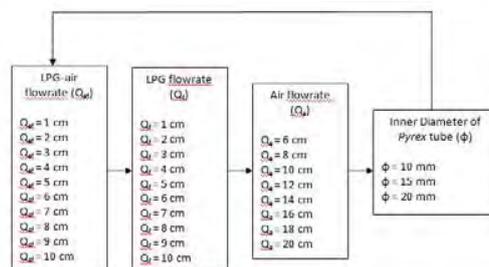

Figure 2: Scheme of experiments (by scale flow meter and rotameter)

## 3. RESULTS AND DISCUSSION

Flame propagation or flashback data were processed by convert video into still image. Result was obtained as depth of penetration or flame penetration distance and flame propagation velocity. Software *Zoombrowser EX* and

ImageJ are used to process the result. Visualization on this experiment showed that flame flashback occurred along the wall of Pyrex tube.

Experiments on a Pyrex tube with a diameter of 10 mm showed that the reduction in the fuel flow rate does not caused a flashback phenomena. In this experiment, the flame will show the lift-off phenomena and then followed by a blow-off flame. The flame will be extinguished immediately. This occurrence can be seen in Fig. 3.

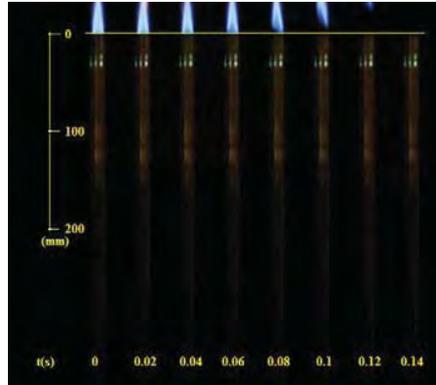

Figure 3: Blow-off phenomena on the tube with a diameter of 10 mm

In a tube with a diameter of 15 mm and 20 mm flashback phenomena occurred in certain air-fuel ratio. Examples of phenomena can be seen in Fig. flashback. 4.

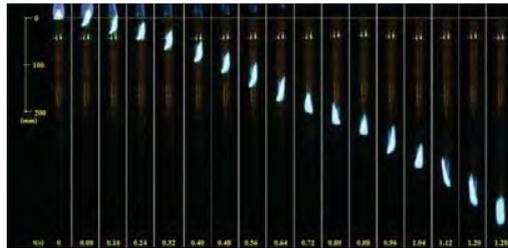

Figure 4: Examples of flashback phenomena on the tube diameter 15 mm

Burning load versus air fuel ratio on flame flashback experiments at the fuel mass rate range 0-0.024 kg/s for the diameter tube 15 mm and 20 mm can be seen in Fig.5. The air mass rate has range 0 – 0.3766 kg/s.

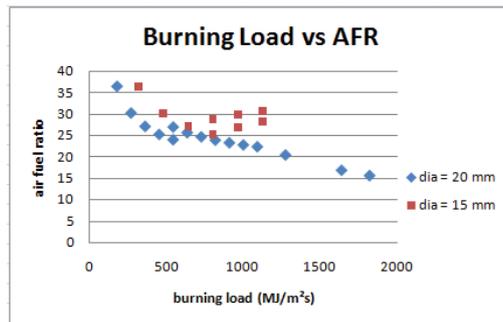

Figure 5: Burning load versus air fuel ratio on flame flashback experiment

Based on Fig.5, it can be shown that the tube with a diameter of 20 mm has the greater burning load when the air fuel ratio getting smaller as the limit of flashback phenomena. Whereas flame flashback on the tube with a diameter of 15 mm occurred when the fuel mass rate has range 0-0.0084 kg/s. these data obtained was not as much flame flashback data on the tube with a diameter of 20 mm.

The relationship between time and flame penetration in flashback phenomena with burner tube 15 mm and 20 mm are shown in Fig.6 and Fig.7. In the burner tube diameter of 15 mm, different charts shown on air fuel ratio AFR = 27.016 or the mass

rate of air 0.1305 kg / s and the rate of fuel mass 0.0048 kg / s. Meanwhile, other fuel blends show a nearly proportional relationship.

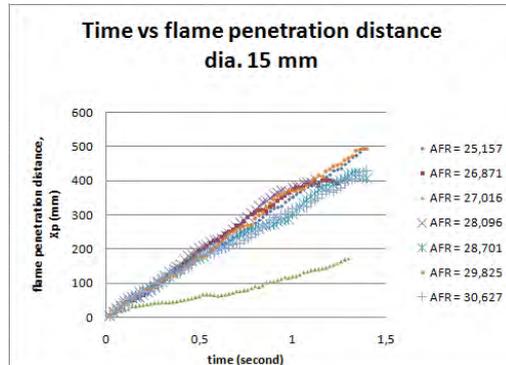

Figure 6: Time versus flame penetration distance in diameter 15 mm

Based on Fig. 7, the greatest flame penetration distance shown in AFR = 25.564 or the air mass flow rate 0.2161 kg/s and the fuel mass flow rate 0.0084 kg/s.

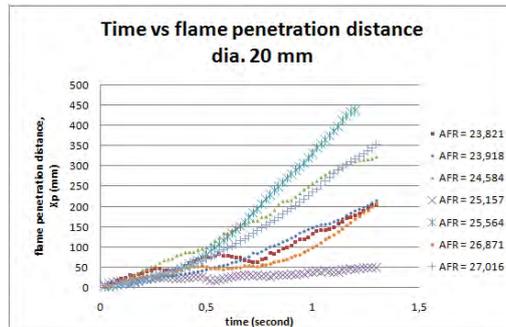

Figure 7: Time versus flame penetration distance in diameter 20 mm.

The relationship between time and flame propagation velocity on the diameter of 15 mm is shown in Fig. 8. Form of a graph is the same as Fig. 6, only the value of the flame propagation velocity reaches 25 m/s at AFR = 29.825 or air mass flow rate 0.2161 kg/s and the mass flow rate of fuel 0.072 kg/s. Meanwhile, the smallest value at the same time shown on the graph with the air fuel ratio AFR = 27.016 or the mass rate of air 0.1305 kg/s and the fuel mass rate of 0.0048 kg/s.

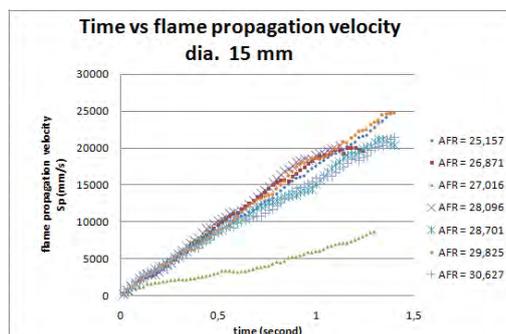

Figure 8: Time versus flame propagation velocity in diameter 15 mm

The relationship between time versus flame propagation velocity of tube diameter 20 mm is shown in Fig. 9. The greatest flame propagation velocity occurred when AFR = 25.564 or the air mass flow rate 0.2161 kg/s and the fuel mass flow rate 0.0084 kg/s. While the smallest flame propagation velocity is shown in AFR 25.157 or air mass flow rate 0.1519 kg/s and the mass flow rate of fuel 0.006 kg/s.

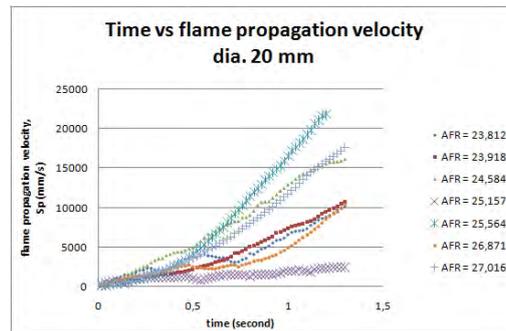

Figure 9: Time versus flame propagation velocity in diameter 20 mm

#### 4. SUMMARY AND CONCLUSION

From the analysis of the results is concluded:

- There is no flame flashback in a tube with a diameter 10 mm, however, there was a blow-off phenomena occurred.
- The relationship between time and flame penetration distance and the relationship between time and flame propagation velocity on the tube diameter of 15 mm, has a graphic that huddled together except the AFR = 25.564 or the air mass flow rate 0.2161 kg/s and the mass flow rate of fuel 0.0084 kg/s.
- Furthermore, empirical formula will be defined based on experiment data to obtained the relationship between air fuel ratio, flame penetration distance and flame propagation velocity, include dilution coefficient,  $\phi$  ; Froud numbers,  $Fr$  ; and Lewis numbers,  $Le$ .
- Numerical simulation of flame flashback phenomena on LPG combustion will be also presented as comparison by experiment.

kasai@material.tohoku.ac.jp*

Iron ore sintering process is a major supplier of the agglomerate burden to the blast furnace. The heat source of the process is mainly coke and therefore it emits a certain amount of CO<sub>2</sub>. Because of a large mass of the sinter production, the ratio of CO<sub>2</sub> emission in an integrated steelworks is nearly 20% and it occupies about 3% of the total emissions in Japan. Biomass will be an alternative energy source of the process since it is recognized as a carbon neutral fuel. Another possibility is metallic iron and lower oxides of iron contained in mill scales. Problems when using such fuels and their possible solutions are discussed. Further, updated technologies for the reduction of CO<sub>2</sub> emissions in the sintering process of iron ores are introduced.

### ABSTRACT

So far material science is promoted by mixing of different atoms as alloys, compounds, and composites. The basic mechanism of the processes of these materials is electronic interactions of outer-electron system of component elements and electronic information of elements is summarized as *Periodic table*. The electronic interactions in these materials are classified into ionic bonding, covalent bonding, and metallic bonding. The state of bonding between two atoms is evaluated by transfer integral of electron wave functions, if electronic picture is approximated by atomic like one.

Growth processes of practical multi component materials are dominated by *Energy*, which includes two pictures; dynamical picture includes potential energy and kinetic energy, and electromagnetic picture includes electronic energy and magnetic energy. Quantum dynamic theory (QD) unified these two contradictive pictures as Schrödinger equation. Thus, although QD is the most advanced tool to understand the fundamental process of materials, for understanding of processes and characteristics of materials we use a simplified picture of electronic structures. In the case of application of outer-core electron systems of component elements, the energy for growth or synthesis is *Thermal level*, less than 0.25 eV. On the other hand, in that of inner-core electron systems the energy is much higher than the thermal level, which will be higher than ~10 eV. The most apparent proof of the collision processes related to the inner-core electron system is that the reaction probabilities of inner-core electron systems depend on the discrete energies of the electron systems. Besides the transition probability of an electron between the initial state to the final state should obey the selection rule. From these reasons, the experimental results should clearly show discrete energy dependences.

For obtaining the apparent discrete energy dependences of the condensate, the production after the collision should be quenched and fixed the result of the reaction. We propose the surface ion recombination process on the insulative substrate for these requests. Following is the summary of the procedures and the result of condensation of inner-core electron excited zinc films

#### Boundary conditions for correlated condensation of excited zinc atoms.

In ion recombination process, Zn<sup>-</sup> ions are fixed on the Al<sub>2</sub>O<sub>3</sub> substrate with 6.5<sup>□</sup> diameter by using positive bias potential. The density of Zn<sup>-</sup> ions shows concentric distribution. The electric field generated by the negative charge is perpendicular to the surface, parallel component of the electric field is cancelled each other. Therefore, ion recombination on the substrate surface produces the oriented condensate perpendicular to the growth surface.

#### Energy dependence of the condensation processes.

Total energy of the ion recombination process is controlled by the bias potential of the substrate. The substrate surface is electrified by the incident electrons up to the same potential energy with the inverse potential. Electron configurations of Zn<sup>-</sup> and Zn<sup>+</sup> are (Ar)3d<sup>10</sup> 4s<sup>2</sup>4p and (Ar)3d<sup>10</sup>4s<sup>1</sup>, respectively. These electron states are the final states of inner-core electron states which are excited. Quantum dynamic selection rule,  $\Delta l = \pm 1$ , select transition path of an excited electron. We observed enhanced condensation processes at 10 eV, 90 eV, 100 eV, 140 eV, and 230 eV.

#### Crystal structures of the condensates.

Strong diffuse scattering of X-ray diffraction intensities were observed at the condensations with 10 eV, 90 eV, 100 eV and 230 eV. Enhanced Bragg diffraction intensities of X-ray were observed 10 eV, 100 eV, 140 eV and 230 eV. From analysis of these results, enhancements of diffuse scattering were induced by the transition from 3p (90 eV) state of Zn atom to 4s<sup>1</sup> in Zn<sup>+</sup>, and the enhancements of Bragg diffraction were induced by that to 4p state of Zn<sup>-</sup> from 3d (10eV) or 3s (140 eV), respectively.

#### Electronic structures of the condensates.

Unique energy dependences of X-ray diffraction intensity show single excitation process and double one. We confirmed the electronic structure of the condensates by using X-ray photoelectron spectroscopy (XPS). We confirmed inner-core excited states of zinc atom in the case of double excitations only. The lifetime of the excited state induced by the single excitation process is too short to confirm by XPS. Three excited states were found, 3d<sup>10</sup>L, 3d<sup>9</sup>, 3d<sup>8</sup>, which are the state of electron transfer

from the ligand to  $3d^9$ , one electron excited  $3d$  state, and two electron excited  $3d$  state, respectively. Excited states depend on the density of excited zinc atoms, carbon and oxygen as ligands.

#### **Morphology of the condensates.**

Morphologies of the condensates depend on the total energy of the ion recombination. Grain size of the condensates is roughly proportional to the total energy because the average charge density is proportional to the energy of incident electrons. The microcrystal condensed at off resonant conditions show hexagonal morphology, however, that at double excitation cases show modified edge structure like Wulff's pattern. The patterns of platelets strongly depend on the substrate temperature.

#### **Deformation of the condensates.**

X-ray diffraction intensities and XPS spectra show time dependence at room temperature. This is because of the existence of fluidity of the condensates. The condensation process includes high energy process and the products of ion recombination are quenched. The high internal energy state is easily speculated from the strong diffuse scattering of X-ray. Therefore as grown condensates at double excitation processes are in a high energy state and showed long-term relaxation process in diffuse scattering intensity of X-ray diffraction, whose lifetime was confirmed as around 44 weeks.

The condensate is not homogeneous because of the charge density distribution induced by bias potential and geometrical condition of the substrate. After one year from the deposition, the condensates showed decomposition into liquid like materials and thin solid plates. The shapes of liquid type materials are very similar to "highviscous oil" with disk type morphology. Solid thin plate showed unique characteristics, which deformed by electron irradiation with 5 keV and  $3 \times 10^{19} \text{ cm}^{-2}$  electron irradiation density. The penetration depth of electron with 5 keV is 6 nm. We estimated the Young's modulus of the thin plate with 1  $\mu\text{m}$  in thickness. The derived Young's modulus was the order of liquid level.

Recrystallized microcrystals,  $\sim 0.05 \times 2 \times 0.6 \mu\text{m}^3$ , showed unique behaviors by electron irradiation with 5 keV and electron irradiation density  $> 10^{19} / \text{cm}^2$ . As increasing the density of electron irradiation, the microcrystal slightly bent and vibrated slowly and then melted from the top of the microcrystal. This behavior is very similar to the melt of plastic stick or glass stick. After growth of the droplet, a new microcrystal with almost the same size regrew, finally this new crystal stopped the growth under the electron irradiation.

### ABSTRACT

In view to develop gas sensors, a first generation of lead-free thin films was deposited by different techniques on commercial Si and Al<sub>2</sub>O<sub>3</sub> substrates. During our research project, the correlation between the micro structure of films, the structure of the embedded sensors and the applied temperature range, is being studied. In the first year, doped and undoped BaTiO<sub>3</sub>, KNbO<sub>3</sub> and ZnO thin films have been deposited by sol-gel and PLD techniques. BT and BST films have shown a polycrystalline structure with very fine and regular grains, while disoriented grains with an average size ranging from 50 to 200 nm were observed on the KNbO<sub>3</sub> film surface, and ZnO films exhibited a columnar growth. All films were characterized and finally embedded to make semiconductor gas sensors which have been tested under different gases. In this first generation of sensors, ZnO sensors have shown encouraging preliminary results under CO and H<sub>2</sub>S gases.

## Crystallographic Properties of Aluminum-doped Barium Zirconium Titanate Thin Films by Sol Gel Process

Rachmat Andika and Muhammad Hikam

Department of Physics, Faculty of Mathematics and Sciences, University of Indonesia, Depok 16424  
E-mail: rachmat.andika11@ui.ac.id

### ABSTRACT

We studied the crystallographic of Barium Zirconium Titanate thin films with Aluminum doped (BZAT). These films were prepared by sol-gel process and followed by spin coating. The sintering temperature is taken from 800 °C to 900 °C. We found that the crystallographic system of BZAT thin films have tetragonal structure with the lattice parameter slightly changed by various Aluminum partial substitution. When 0.01 Al mole added, the grain size of the films is 29.42 nm at 800 °C. The sintering temperature 900 °C increased the grain size into 50.95 nm. We also calculated the spontaneous polarization theoretically and we found the optimum value of BZT thin film with 0.01 mole Al heated at 800 °C, is 0.143 C/m<sup>2</sup>. This way, we could predict that the film has ferroelectric phase.

### ABSTRACT

*Quasi-solid state dye-sensitized solar cells (DSSC) having bilayer structure were made by using nanocrystalline anatase-rutile TiO<sub>2</sub> to enhance the photovoltaic performance. The bilayer structures were coated to FTO glass using doctor blade technique with total active area of 0.4 cm<sup>2</sup>. Cyanidin dye extracted from mangosteen pericarp was used as photosensitizer. Bilayer anatase-anatase was formed with surface area of 99.9 m<sup>2</sup>/g and pore volume of 0.23 cc/g while anatase-rutile structure has surface area of 103.5 m<sup>2</sup>/g and pore volume of 0.21 cc/g. Overall energy conversion efficiencies under illumination of 10 mW/cm<sup>2</sup> of 0.461% and 0.1365% were achieved for DSSC employing anatase-anatase and anatase-rutile TiO<sub>2</sub> structure, respectively. Both efficiencies were higher than that of monolayer anatase and rutile TiO<sub>2</sub> structure whose efficiencies in the range of 0.02% to 0.037%. The photocurrent action spectra of bilayer structures performed high efficiency spectrum in the wavelength range of 420 – 480 nm owing to cyanidin effect of dye.*

### ABSTRACT

Atomic layer deposition (ALD) technique shows superior application in the fabrication of  $\text{TiO}_2$  inverse opals (IO), compared with conventional infiltration method. In the present report, the gradient and uniform  $\text{TiO}_2$  IO structures were infiltrated by ALD method in a continuous-flow and internally developed stop-flow process, respectively. The corresponding optical and optoelectrical properties of  $\text{TiO}_2$  IO structures were investigated. The prepared uniform IO structure of 288 nm was used as a photoanode for dye-sensitized solar cells. An efficiency of 2.22% was achieved, which was much higher than that of prepared by conventional solution-infiltration method. It is indicated that ALD method is an effective approach for fabricating  $\text{TiO}_2$  IO photoanode.

### **ABSTRACT**

*A novel functional material has been synthesized by modification of multi-walled carbon nanotubes (MWNTs) with nanostructured zinc oxide (ZnO). Multi-walled carbon nanotubes have unique electronic and photonic properties, as well as nanostructured zinc oxide [1]. Both have advantages when combined as to provide a material with extremely high surface area-to-volume ratio, which is required for the sensor structure. So far, CNT-based gas sensors have been investigated for the detection of H<sub>2</sub>, N<sub>2</sub>, NO<sub>2</sub>, and NH<sub>3</sub> [2]. In this study, modification of multi-walled carbon nanotubes with nanostructured zinc oxide is conducted by simple screen printing and ultrasonic spray pyrolysis (USP) methods, which consists of the fabrication of MWNTs paste, the formation of ZnO sol, and calcination. The deposited thin films are then characterized using several characterization techniques, such as X-ray diffraction and SEM. The performance testing of the sample as a CO gas sensitive layer has also been investigated and the measurement results on 100 ppm CO gas exposure at 250°C showed the sample had a sensitivity of 85%, response time of 5 minutes and recovery time of 20 minutes.*

### ABSTRACT

Has done an investigation on composite materials  $(1-x)\text{Ba}_{0.5}\text{Sr}_{0.5}\text{Fe}_{11.7}\text{Mn}_{0.15}\text{Ti}_{0.15} / x\text{La}_{0.7}\text{Ba}_{0.3}\text{MnO}_3$  with conventional ceramic method. Investigations carried out on the structure and the complex impedance of materials using X-ray diffraction patterns, SEM, and impedance spectroscopy. Data from XRD, SEM showed that the phase  $(1-x)\text{Ba}_{0.5}\text{Sr}_{0.5}\text{Fe}_{11.7}\text{Mn}_{0.15}\text{Ti}_{0.15} / x\text{La}_{0.7}\text{Ba}_{0.3}\text{MnO}_3$  contained in the composite material according to the ratio of material to move  $x = 0$ ,  $x = 0.3$ ,  $x = 0.5$ ,  $x = 0.7$ ,  $x = 1$ . From the pattern of impedance spectroscopy shows that  $x = 0.5$  and  $x = 0.7$  has a value of complex impedance and pattern forming semicircle in the frequency range between 1 kHz to 1MHz.

## ABSTRACT

*This paper presents the possibility of 100 W sustainable society. From the analysis of historical data of electrical power consumption in Japanese society, it is shown that 100 W society with adequate electrical products existed in 1970s. The most important key for realizing 100 W society is the life style which live together with family, total four persons. This model was confirmed by the present situation in Hioki city, which showed the similar electrical power consumption, 106 W for a home of four persons.*

## Keywords

*Sustainability, Electrical power consumption, Life style*

## 1. Introduction

Recently we can find the word “Sustainability” in many fields. The meaning of this word includes the warning or risk for our present society [1]. The developed countries are making the new program to answer the demands and requests for improving our environment [2]. Our societies notice the unsustainability of the Earth, which is accelerating environmental degradation, loss of biodiversity, shortage of energy, etc, for next generation.

In this report, we discuss the history of electrical energy consumption in Japanese society for discussing a model for sustainable society in near future. The reason why we pick up the electrical energy consumption as an index to analyze the sustainability is that the electrical power consumption is proportional to the industrial activity and related to the life style of a family.

Electrical power consumption indicates the economic growth condition of the society. We report the history of electrical power consumption of Japanese society from 1951 to 2011. In these period, Japanese society had five big economic crises; 1st oil shock[3], 2<sup>nd</sup> oil shock[4], collapse of bubble economy[5], Lehman Shock[6], and East Japan earthquake (FUKUSHIMA)[7].

Electrical power consumption (EPC) is separated into industrial use and home use. The total electrical power consumption of home use increases almost linearly year by year in Japan. On the other hand, that of industrial use directly reflects the economic conditions. Firstly we discuss on the correlation of the electrical power consumptions between Industrial use and home use in Japanese society, in which the most important change is the decrease of EPCs in both industry and home after FUKUSHIMA. The other past economic crises showed a linear model between industrial use and home use, in which the ration of EPCs between industry and home increased linearly.

We discuss one index related to EPC for the sustainable society, which is the electrical power consumption per person (EPCPP). The maximum EPCPP in Japan was 270W at 2010 just before FUKUSHIMA. On the other hand, EPCPP in Indonesia is 20 W. Now, recent economic growth rate in Indonesia suggests the same GDP level as Japan near 2050[8].

The shortage of fossil energies is very clear if we consume energy in the same rate. Especially energy consumption in Asia area is increasing rapidly because of economic growth. In this report we want to discuss our sustainable society for next generation and make clear what we should do in our daily life or how we can change our life style. This will be one duty for our next generation. Discussion points are followings;

- 1) Correlation between EPCPP and number of family in one home
- 2) Number of electrical products and essential electrical products
- 3) Electrical energy management and storage of electrical energy
- 4) Peak shift of electrical energy consumption

## 2. Electrical Power Consumption in Japan during 1951 to 2011

Electrical power consumption reflects the economic growth condition and life style of the nation because the electrical energy is easily transferred to the other usages with high conversion efficiency. Figure 1 shows EPCs of industrial use and home use during 1951 to 2011[9]. Home use and business use are classified by the maximum electrical current of the contact,

in home use  $I_{\text{home}} < 60$  A and in business use  $I_{\text{business}} > 60$  A. Industrial use is classified by input voltage, which is higher than 6000V.

Industrial use shows clearly the influences of economic crises. The 1<sup>st</sup> oil crisis due to the 4<sup>th</sup> Middle East War at 1973 induced the shortage of oil supply and the increase of the price of oil, which suppresses EPC in industry and business uses. The typical examples of suppresses of EPC are stop of escalators in departments, shortening of lighting time of street illuminations, closing gas station at Sunday, change of the schedule of the last train, shortening of the time of broadcasts, etc. However, EPC of home use increased gradually even though industrial use showed the very sharp decrease.

The 2<sup>nd</sup> oil crisis due to Islamic Revolution in Iran at 1979 showed a similar dependence in industrial use as the 1<sup>st</sup> oil crisis. This is the effect of training of the 1<sup>st</sup> oil crisis and the start of the movements of saving energy, development of high efficiency products including the low cost items. In this second economic crisis EPC of home use showed small change which correlated to the industrial use more strongly, which suggests the expansion of the movement of saving energy in home use. After the decrease of economic depression of USA, the EPC of industrial use increased with almost the same rate before the 1<sup>st</sup> oil crisis until the disintegration of the bubble economy of Japan. This is an important index for the sustainability of the society which suggests that the high growth rate of EPC will induce an economic crisis.

The EPC of home use decreased the growth rate fifty percent. After three years from the end of bubble economy, EPC of industrial use increased gradually until Lehman shock at 2008. The EPC of industrial use after Lehman shock showed negative growth rate with -350 million kWh per year, which is the biggest decrease of EPC. On the other hand EPC of home use increased with almost the same rate before Lehman shock. The correlation of EPCs between industrial use and home use suggests the change of the society. The characteristic of EPCs in recent three years shows clear positive correlation. This feature is very unique which has never seen before.

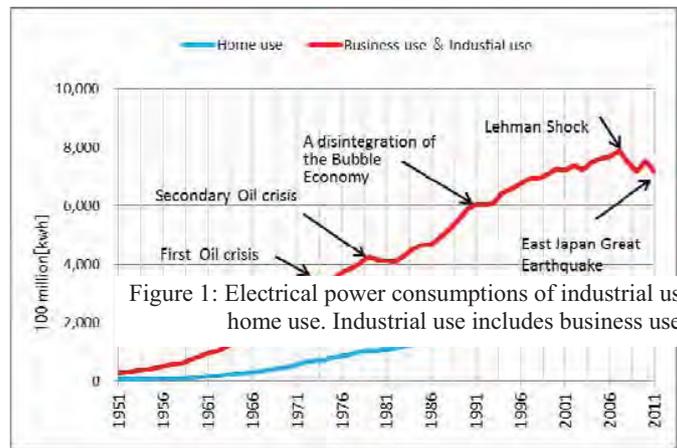

Figure 1: Electrical power consumptions of industrial use and home use. Industrial use includes business use.

### 3. Correlation of EPCs in Industrial Use and Home Use

The simplest method to show the correlation between two quantities is to use the ration between them. Figure 2a shows the ratio of EPCs of industrial use and home use.  $W_r$  is the ration of  $W_i/W_h$ , in which  $W_h$  and  $W_i$  indicate the EPCs of home use and industrial use, respectively. The EPC ratio  $W_r$  shows the minimum at 1960, indicated by Y1, and increased rapidly until Y2 at 1966 and decreased gradually until Y3 at 1970. These relations are impossible to see from Fig.1 directly. The structure after Y3 is almost linear except for A1, which is after Lehman shock.

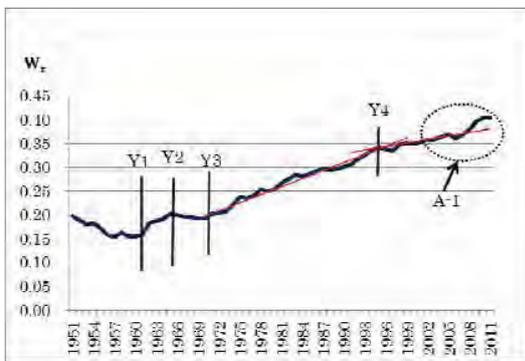

Figure 2a: Ration of EPCs of home use and industrial use,  $W_r = W_i/W_h$ , where  $W_h$ ,  $W_i$  are EPCs of home use and industrial use, respectively.

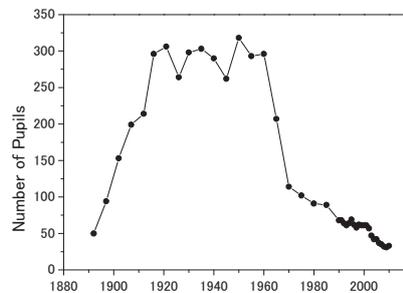

Figure 2b: Change of number of pupils at Sumiyoshi elementary school.

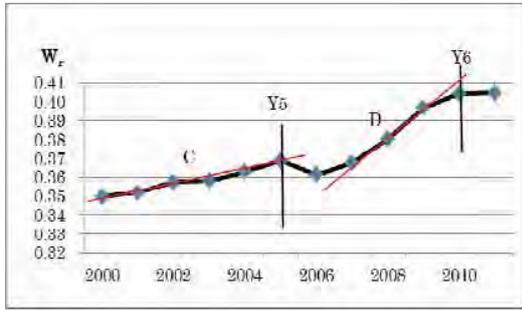

Figure 3: Expanded view of the EPC ratio  $W_r$  of A-1 in Fig. 2a. This area suggests recent unique changes due to different factors.

The first decrease of  $W_r$  is due to the growth of EPC of industrial use relative to that of home use. The rapid increase of  $W_r$  during Y1 to Y2 suggests a big change in Japanese society. Figure 2b show the change of number of the pupils at Sumiyoshi elementary school in Kagoshima, Japan during 1890-2010. Approximately the number of pupils was constant in 1920-1960. Then the number of pupils rapidly decreased to 60 % in the period of 1960 and 1970. The increase of  $W_r$  and the decrease of number of pupils are correlated with each other. The decrease of number of pupils is due to the immigration of peoples who live in rural communities to cities. The gradual increase of  $W_r$  from 1970 suggests the relation with the gradual linear decrease of population in rural side. Although Figure 2b is an example of one elementary school, this example is a typical one which shows that there was a large immigration of people from rural side to urban side for supporting the labors of newly constructed companies in 1960-1970.

From these correlations between EPCs and the immigration from rural area to urban area we propose a model to explain a main factor dominating EPC. The minimum unit for EPC is "Home" and the number of persons per home dominates the practical EPC. The immigration to urban side from rural one induces the increase of the number of minimum home of one person. This model is applicable to the developing period of the society.

A-1 area in Fig. 2a is slightly different from the other area in it because, although the population of Japan is almost constant the ratio  $W_r$  of EPCs shows relatively large change. Figure 3 shows expanded view of A-1 area in Fig. 2a. The kink at Y5, 2005, is due to the decrease of EPC of home use because there is no kink in EPC of industrial use. This curve is classified into two area indicated by lines C and D.

The line C suggests the weak correlation between EPCs of industry and home in spite of individual small each changings. One reason of the kink at Y5 may be the start of ecological movement in the society. The steep increase of  $W_r$  in the line D is related to Lehman crisis, in which EPC of industrial use decreased suddenly. The EPC of home use in the line D was almost constant. The transition area between the line C and D suggests the mind of the society for constructing new stage in their daily life. The last two years in Fig. 3 is very unique. The EPC of home use became the maximum at 2010. In 2011 March, East Japan Great Earthquake occurred. The EPC ratios in these two years were the same magnitude. This is due to the same time dependence of each EPCs. The same dynamic characteristic is the result of a common factor. Although these two years are very short period to get important conclusion, its meaning is very important because of the stable balance of Japanese society.

#### 4. EPCPPs in the Present World

We think the history of EPC in Japan is a model for developing countries in near future. The EPCPPs in different countries were summarized in Fig. 4 as a histogram. EPCPPs distribute in the range of 1W to 1688 W. The countries of high energy consumption are the countries with rich energy resources like water power or oil [11].

The global average of EPCPP is 90 W and the peak of the histogram located at 101-200 W. The present EPCPPs of Japan and Indonesia are 265 W and 20 W, respectively. The EPCPP of Indonesia is the same level of Japan at early stage of 1960s. We can speculate the EPCPP of home use in Indonesia in near future by using the present model if we can get the change of the number of persons of individual home. For sustainable society in really near future we propose the target EPCPP as 100W. The reason is very clear because 100 W is the middle of the global average rate and the peak of the histogram of EPCPP, that is, it is easy to shift the value of global average to 100 W in a meaning of statistics.

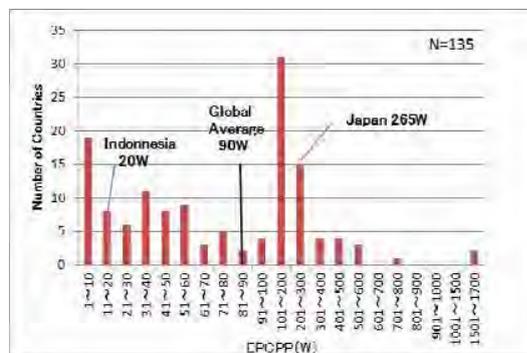

Figure 4: Electrical power consumption per person (EPCPP) in countries at 2010.[11]

### 5. 100 W Sustainable Society

Another reason of 100 W is a practical meaning of life style of Japan. For Japanese society, EPCPP of 100 W was achieved at 1978. This era was the time with high growth rate of economy, which is very similar to the present Indonesian economy; problems of waste material managements and shortage of future energy. The table 1 is the saturation level of electrical products for home uses at 1978 and 2010. The electrical products of high diffusion rates higher than 95 % were refrigerator, washing machine, color TV, and vacuum cleaner. These electrical machines are symbolic electrical products of the modern electrified society. Recent energy saving techniques suppress the electrical power consumption more than 50 % as shown in Table 1. These new techniques assist the possibility for the uses of new electrical products for next generation.

Product	Diffusion Rate (%) 1978	Diffusion Rate (%) 2010	Energy-saving
Rice Cooker	56	89	——
Refrigerator	99	99	2001⇒2010 ▲65%
Washing Machine	98	99	1995⇒2005 ▲75%
Color Television	98	99	1997⇒2012 ▲70%
Vacuum-cleaner	95	99	——
Air-conditioning	30	89	2001⇒2011 ▲14%
Microwave Oven	28	97	——
Electric Hot-water System	0	8	——

Table 1: Electrical power consumption per person (EPCPP) in many countries at 2010. Diffusion rate of products and information about electrical energy saving. [10,12,13]

The main reason of the increase of EPCPP from 100 W to 265 W is the increase of the electrical products related to heat loads; electric hot-water system, microwave oven, air-conditioner, rice cooker, etc. especially EPC of electrical hot-water system is very high, which is introduced to improve the electrical power supply from the power plant. For future life we have to improve the system for hot water supply by using solar heat energy.

The products using heat energy have another effect which means the function to store the energy. The hot water system keep hot water without the power supply for several hours and refrigerator keep the foods cool for a few hours. This function is the same as a capacitor for electrical system. The present data on thermal insulation are not adequate for future sustainable society, which should be improved by ourselves.

Persons in Home	EPCPP in Hioki 2012 (W)	EPCPP in Indonesia 2012 (W)
1	212	
2	180	
3	129	
4	106	* 10
5	75	
6	67	

Table 2: EPCPP and number of persons in a home in Hioki, Japan and Depok in Indonesia.

EPCPP depends on the number of persons in the home. Table 2 shows the data of EPCPP of Hioki city in Japan. Hioki city is located in rural area 25 km from the capital of Kagoshima prefecture. EPCPP linearly decreases almost linearly. If we apply linear model, we obtain the model EPCPP (W) as follows,

$$EPCPP = 234.5 - 30.4N \quad (1),$$

where N is the number of persons who live in one home and the error is 10 %. This result shows the real energy consumption of one person in the home is 30.4 W. At the present time although the average EPCPP in Japan is 265 W, if four persons live in one home EPCPP decreases to 105 W. The EPCPP at 1978 in Japan was 100 W and the number of persons in one home was 3.5 persons. If we admit 15% error for the model, 100 W sustainable society will be possible by the home where four persons live together. EPCPP in Indonesia is relatively lower than Japanese case. Average value of EPCPP is 20 W. The denoted data of Indonesia in the table is average of very small resources. We need data more for making plan for future sustainable society in Indonesia.

## 6. Conclusion

We analyzed the historical time dependence of EPC of Japanese society. The industrial use, which include business use, was strongly reflected by the economic situation, however, that of home use was insensitive to economic crises except for the case in 2010-2011. In the first stage of economic growth, the immigration of laborers from rural area to urban area makes EPCPP increase rapidly. This is the first point which we have to think the change of life style and energy consumption. The second point is the ration of EPCs between home use and industrial use. EPC ratio,  $W_r$ , clearly indicated the difference of time dependence of both EPCs. This measure quantity suggests the correlation of EPCs between industrial use and home use. From the result of  $W_r$  we can obtain a model with constant EPCs ratio, which means the balanced society between home and industry.

The reason of 100 W is the relation of life style which was expressed by the high diffusion rate of main electrical products. In 1978, Japanese society achieved to the first stage of improvement of the life style by the electrification. The average number of persons in a home was 3.5 and the electrical power consumption at that time was 100 W. We confirmed the relation between EPCPP and number of persons in one home as life style of Japanese society at 2012. Surprisingly, EPCPP of the home with four persons was 106 W. These results exactly suggest that 100 W sustainable society is possible.

### ABSTRACT

The emergence of white layer in each process of Electric Discharge Machining (EDM) became the focus of attention of the experts. It's harder than the base metal would be advantageous to withstand friction engine components, such as the plastic molding industry. From various studies it has been reported that the increase in the value of hardness of white layer either due to migration of the electrode material and dielectric fluid to the white layer. This paper discusses the influence of electrodes Cu, CuCr and graphite as well as jatrophacurcas dielectric fluid to the surface of the material SKD 61, microhardness of the white layer, Tool Wear Rate (TWR) of Material Removal Rate (MRR), Surface roughness (Ra) and the microstructure. Initial studies conducted are the transesterification and characterization of jatrophacurcas to determine the dielectric strength and the content of metal elements. Furthermore, the EDM testing is done to dies steel of SKD 61 using the electrodes of Cu, CuCr and Graphite. The use of jatrophacurcas yield the best MRR when using Graphite electrodes followed Cu last CuCr. While the smallest TWR produced by Cu electrode, CuCr and then the highest is Graphite. The relative wear which is the ratio TWR with MRR, for the three types of electrodes are always great at small current then decreases and then tends to be stable with the increase of electric current. Jatrophacurcas for the three types of electrodes provide higher TWR than kerosene. This means that migration of materials is beneficial because larger material, but in terms of the geometric accuracy of the product can lead to decreasing of dimensional tolerances. Vickers hardness values of white layer is achieved by CuCr electrodes, Graphite lowest. Microstructural observation results of EDM white layer using graphite electrodes produce a more uniform thickness than the white layer using Cu and CuCr electrodes. The conclusion of this study that jatrophacurcas can be used as a dielectric fluid in EDM process, because electrode wear during EDM process is relatively high compared to kerosene that is mean more profitable in the surface treatment process of dies steel of SKD 61.

## ABSTRACT

In metal forming process by die casting method, nitriding plays an important role in increasing the life of dies and good quality product. Innovation surface treatment processes performed before nitriding aims to improve the efficiency and depth of nitride layer on Modified H13 Steel. Nitriding has done in a gas vacuum furnace, at temperature of 510°C for 5 hours. Shot peening has done by using steel balls with a pressure of 461 kPa. Shot blasting has done as a method of cleaning the material surface using SiC particles. Characterization of the sample surface before and after the variation process is focused on changing the microstructure, micro hardness distribution, and depth and composition nitriding layer. Of the process that preceded nitriding shot peening, obtained maximum hardness 1196 HV with effective depth of diffusion layer of 72  $\mu\text{m}$ . This value is greater than the nitriding without any prior surface treatment, which produces a maximum hardness HV 1101.4 with effective depth of diffusion layer of 54  $\mu\text{m}$ . Variation nitriding by shot peening process produces white layer thickness 4.1  $\mu\text{m}$ ; thicker than nitriding without shot peening process 3.7  $\mu\text{m}$ . While on nitriding that are not preceded treatment did not reveal any white surface layer.

### ABSTRACT.

In this study, the optimization of material removal rate (MRR) and surface roughness (SR) simultaneously in a WEDM process by using Taguchi method with fuzzy logic has been applied. The Wire EDM process parameters (flushing pressure, on time, open voltage, off time and servo voltage) were optimized with considerations of multiple performance characteristics, i.e., MRR and SR. Based on the Taguchi method, an  $L_{18}$  mixed-orthogonal array table was chosen for the experiments. Fuzzy reasoning of the multiple performance characteristics has been developed based on fuzzy logic, which then converted into a fuzzy reasoning grade or FRG. As a result, the optimization of complicated multiple performance characteristics was transformed into the optimization of single response performance index. Experimental results have shown that machining performance characteristics of Wire EDM process can be improved effectively through the combination of Taguchi method and fuzzy logic.

### ABSTRACT

Application of a light-weight material, such as an aluminum alloy, on a turbine impeller can enhance the efficiency of an Organic Rankine Cycle power plant that operates at temperatures below 150 °C. The density of an aluminum alloy only one-third that of steel. However, increased strength of aluminum alloys is needed for turbine impeller qualification. Investment casting was chosen to produce radial inflow turbine impeller due to their complex geometry and precision. It can replace machining process, which is time-consuming and less efficient because of material removal. This study describes the investment casting process used to produce a radial inflow impeller turbine. The study also identifies defects, microstructures and properties of radial inflow turbine impeller. The turbine impeller were produced from Al-7Si-4Mg alloy with 0.38, 3.82, and 6.0 wt. % Cu. Visual examination showed that the turbine impeller was free of macro defects and misruns. Microstructures were characterized by Optical Microscopy and SEM. The structures consisted of  $\alpha$ -Al, Si eutectic, AlMgSi, AlMgFeSi (Chinese script) and CuAl<sub>2</sub>. The higher hardness value of 54HRB was affected by Cu content due to the good mechanical properties of fasa CuAl<sub>2</sub>

### ABSTRACT

*This paper presents the results of research on the manufacturing of steam turbine blade by using investment casting technology. Metal forming technology with precision casting process or investment casting is the right technology for the manufacture of turbine blades, because it can produce casting products that has advantages in size and shape accuracy, surface finish and the ability to produce thin casting, which the usually foundry can not be done. The purpose of this research is to produce a good quality of the casting products as an effort to reduce import dependency of steam turbine blade and to be the alternative way of making steam turbine blades in Indonesia, in addition to the machining process. Based on the experimentation trial implemented on casting products of stainless steel 304, the result indicates that the injection temperature for the wax NF-411 and optimal nozzle in hydraulic injection machine are 64°C and 30°C, injection pressure 1.75 MPa and injection time 9 seconds. The best casting induction furnace achieved at temperature 1.620°C as for to the number of ceramic mould coat which is good to be obtained at 7 layers. The testing results show that: (1) chemical composition meet the existing standard, (2) hardness 160 HB, (3) shrinkage 2.83%.*

### ABSTRACT

The RERTR Program (Reduced Enrichment in Research and Test Reactors) is an attempt to utilize uranium fuel enriched below 20% for nuclear research reactors. Since the program was launched by the United States in 1978, the International Atomic Energy Agency (IAEA) has recommended that  $U_xSi_y$  alloys, particularly  $U_3Si_2$  and  $U_3Si$  compounds, be used to fuel nuclear research reactors with uranium loading rate up to 4.8 gU/cm<sup>3</sup>. Unfortunately, there are difficulties in reprocessing  $U_3Si_2$  and  $U_3Si$  compounds due to the Si content. To overcome this problem, the IAEA initiated international cooperation to find the best solution in the development of new nuclear fuels to substitute the  $U_xSi_y$  alloys. In order to synthesize nuclear fuel containing high loading of uranium, research in developing uranium nitride (UN) from uranium metal has been conducted by reacting the massive uranium metal with hydrogen gas at a temperature of 573 K followed by dehydriding at a temperature of 773 K under vacuum pressure and nitriding at a temperature of 1073 K by introducing nitrogen gas in the reaction chamber. The X-ray diffraction analysis results showed that the hydriding process caused the uranium metal to turn into a stable compound,  $UH_3$ , which was identified by the changes of the massive shapes into fine metal powders. Dehydriding process at a temperature of 773 K caused the  $UH_3$  compound to decompose into U metal powders, and when the metal powders were reacted with  $N_2$  gas at 1073 K a stable phase identified as UN was formed. The results showed that it is possible to produce UN powders by hydriding, dehydriding, and nitriding process, although special handling of  $UH_3$  and UN powders is required due to their pyrophoric nature.

### ABSTRACT

Appropriate technology is widely recognized as a good solution in providing alternative technology for underdeveloped people who live in a very limited circumstance. However, it is often seen as an idea without clear explanation from engineering perspective. One of critical process in appropriate technology design process is materials selection. This study aims to provide applied logic for selecting materials in the design process. The logic is constructed by surveying previous notions from researchers. Reasoning techniques are explored by using design thinking. This study reveals that there are four focuses which must be applied to find sufficient materials for an appropriate technology. This study also concludes that, unlike pure engineering efforts which tend to substitute materials given in a technology design with locally available ones, appropriate technology start from existing resources to produce its design. It requires soft selection by involving local people in exploring any potential materials which already available in their own area. By looking at previous studies which tended to ignore the contribution from local people in exploring potential materials, this study embraces their involvement and then encourages insights for further research around it.

### ABSTRACT

Zinc oxide (ZnO) is an inorganic semiconductor material which has been widely studied due to its various potential applications. Over the past decades, one-dimensional (1-D) nanostructures such as nanowires and nanorods have stimulated significant scientific interests because of their unique properties in comparison to bulk materials. For the application of dye sensitized solar cell (DSSC), 1-D ZnO nanostructures are more desired than the spherical nanoparticles since the former provides ballistic effect leading to faster electron transfer which in turn can increase the device performance. Motivated by this consideration, in the current study ZnO nanorods were deposited on ITO glass substrate via chemical bath deposition (CBD) process where the seeding solution was prepared at 0°C. In order to increase their crystallinity and optical properties, the as-deposited ZnO nanorods were subjected to post-hydrothermal treatment at 150°C for 3, 6 and 9 hours. The scanning electron microscope (SEM) analysis revealed that the ZnO nanorods were successfully grown as vertically-aligned hexagonal structure, while the X-ray diffraction (XRD) study showed that the intensity of (002) crystal plane is the highest peak for all nanorod samples. The optical study by UV-Vis spectroscopy showed that the absorption edge of the as-deposited sample was slightly red-shifted to visible region after post-hydrothermal treatment. The ZnO nanorods sample derived from post-hydrothermal treatment for 6 hours provided the optimum nanostructural characteristics with an average diameter of 228 nm, crystallite size of 27.97 nm and the band gap energy,  $E_g$ , of 3.12 eV.

### ABSTRACT

In the present work, ZnO nanorods array were successfully grown on ITO substrate via chemical bath deposition method (CBD). The seeding solution was prepared at low temperature (0°C) using zinc nitrate tetrahydrate and hexamethylenetetramine. The as-deposited ZnO nanorods were hexagonal wurtzite structure growing vertically on the substrate. Various reaction times from 3 to 5 hours were applied upon the CBD process at 90°C. The results showed that the duration of reaction time has affected the nanorods array properties. With the increase of reaction time from 3 to 5 hours has increased the diameter and crystallite size of nanorods from 325 to 583 nm, and from 22.68 to 34.28 nm. As a result, the band gap energy,  $E_g$  of ZnO nanorods decreased from 3.63 to 3.13 eV.

### ABSTRACT

A shaft of electric motor fin-fan cooler failed after two years operation. The inspection revealed that the v-belt attached on the electric motor loosed before the failure occurred. Visual investigation results showed the brittle fracture with less plastic deformation. Multiple crack origins observed on the edge of the shaft indicates that the more than one stress concentration generated within the shaft. Microstructure observation revealed fine grain on the edge and become coarse into the center of the shaft. The hardness test results were in good agreement to the microstructure observation where the edge are is harder than the center. Fractography using SEM revealed inclusions located within the shaft and some inclusions are clustered on the area where the cracks initiate to propagate. The presence of intermetallic inclusions was identified by microanalysis using EDS. Inclusions that are brittle in nature become stress concentrations for the operating load since its properties is close to ceramic. The presence of fine grain and inclusions on the edge of the shaft become detrimental to the shaft properties and the presence of fine grain aggravate the failure for its effect according to Hall-Petch theory.

## ABSTRACT

Several natural dyes have been extracted from tropical fruit shells such as *Musa aromatica* and *Citrus medica* var Lemon fruit shells. The resulting dyes have been used as sensitizer at dye sensitized solar cell (DSSC). The main pigments, which are carotenoids, was obtained by extraction and purification at dark room. Ethanol and water are used as solvents. The dyes have been characterized through UV-Vis spectrophotometer. The thin film of TiO<sub>2</sub> anatase has been sintered at 450°C to enhance film compactness. According to the experimental results, the DSSC conversion efficiency which has been prepared by carotenoid dye from *Musa aromatica* fruit shell extract is 0.21%, 0.614 V of open-circuit voltage ( $V_{OC}$ ), 0.280 of short-circuit current density ( $J_{SC}$ ) mA/cm<sup>2</sup>, 56  $\mu$ W of maximum power ( $P_{max}$ ) and 0.43 of fill factor (FF). Then, the DSSC conversion efficiency which has been prepared by carotenoid dye from *Citrus medica* var Lemon fruit shell extract is 0.05%, 0.460 V of  $V_{OC}$ , 0.093 mA/cm<sup>2</sup> of  $J_{SC}$ , 14  $\mu$ W of  $P_{max}$  and 0.44 of FF. The measurement of I-V curve demonstrated that carotenoid was potential component as sensitizer for DSSC.

### ABSTRACT

Barium titanate BaTiO<sub>3</sub> (BTO) - barium hexaferrite BaFe<sub>12</sub>O<sub>19</sub> (BHF) nanocomposite could be as a raw material of multiferroic. Multiferroic is a class of materials with coupled electric, magnetic and structural order parameters that yield simultaneous effects of ferroelectric, ferromagnetism and ferroelasticity in the same material. This material has potential applications in such as spintronic devices and sensors. This work was an earlier research towards formation of multiferroic material. Knowing magnetic properties that will lead to a better understanding of magnetoelectric coupling in multiferroic material is the objective of this research. The samples were BTO and BHF prepared by sol-gel and then were mixed in bulk system by a conventional techniques in various of volume fraction between BTO : BHF = 1:1 ; 1:2 and 2:1, then samples were sintered at 925°C for 5, 10 and 15 hours. Composite phase study was carried out using X-Ray Diffraction (XRD). MPS Magnet – Physik EP3 – Permagraph L was used to characterize magnetic properties. XRD results confirm that composite with volume fraction of BTO : BHF = 1:1 with sintering at 925°C for 5 hours consists only of 2 phases BTO and BHF. There is impurity phase BaFe<sub>2</sub>O<sub>4</sub> beside BTO and BHF phases at samples with volume fraction BTO:BHF = 1:2 and 2:1 for longer sintering. Composite with volume fraction of BTO:BHF = 1:1 for 5 hours sintering has a high value of remanent magnetization 0.081 T and the lowest value of intrinsic coercive 333.6 kA/m leading to good characteristics of multiferroic materials.

### ABSTRACT

Polymer blends are potential candidates for solar-energy conversion, due to their flexibility, ease of processing, and low costs. We report herein 2.6 cm<sup>2</sup> active area of flexible polymer solar cells based on blends of polymeric semiconductor [poly(2-methoxy-5-(3,7-dimethyloctyloxy)-(para-phenylene vinylene)] (MDMO-PPV) and the soluble fullerene C60 derivative [6,6-phenyl C61-butyric acid methyl ester] (PCBM). Devices were prepared by etching an electrode pattern of Indium Tin Oxide (ITO) covered on poly[ethylene terephthalate] (PET) substrate. A layer of conducting poly(3,4-ethylenedioxythiophene):poly(styrene sulphonate) (PEDOT:PSS) were screen printed on top of the ITO. Followed by spin coated a polymer blends of MDMO-PPV/PCBM in chlorobenzene onto PEDOT:PSS layer. Finally, evaporation of a silver electrode and PET film lamination completed the devices. The typical overall power efficiency of the prototype devices in an active area of 2.6 cm<sup>2</sup> was 0.004 % with open circuit voltage of 1.473 Volt, short circuit current of 5.84 x 10<sup>-06</sup> Ampere, and maximum power of 2.12 x 10<sup>-06</sup> Watt.

### ABSTRACT

Thin wall ductile iron (TWDI) is introduced to fulfill the needs of lighter material in automotive parts that will reduce fuel consumption. Problem occurs during the production of TWDI due to the casting thickness. TWDI casting thickness classified to below 5 mm. Many designs have been made to answer the problem in producing thin wall ductile iron. Soedarsono et al established vertical step block casting design. This design based on Y-block principle that allows direct pouring of liquid metal to the mold without passing any gating system. This design will increase casting yield. The parameter of this research is pouring basin placement to study the effect of plate arrangement to filling and solidification. This research is conducted to see the effect of pouring basin placement to microstructure and mechanical properties of TWDI. The Design is made to produce 5 plates with different thickness that is 1, 2, 3, 4, and 5 mm. All of the plates arranged parallel in line. Pouring basin located in 2 ways. The first type located pouring basin above the plate of 5 mm thickness while the second one located it above the plate with 1 mm thickness. The first type coded as T4 while the second coded as T5. The moulds made from furan sand. The result shows although cold shut occurred in both pouring basin placements due to pouring discontinuity but shrinkage only formed in T5 on its plate with 1 mm thickness. Microstructure of all the plates presented nodule graphite in pearlite matrix. Carbide and skin effects also detected. Average nodularity is above 80% while the nodule count is between 614 to 1269 nodule/mm<sup>2</sup>. Most of the Brinell hardness number exceeded maximum limit given by JIS G5502 but the UTS is below the minimum limit except for 3 mm plate thickness of T5. All elongation values below the minimum standard. The results confirm that pouring basin location is important in casting design following Y-Block principle.

### ABSTRACT

Composite as main materials for ballistic applications has been developed in order to reduce density which leads to lower fuel consumption and faster mobilization. Composite is required to own high hardness and high impact strength for good ballistic performance. Particulate composites Al-7Si-Mg-Zn reinforced by SiC is designed for ballistic applications due to its light weight and high hardness. Whilst the high hardness showed brittle properties, heat treatment process is applied to this composite to reduce it. This research aims to study the effect of magnesium as alloying element to composite Al-7Si-Mg-Zn reinforced by SiC particulate which applied to precipitation hardening. Composites Al-7Si-Mg-Zn-SiC with 2, 4 and 6 wt. % Mg is solution treated at 500 oC for 1 hour, followed by ageing at 200 oC. The characterization was carried out by hardness testing, microstructure observations, SEM and EDX observations, impact testing and fractographic observations. Results showed that Mg does not affect hardness of composite by precipitation hardening. Composite with 2, 4, 6 wt. % Mg had 63.83, 62.27, 62.48 HRB on its peak hardness. Mg did not become precipitate in matrix Al-7Si-Mg-Zn because of its low diffusivity in aluminium. Mg worked as wetting agent that reduces interface tension between aluminium matrix and SiC particles in order for composite to own better interface bonding. Therefore impact testing showed significant increase of impact strength with the increase of Mg content. Composite with 2, 4, 6 wt. % Mg had 2075, 3006, 3257 J/mm<sup>2</sup> impact strength respectively.

## ABSTRACT

Energy saving is one of popular topic in environmental issue in recent years. In the field of transportation, energy savings can be done either by reducing the weight of the vehicle. Therefore the usage of lighter raw materials plays an important role. Steel is commonly used as one of structural and hull materials for shipbuilding application. The usage of higher strength steel materials can reduce weight of vessels itself.

This paper concerns to the controlled process in producing higher strength steel materials for shipbuilding applications. Krakatau Steel has been successfully producing 490 MPa Class high strength steels materials for this application, with standard class of ABS-AH36 and NK-KA36. The addition of solid solution strengthening elements up to 0.3% Ni, 0.3% Cu and grain refinements strengthening elements up to 0.06% Nb, 0.08% V into steel containing 0.07% C and 1.2% Mn, combined with controlled rolling process resulted in high yield strength of 450-570 MPa, tensile strength of 510-630 MPa, and fine ferrite grain size of 5-9  $\mu\text{m}$ . This steel has excellent charpy impact properties up to 270 Joule at 0 °C and very low Drop Weight Test (DWT) transition temperature of -40 °C and also good weldability.

### Keywords:

Hull, structural steel, high strength, HSLA, micro alloy, weldability

## 1. INTRODUCTION

Steel is commonly used as raw material for structural in several applications. In the shipbuilding application, steel materials can be directly used as hull and structural materials or can be manufactured into several forms such as boiler, pressure vessels, pipe and other forms which are used in the vessels.

Energy cost becomes higher and higher in the recent few years. In the field of transportation, energy cost is one of important factor which have big impact for transporter companies. Energy saving in term of reducing operating cost of transportation can be done by reducing the weight of the vehicle. Therefore usage of lighter weight steel material with higher level strength can reduce weight of the vessels itself.

Since early 1980's, Krakatau Steel has been producing 400 MPa class steel for shipbuilding application with Lloyd's Register Class Certification. And furthermore, in the early 1990's until the early 2000's Krakatau Steel has also produced the same material with other Class Certification such as BKI, GL, NV, DNV, ABS and NK. In 2007 Krakatau Steel has been successfully developing higher strength 490 MPa class steel for this application with NK and ABS Class Certifications.

This paper briefly describes the experience of the company in producing 490 MPa Class High Strength Low Alloys Steel (HSLA Steel) product for hull and structure of shipbuilding application.

## 2. PRODUCT REQUIREMENTS AND DESIGN

The chemical requirements of NK and ABS Class for KA36 and AH36 grade compare to typical of chemical composition of the products and target mechanical properties of the product are shown in Table 1 and Table 2, respectively. The steel material design considered both the uniformity of the targeted mechanical properties and its microstructure.

*Table 1 Chemical Requirements and Typical of Chemical Composition of the Products*

Element (%)	NK Standard	ABS Standard	Typical
C	0.18 max		0.05 – 0.09
Mn	0.90 – 1.60		1.00 – 1.40
Si	0.50 max	0.10 – 0.50	0.15 – 0.40
P	0.035 max		0.020 max
S	0.035 max		0.010 max
Al	0.020 min	0.015 min	0.025 – 0.050
Nb	0.02 – 0.05		0.030 – 0.040
V	0.05 – 0.10		0.060 – 0.080
Ti	0.02 max		0.020 max
Cu	0.35 max		0.10 – 0.20
Ni	0.40 max		0.10 – 0.20
Cr	0.20 max		0.10 max
Mo	0.08 max		0.02 max
Nb+ V+Ti	0.12 max	-	0.12 max
CE	0.36 max	0.38 max	0.34 max
Pcm	-	-	0.17 max

*Table 2 Target of Mechanical Properties of the Products*

Properties	NK KA36 Standard	ABS AH36 Standard	Typical
Yield Strength (Trans)	355 min		450 – 550
Tensile Strength (Trans)	490 – 620		510 – 600
Elongation	16 min		17 – 26
Charpy, 0°C (J)	34 min (Long) 24 min (Trans)		> 100 J
Drop Weight Test (DWT) 0°C	No Break		No Break

In general, steel raw material for hull structural steel of shipbuilding application should have following characteristics such as: *High Ductility, Good Toughness, Excellent Weldability, Good Corrosion Resistance Properties and also should have Higher Strength*. To obtain these characteristics, the quality of hot rolled steel plate products that must met the following requirements:

- Good surface condition (free from surface defects),
- Good internal quality (lower micro inclusion, lower segregation), and
- Homogenous microstructure (fine grain structure of fine ferrite and fine lamellar pearlite, no banded structure).

### **3. CONTROLLED PROCESS IN PRODUCING HOT ROLLED STEEL PLATE FOR HULL STRUCTURAL STEEL OF SHIPBUILDING APPLICATION**

The production of steel for hull structural steel of shipbuilding application is carried out in the existing slab steel plant and hot strip mill with processing route as generally shown in Figure 1. In the Electric Arc Furnace, the raw materials which consist of 20% scrap and 80% of sponge iron are melted. This melted steel is then further processed in the Ladle Furnace to reduce the sulphur content of the steel and to adjust the chemical composition of the steel by addition of alloying elements. Subsequently, the steel is continuously cast in the continuous casting machine to produce steel slab.

The steel making and casting practices adopted for NK – KA36 and ABS – AH36 grade can be summarized as follows:

- Hot metal desulphurization
- Calcium treatment by CaSi wire injection for inclusion shape control
- Casting into tundish with argon gas purging and extended shroud to minimize re-oxidation during set up
- Controlling the cooling intensity, superheat, and casting speed
- Metal retention in ladle at ladle change

This practice is developed not only to achieve the required chemical composition but also to obtain steel with high cleanliness, free from internal and surface defect.

In the hot strip mill, the steel slabs which come from the slab steel plant are subsequently hot rolled to the specified thickness. The Thermo-Mechanical Control Process is applied during rolling to get fine grain microstructures of HRC and to achieve the required mechanical properties. Figure 2 shows the basic principle of Thermo-Mechanical Control Process during rolling applied in the hot strip mill. Slab is reheated up to about 1200 °C and soaked at that temperature in the reheating furnace. The slab is then control-rolled with high reduction at above the non-recrystallization temperature in the roughing mill in order to achieve fine austenite grain size. This steel is then rolled at a temperature between non-recrystallization and  $A_{r3}$  transformation temperature in the finishing mill. This process will introduce the deformation bands within the austenite grains which promote the nucleation sites for ferrite grains. It consequently results in the formation of finer ferrite grain after austenite – ferrite transformation. The steel strip is finally coiled at about 600 °C.

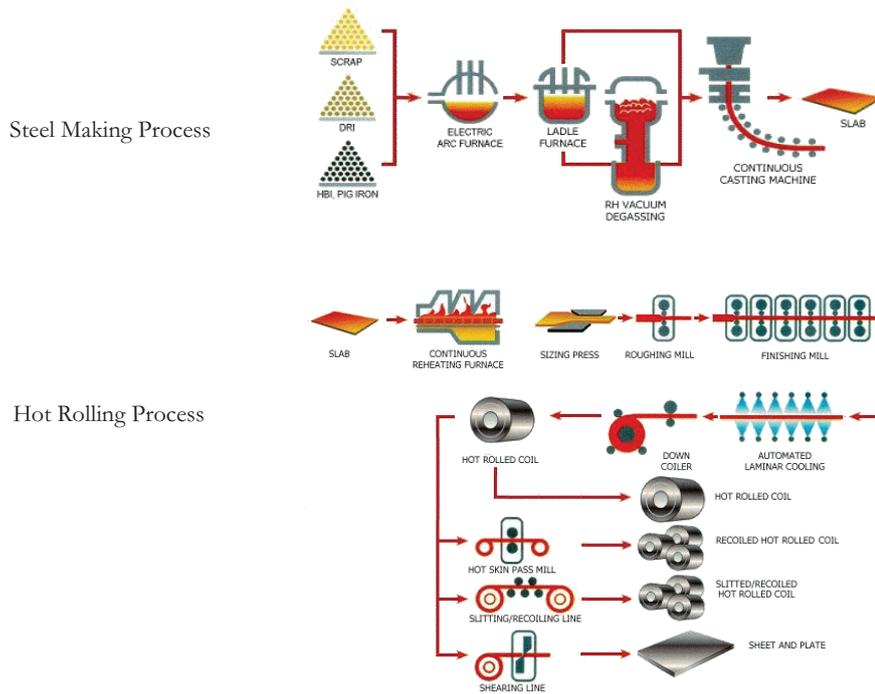

Figure 1 The Production Process Line in Steel Making and Hot Rolling

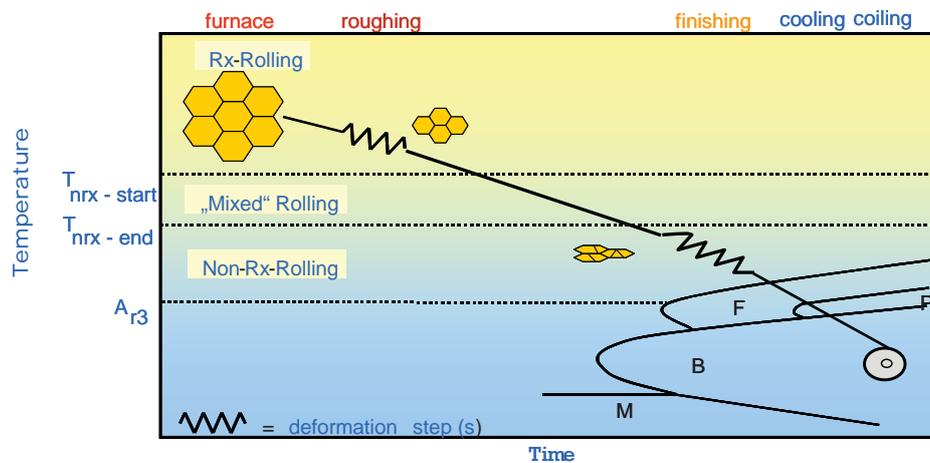

Figure 2 A schematic of Thermo-Mechanical Control Process during Control Rolling

## 4. RESULT AND DISCUSSION

### 4.1 Mechanical Test Results

#### 4.1.1 Tensile Test Result

The results of tensile test which were taken from production data of hot rolled steel plate in transversal direction are presented at Table 3. The yield strength and tensile strength of the steel with thickness range of 4 - 22 mm are 460 to 560 MPa and 510 to 610 MPa, respectively. The elongation of the steel is 16% to 25% in transversal direction. The value of yield strength, tensile strength and elongation in transversal direction are within the range of the specified values for the NK – KA36 and ABS – AH36 specification and achieve the targeted values.

Table 3 Tensile Test Result of Hot Rolled Steel Plate

Thickness Range (mm)	Yield Strength (Mpa)	Tensile Strength (Mpa)	Elongation (%)	Testing Direction
4 - 6	520 – 560	550 – 610	16 – 21	Transversal
8 - 16	470 – 540	520 – 600	17 – 22	
18 - 22	460 – 540	510 – 580	18 – 25	
NK and ABS Class Standard	355 min	490 – 620	13 min ( $t < 5$ mm) 15 min ( $5 \leq t < 10$ mm) 16 min ( $10 \leq t < 15$ mm) 17 min ( $15 \leq t < 20$ mm) 18 min ( $20 \leq t < 25$ mm)	Transversal

#### 4.1.2 Charpy Test Result

The results of Charpy Impact Test conducted at temperature range of -40 °C to 25 °C are presented in Figure 3. As can be seen in this figure, charpy values in longitudinal and transversal direction within that temperature range are 150 – 300 J and 100 – 280 J respectively. Until test temperature as low as -40 °C, transition temperature phenomenon is not observed. These charpy values indicate that the material has a very good toughness even at very low temperature.

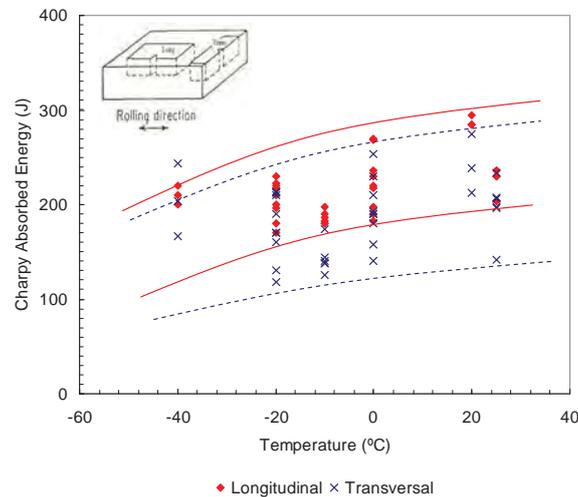

Figure 3 Charpy Test Result of Hot Rolled Coil

In order to simulate the usage in a prolonged period, charpy impact test is conducted on strain aged samples. Comparison of charpy values on longitudinal direction for as rolled and strain aged samples are shown in Figure 4. Strain aged samples are achieved by heating samples at 250 °C for 60 minutes after they are previously subjected to 5% strain. As presented in the figure, charpy values of strain aged samples until temperature of 0 °C are high enough i.e. more than 90 J, and then tend to decrease at temperature below 0 °C.

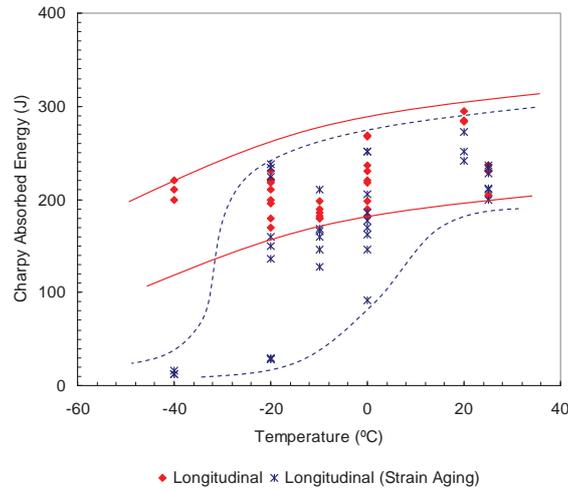

Figure 4 Charpy test results for strain aged and non strain aged samples

Lateral expansion values at temperature of -40 °C, -20 °C, 0 °C, and 20 °C are shown in Figure 5. A slight decreasing on lateral expansion values is observed at a test temperature of -40 °C.

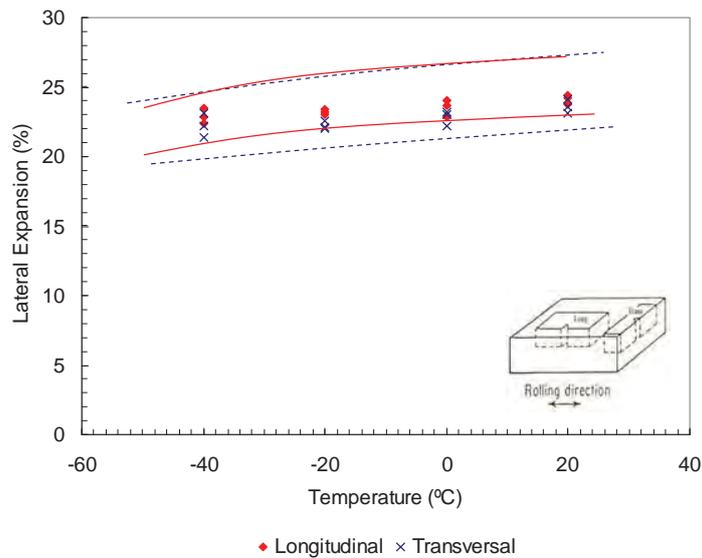

Figure 5 Lateral expansion value

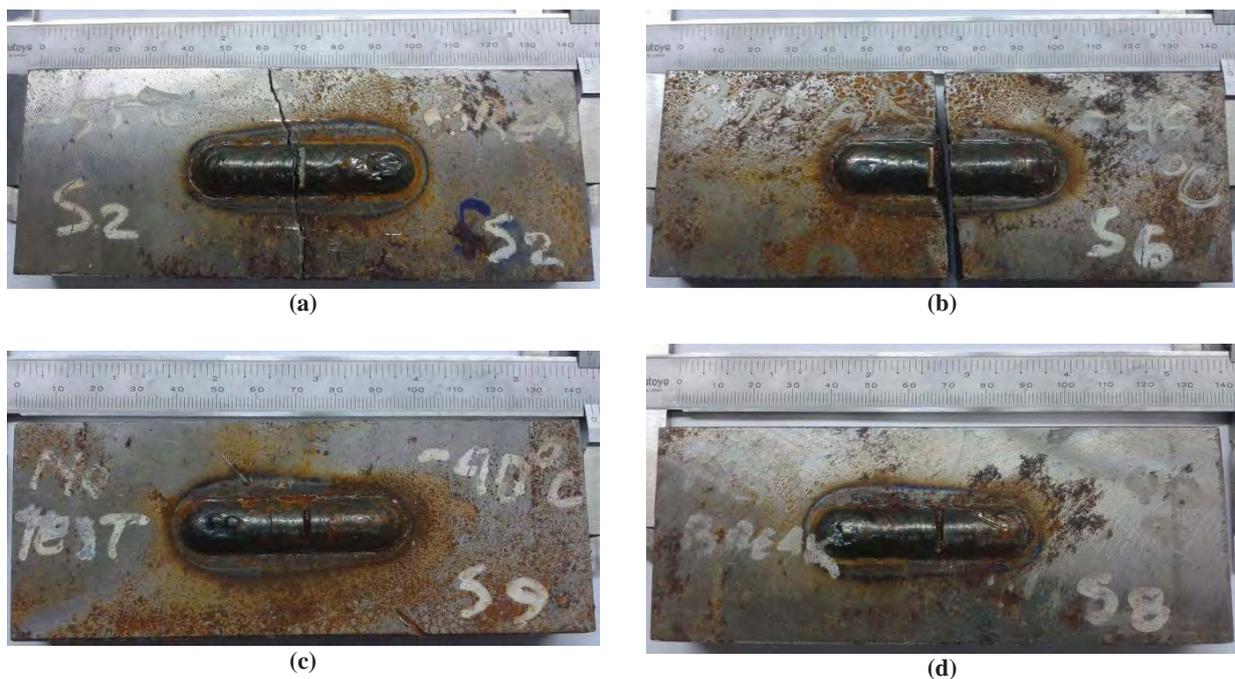

#### 4.1.3 Drop Weight Test Result

Drop Weight Test (DWT) referring to ASTM E208 is conducted to determine the nil-ductility transition temperature (NDTT). The NDTT is the temperature above which a steel will fracture in a ductile mode and exhibit plastic deformation at nominal stresses beyond its yield strength. Below this temperature, steel will fracture in a brittle mode when loaded to its yield strength. The NDTT is determined when one specimen at a lower temperature results in a “break” condition, while two tests at the same temperature show “no-break” results. DWT results summary and photograph of three different test results are presented in Table 4 and Figure 6 respectively. Based on the results, temperature of -40 °C is considered as NDTT.

**Tabel 4** Drop Weight Test result

No.	Heat No	Coil No	Temperature (°C)	Result <sup>*)</sup>
1	57790P	475701	-35	No Break
2	57790P	475701	-35	No Test
3	57790P	475701	-40	No Break
4	57790P	475701	-40	No Test
5	57790P	475701	-40	Break
6	57790P	475701	-40	No Test
7	57790P	475701	-45	No Test
8	57790P	475701	-45	Break
9	57790P	475701	-45	Not Break
10	57790P	475701	-45	No Test
11	57790P	475701	-50	No Test
12	57790P	475701	-50	Break

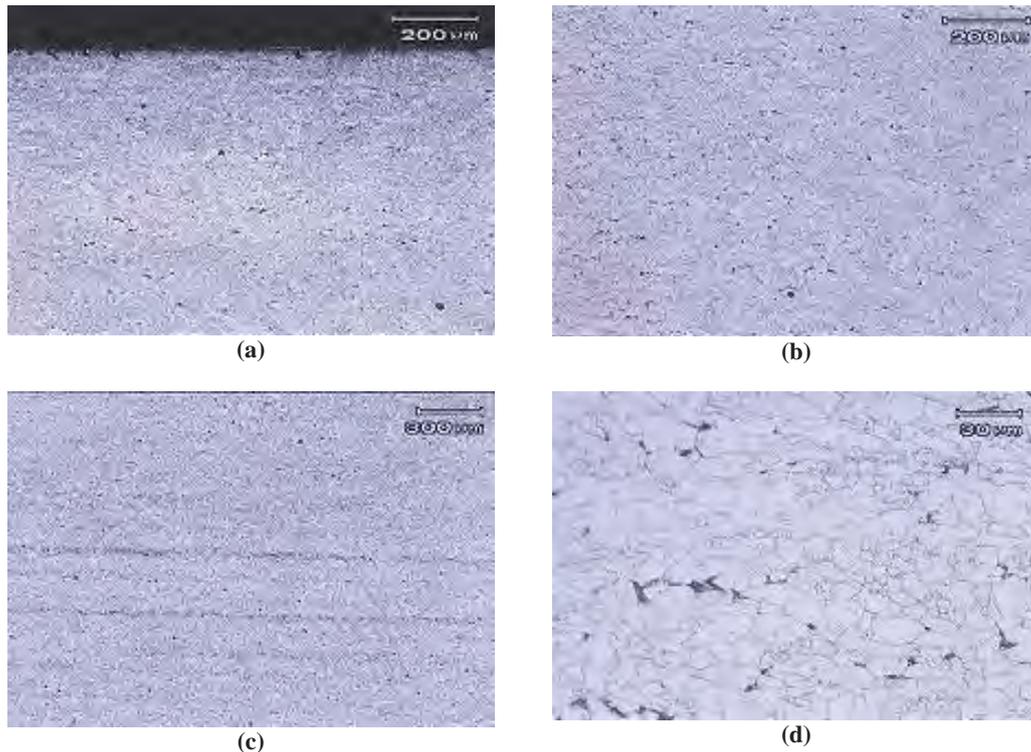

\*) *No Test* : crack propagations on welding area and base metal are not observed  
*No Break* : specimen develops a visible crack in the crack-starter weld bead that is not propagated to either edge of the tension surface  
*Break* : specimen is fractured to one or both edges of tension surface

**Figure 6** Drop weight test results at various temperature tests: (a) break condition at -55 °C, (b) break condition at -45 °C, (c) no test condition at -40 °C, and (d) no break condition at -40 °C

## 4.2 Metallographic Observation

Microstructure of the hot rolled steel plate is shown in Figure 7. Fine ferrite with grain size of 5.0 – 9.0 μm (ASTM no 12.3 – 10.7) and fine lamellar pearlite were observed by means of optical microscopy. Banded pearlite structure is not observed at surface, quarter thickness, and half thickness of the samples.

**Figure 7** Microstructure of the hot rolled steel plate in surface position (a), quarter thickness (b) and (d), and half thickness (c)

## 5. SUMMARY

The appropriate properties of hot rolled steel plates NK – KA36 and ABS – AH36 specification for shipbuilding application could be obtained by strictly chemical composition control during slab steel making process combined with reduction and temperature control during hot rolling process.

### ABSTRACT

Limitation of iron ore reserve having high quality ore and of energy has enhanced development in iron and steel producing technology and method. The ITmk3 process is one of iron making technology that can cope with the problems. It uses composite pellet as feeding material. In this process the ratio between iron and carbon are very important. Carbon holds an important role in the reduction process of iron. The transformation from iron oxides to iron metal will complete if composite pellet contains enough carbon. This paper discusses the influence of carbon ratio in iron reduction process. Nickel saprolite and coal are used as iron and carbon source. They are grinded, crushed, sieved, mixed and formed in cylinders. The weight ratios of ores to coal are 1:1 and 2:1. The reduction held in a furnace at 1100°C for 60 minutes and 1250°C for 120 minutes. The results show that the reduction could not complete. Weak peak of FeNi is due to reduction process do not immediately follow the dehydroxylation process.

### ABSTRACT

Ilmenite (FeO.TiO<sub>2</sub>) ore from Bangka island-Indonesia is a potential raw material for synthesizing titanium dioxide (TiO<sub>2</sub>) to be used as pigmen and photocatalyst. The manufacture of TiO<sub>2</sub> particles from ilmenite can be done through the process of solvent extraction using sulfuric acid route. Therefore, the solubility of this ilmenite ore in sulfuric acid environment is one of key factors to obtain the desired TiO<sub>2</sub> particles. The current research is aimed at comparing the solubility of pristine Bangka ilmenite ore with that of precedingly decomposed by sodium hidroxide (NaOH) in both pressurized reactor/autoclave and atmospheric reflux reactor. The dissolution of both precursors was carried out in a pressurized reactor and an atmospheric reflux reactor with various temperatures of 75, 100, 125, 150 and 175 °C. The results showed that the optimum dilution was achieved at 150 °C in a pressurized reactor and an atmospheric reflux reactor. The obtained recovery of ilmenite was 88.8 % for a pressurized reactor and 75.5 % for an atmospheric reflux reactor. The solubility of titanium increased steadily to reach a recovery of 68 % at f 150 °C and decreased significantly afterwards. It was also found that the increase of iron solubility was proportional to the rise of processing temperatures.

### ABSTRACT

Anatase TiO<sub>2</sub> enrichment from Bangka ilmenite (FeTiO<sub>3</sub>) has been conducted. First, ilmenite was mechanically activated using a planetary ballmill to obtain sub-micron sized particle followed by magnetic separation. Chemical treatment, dissolution of iron using hydrochloric solution, was performed to obtain titania rich residue. EDX data shows that the iron content was reduced in the titania residue. Ammonium hydroxide (NH<sub>4</sub>OH) solution was added to the washed precipitate, before adding H<sub>2</sub>O<sub>2</sub> solution (10%) that acted as a coordination agent to leach titanium from the residue in the form of ammonium peroxy titanate solution. The peroxy titanate powder was obtained by evaporating the ammonium peroxy titanate solution. XRD data show that TiO<sub>2</sub> anatase was formed after peroxy titanate powder was calcined at the temperature of 600°C. EDX data also shows that the obtained anatase TiO<sub>2</sub> still has impurities, such as silicon (0.98%) and iron (2.75%). Its photocatalytic activity was studied on photodegradation of Congo Red and compared with the photocatalytic activity of commercial TiO<sub>2</sub>, Degussa P-25. The photoreactivity test on degradation of Congo Red solution with the as-prepared Anatase gave 20% degradation which is still inferior compared to the results given by Degussa P25 (92%). This indicates that the impurities in as-prepared Anatase may cover the titania surface hindering the contact between Congo Red as well as UV-light and the active titania species.

### ABSTRACT

NiTi is alloy that has unique properties include shape memory dan superelasticity. However, it has disadvantages which cause allergic and toxicity to the body from the Ni release. In order to reduce Ni release and increase corrosion resistance an Electropolishing Pretreatment- Photoelectrocatalytic Oxidation (EP-PEO) and Advanced Oxidation Process (AOP) coating were synthesized in order to produce TiO<sub>2</sub>. Scanning Electron Microscope (SEM) was depicted various morphologies of NiTi orthodontic wire surface. Ni release experiment in various saliva by using Inductively Coupled Plasma (ICP) was shown reducing Ni release significantly both in saliva pH 3 dan pH 6.25 in AOP coating for 2 months monitoring. This results confirmed that the Ni release was evidently decreased and the corrosion resistance significantly improved after coated with AOP.

### ABSTRACT

Bacterial cellulose-based carbon nanotube has been synthesized by catalytic graphitization method. Bacterial cellulose (BS) is a source of cellulose produced from fermentation of medium by *Acetobacter xylinum*. Since it contains unbranch polymer linked by  $\beta$ -1,4 glucopyranose with hydroxyl groups, BS is able to use as precursor in synthesis of carbon nanotube. Due to catalytic graphitization, chitosan served as coupling agent and dispersant of catalyst and various concentration of catalyst  $\text{FeCl}_3 \cdot 6\text{H}_2\text{O}$  also were used. Graphitization was conducted in furnace with inert nitrogen gas atmosphere at  $800^\circ\text{C}$  for 2 hours. SEM-EDS were used to evaluate the morphology and semi-quantitative analysis of sample. TEM was used to determine the microstructures and crystallographic. When the chitosan was added 0.5%, its served as coupling agent and dispersant of catalyst with BS. Chitosan improved physical properties, relieved its brittleness, and caused the optical properties of BS. Catalyst of  $\text{FeCl}_3 \cdot 6\text{H}_2\text{O}$  was used to assist the formation and growth of carbon nanotube. The amount of carbon was not affected by time aging. 0.1 M  $\text{FeCl}_3 \cdot 6\text{H}_2\text{O}$  was the optimum concentration to produce carbon nanotube with 81, 58% the mass of carbon, plane orientation (002) (100) and the diameter of carbon nanotube is 25 nm.

### ABSTRACT

Refinery wastewater treatment is needed especially in the oil-producing arid regions such as oil refineries due to water scarcity. One of potentially applicable process to treat refinery wastewater is a submerged membrane technology. However, the application of submerged membrane systems for industrial wastewater treatment is still in its infancy due to the significant variety in wastewater composition and high operational costs. The aim of this study was to investigate ultrafiltration (UF) membrane morphology and performance for refinery produced wastewater treatment. Submerged UF bundle was equipped using polyvinylidene fluoride (PVDF) hollow fibers. Hydrophilic PVDF membranes were prepared via the phase inversion method by dispersing lithium chloride monohydrate (LiCl.H<sub>2</sub>O) and titanium dioxide (TiO<sub>2</sub>) nanoparticles in the spinning dope. The comparison of morphological and performance tests was conducted on prepared PVDF ultrafiltration membranes. Distinctive changes were observed in membrane characteristics in term of ionizable functional groups, membrane wettability, tensile testing and roughness measurement. Mean pore size and surface porosity were calculated based on permeate flux. The experiment was conducted using refinery wastewater as influent and an experimental set-up comprised mainly of submerged membrane UF reservoir, circulation pump, and aerator were used throughout investigation, which operated at vacuum pressure. Fouling characteristics for hydrophilic PVDF hollow fibers fouled with suspended solid matter was also investigated. Mixed liquor suspended solid (MLSS) of 3 g/L and 4.5 g/L were assessed by using submerged PVDF membrane with varied air bubble flow rates. Results showed that effect of air bubbles flow rate of 2.4 ml/min increased the flux, total suspended solids (TSS) and sulfide removal of 148.82 L/m<sup>2</sup>h, 99.82 % and 89.2%, respectively due to increase of turbulence around fibers, which exerts shear stress to minimize particles deposited on membrane surface. It was concluded that submerged ultrafiltration membrane is an available option to minimize energy process for treating such wastewater solution.

### **ABSTRACT**

The effect of ECAP(equal-channel angular pressing) route on the high-strain-rate deformation behavior of ultra-fine-grained aluminum alloy was investigated. The 8-pass ECAPed specimens deformed via three different routes consisted of ultra-fine grains 0.5  $\mu\text{m}$  in size, and contained a considerable amount of second-phase particles, which were fragmented and distributed in the matrix. In the torsion tests, the maximum shear stress significantly increased with increasing number of ECAP passes, while the maximum shear stress and fracture shear strain were lowest in the specimen deformed via route A among the three 8-pass ECAPed specimens. Observation of the deformed area beneath the fractured surface revealed the adiabatic shear bands of 100  $\mu\text{m}$  in width in the specimen deformed via route A, which minimized the maximum shear stress and fracture shear strain, whereas they were hardly formed in the specimens deformed via route B or C. The formation of adiabatic shear bands was explained in terms of critical shear strain, deformation energy required for void initiation, and microstructural homogeneity related to ECAP routes.

### ABSTRACT

This work concentrates on assessment of the TEP change of AA6061 during isothermal aging at 177 °C and the following interrupted aging at 65 °C. The results show that the TEP is sensitive to follow the microstructural changes undergone during all aging stages. Multiple sub-ambient temperature dependences TEP of binary Al-X alloys as well as the AA6061 subjected to the above mentioned heat treatments were undertaken. The solute level of individual element of the alloy, particularly those contributing to the clustering/precipitation, can be extracted and evaluated

### ABSTRACT

Numerical simulation by finite element method has become a powerful tool in predicting and preventing the unwanted effects of sheet metals technological processing. One of the most important problems in sheet metal forming is the compensation of springback. To improve the accuracy of the formed parts, the die surfaces are required to be optimized so that after springback the geometry falls at the expected shape. This paper presents and discusses numerical simulation procedure of die compensation by using the methods of Simplified Displacement Adjustment (SDA). This analysis use Benchmark 3 models of Numisheet 2011. Sensitivity analysis was done by using finite element method (FEM) show that the springback values are influenced by element size, integration points and material properties.

### ABSTRACT

In this research, it has been carried out the development of a strength analytical method of a thin-walled steel square pipe (Square Hollow Section/SHS) affected by the interaction of concentrated-compressive load and bending moment then it verified by experimental approach. The experimental approach was consisted of measuring a basic material property and the strength of the investigated SHS pipe. The basic material property identified parallel to rolling direction ( $0^\circ$ ) and perpendicular to rolling direction ( $90^\circ$ ). The analytical data obtained from cut-off strength method is generally scattered within the acceptable limits of  $\pm 20\%$  and tends to be in unconservative region. The actual data measured from experiments shows that SHS beam with  $t = 0.6$  mm and longitudinal axis parallel to the rolling direction of base material has higher strength compared to the one of the SHS beam with  $t = 0.6$  mm and longitudinal axis perpendicular to the rolling direction, meanwhile the SHS beam with  $t = 1.2$  mm is tends to be equal. This means that the rolling direction of base material can be considered to be a parameter in the strength design of a thin-walled SHS beam.

## ABSTRACT

Friction welding is one solution to solve the problems joining of metals which are difficult to be welded by fusion welding such as aluminum. The process was run by rotating a rod upon another metal and force was applied. Consequently, heat arose below the melting point and made the metals molten joined together as force continuously applied. In this research aluminum 6xxx series were used as this metal have good corrosion resistance, good machinability but not ease to weld. Among important parameters in linear welding are friction time, friction pressure and rotation speed; we only concern in the first one. The friction time variations were 20, 45, 80, and 120 seconds respectively. Whereas the pressure and the rotation speed were kept constantly. The joined aluminum then tensile strength tested using universal testing machine, hardness tested using Electrical Brinell hardness Tester Hauser Henry SA and also observed under optical microscope. The highest tensile strength of 61.07 MPa was gained from friction time of 45 seconds, while the least of only 28.81 MPa when using friction time of 20 seconds. Hardness in the welding areas was almost the same as that of base metal, whereas in the heat affected zone tend to little bit decreased. Friction time of 20 seconds gave the hardest in the welding are almost the same as base metals, whereas the softest as result of 120 friction time. Optical microscope observations show that there were porosities in the welding areas. It probably caused by some trapped gas which formed inter-dendritic porous.

## 1. INTRODUCTION

Aluminum is kind material, which has some advantages, i.e. it is light, soft and easy to be machined [1]. In order to be able to used as material for construction aluminum should be alloyed. However, both pure and alloyed aluminum are not easy to be joined by fusion welding. The reason is it has high heat factor, oxidation easy and form aluminum oxide  $Al_2O_3$  which high melting point. Alternatively, aluminum alloy could be joined by friction welding. In the previous research, we have successfully applied friction stir welding for joining plate of aluminum alloy AA 1100 by varying speed and feed [2, 3]. The results were not significantly different from another researcher [4, 5]. This series of aluminum alloy, however, have limited application as material construction. Whereas, aluminum alloy (Al-Mg-Si) serial number 6061 have been applied for high-strength structural members, vehicles, rolling stock, marine applications, architectural applications [1]. This aluminum alloy is able to be heat treated, good machine ability, good weld ability and corrosion resist.

Friction welding is a solid state welding process [4] in which the heat for welding is produced by the relative motion of the two pieces being joined. Friction welding achieves 100 per cent metal-to-metal joints, giving parent metal properties. It is the only joining process to do this. No addition material or fillers are required and there are no emissions from the process. The process involves making welds in which one component is moved relative to, and in pressure contact, with the mating component to produce heat at the faying surfaces. Softened material begins to extrude in response to the applied pressure, creating an annular upset. Heat is conducted away from the interfacial area for forging to take place. The weld is completed by the application of a forge force during or after the cessation of relative motion. The joint undergoes hot working to form a homogenous, full surface, high-integrity weld.

Apart from speed and feed rate, other parameters influence the quality of welding such as time and force applied during the process [5]. The quality of weld and mechanical properties of weld depend on the correct choice of these parameters. In this research we were developing the use of aluminum alloy (Al-Mg-Si) to be joined by rotary friction welding by devoting on attempt to find the best mechanical properties and micro structure of the welded area by varying the time of friction.

## 2. EXPERIMENTAL PROCEDURE

A simple set up of a rotary friction welding machine are shown in Fig. 1. This machine was modified from ordinary lathe adapted from [6]. Ideally, the machine should be equipped with a braking system to stop the machine when the process completed. However, in this research the chuck in the movable head was modified to make the welded parts rotating together until the machine stop.

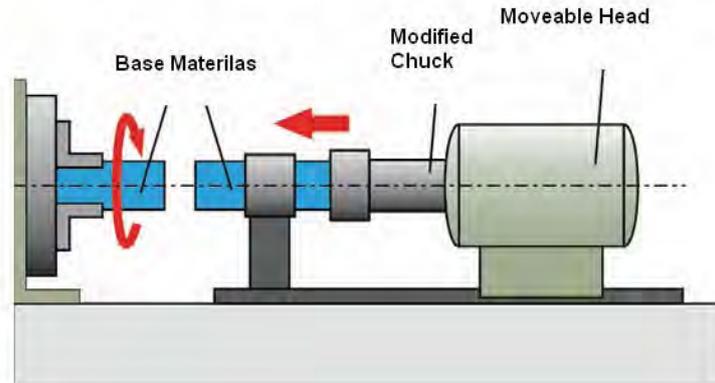

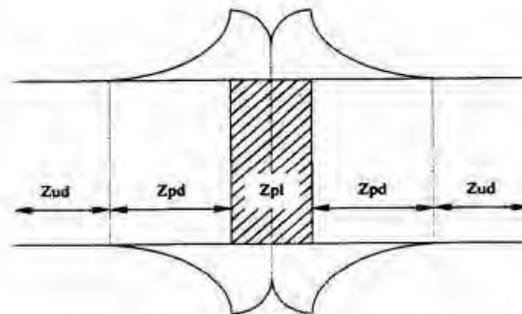

Figure 1: Equipment of rotary friction welding.

The parts to be welded were solid rods of diameter 20mm. Initial preheating was developed by giving friction about 10 seconds. The friction time for welding process were varied as 20s, 45s, 80s and 120s, whereas, the spindle rotation was kept constantly at 1600 rpm. After the friction time was achieved, the rod in the modified chuck was released to let the welded rods turn together.

The welded rods then prepared for tested its tensile strength using ASTM A370-speciment 3 using Universal Testing Machine of 3000kg capacity and 13mm maximum stroke. They were also observed their hardness using Electric Hardness Hauser Henry SA in three areas i.e. fully plasticized ( $Z_{pl}$ ), partially deformed ( $Z_{pd}$ ) and undeformed ( $Z_{ud}$ ) areas as shown in Fig.2. Penetration given was 1kg for about 15 seconds. Furthermore, the welded rods were also observed its microstructure using optical microscope Olympus BX41. The observation areas were the same as hardness tests. Some procedures for preparing the observations were carried out carefully to maximize the results.

fully plasticized ( $Z_{pl}$ ), partially deformed ( $Z_{pd}$ ) and undeformed ( $Z_{ud}$ ) regions

Figure 2: Three regions of observation for hardness and micro structures of welded rods.

### 3. RESULTS AND DISCUSSION

#### 3.1 Results

A sample result of successfully welded rods was presented at Fig. 3. The rods developed like an anchor as they were joined. There are some marks at left and right rods caused of clamping force of chucks. These samples then sawn longitudinally. Before they were observed under microscope, they were etched and some macro photos were taken to check the quality of bond.

Figure 3: A pair of successfully welded rod

Macro photos of each region observed were shown at Fig.4. It is clear that there are porosities in each welded areas. The porosity is one of disadvantages of aluminum alloy when they are welded. High difference of solubility of Hydrogen between in solid and liquid phase lead to this gas tend to trapped and make smooth porosities when it was heated and then quenched as in welding process [7]. Some porosity was long caused by shrinkage when the welded zone cooling down [8].

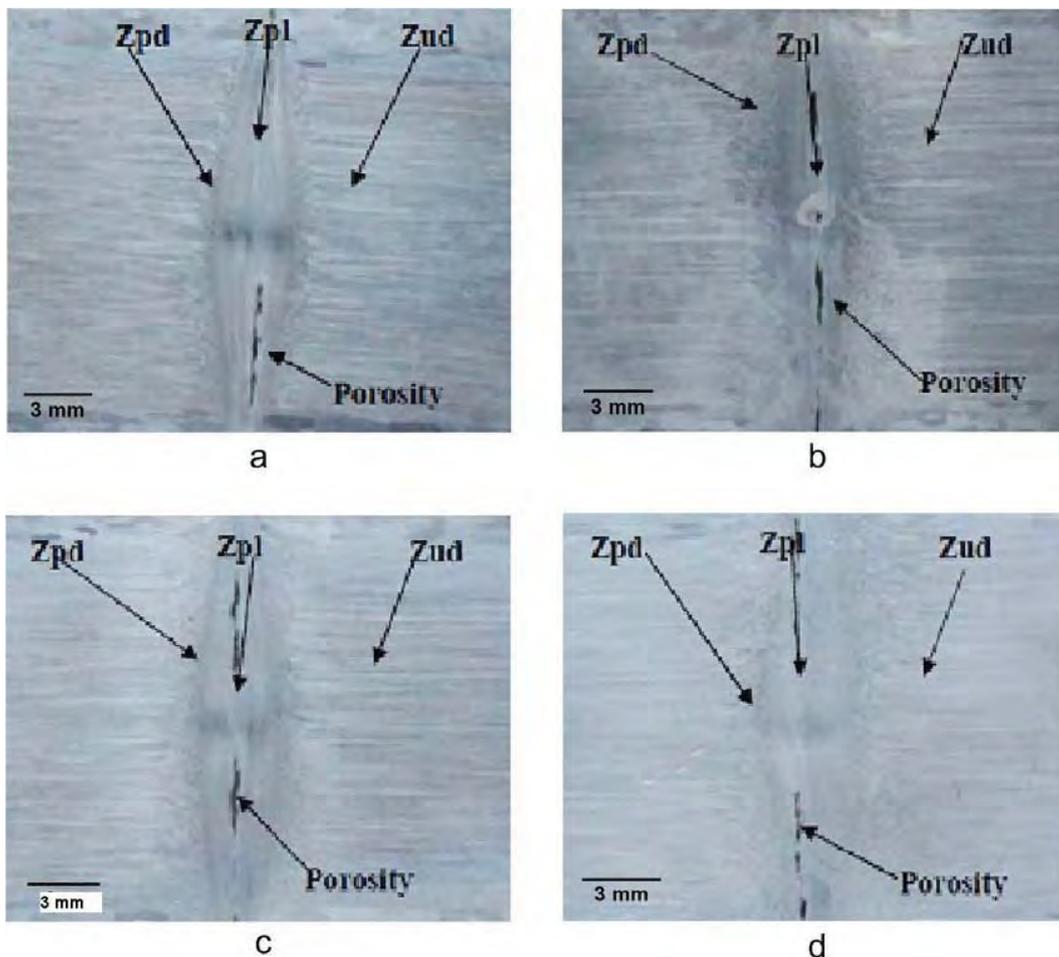

Figure 4: Macro photos of welded rods with variation in friction time (a) 20 seconds, (b) 45 seconds, (c) 80 seconds, and (d) 120 second. All of photos shown that many porosities in the fully plasticized zone.

### 3.2 Microstructure observation

Microstructure observation was carried out to know changing of microstructure after friction welding. The micrographic photo was compared to the one in the literature [7]. The spots shown at Fig 5 which are well dispersed in the aluminum Al-Mg-Si matrices are  $Mg_2Si$  (black) and  $Fe_3Si Al_{12}$  (grey). The later was come out because in the aluminum alloy there are 0.677% Fe and 0.65% Si.

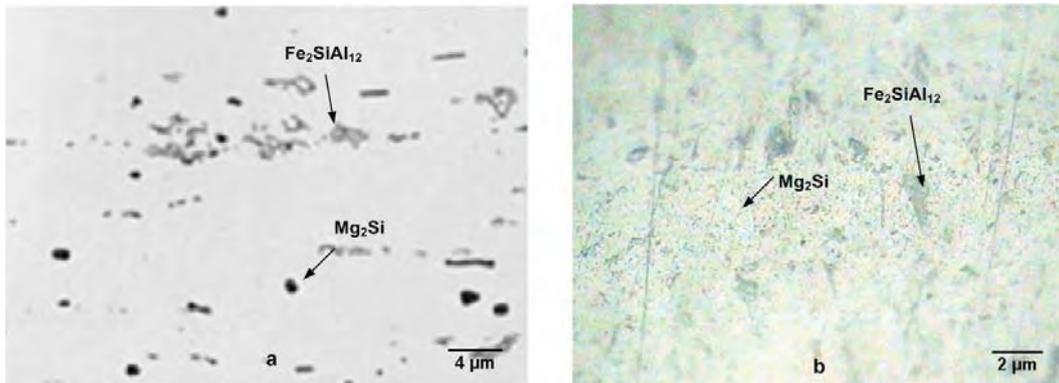

Figure 5: Microstructure at base metal as observed under microscope (right) and compared that of in the ASM Hand Book Metallography and Microstructures (left) [2].

Other observations at different zones were presented at Fig 6. To make it brief only observation in the plasticized zone is presented.

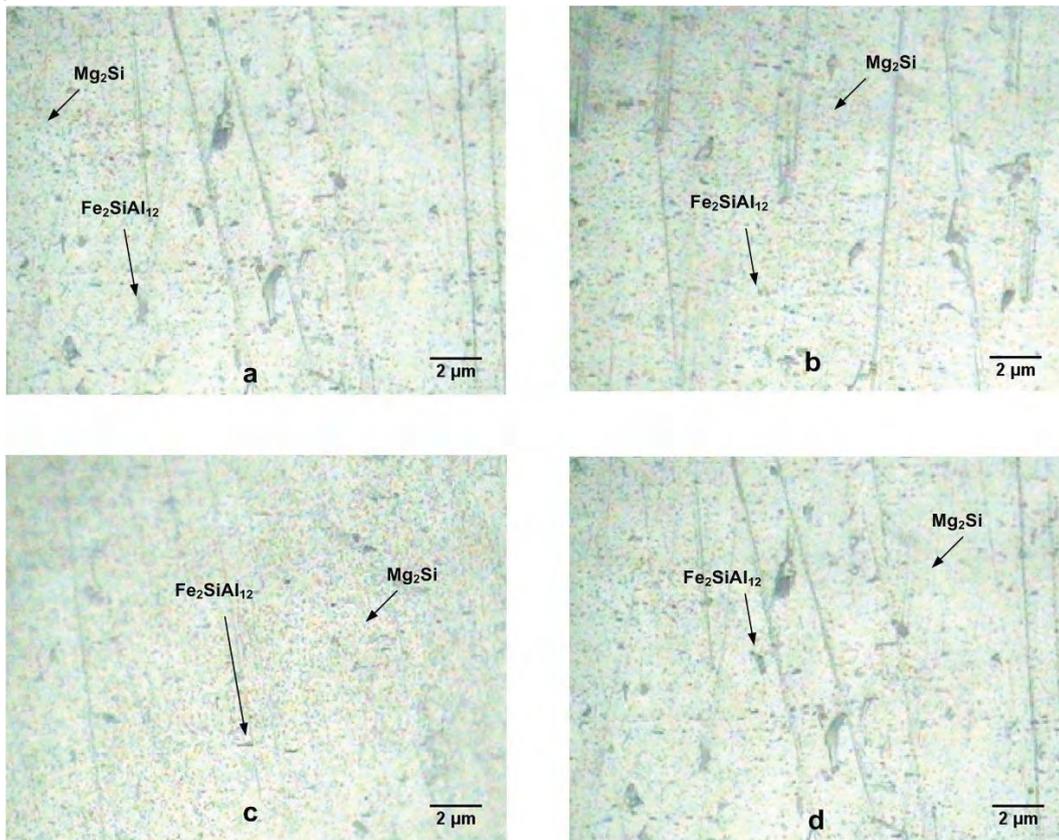

Figure 6: Microstructure of plasticized deformation zone (Zpl) as friction time varied (a) 20 seconds, (b) 45 seconds, (c) 80 seconds and (d) 120 seconds.

According to observation in the Zpl zone, particles of  $Mg_2Si$  were spread and smooth. It is because in this zone the direct friction during welding. Among different friction time there were no such significant differences in their microstructure. However, when it is compared with base metal, the particles of  $Mg_2Si$  in this zone are smaller and smoother.

### 3.3 Tensile Test

Tensile test was carried out to know average tensile strength of the joined rods. Each variation parameter was conducted three times to ensure the result, and graphically presented as in Fig 7. It is clear that there is big difference between tensile strength between base metal and the welded specimens. It is because the structures of the welded rods were changed as effect of deformation. The highest tensile strength of 61.07 MPa was achieved when using friction time of 45 seconds. It can be described that the porosity in this parameter was smallest among others. The wider the porosity the weaker the tensile strength is.

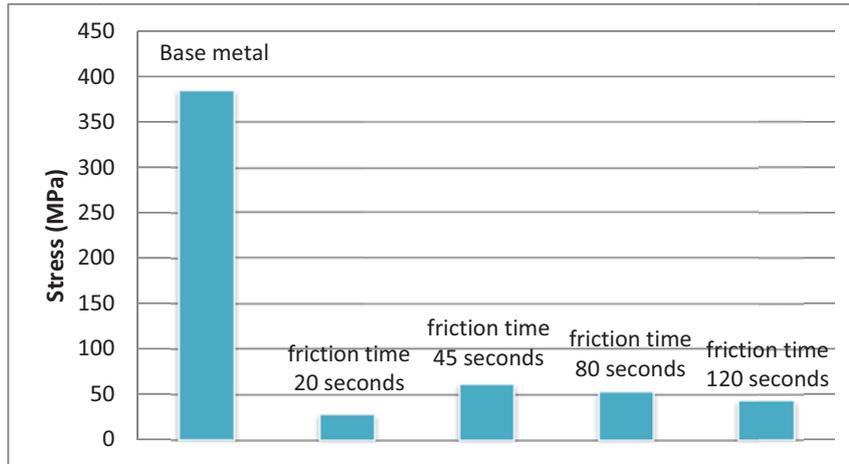

Figure 7. Tensile strength as variation of friction time compared to that of base metal.

The weakest tensile strength achieved when friction time was 20 seconds. Short time of friction would generate not enough heat so cooling time is also shorter. Consequently, the grains are bigger. The smaller the grain size the more grain boundary formed. The more grain boundary the more difficult is the dislocation movement. Finally, it will strengthen the materials.

### 3.4 Hardness Test

Hardness test was also carried out in three different zones as shown at Fig.8.

Figure 8: Hardness average as variation of friction time

From the figure 8 above it is clear that hardness of plasticized zone (Zpl) and base metal (Zud) are insignificantly different, or it can be said that hardness of the welded area is similar to that of base metal. It is effect of friction welding where there was no inserted metal as filler. Nevertheless, hardness in the welded zone would not higher than in the base one, as hardening will not occur during welding [6]. The highest hardness of 68 BHN was achieved when applied friction time of 45 seconds. In this parameter, the grain of  $Mg_2Si$  is smoother and well spread and biggest in number. The smoother grain its structure more densely and bond between atoms is stronger.

### 4. CONCLUSION

From result and discussion it can be concluded that:

1. The strength of welded rods by friction welding was lower compare that of base metal as effect of macro porosities.
2. Micro structure of  $Mg_2Si$  in the welded area (plasticized zone) was smoother and well dispersed than that of partially deformed zone. Consequently, this area is harder and stronger than the later.
3. Friction time of 45 seconds results in highest strength as well hardness than others.

### 5. FUTURE WORKS

Some attempt should be done to reduce the porosities in the welded area such as increasing time of preheating. The machine for this friction welding should be designed that the machine should be stopped as the welding completed.

### Introduction

Nanometer-thick ferroelectric films are of interest due to its distinct ferroelectric properties from the bulk as well as its applicability for resistive switching memory applications. To date, resistive switching behavior of ferroelectric ultrathin films only observable locally via scanning tunneling microscopy (STM) or conducting atomic force microscopy (AFM). This is due to enormous challenge of fabricating nanometer-thick ferroelectric films, continuous over large area. In this work, we present two dimensional ferroelectric films realized via Langmuir-Schaeffer monolayers transfer.

### Results and Discussion

X-ray diffraction (XRD) and AFM analysis of nanometer-thick oligomeric vinylidene fluoride OVDF and P(VDF-TrFE) films reveals the presence of ferroelectric phase and continuous film morphology over millimeters scale. Ferroelectric characterization reveals remanent polarization and coercive voltage of  $0.4 - 1.8 \mu\text{C}\cdot\text{cm}^{-1}$  and  $\pm 0.5 \text{ V}$  respectively. Current-voltage (I-V) and capacitance-voltage (C-V) measurements indicate resistive switching behavior of up to 3 orders of magnitude. The resistive switching behavior is proven to be reproducible through multiple switching for single device and switching of multiple memory cells. Further memory characterization shows stable ON/OFF ratio after switched for  $10^4$  cycles and retains more than 80% its initial ON/OFF current ratio extrapolated to  $10^6$  s. In addition, the memory elements can be reversibly switched between ON and OFF state by voltage pulse as short as  $250 \mu\text{s}$  at  $\pm 1.0 \text{ V}$ . Detailed I-V characterizations confirm the charge tunneling mechanism. On the other hand, the dependence of ON/OFF current ratio on remanent polarization and the cease of resistive switching behavior above the ferroelectric critical temperature verified that the resistance switching is of ferroelectric origin. The robust and continuous ferroelectric films over large area enable fabrication of ferroelectric resistive switching devices at the macroscopic level, representing the first realization of organic ferroelectric switching memory devices by solution processing.

### Conclusion

Resistive switching memory devices based on organic ferroelectric materials has been demonstrated. Formation of robust, continuous, nanometer-thick ferroelectric films can be realized by Langmuir-Schaeffer monolayers transfer. The resistive switching behavior can be implemented for instance as building block for 2D and 3D memory arrays based on crossbar structure as well as hardware basis for memristors' neuromorphic computing.

## ABSTRACT

Atmospheric corrosion resistant High-Strength Low-Alloy (HSLA) steel is intended for structural applications where a combination of high strength and enhanced atmospheric corrosion resistance are desired. It has approximately 4 times the atmospheric corrosion resistance of structural carbon steel, good formability and weldability. The extra strength of HSLA steel makes it more durable and offers a longer useful life span for chimney, bridge, tubular bridge, container and tank.

This work is concerned with the development of 550 MPa Class High Strength Low Alloy (HSLA) steel strips for atmospheric corrosion resistant applications. The addition of corrosion resistant elements up to 0.40% Cu, 0.50% Cr and 0.50% Ni into steel containing 0.16% C and 1.2% Mn, combined with controlled rolling process resulted in high yield strength of 425 ~ 500 MPa and tensile strength of 570 ~ 600 MPa with good formability and weldability.

## Keywords

Atmospheric Corrosion Resistance, HSLA, Corrosion Resistant Elements, Structural Steel

## 1. INTRODUCTION

Atmospheric corrosion resistant High-Strength Low-Alloy (HSLA) steel is intended for structural applications where a combination of high strength and enhanced atmospheric corrosion resistance are desired. It has approximately 4 times the atmospheric corrosion resistance of structural carbon steel, good formability and weldability. Thus atmospheric corrosion resistant steel have strength 35 – 40% higher than carbon steel (effect of vanadium addition). The extra strength of HSLA steel makes it more durable and offers a longer useful life span for chimney, bridge, tubular bridge, container and tank.

Since early 1930s with discovering weathering steels by US Steel Corporation many kind of atmospheric corrosion resistant steels is become widely used in structural and construction application. The steels are born to fulfil increasing demand of bridges and vehicles with higher strength, lower weight, lower maintenance cost and good corrosion resistance properties. In corrosive atmosphere with higher pollutant content of marine and industrial environment, appropriate material selection is become one important factor for longer life time materials. Compare to an ordinary plain carbon steels for structural, atmospheric corrosion resistant steel which is used in this application has better corrosion resisting properties. By adding certain amount of chromium, nickel, copper or phosphorus shows better corrosion resistance due to formation of protective oxide layer in several years of exposure.

This paper briefly describes the experience of Krakatau Steel in developing 550 MPa Class High Strength Low Alloy (HSLA) steel strips for atmospheric corrosion resistance applications. The development has been carried out by addition of corrosion resistant elements combined with controlled rolling process resulted in high strength product with good formability, weldability and corrosion resistant.

## 2. PRODUCT DESIGN

The requirements of the developed steel are in accordance to Baja Tahan Korosi Cuaca (BTKC) grade C standard, that equivalent to USS COR-TEN C standard. The requirements, which comprise chemical composition and mechanical properties, compare to typical of chemical composition and target mechanical properties as summarised in table 1 and table 2.

Table 1: Standard and Design of Chemical Composition (wt, %)

	C	Mn	Si	P	S	Cu	Cr	Ni	V
Design KS	0.16 max	0.90-1.20	0.30-0.60	0.020 max	0.020 max	0.30-0.40	0.40-0.60	0.30 max	0.05-0.08
Standard	0.19 max	0.80-1.35	0.30-0.60	0.040 max	0.050 max	0.25-0.40	0.40-0.70	0.40 max	0.04-0.10

Table 2: Mechanical properties

	YS (N/mm <sup>2</sup> )	TS (N/mm <sup>2</sup> )	A (%)
Design KS	425 - 500	570 - 600	22 - 28
Standard	415 min	550 min	21 min

The addition of corrosion resistant elements up to 0.40% Cu, 0.50% Cr and 0.50% Ni into steel containing 0.16% C and 1.2% Mn, combined with controlled rolling process resulted in high yield strength of 425 ~ 500 MPa and tensile strength of 570 ~ 600 MPa with good formability, weldability and corrosion resistant.

### 3. PRODUCTION PROCESS

The production of steel for atmospheric corrosion resistant applications is carried out in the slab steel plant and hot strip mill with processing route as generally shown in Figure 1. In the slab steel plant, there are three main stages of the process such as melting process, secondary treatment and casting. Melting process in the electric Arc Furnace uses the raw material which consists of 20% scrap and 80% of sponge iron is melted. This melted steel is then further processed for secondary treatment in the Ladle Furnace to reduce the sulphur content and to adjust the chemical composition by adding some alloying elements. Subsequently, the steel is continuously cast in the continuous casting machine to produce steel slab.

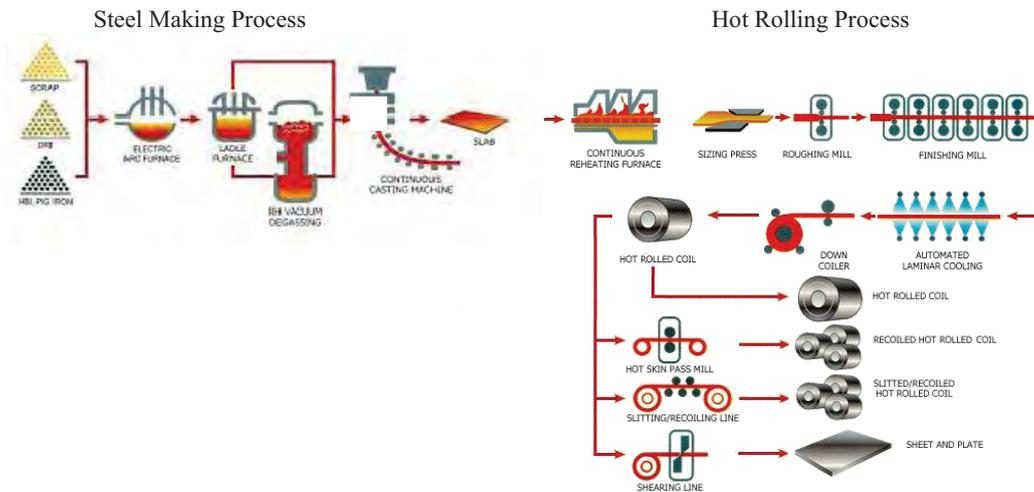

Figure 1: The Production Process Line in Steel Making and Hot Rolling

The steel making and casting practices adopted for this grades can be summarized as follows:

- Hot metal desulphurization
- Calcium treatment by CaSi wire injection for inclusion shape control
- Casting into tundish with dam and weir to float up the inclusions
- Argon gas purging and extended shroud to minimize re-oxidation during set up
- Controlling the cooling intensity, superheat and casting speed
- Metal retention in ladle at ladle change

These practices are developed not only to achieve the required chemical composition but also to obtain steel with high cleanliness, free from internal and surface defect.

In the hot strip mill, the slabs which come from the slab steel plant are subsequently hot rolled to the specified thickness. The Thermo-Mechanical Control Process is applied during rolling to get fine grain microstructures of HRC and to achieve the required mechanical properties.

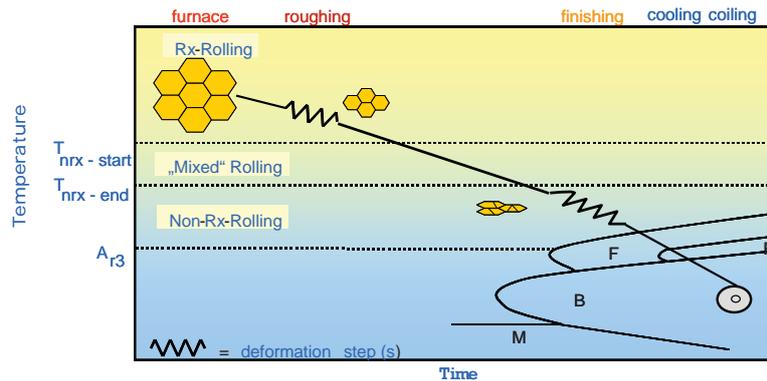

Figure 2: A schematic of Thermo-Mechanical Control Process during Control Rolling

Figure 2 shows the basic principle of Thermo-Mechanical Control Process during rolling applied in the hot strip mill. Slab is reheated up to about 1200°C and soaked at that temperature in the reheating furnace then control-rolled with high reduction at above the non-recrystallization temperature in the roughing mill in order to achieve fine austenite grain size. This steel is then rolled at a temperature between non-recrystallization and  $A_{r3}$  transformation temperature in the finishing mill. This process will introduce the deformation bands within the austenite grains which promote the nucleation sites for ferrite grains. It consequently results in the formation of finer ferrite grain after austenite – ferrite transformation. The steel strip is finally coiled at about 600°C.

#### 4. RESULT AND DISCUSSION

##### 4.1 Mechanical Test of Hot Rolled Coil

The results of tensile test which were taken from production data of hot rolled coil are presented at table 3. The tensile strength values of hot rolled coil with 14.0 and 16.0 mm in thickness are 585 – 600 MPa and 570 – 590 MPa, respectively. The yield ratio of the developed steels is around 75 – 83 %, indicate that material have higher stiffness properties. All the tensile values are within the range of specified values for the BTKC Grade C specification and achieve the targeted values.

Table 3: Tensile Test Result of Hot Rolled Coil

Thickness (mm)	Yield Strength (MPa)	Tensile Strength (MPa)	Elongation (%)	Yield Ratio (%)	Direction
14.0	440 - 500	585 - 600	24 - 28	77 - 83	Transversal
16.0	425 - 460	570 - 590	22 - 26	75 - 79	Transversal

##### 4.2 Corrosion Rate

Figure 3 and Table 4 shows the weight loss profile and corrosion rate of weathering resistance steel and carbon steel after 6 years exposed at marine and industrial area. As can be seen in the figure 3, after 6 years exposed in marine and industrial area the average weight loss for plain carbon steel were 0.097g/mm<sup>2</sup> and 0.105g/mm<sup>2</sup>, almost 2 times higher than weight loss for weathering steel where the average were 0.056 g/mm<sup>2</sup> and 0.062g/mm<sup>2</sup>, respectively. Weight loss for weathering steel were sharply increased in the first year and became slightly decreased after 3 years of exposure, while plain carbon steel were sharply increased until 6 years of exposure. This weight loss value indicates that weathering steel has better atmospheric corrosion resistant properties than ordinary plain carbon steel.

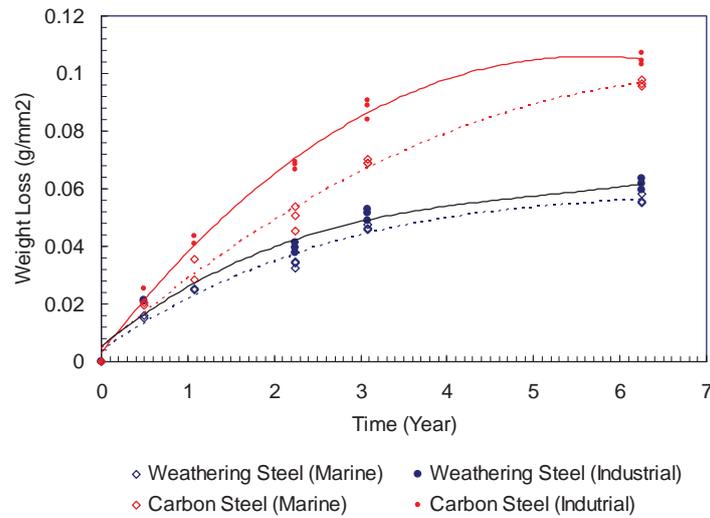

Figure 3: Variations of weight loss of steels in marine and industrial area

Table 4. Corrosion Rate after 6 years of exposure

Exposed Area	Steel Grade	Corrosion Rate (mpy)
Industrial	Carbon Steel	1.699
	Atmospheric Corrosion Resistant Steel	0.996
Marine	Carbon Steel	1.560
	Atmospheric Corrosion Resistant Steel	0.907

## 5. SUMMARY

Product design by addition some elements up to 0.40% Cu, 0.50% Cr and 0.50% Ni into steel containing 0.16% C and 1.2% Mn, combined with controlled rolling process in producing 550 MPa Class High Strength Low Alloy (HSLA) steel strips for atmospheric corrosion resistant applications has ensured the mechanical properties with good formability, weldability and corrosion resistant.

## 2. Analytical and Experimental Setup

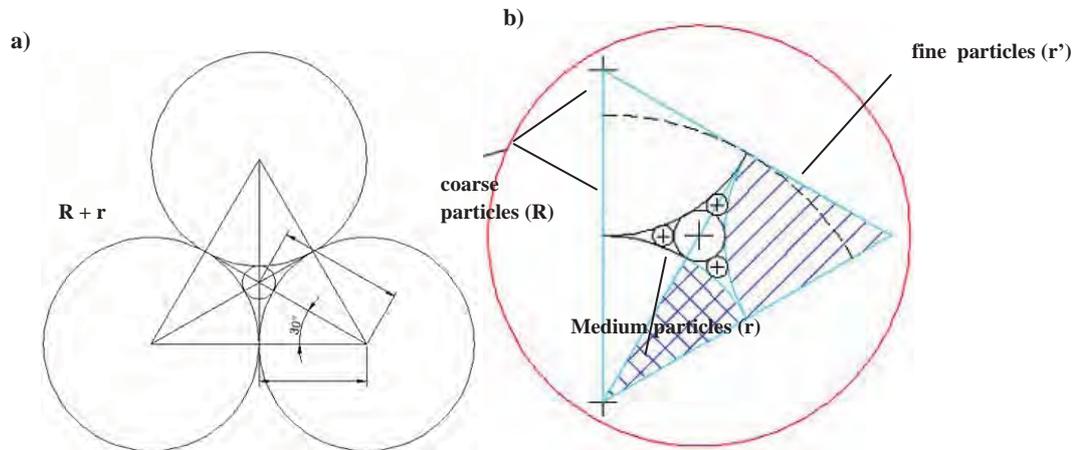

### A. Analytical of Geometric

The experimental began by preparing the mold bushing P/M (Fig. 1a), which consists of 4 components such as carbon steel shell (die), solid carbon steel rod (core), flange (base), and hollow carbon steel rod (punch). Prepare powder duralumin size by large (412 μm), medium (107 μm), fine (20 μm), and graphite as a lubricant P/M. Then made two analytical and experimental research design. The network mode is ordered of the particles forming the mold space also called discrete element models, have been used previously to study two-dimensional particle as in Fig. 1b, and detail of particles distribution in Fig. 1c.

**Figure 1.** Tools and ordered of P/M particles

a). Components of P/M process, b). Coordination of coarse particles, c). Particles coordination of P/M system

**Figure 2.** Geometry of powder in P/M

a). Radius correlation of particles, b). Filler interstitial of ordered particles

Powder radius (average) that can be inserted in triangle gap between powder grains (coarse powder). If the powder grains are considered the uniform, it can be shown in Fig. 2a, it can be searched by the equation;  $\frac{Base}{Hypotenusa} = \cos 30^0$  (1)

Result of operated equation 1 is  $\frac{R}{R+r} = \frac{\sqrt{3}}{2}$  and the final is  $r = 0.26 R$

While the triangular gap (the gap) formed between the particle grains themselves extent can be calculated as follows:

The gap area =  $2 \times (\frac{1}{2} \text{ blue triangle area} - (\text{Area of pie} + \text{small area of pie}))$  (2)

and  $\frac{1}{2} \text{ blue triangle area} = \frac{1}{2} a \times t = \frac{1}{2} R \times \sqrt{(2R)^2 - R^2} = 1.73 R^2$

Area of big pie (AoBP) =  $\frac{\pi R^2}{6} = \frac{3.14 R^2}{6} = 0.523 R^2$  and Area of small pie =  $\frac{AoBP}{2} = \frac{0.523 R^2}{2} = 0.2616 R^2$

Area of big gap =  $2 \times (1.73 R^2 - (0.523 R^2 + 0.2616 R^2)) = 1.8908 R^2$

Powders finer (fine powder) can be inserted between the slit powder with medium powder. To find the radius of a small powder, widely sought large gap formed powder with a small powder first (small gap), in the following way:

$$\text{Area of small gap (AoSG)} = \frac{\text{AoBG} - \text{Area of medium grains}}{3} \quad (3)$$

$$\text{AoSG} = \frac{1.8908 R^2 - \pi r^2}{3} = \frac{1.8908 R^2 - 3.14 \times (0.26 R)^2}{3} = \frac{1.04944 R^2}{3} = 0.3498 R^2$$

To find the radius ( $r'$ ) of a fine particles in Fig. 2b, used the ratio of the large gap with a small gap.

$$\frac{\text{AoBG}}{\text{radius of medium grains}} = \frac{\text{AoSG}}{\text{radius of fine grains}} \quad \text{where} \quad \frac{1.8908 R^2}{0.26 R} = \frac{0.3498 R^2}{r'} \quad \text{finally } r' = 0.048R$$

## B. Quantity of Powder

The coarse particles number are powder forming ( $N_p$ ), formulated:  $N_p = \frac{V_{die\ cavity} - V_{core\ rod}}{V_{particle\ sphere}} = \frac{\pi l R_d^2 - \pi l R_c^2}{\frac{4}{3} \pi r_p^3}$  (4)

$$N_p = \frac{l (R_d^2 - R_c^2)}{\frac{4}{3} r_p^3} = \frac{3 l (R_d^2 - R_c^2)}{4 r_p^3}$$

The medium particles number are first filler powder ( $N_{f1}$ ), calculated based on the fraction of particles in the mold cavity formed by the particles forming the powder, formulated:

$$N_{f1} = 3 N_p = \frac{9 l (R_d^2 - R_c^2)}{4 r_p^3}$$

The fine particles number are second filler powder ( $N_{f2}$ ), calculated based on the fraction of particles in the mold cavity formed by the powder particles forming and powder filler first, formulated:

$$N_{f2} = 3 N_{f1} = \frac{27 l (R_d^2 - R_c^2)}{4 r_p^3}$$

Volume particle powder bushing ( $V_b$ ), formulated particles mixture fraction, coarse : medium : fine is 12 : 3x12 : 3x3x12 or 1 : 3 : 9. In the experiment the mixture fraction weight fraction of particles is more practical than a mixture of grains, which is the volume of grain ( $V$ ) =  $\frac{4}{3} \pi R^3 \gamma_{dul}$  so the weight of the mixture of particles included in the printed P / M for fraction of weight [ in g ] coarse : medium : fine is 10247 : 185 : 1

## C. Experimental

In this experimental duralumin filling powder into a mold bushing is determined on the basis of volume. And bushing the P/M were used as specimens grouped by similar sized powder particles and the variation (fraction size is coarse : medium : fine).

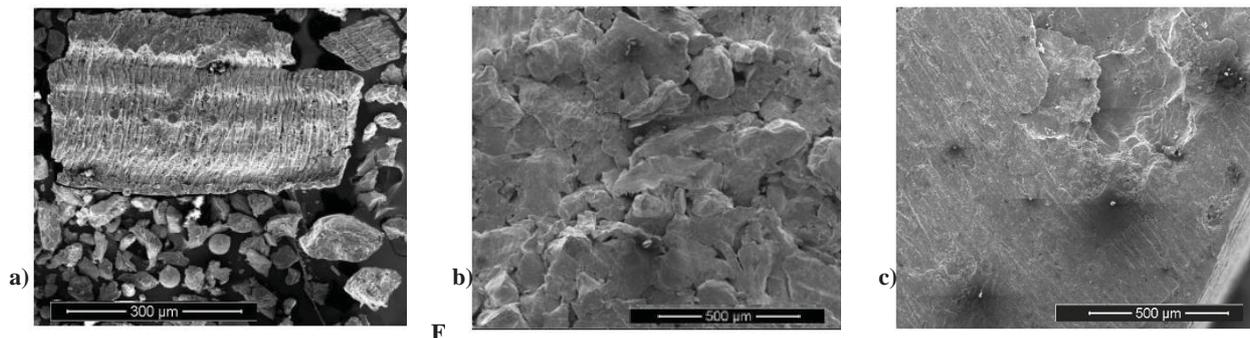

### Preparation of Specimens

Lubricate bushing with graphite mold components, mold components are stacking the electric furnace and did preheating to a temperature of 350°C. Lift the punch by lowering the hydraulic pressure and input duralumin powder particles that have been weighed or stirred into molds and lower punch until the hydraulic pressure machine indicated number Zero. Thermoregulation set at 450°C temperature after the temperature reaches the lower mold punch until the manometer indicates the pressure 400 bar and maintain the pressure for 15 minutes. Lower hydraulic pressure to zero bars so punch lifted up, take molds of the furnace and remove the specimen from the mold.

### Test of Specimen

The optical emission spectrometry (OES) test to see the major alloying element in powder duralumin. Two important considerations OES tests performed, namely: 1). for determining the ideal density specimen, 2). the hot compacting process (a combination of pressure and sinter) diffusion occurs between base metals and master alloys. Picnometry test to measure the physical properties (density and porosity) specimen. Picnometry test is done by weighing the specimen in air and in water, to operate the press. Picnometry actual density values obtained and the porosity of the specimen P/M. Tested scanning electron microscopy (SEM) to obtain images porosity (qualitative and quantitative) and the length of contact (neck) between powder particles. In this research, surface hardness P / M in the test using Vickers micro hardness ( $H_V$ ) with a load of 100g. Besides, SEM porosity test done as validation (method of calculation).

## 3. Result and Discussion

a). Powder particles, b). Sphere geometry of disordered particles, c). Sphere geometry of ordered particles

Generally the quality of near net shape manufacturing processes such as metal forging, metal casting, and powder metallurgy are determined by optimizing the arrangement of the micro-spatial variation in the control of the compression, vibration, and fine particles inserts. Method of fine particles inserts results of randomized trials and control the number of particles in the mold as in Fig. 3b and 3c, respectively. Fig. 3b shows the amount of porosity greater than Fig. 3c, this is due to P/M with disorganized grain constituent particles during the hot press process locked up, causing a permanent gap until the agglomeration process is complete. While the P / M with items ordered (Fig. 3c) during the hot press slide between the particle filler occupy particle gaps and reduce the cavity space between the grains of the agglomeration process to complete. According to Božić et al. [4], the microstructural analysis of ordered of dislocations within the boundaries created sub-grains resulting in higher grain density around Al<sub>2</sub>O<sub>3</sub> particles. The statement was supported by result of research as in [5], the addition of small amounts of lead and zinc to the composite increases the hardness and wear resistance.

**Table 1.** Nomonal composition of duralumin in experiment

Duralumin [wt%Cu]	Weight of elements [%]								Theoretical mass density [g.cm <sup>-3</sup> ]
	Cu*	Mn	Si*	Mg*	Zn	Fe*	Sn	Al*	
	<b>8.38</b>	<b>7.20</b>	<b>2.52</b>	<b>1.59</b>	<b>7.14</b>	<b>7.26</b>	<b>7.17</b>	<b>2.55</b>	
95.5Al4.5Cu	4.49	0.07	0.70	0.22	0.27	1.32	0.01	Res	2.89

**Description.** Bold numbers, italic, and regular each shows the element of theoretical density, the percentage of elements OES test results, and the elements density of the material in duralumin (partial).

Effect of content elements (Table 1) in the experimental determine the theoretical density of material (duralumin). According Wahyono et.al [6], duralumin mass density values can be determined analytically based on the equilibrium system is

formulated:

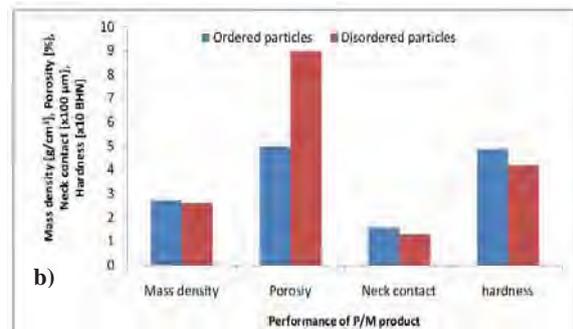

$$\gamma_{dural} = \frac{\sum \%u_i \cdot \rho_{u_i}}{100} = \frac{\%u_1 \cdot \rho_{u1} + \%u_2 \cdot \rho_{u2} + \dots + \%u_n \cdot \rho_{un}}{100} \quad (5)$$

where %, u respectively show the percentage, the chemical elements. And the use of Archimedes' principle which application

in Pycnometry apparatus refers to the ASTM standard D3800 is formulated;

$$\gamma_{P/M} = \frac{W_A \times \gamma_W}{W_A - W_W} \quad (6)$$

where W<sub>A</sub>, W<sub>W</sub>, and γ<sub>W</sub> each specimen showed heavy in the air and in water, and the mass density of water. Quantity of porosity P/M products were analyzed by Saltykov refers to the standard ASTM B311-93 and ASTM C948. Possible reduction in the amount of porosity in particles ordered is caused by mass density effects. It is caused by a large cavity insulation inserts gap filler particles. Generally, a lower mass density of casting product shows a higher porosity level, and a higher mass density of casting product shows a low porosity. Reference [7], the void are filled by the medium and small particles and these particles will melt in hot compacting so wet as a result of large particles contact neck between the particles increases to produced good wetting.

a). Bushing product of experiment, b). Chart of experiment results

Sample (bushing product of P/M) surface in Fig. 4a, the disordered has a lower hardness than ordered particles as in Fig. 4b. Hardness tests were carried out with Vickers micro hardness (Hv) and hardness test results are converted into Brinell hardness (BHN) in accordance with Approximate Hardness Conversion Numbers for Wrought Aluminum Products of ASTM E140-02 and hardness values obtained in Fig. 4b. Increased P/M hardness on the ordered particles not only due to higher density of grain but the hot compaction process also contributed. Rationally porosity lowered number of strength elements of solid material and the strength of P/M to the disordered lower than ordered particles. The porosity of a powder metallurgy component is greatly depends on the sintering temperature and in order to optimize the wear resistance it is important to keep porosity down to a minimum, Gaál [8] and Goutam [9]. According to Huang [10], Voids in sintered powder compacts exert a detrimental effect on the mechanical properties and total change of the void volume fraction in the porous metals during deformation arises partly from the growth of existing voids and partly from the nucleation of new voids.

Particle P / M were prepared by direct mixing weight fraction forming a more homogeny. Analysis of the microstructure (SEM) on the adhesion between the contact points between the grains showed coarse, medium, and fine particles. The length of the

contact point of contact between the particles can be measured and a comparison with a circumference of primary particles (coarse). Further contacts neck P/M disordered and ordered compared. In this study, neck contact 155 to 160  $\mu\text{m}$  and 165 to 173  $\mu\text{m}$  for disordered and ordered particles, respectively. The presence of pressure and temperature combination in hot pressing is caused by the high melting rate of filler, a consequence of sufficiently correct necking or wetting process control in P/M. The bulk of the powder contained numerous agglomerations of the smallest particles is porousless and characterized by the presence of prior particle boundaries, Dhokey et al.[11].

#### 4. Conclusion

- The inclusion of medium and fine particles in coarse particle gaps are able to increase mass density and micro hardness, and decrease porosity, and in bushing product of P/M significantly.
- The results of analytical and metallographic examination indicate the type of porosity in arrangement system of the P/M process of powder duralumin is a type of micro porosity. Explicitly neck of contact between particles in the arrangement has positive influence on increasing the density so that porosity decreases of the P/M.
- Inserts fine and medium particles in large grain gaps were enlarging contact line or neck of particles affecting linearly to hexagonal networking.

### **ABSTRACT**

This article introduced a novel technique which involved Concurrent Engineering (CE) strategy and Analytical Network Process (ANP) technique to form a ranking methodology as a part of the Conceptual Design Selection (CDS). The proposed method is referred as Concurrent Network (CN). The objective of this study is to simultaneously consider of all features of product elements by implementing CE strategy. Furthermore, CN enables interdependence and interrelationship analysis between product elements by application of ANP. In this study, CN is utilized for a conceptual design of metal matrix composite (MMC) brake disc. The results show that by using CN, all important product parameters can be considered simultaneously during the CDS and the importance weights of manufacturing process parameters and material parameters which are related to MMC brake disc performance are attained.

### ABSTRACT

One of the components of the vehicle are of particular interest is the brake system , because its main function is to stop the rotation axis, set the axis of rotation and to prevent unwanted rotation. One classification system is the drum brake that has been widely made of cast iron, cast iron and cast steel special. This study makes drum brake of composite materials aluminum-based, with reinforcement is silicon carbide (SiC), obtained optimum composition of 15%, so it is written (Al-Si) -SiC/15%. Physics testing includes testing of thermal conductivity and thermal expansion coefficient, and Chemistry testing the corrosion penetration rate when the test material was coating with regular polish, with chrome, with nickel and with nickel + chrome. The final results showed that the value of conductivity and thermal expansion coefficient of the composite material is lower than cast iron, aluminum and other alloys. That is pretty good heat resistance when applied to drum brake material. Lowest corrosion rate on coating material with a layer of Ni-Cr.

### ABSTRACT

The present work concerns in developing alternative interconnect material for solid oxide fuel cell (SOFC) application. For this purpose, ferritic stainless steel is used as the substrate material while various nickel composite layers were coated on the substrate in order to improve its oxidation resistance at SOFC application temperature. Nickel layers were deposited on ferritic stainless steel by high velocity oxy-fuel (HVOF) method. In order to create nickel-oxide layer, the coated samples is then heated at temperature of 950°C for 1 hour, whereas sol-gel coating was performed on the coated samples in order to create nickel manganese oxide spinel composite layers. All samples were then oxidized at temperature 800°C for 8 hours, in order to evaluate their oxidation characteristics at SOFC service temperature. Before and after oxidation, x-ray diffraction (XRD) and scanning electron microscope (SEM) were performed to all samples. It was observed that coated samples effectively inhibit the formation of chromium oxide that normally occurs on stainless steel surface at SOFC service temperature.

### ABSTRACT

Severe plastic deformation (SPD) using various pass number of Equal Channel Angular Pressing (ECAP) experiment and followed heating at 400°C has been done for rod brass Cu-Zn 70/30 to investigate the operation on microstructure and hardness of the alloy. Optical microscopy and SEM are used to examine the microstructure change. Mechanical testing such as macro and micro hardness test is used in order to examine the change of mechanical properties. The grain structure of the alloy was refined from 34 µm to 2 µm after 4 passes ECAP and increased to 4 µm after post heating. The hardness of the alloy significantly increased from 78 Hv to 235 Hv after 4 passes and decreased to 135 Hv after post heating after ECAP. The microstructure and mechanical properties of the alloy was homogenous after 4 passes ECAP because the strain was found more homogenous.

### **ABSTRACT**

This paper presents the importance of simulation of metal flow in deep drawing process which employs an antilock brake mechanic system. Controlling the force and friction of the blank holder is imperative to assure that the sheet metal is not locked on the blank holder, and hence it flows smoothly into the die. The simulation was developed based on the material displacement, deformation and deep drawing force on flange in the radial direction, that it is controlled by blank holder with antilock brake mechanic system. The force to blank holder was applied periodically and the magnitude of force was kept constant during simulation process. In this study, the mechanical properties of the material were chosen such that they equivalent to those of low carbon steel with its thickness of 0.2 mm. The diameter and the depth of the cylindrical cup-shaped product were 40 mm and 10 mm, respectively. The simulation results showed that the application of antilock brake mechanic system improves the ability to control the material flow during the drawing process, although the maximum blank holder force of 13000 N was applied. The optimum condition was found when the drawing process was performed using blank holder force of 3500 N, deep drawing force of 7000 N, friction coefficient of 0.25 and speed of punch stroke of 0.84 mm/sec. This research demonstrated that an antilock brake mechanic system can be implemented effectively to prevent cracking in deep drawing process.

### ABSTRACT

Mg, in the form of  $MgH_2$ , is one kinds of materials widely used as hydrogen storage materials. Absorption and desorption properties of hydrogen which comes from metal hydride depend on materials itself, addition of elements, as well as manufacturing method. In this research, Mg as hydrogen storage were prepared by mechanical alloying with Ni, Cu, and Al as element addition and variation milling time for 10, 20 and 30 hours. Some morphological analyses (XRD, SEM) were done to observe phase transformation. Absorption and desorption properties characterization were employed by DSC and hydrogenation tests. The improvement in milling time decreased particle size, therefore enhanced wt% of absorbed hydrogen and decrease onset desorption temperature. However, the excessive of agglomeration and cold welding on mechanical alloying process resulted in bigger particle size. Alloying elements, Al and Cu, served as catalyst, while Ni acted as alloying which reacted with hydrogen. Mg10wt%Al with 20 hours milling time at hydrogenation temperature 250°C, 3 atm pressure, and 1 hour holding time resulted in the highest weight percent of  $H_2$  (0.38%wt). However, Mg10wt%Al with 30 hours milling time had the lowest onset temperature, 341.49°C

### **ABSTRACT**

Joining of dissimilar metals is to compose different properties of metals in order to minimize material costs and at the same time to maximize the performance of the equipment and machinery. There are a lot of methods of joining of dissimilar metals. However, the fusion welding is mostly used in a wide range of industries. This research is carried out for the process of dissimilar welding between carbon steel plates of ASTM A516-70 and austenitic stainless steel plates ASTM A214-316L by using gas metal arc welding (GMAW). Welding design used is a V-groove by using the buttering process and without buttering (non-buttering) process. Types of filler metals used are ER309L and ER316L-Si. The weldment is then tested by using destructive test (DT) and non-destructive test (NDT). Weldment is also characterized by using X-Ray Diffraction (XRD). The results show that the mechanical properties of weldment with buttering process are better compared with the weldment with a non-buttering process. The macro and microstructure of weldment with buttering process revealed finer grained and homogeneous structures compared with the one by using a non-buttering process. Moreover, welds characterization by using XRD show that the precipitation of chromium carbide on HAZ of weldment with buttering process is lower than that of weldment with a non-buttering process.

### ABSTRACT

Metal matrix composites (MMCs) are new materials, which are very essential for industry manufacture applications, such as automotive, aerospace and military. So far, an enhancement of the MMCs hardness has been interestingly studied. In this paper, we study the formation of Al-5%Cu-4%Mg matrix with SiC<sub>p</sub> reinforcement by thixoforming process. Several important parameters for increasing the MMCs hardness, such as volume fraction of reinforcement, ageing time and temperature, have been investigated. It is found that the distribution of SiC particles in Al matrix is non homogeneous for both MMCs with 5 vf.% SiC and 10 vf.% SiC. It also is found fine and coarse globular and non-dendritic structures in the matrix as indicated that thixoforming process has succeed. The hardness increased with higher vf.% SiC as well as longer aging time after thixoprocess, therefore such parameters should be considered in order to obtain the optimum performance of Al-5%Cu-4%Mg/SiC MMC.

### ABSTRACT

The deformation after ballistic impact loading of silicon carbide reinforced aluminium alloy composite is investigated in this research. The composite consists of 10 % volume fraction of silicon carbide particulate in a matrix of Al-7Si-Mg-Zn alloy and were produced through the squeeze casting process with a pressure of 1 MPa at semi-solid melting temperatures of 590-610 °C. The mechanical property of the composite was examined with hardness test. The ballistic tests were performed with two types of projectiles, 9 mm calibre and 5.56 mm calibre of projectiles. Then the deformed surfaces were studied with optical microscopy. During ballistic testing, the 9 mm projectile did not pierce the composite plate although the test resulted in significant cracks on the backside of the plate. The cross section observation of the plate showed ductile deformation in the matrix and silicon carbide particulates give significant rule in withstanding the penetration of the projectile. The 5.56 mm projectile pierced through the composite and caused a brittle fracture of the matrix.

### ABSTRACT

Aluminum composite reinforced ceramic particles can be created through stirring process (Stir Casting) so that the molten aluminum to form a vortex as a space for the reinforced of  $Al_2O_3$  particles well distributed on the aluminum melt. Engineering ceramic particles and vortex formation process will determine the distribution of particles in molten aluminum metal. Mg was added during the melting and argon was flushed to improve wetting system and protect oxidation. In this study, billet Al.6061 was combined with various percentage of  $Al_2O_3$  from 5Vf % to 20Vf%. The results showed that the optimum tensile strength obtained at 10Vf %  $Al_2O_3$  with the value of 190 MPa.

## ABSTRACT

Broadly, P/M process to produce of engine and automotive components high quality. Advantage of P/M process is efficient of used material is higher than near net shape processes such as casting and forging. Principally, product quality of P/M process is determined by its density. Generally the quality of the product manufacturing process is measured from the physical, mechanical, and metallography properties. Variety of experimental methods of compression, vibration, and temperature has been used to control density P/M. This article describes the approach to the calculation of geometry of the grain size fractions to control P/M density. The study analyzes P/M density is based on space equilibrium of mold cavity by rounded powder particles with coarse, medium, and fine sizes. In this article the results of density calculations validated by experiment of P/M HIP process of 10 metric tons pressure, 500°C temperature and 20 minutes holding time. Object of study is the bushing from duralumin powder is contained in a mold with homogeneous size and grain size fractions 12 : 3x12 : 3x3x12. Testing of P/M density, hardness, metallographic was conducted by Picnometry, Micro Hardness Tester, SEM, respectively. The test results and analysis states that density and P/M hardness on a powder feeding with a grain size fraction is higher than homogeneous filler grain size. And the results of metallographic characteristics of SEM studies show the size comparison of the bonding neck on the grain size fraction increased from 0.05 to 0.09 time point particles forming.

## 1. Introduction

In particular manufacturing machinery and automotive industries, metal has several advantages over conventional material composite materials and ceramics, but the availability of world decreases. Therefore use of metal to be optimized either transformed into finished products as well as further utilization of waste generated such as chips, fins, scrap. The process of casting and P/M is a metal working process that transformable waste metal into finished products or components. One of the advantages of the process of casting, forging, and P/M can produce a near net shape parts. Product quality problems near net shape is determined by the density and porosity. Generally manufactured product with low density is high porosity and effect of porosity variations in the properties of other materials such as mechanical, metallographic, chemical, electrical, and be able to form. According Ademeso et al. [1], bulk density and porosity are two of the physical properties that have been found to significantly affect the mechanical properties, particularly. The bulk density values ranged from 2.63 to 2.81 and the porosity from 0.16 to 0.03. The P/M is a metal processing technology that can transform the metal particles into a finished product by micro-porosity.

During this time, porosity in the product manufacturing is one of types of defects that lead to decreased quality of product. Generally porosity occurs in the macro scale and distribution is not homogeneous, but are distributed homogeneously micro-porosity be a positive influence in the system. Because at a basic level possible crystal micro-porosity provide dynamic behavior of the atoms to rotate or translation affecting dimensional stability. Now micro-porosity combined with other material properties to provide an exchange (impregnation) and ion separation (filter), and the catalysis of hydrogen cracking. Therefore the porosity of the solid material must be disposed micro-porosity arrangement that provides dynamic behavior. Attempt to relate the dynamics of the molecules are linked to the harmony arrangement (ordered) of crystal lines as metal organic frameworks (MOFs), Travis [2]. Experiment the P/M with a variety of compression and vibration have been made in an effort to control the optimization of structuring micro-gap to control micro-porosity but the results have not been up to since their porosity and macro-size distribution is not homogeneous to form clusters or groups. Porosity is often caused shrinkage in the sintering process is not controlled, more distortion in the P/M products.

Generally, the optimization of the ordered of the micro powder particles space P/M through the variation of compression and vibration. In this research performed a micro structuring innovation space particles P/M with inserts of powder particles. In disordered of space through the insertion of micro powder particles, described by the coordinate geometry calculations system and principles of algebra micro space formed by the coordination of the powder particles P/M. By Won-Chun Oh [3], the phenomenon of the aggregate pattern is determined by the difference in the shape and size of the metal particles. In this article coordination powder particles consist of large particle size (forming particles), medium (primary fillers), and small size (secondary fillers). The aim structuring powder particles to form a point of contact between the particles forming, the main filler, and second filler to produce micro porosity with homogeneous distribution.

## Optimization Design of Airfoil Propellers of Modified NACA 4415 Using Computational Fluids Dynamics

### ABSTRACT

Utilization of wind power in Indonesia is less attractive compared with utilization of conventional fuel. This is because the price of wind energy is not competitive when compared with fossil energy prices, and as a result of the implementation of energy pricing policy through subsidies. Before designing the Wind Energy Conversion System, simulation of computational fluid dynamics needs to be done in order for reducing designing time and cost. In this research, modeling and simulation work has been done to figure out the optimum aerodynamics coefficient of wind turbine blades at different Reynolds number. This blade is a modification of standard airfoil of NACA 4415. The aerodynamics coefficient of modify and standard airfoil is then compared. FLUENT software and Spalart-Allmaras Turbulent Model are used in this work. Based on the comparison of the coefficient of aerodynamic, modification NACA 4415 airfoil has better performance at Reynolds number of  $4.1 \times 10^4$  to  $2.5 \times 10^5$ . The experiment results also showed that based on a numerical study of the modification NACA 4415 airfoil can be used as a basis for the establishment of wind turbine blades.

### ABSTRACT

Surface hardening on local disc brakes with DC-plasma nitrocarburizing apparatus has been carried out. Local disc brake was nitrocarburized at temperatures of 700 °C, 800°C, and 900°C for 3 hours, respectively. The results show that the hardness of sample of local disc brake before nitrocarburization was 167.86 Kgf/mm<sup>2</sup>, after the sample was nitrocarburized at temperature 900 °C for 3 hours, the hardness increased up to 649.38 Kgf/mm<sup>2</sup>. Matrixes on the base material were austenite, ferrite, and perlite.

### ABSTRACT.

PbSn composites have been prepared by powder metallurgy for Advance Energy Transfer Bullet Application. Sn compositions was variety 5, 10, 15wt%. The compacting pressure performed at 10, 15, and 20 MPa. Temperature and holding time of sintering constantly in 150°C for 2 hours. The microstructure and mechanical performance of PbSn composites are investigated by Scanning Electron microscope (SEM), and compression tests. The results show that the Pb-15wtSn Composite which is compacted in 20 MPa has result greatest density which was 10.969 gr/cm<sup>3</sup> and the smallest porosity (1.5%). Mechanical performance test of PbSn composite show the greatest hardness, compressive strength and modulus elasticity reach are 11.01 HV, 46.82 MPa and 34.96 GPa

## ABSTRACT

This paper discusses a research that aims to improve the efficiency of fuel consumption. The equipment consist of: the combustion process control engineering, engineering distribution system of fuel and system burner. Those system equipment used for the combustion reaction in which oxygen as an oxidant. The result is a detailed design for manufacture and for testing the prototypes of fuel-gas control system (SKID) and oxy-fuel burner (OFB) devise.

The advantages of this product is a production system equipment to be more fuel efficient. Fuel saving potential is expected to 20-25%, and the gas stag emissions reduced by 65%. In addition to this product designed is safely, also increase production, reduce production downtime and improve production quality.

## Keywords

*Control of oxygen supply, fuel savings, reduced emissions.*

## 1. INTRODUCTION

Industrialists were needed of better fuels economy, especially at this time, where there is no term fuel price will go down. It is very difficult for the people, businesses and governments. Although everything else was difficult matters concerning fuels, but no idea who published / recommended to try to reduce fuels by analyzing the way back from basic techniques and their combustion reaction control equipment used in the production process.

If we look at the developed countries, the actual burning technique in the world now is up to seven. While Indonesia has reached level two. This is why Indonesia miss 60-75 years in combustion engineering. To catch up is very difficult to obtain the result that there is no cooperation between industry and universities. Industry research affairs handed off to college while the government as an facilitator.

Industries that require fuels saving techniques are primarily in the industrial production process requires heat generated from solid fuels, liquid or gas. The industry group such as:

- The steel industry work in temperatures: 1650 °C
- Rolling mill steel works at temperature 1050 °C
- Casting of iron works at temperatures: 1400 °C
- Copper smelting works at tempt: 1450 °C
- Aluminum smelting works at tempt: 950 °C
- Tin smelting works at temperatures: 850 °C
- Manufacture of glass work on temperature: 1650 °C
- The industry works on temperature: 1650 °C
- PLTG working temperature: 1150 °C
- Pulp and paper
- Chemical industry

Industries mentioned above requires approximately 12.98 million kiloliters of fuel per year (2008). Conceivably that could save you 20% only.

The research aims:

- Increase production
- Improved fuel economy

- Reduced production down time
- Improving the quality of production
- Reduce emissions and improve exhaust gas.
- Shorten the flame (flame) out of the appliance combustion (burner).

The results of this studies will reduce fuels consumption in the industrial sector between 20-25%. If this happens, then the government feels lucky because it will reduce the cost of fuel imports and reduce the subsidy borne by the government, jobs and raise per-capita income is called CRS (Carbon Reduction Sales)

## 2. THE METHOD

### 2.1 Reaction combustion using air as an oxidant.

As an example we use the fuel and the combustion reaction CH<sub>4</sub> as follows:

The air is made of 20,5% O<sub>2</sub> + 79,5% N<sub>2</sub>, or 1 part of O<sub>2</sub> + 3,878 part of N<sub>2</sub>, the reactions above can be changed as follows :

→ The air as an oxidant

Nitrogen is an gas inerts, the total volume of incoming and outgoing fixed in the reaction, only the temperature is different.

### 2.2 Combustion reactions using oxygen as an oxidant

By using oxygen as an oxidant, the reaction CH<sub>4</sub> combustion by the following :

The Simpler reaction, without N<sub>2</sub> participate in burning.

### 2.3 Comparison of Reaction

From combustion reactions (2) and (3) can be summarized as follows:

- The amount of exhaust gas is greatly reduced because without nitrogen.
- Heat carried nitrogen to the chimney does not occur
- Heat combustion will rise, the hot gas flow in the combustion chamber down.
- The temperature in the combustion chamber will rise.

With the increase of heat in the combustion chamber fuel consumption to be reduced or increased machine production capacity

### 2.4 Analysis of Combustion Process

The results of the analysis using the combustion reaction in the foundation theory of thinking, is as follows see at Table 1:

Table 1. Flues gas composition

SISTIM PEMBAKARAN	KOMPOSISI GAS BUANG					TOTAL
	CO2	H2O	SO2	O2	N2	
Heavy oil + udara	159.79	120.09	0.49	0.35	850.15	1130.87
Heavy oil + oxygen	159.79	120.09	0.49	0.35	0.56	281.28
NG + udara	104.00	200.50	0.001	0.00	789.57	1094.07
NG + oxygen	104.00	200.5	0.00	0.00	0.50	305.00

From the analysis above combustion reaction can be seen that:

1. Exhaust gases in the combustion process with air as an oxidant number 4 fold from flue gases in the combustion process with oxygen as an oxidant. This brings the hot exhaust gases to the chimney, so a lot of heat loss.
2. Due the volume flues of gas less (on combustion using oxygen), the gas flow in the combustion chamber is low, it will improve the absorption of heat and energy loss less.
3. From the above combustion reaction, the energy carried by nitrogen to the chimney reaches 42% and it will be 0% if the combustion process uses oxygen as an oxidant. In practice, the combustion efficiency is never achieved by 42% because

some of the heat is used to heat the combustion equipment components and partly lost due to the flow of air around the kitchen.

4. Exhaust emissions of pollutants can be controlled by regulating the amount of oxygen used in the process (at least 4% oxygen in the exhaust gas).
5. Target research: achieving fuel savings between 20-25%.
6. The amount of fuel depending on the working temperature, the type of kitchen that is used and the type of fuel used.
7. All analyzes should use the energy and mass balance analysis.

### 3. THE RESULTS AND THE DISCUSSION

#### 3.1 THE MAKING SYSTEM

Prototyping activity / workshop models made at Corporate Partners assembly in the Laboratory of Industrial and Production Department of Mechanical Engineering Faculty of Engineering, University of Pancasila. Before we begin the prototyping activities should be made standard operating procedures (SOP) for each manufacturing parts. Engineering design of these controls will be a basic tool assortment research and development in the field of energy research.

The composition of the equipment consists of a 3-group as follows:

- Storage tanks for oxygen, fuel, and air (fuel distribution system, air and oxygen)
- Tools discharge regulator, the pressure of the gas, the fuel and air (SKID) (controls, safety systems and instrumentation)
- Combustion chamber, combustion equipment (burner) and sensors (temperature, pressure and flow).

Schematic arrangement shown in Figure 1.

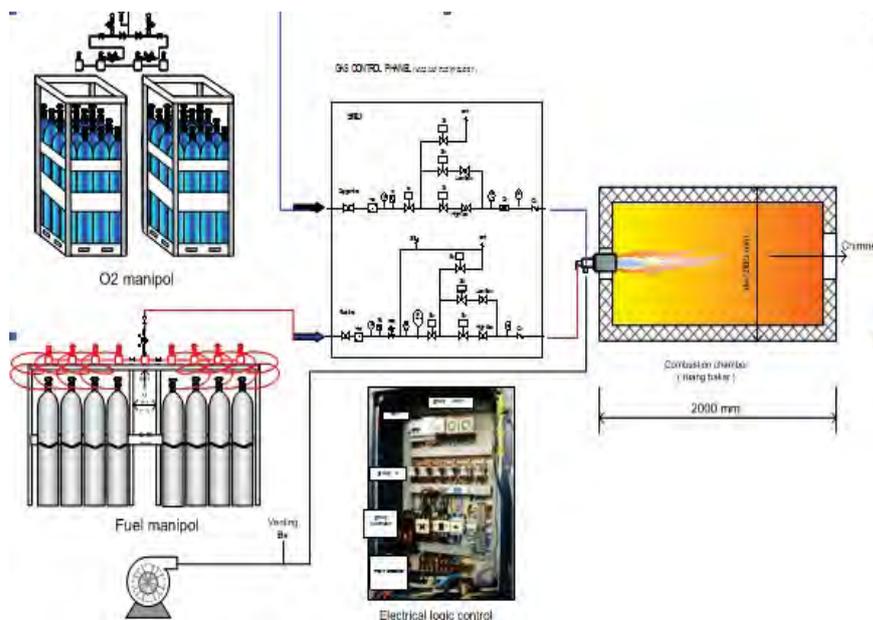

Figure 1 arrangement of equipment

#### 3.1.1. Storage tanks of fuel and oxidizer.

- The oxygen tank did not buy but just renting, which is used to buy gas and manifold system to buy spare-partsnya and assembled themselves.
- The LPG tank should buy, then made a manifold to regulate the gas supply in accordance with the needs and the discharge pressure to process. The LPG tank can be replaced with a liquid fuel such as kerosene or diesel fuel or other gases.
- The Industrial blower is required when using air as an oxidant or when using oxygen as an oxidant to cool the inner wall of flint.

#### 3.1.2. The Controls

SKID consists of the pressure regulator, the regulator discharge of fuel and oxidizer. The tool becomes complex because it comes with a safety system at the time of use. Control devices purchased and then assembled themselves in order to guarantee the safety of the system.

Electrical logic controller to regulate the working order of each process in accordance with the wishes of the researchers. This tool also regulates workplace safety system.

### 3.1.3. Combustion chamber.

- Combustion chamber made of steel pipe diameter of 1000 mm and a length of 2000 mm on the outside and on the inside of the castable. Castable type C-18 is required to work until the temperature 1800°C.
- The bodies later combustion chamber installed 10 sets of temperature sensors to determine the spread of heat occurs in the combustion chamber.

### 3.1.4. Fuels (burner).

- Installed a burner to create combustion. Burner split model, spare parts designed and built himself. Burner is not sold in the market.

### 3.2. Research Methods

Combustion method was used in this research in accordance with Table 1 above, the observations attached Table 2, 3 and 4 are referred to the following reaction:

1. Heavy oil combustion air.
2. Heavy oil combustion with oxygen.
3. Burning natural gas to oxygen

Table 2. The reaction of heavy oil combustion with air as an oxidant

#### 4. CONCLUSION

1. Exhaust emissions of pollutants can be controlled by regulating the amount of oxygen used in the process (at least 4% oxygen in the exhaust gas).
2. The fuel savings achieved between 20-25%.
3. The amount of fuel depending on the working temperature, the type of kitchen that is used and the type of fuel used.

### ABSTRACT

Smart concrete is an innovative material because it can serve as a sensor without any additional sensors in it. It is reinforced with carbon fiber that has gone through the pyrolysis process at high temperature to produce carbon content above 90%. The carbon fiber used in this study was Polyacrylonitrile. The working principle of carbon fiber sensor works piezoresistivity that respond to changes in mechanical (stress and strain) to electrical impulses. The resistivity changes that will be converted into units of load on the display circuit system. Key to success of this research was the concrete formulations and systems were sensitive and accurate readings so that any small change in resistivity could be directly detected. Variations in carbon fiber were added to the 0-1% by weight of cement with interval 0.5. Fly ash was added as a filler to reduce the use of cement. Results obtained from dynamic cyclic testing showed that the compressive strength was the best in the concrete without carbon fiber, then decline in line with the increased number of carbon fiber. But inversely proportional to the resistivity of the concrete produced. Smart concrete must have a high sensitivity to changes in stress / strain, it should also meet the required concrete strength both press and flexible to avoid initial crack.

### ABSTRACT

The millimeter wave (MMW) sintering of alumina ceramic had been performed. The results revealed that MMW sintered alumina has higher density than that of conventional method on all sintering temperature. However microstructure evaluation demonstrates that grain growth of MM wave annealed alumina is faster than in conventional annealing. It indicates that MM wave enhanced mass transport and solid state reaction rates during sintering. The empirical observations of microwave enhancements have been broadly known as microwave effect. Even though no satisfactory theory existed to explain the effect but the presence the electromagnetic waves (EMW) during microwave heating is clearly the key. In this paper, microwave effect on grain growth of alumina ceramic is presented. Some effective and unique characteristics of the EMW sintering were also discussed as well.

### ABSTRACT

As versatile biomass-based diol precursors, N,N'-1,2-ethanediybis-(4-hydroxy-pentanamide) (1) and 4-hydroxy-N-(2-hydroxyethyl)-pentanamide (2) are potential monomers to synthesize novel polyurethanes through adding di-isocyanates. This study reported the structural analysis and molecular behavior of polyurethanes obtained from polymerization of the diol precursors with aliphatic and aromatic di-isocyanates (hexamethylene diisocyanate, HDI (3), and phenyl-diisocyanate, PDI (4)) in (N,N-dimethylacetamide (DMA) solvents with triethylamine (TEA) catalysts. <sup>1</sup>H-NMR, <sup>13</sup>C-NMR and Elemental Analysis confirmed structure of the polyurethanes built from both diols and di-isocyanates and FTIR indicated interaction among polyurethane molecules showed at lower wave numbers such as 2855-2976 cm<sup>-1</sup> for hydrogen-bonded –NH groups and 1621-1643 cm<sup>-1</sup> for hydrogen-bonded –C=O groups. Furthermore a study on influence of the inter- and intra-molecular hydrogen bonding on the thermal and mechanical properties of the polyurethanes would be an interesting investigation for the next study.

### ABSTRACT

In ceramic tiles industry, the process of ceramics classification plays an important part. At present, the process of classification is carried out manually by using the human eyes observation. However, the capability of the human eyes is very limited. This condition leads to the low accuracy of the ceramic tile selection. This paper proposes a mechanism which could classify the ceramic tiles automatically using local texture feature. The result of our experiment shows a recognition rate of 76%, which means that this method can be used to classify the ceramic tiles.

### ABSTRACT

In this investigation, mullite ceramics were produced by mixing  $\text{Al}_2\text{O}_3$  and amorphous silica xerogel (SX) extracted from sago waste ash. The composition was prepared by adding an amount from 0 to 80 mol% of  $\text{Al}_2\text{O}_3$  into SX. The samples were dry pressed and sintered in the temperature range between 900°C and 1200°C. Their properties have been characterized on the basis of the experimental data obtained using thermal analysis (DSC/TGA, X-ray diffraction and scanning electron microscopy (SEM)). The results show that two major differences become obvious when comparing the samples loaded by the smaller and larger amount of  $\text{Al}_2\text{O}_3$ . First, cristobalite formation is retarded in the sample loaded by the larger amount of  $\text{Al}_2\text{O}_3$ . Second, at 1200°C, the observed volume fraction of mullite is higher in the sample loaded by the larger amount of  $\text{Al}_2\text{O}_3$ . The DSC analysis indicates that the mullite crystallization takes place at 1200°C for 60 mol%  $\text{Al}_2\text{O}_3$  loaded SX sample as confirmed by the XRD pattern. It was found that there was not a complete reaction of mullitization for sample sintered up to 1200°C.

### **ABSTRACT**

The acoustical properties of polyester/ramie fibre composite materials that was applied as a sound absorbing material is discussed in this paper. The aim was to determine the correlation between Normal Incidence Sound Absorption Coefficient (NAC) and Random Incidence Sound Absorption Coefficient (RAC) of the fibre composites. The acoustic measurement with Impedance Tube Kit followed the ASTM 1986 E – 1050 – 98 standard. The portion of the ramie fibre was modified with fibre length varied from 0.25 cm, 1 cm to 1.5 cm but at a constant fibre diameter. A constant volume fraction of fibre 20 % was used. The Beavers method was applied to characterize the fibre's diameter. Results indicated that the sound absorption performance of the composite fibre can reach as high as 99% at frequency of 1225 Hz at aspect ratio of 42. A correlation between NAC and RAC was presented based on a quantitative result.

### ABSTRACT

Electroless plating is one method to coat Al<sub>2</sub>O<sub>3</sub> particles reinforced. This process has been carried out to coat Al<sub>2</sub>O<sub>3</sub> with electrolyte solution which content of nitride acid (HNO<sub>3</sub>), Al and Mg powders. The metal oxide layer of spinel phase (MgAl<sub>2</sub>O<sub>4</sub>) is formed on the surface of Al<sub>2</sub>O<sub>3</sub> which can improve wettability of Al<sub>2</sub>O<sub>3</sub>. The addition of Mg powder into solution was various from 0.002 to 0.012 mol while Al powder was kept constant i.e. 0.018 mol. The effect of Mg on formation of metal oxide layer on Al<sub>2</sub>O<sub>3</sub> particles have been studied. It is found that the addition of 0.004 mol of Mg generated homogeneous thin spinel layer (MgAl<sub>2</sub>O<sub>4</sub>) on the surface of Al<sub>2</sub>O<sub>3</sub> particles. This condition was applied to form spinel layer on Al<sub>2</sub>O<sub>3</sub> particles reinforced for making Aluminium Matrix Composites (AMC) with 12.5Vf% of Al<sub>2</sub>O<sub>3</sub> particles reinforced. It is found that tensile strength and hardness as well as wear resistance of AMC has been improved compare to unreinforced.

## ABSTRACT

In Indonesia, a lot of wastes of glasses and metals have potency to be one of brake raw materials. For example, little bottles of used food packages are usually directly thrown into environment. The scraps of metal machining wastes are usually collected to be manufactured into other products. In this research, both wastes are used as fillers for brake friction materials, the effects of them on the thermal properties are studied in details. The glass wastes are crushed, grinded and filtered to simplify the mixing process with other raw materials when the fabrication of brake fiction materials done. During fabrication, samples are cured at 190°C for 3 hours. The samples are characterized using x-ray diffractometer and thermogravimetric analysis. Based on these characterizations, the increase of glass powders content plays role in increasing the percentage of crystallinities. This is suspected the glass used as ingredient of friction material has crystalline structure. The glass waste quantity does not influence significantly on the thermal properties. During heating up to 1200°C, the mass loss occurs due to epoxy, bamboo fiber and styrene butadiene rubber decompose. The optimum composition is found at sample B2, a sample with lowest total mass loss (2 mg).

### ABSTRACT

Dye-sensitized solar cell (DSSC) is one of the very promising alternative renewable energy sources to anticipate the diminishing in the fossil fuel reserves in the next few decades and to make use of the abundance of intensive sunlight energy in tropical countries like Indonesia. TiO<sub>2</sub> nanoparticles have been used as the photo electrode in DSSC because of its high surface area and allow the adsorption of a large number of dye molecules. In the present study, TiO<sub>2</sub> aerogel have been synthesized via sol-gel process with water to inorganic precursor ratio ( $R_w$ ) of 2.00, followed with subsequent drying by CO<sub>2</sub> supercritical extraction (SCE). As comparison, the TiO<sub>2</sub> xerogel was also prepared by conventional drying and annealing. Both types of gels were subjected to conventional and multi-step annealing. The resulting nanoparticles in aerogel and xerogel have a band-gap energy of 3.10 and 3.04 eV, respectively. The open circuit voltage ( $V_{oc}$ ) measurement reveals that the DSSC fabricated with aerogel provided a higher voltage (21,40 mV) than xerogel (1,10 mV).

### ABSTRACT

So far, application of RRA (Retrogression and Re-aging) heat treatment in improving SSC (stress corrosion cracking) resistance of aluminum alloy 7075 is limited to thin samples as it is constrained by short retrogression time at high temperature. The aim of this research is to obtain thick aluminum alloy 7075 plate with good SCC resistance through RRA modification. In RRA modification, the retrogressed alloy samples were rolled at three different temperatures (27° C, 120° C, and 180° C) and at three different thickness reductions (10%, 15%, and 20%) followed by re-aging at 120° C for 16 hours. SCC resistance was determined from time to failure ( $t_f$ ) at fixed loading at 0.8 yield strength of material in test solution of 3 wt % NaCl at pH 4. The sample with longest time to failure is referred to as the most SCC-resistant. Generally, modified RRA alloy has better SCC resistance compared to T6 alloy and conventional RRA alloy. Highest SSC resistance was found at three conditions, namely 27° C-20% reduction, 27° C-15% reduction, and 180° C-20% reduction). Micro-structurally, these conditions produce large precipitates with wider space in grain boundaries. Around grain boundaries, they also produce smaller intermetallic particles with broader distribution.

### ABSTRACT

The presence of carbon dioxide (CO<sub>2</sub>) and water in the fluid can cause severe internal corrosion in the pipelines. This study aims to observe corrosion behavior during the changes in flow rate and acidity conditions in order to obtain the relationship between the parameters by the measured corrosion rate. Corrosion rate measurements were performed for API 5L X52 steel material by using polarization method in 3.5% NaCl solution with saturated CO<sub>2</sub> injection. Solution with different acidity were applied which has pH 4, 5, and 6 respectively. To simulate the flow rate, a Rotating Cylinder Electrode RCE was used at various rotation rates 0, 375, 750, 1500, and 3000 rpm, at room temperature (25°C) and atmospheric pressure. Based on testing results, the changes in rotation converted to flow rate showed that the corrosion mechanism of API 5L X52 steel in NaCl solution with saturated CO<sub>2</sub> content was mainly controlled by mass transport at pH=4 whereas chemically controlled involved both at pH=5 and pH=6 conditions.

### ABSTRACT

The oxidation of hot-dip aluminized AISI 1020 steel coated with NaCl in static air at 700 °C for a duration of time 49 h was studied by employing thermogravimetry, Scanning Electron Microscopy (SEM), Electron Dispersive Spectroscopy (EDS) and X-ray Diffraction (XRD) analysis. It was found that NaCl deposits markedly accelerated the oxidation of the AISI 1020 steel. The aluminide coating on the bare steel gives the best oxidation protection by forming continuous alumina scale ( $\text{Al}_2\text{O}_3$ ). The degradation of aluminide layer and alumina scale on the steel are associated by chloridation/oxidation cyclic reactions. In addition, the released chlorine will be as catalytic actions and leads to the formation of loose  $\text{Al}_2\text{O}_3$  during corrosion.

## ABSTRACT

The main objective of this research is to investigate the effectiveness of Myrmecodia Pendans (MP) wood extract on corrosion of material API 5L Grade B in 3,5% NaCl solution using potentiodynamic polarization curve, Gas Chromatography-Mass Spectrometer (GC-MS) and Electrochemical Impedance spectroscopy (EIS). MP usually called as sarang semut in Indonesia. We analyzed MP in different concentration of extract. There are 500, 1000, 1500, 2000 and 2500 ppm. The experiment was started by extraction of the MP. According to the polarization potentiodynamic data, the rate corrosion could be decrease about 90,36% on concentration 500 ppm. It means MP extract could serve as an effective inhibitor for the corrosion. This is consistent with the initial hypothesis that MP contains antioxidant compounds that can inhibit oxidation thereby reducing the corrosion rate.

### ABSTRACT

Cobalt based oxide are promising as coating material for solid oxide fuel cell interconnect due to their high oxidation resistance and conductivity. In this report, Co-based coating layer was deposited on AISI 430 ferritic stainless steel substrate using thermal spray methods. The high temperature oxidation behavior of Co-based coating was studied in air atmosphere at 800 °C. Optical and SEM observation shows that the total thickness of Co-based layer was about 100-120 µm. The coatings were mainly growth by the melted particles impacting on the substrate that flatten to form splats which later on piled on top of the others. Phase identification by XRD showed that the coating layer contained  $\text{Co}_3\text{O}_4$ , and NiO oxides. EDS analysis indicated that the coating layer were sufficient to prevents the formation and the growth of  $\text{Cr}_2\text{O}_3$  scale. The Co-based coating shows relatively a large mass gain during oxidation compared to the uncoated steel, with parabolic rate constant,  $K_p = 4 \times 10^{-15} \text{ gr}^2 \cdot \text{mm}^{-4} \cdot \text{ks}^{-1}$ .

### ABSTRACT

A high strength bolt with hot dip galvanizing treatment failed shortly after being installed for two days on padeye of a mooring dolphin. The bolt was installed with increasing stress on the second day in which the value was nearly twice. Investigation results showed the bolt fractured with the nut head separated from the pin. Corroded fracture surface with brittle characteristic and no plastic deformation observed dominating the failed area. Characterization of hardness and chemical composition followed with microstructure and fractography observation on the fracture surface then conducted in order to analyze the reason for this brittle fracture occurrence. Results indicate that, while the bolt conforms to the material specification in term of chemical composition, the hardness value was high. The microstructure observation reveals a transgranular crack propagation and cleavage failure occurred. The cleavage failure was clearly observed under fractography observation using scanning electron microscope. Failed galvanize layer due to mechanical failure becomes preferential site for hydrogen evolution in marine environment, which leads to hydrogen diffusion into the matrix, thus results in hardness increase. The increasing stress during installation become detrimental to the bolt and facilitate the hydrogen induce cracking. Detrimental effect of hot dip galvanize layer is pointed out in the application of high strength material in marine environment.

### ABSTRACT

Corrosion due to carbon dioxide ( $\text{CO}_2$ ) has a major impact on the oil and gas industry by severely affecting production and process facilities. One of the most economic methods to prevent the corrosion of piping and plants is the application of corrosion inhibitors. The presences of corrosion product such as iron carbonate ( $\text{FeCO}_3$ ) film may affect to the performance of corrosion inhibitor. In addition to that, fluid flow effect in pipeline may also influence the performance of corrosion inhibitor. Thus, the present work is conducted to study the effect of  $\text{FeCO}_3$  film to the performance of corrosion inhibitor under fluid flow effect. The experiments were done in glass cells at  $80^\circ\text{C}$ . The hydrodynamic condition experiment was simulated using rotating cylinder electrode (RCE). Corrosion inhibitor was added at two different concentrations in the iron carbonate film formation. A corrosion rates were measured by linear polarization resistance (LPR) method. The film was later analyzed using scanning electron microscopy (SEM). It was found that a better corrosion protection is still offered by corrosion inhibitor even with presence of  $\text{FeCO}_3$  film. A synergistic effect is offered by these two films of corrosion inhibitor and  $\text{FeCO}$  in reducing corrosion rate.

### ABSTRACT

$\text{Ca}_x\text{Ni}_{1-x}\text{O}$  was prepared by conventional solid state reaction. The properties of undoped and CaO doped NiO ceramics have been studied. The raw mixture of CaO and NiO were ball milled for 24 hours. The samples were calcined at 1000°C for 2 hours, pressed into pellet shape at 200 MPa and sintered at 1300°C for 4 hours. The sintered samples were subjected to XRD, Scanning Electron Microscopy (SEM) and Impedance Analyzer for phase identification, microstructural observation and dielectric analysis. The grains size becomes larger with the increment of dopant amount. Enhanced dielectric constant was observed for all Ca doped NiO at the frequency range from 100 Hz to 1 MHz. The dielectric constant of sintered  $\text{Ca}_x\text{Ni}_{1-x}\text{O}$  decreased with an increasing frequency. The result indicates that Ca ions have effectively changed the properties of NiO.

## Plasmonic Photocatalyst Ag/AgCl Nanohybrids on Titanate Thin Film for Photocatalytic Application

50 Nanyang Avenue, Singapore 639798, Singapore*

### ABSTRACT

Semiconductor photocatalysts have been widely used for the removal of organic compounds in waste water using solar energy in the past decades [1, 2]. An optimal photocatalytic material would have the following properties: to be able to dissociate organic molecules, to have a band gap that absorbs light in the visible range, and to remain stable in aqueous media. Besides, it should be non-toxic, abundant and easy to fabricate to a desired shape. Based on this concept, we demonstrate a novel plasmonic silver/silver chloride nanohybrid on the titanate thin film via a facile and inexpensive approach [3, 4]. The preparation is as follows: Firstly, the sodium titanate thin film was prepared via a traditional hydrothermal method at 200 °C for 6 hours. Then, by using an ion-exchange process, the Na<sup>+</sup> ions in the interlayer of titanate is replaced by Ag<sup>+</sup> ions without changing its morphology. After that, the silver titanate reacts with HCl vapor to form the AgCl particles on titanate thin films. Finally, the visible-light-driven plasmonic photocatalyst Ag/AgCl/titanate is obtained by partially reducing Ag<sup>+</sup> ions from AgCl particles with the aid of Xe lamp illumination.

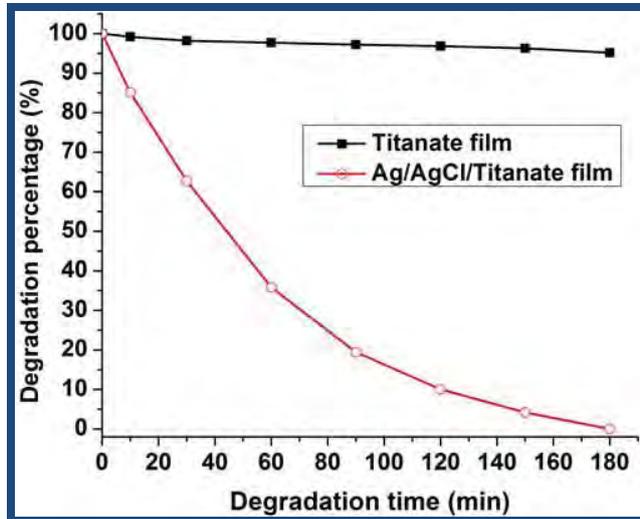

Figure 1 shows that the as-prepared Ag/AgCl/titanate film photocatalyst exhibits higher activity in the visible region of the solar spectrum for the degradation of phenol solution, while the titanate thin film shows negligible activity for the phenol removal. This room-temperature synthesis route could be easily extended to prepare various solar light responsive semiconductors via metal ion exchange and gas reaction process for photocatalytic applications.

### ABSTRACT

Nanocrystalline TiO<sub>2</sub> has been synthesized through non-aqueous sol gel using acetic acid (HOAc) and hydrochloric acid (HCl) as a catalyst. Titanium isopropoxide (TTIP) as precursor was prepared by reaction between TiCl<sub>4</sub> with isopropyl alcohol (IPA) in concentration of 0.3 M. The sol gel process employed at around 60°C using tert-butanol as solvent and HOAc was added as ligand to stabilise the reaction. Controlled hydrolysis and condensation reactions were achieved through in-taking of water molecules released from the esterification reaction of HOAc with tert-butanol. In this paper, the influence of acidic catalyst was described at the volume ratio of HOAc:HCl are 0:2 ; 1:1 and 2:0. The crystallinity and crystal phase of the samples were characterized by X-ray Diffraction and nanocrystalline TiO<sub>2</sub> with anatase phase was resulted. The morphology of the TiO<sub>2</sub> powder was analyzed by Scanning Electron Microscopy. Pore size and the BET surface area were determined by Brunauer-Emmett-Teller (BET) analysis. Nanocrystalline TiO<sub>2</sub> produced was applied for photoelectrode of dye-sensitized solar cell. The optical properties of the TiO<sub>2</sub> photoelectrodes were measured using by UV-Vis Spectrophotometer. The performance of the cell was measured using a solar simulator with light at an intensity of 50 mW/cm<sup>2</sup> generated by a xenon lamp. The best efficiency of 0.5% was achieved for active area of 0.48 cm<sup>2</sup>.

### ABSTRACT

Barium hexaferrite and strontium titanate are respectively well established permanent magnet and piezoelectric materials which are technologically and scientifically attractive due to their potential for various applications in the field of magnetic electronics functional materials. However, the material properties for both require a careful control of grain structure as well as microstructure design to meet specific applications. In this work, we report some results of materials characterization especially particles and crystallites in a  $\text{BaFe}_{12}\text{O}_{19}/\text{SrTiO}_3$  composite which were promoted during mechanical milling. The composite was synthesized using a planetary ball mill with a ball to powder ratio 10:1. Changing in the particle and crystallite-sizes at various milling time up to 60 hours are studied with the aid of particle-size analyzer and X-ray diffraction. It was found that the particle size of composite powders initially increased due to laminated layers formation of a composite and then decreased to an asymptotic value of  $\sim 8 \mu\text{m}$  as the milling time extended even to a relatively longer time. However, based on results of line broadening analysis the mean crystallite size of the particles was found in the nanometer scale. We thus believed that mechanical blending and milling of mixture components for the composite materials has promoted heterogeneous nucleation and only after successive sintering at  $1100^\circ\text{C}$  the milled powder transformed into particles of nanograin. The crystallite growth kinetics at isothermal temperatures follow the relaxation equation with the activation energy value for BHF ( $Q_{\text{BHF}}$ ) and STO ( $Q_{\text{STO}}$ ) are respectively 73.63 kJ/mol and 122.69 kJ/mol.

### ABSTRACT

Strontium titanate (SrTiO<sub>3</sub>) thin film has been deposited on Si (100) substrate using pulsed laser deposition technique. Film deposition was carried out at low temperature (150°C) by maintained the pressure at 10<sup>-4</sup>Torr. Nanometer-thick SrTiO<sub>3</sub> film on Si substrate was characterized using SEM, AFM, XRD, and Raman Spectroscopy. SEM and AFM images show that SrTiO<sub>3</sub> film has growth on Si substrate uniformly. Raman and XRD spectroscopy also support the growth of SrTiO<sub>3</sub> film on Si substrate. Furthermore, to investigate the effect of post-deposition thermal annealing, the samples were annealed up to 900°C. Thermal stability of SrTiO<sub>3</sub>/Si structure was studied by mean XRD spectra. The X-Ray Diffraction pattern indicates the crystallinity improvement through atomic arrangements during thermal annealing process.

### ABSTRACT

The synthetic dyes are a refractory and poisonous material. Most of industrial textile today used the synthetic dyes that can be dangerous to the environment because of the colored wastewater produced from their processes. This study concentrates on the application of Advanced Oxidation Processes (AOPs) for synthetic dyes wastewater treatment. Photocatalysis process as one of AOPs was applied for the degradation of organic content of synthetic dyes wastewater. The reactive dye, C.I. Reactive Red 2 (RR 2) was used as the organic pollutant model at the concentration of 100 mg/l. The TiO<sub>2</sub> concentration of 0.05-0.4 g/ml was used as the photocatalyst. The bulk and nano-size of TiO<sub>2</sub> were coating on the PET plastic and the degradation of organic content was examined in the term of color and COD within 0-12 hrs under solar irradiation. By using 0.4 g/ml of bulk TiO<sub>2</sub>, the color degradation of 88% and COD removal of 46% was achieved. Furthermore, by using 0.4 g/ml of nano-size TiO<sub>2</sub>, the enhancement of color degradation and COD removal was observed, that is 98% and 56%, respectively.

### ABSTRACT

The application of nanocrystalline solids has long been facilitated by the wide range of cutting edge techniques such as sol-gel, vapor condensation, mechanical milling, and chemical anodizing. At present, the nanostructured coating utilizing high energy plasma has been shown to possess unique and often enhanced materials properties in comparison to the cermet coatings via current technology. Now, the behavior of nanostructured materials subjected to plasma electrolytic coating was rendered complex by the choice of factors such as electrolyte, electric parameters, and cell atmosphere. Thus, it is essential to optimize the processing design which could lead to the achievement of excellent materials performance heretofore unattainable via conventional coatings. The present paper is to offer a general overview of recent progress in the area of high performance nanostructured coatings, paying much attention to underlying fundamental issues as well as exploring various applications.

### ABSTRACT

Anode active material  $\text{Li}_4\text{Ti}_5\text{O}_{12}/\text{C}$  has an advantage to increase the life time and the ability to charge and discharge lithium batteries. An experiment was carried out to make  $\text{Li}_4\text{Ti}_5\text{O}_{12}/\text{C}$  more cheaper and simple process. Preparation of  $\text{Li}_4\text{Ti}_5\text{O}_{12}/\text{C}$  was carried out with stoichiometric composition of raw materials  $\text{TiO}_2$  (Merck) and  $\text{LiOH}\cdot\text{H}_2\text{O}$  (Germany) under powder metallurgy method. After mixing and calcinations cassava starch as a source of carbon black coating could be mixed under comparison 1:1 with calcinations powders. Pyrolysis process was done in - situ by the sintering process at temperature variation, i.e. 800, 850 and 900<sup>o</sup>C for 1 hour. XRD test results indicated the presence of anatase  $\text{TiO}_2$  entire sample. The best results of powder  $\text{Li}_4\text{Ti}_5\text{O}_{12}/\text{C}$  with in situ process under 850<sup>o</sup>C for 1 hour had conductivity in the order of 10<sup>-4</sup>S/cm and capacity round 5mAh/g. Carbon coating of cassava starch that is well identify in the black color of sample powder and EDX analysis, gave influence on electrochemical graphics of oxidation and reduction by cyclic voltammeter. The working voltage of  $\text{Li}_4\text{Ti}_5\text{O}_{12}/\text{C}$  is in general 1.55V.

### ABSTRACT

The synthesis and characterization of the magnetic materials of  $\text{La}_{0.8}\text{Ba}_{0.2}\text{Mn}_{(1-x)}\text{Ti}_x\text{O}_3$  system ( $x = 0 - 0.7$ ) by mechanical alloying process have been performed. This magnetic material is prepared by oxides, namely  $\text{La}_2\text{O}_3$ ,  $\text{BaCO}_3$ ,  $\text{MnCO}_3$  and  $\text{TiO}_2$ . The mixture was milled for 10 h and then sintered at  $1000^\circ\text{C}$  for 10 h. The refinement results of x-ray diffraction pattern showed that the doping concentration ( $x < 0.5$ ) was a single phase, which has a structure monoclinic (I12/a1) with lattice parameters  $a = 5.5169(5)\text{ \AA}$ ,  $b = 5.5437(5)\text{ \AA}$  and  $c = 7.8553(7)\text{ \AA}$ ,  $\alpha = \gamma = 90^\circ$  and  $\beta = 89.75(1)^\circ$ ,  $V = 240.25(4)\text{ \AA}^3$  and  $\rho = 6.345\text{ gr.cm}^{-3}$ . The microstructure analysis showed that the particle shapes was polygonal with the varied particle sizes distributed homogeneously on the surface of the samples. We concluded that the maximum number of titanium atoms substituting manganese atom is around  $x \sim 0.43$  without changing the structure of this system.

### ABSTRACT

Nanocrystalline TiO<sub>2</sub> has been synthesized through non-aqueous sol gel using acetic acid (HOAc) and hydrochloric acid (HCl) as a catalyst. Titanium isopropoxide (TTIP) as precursor was prepared by reaction between TiCl<sub>4</sub> with isopropyl alcohol (IPA) in concentration of 0.3 M. The sol gel process employed at around 60°C using tert-butanol as solvent and HOAc was added as ligand to stabilise the reaction. Controlled hydrolysis and condensation reactions were achieved through in-taking of water molecules released from the esterification reaction of HOAc with tert-butanol. In this paper, the influence of acidic catalyst was described at the volume ratio of HOAc:HCl are 0:2 ; 1:1 and 2:0. The crystallinity and crystal phase of the samples were characterized by X-ray Diffraction and nanocrystalline TiO<sub>2</sub> with anatase phase was resulted. The morphology of the TiO<sub>2</sub> powder was analyzed by Scanning Electron Microscopy. Pore size and the BET surface area were determined by Brunauer-Emmett-Teller (BET) analysis. Nanocrystalline TiO<sub>2</sub> produced was applied for photoelectrode of dye-sensitized solar cell. The optical properties of the TiO<sub>2</sub> photoelectrodes were measured using by UV-Vis Spectrophotometer. The performance of the cell was measured using a solar simulator with light at an intensity of 50 mW/cm<sup>2</sup> generated by a xenon lamp. The best efficiency of 0.5% was achieved for active area of 0.48 cm<sup>2</sup>.

### ABSTRACT

Perovskite lanthanum manganites, especially those doped  $\text{LaMnO}_3$  (LMO), have shown potentials for applications in magnetic electronic functional materials. Partial substitution of La ion with divalent ions or Mn ion with trivalent ions gives rise to new properties. Substituted LMO has ability for absorbing electromagnetic waves. In this paper, we report recent investigations on substituted  $\text{LaMnO}_3$  with designated  $\text{La}_{(1-x)}\text{Ba}_x\text{Fe}_{0.25}\text{Mn}_{0.5}\text{Ti}_{0.25}\text{O}_3$  ( $x = 0, 0.25, 0.75, 1$ ) compositions. Materials were prepared by mechanical alloying technique. After heat treatments at sintering temperatures 1100°C, 1200°C and 1300°C to the quasi-crystalline powders, presence of material phases were confirmed by XRD. Single phase material was obtained in samples of  $0.25 \leq x < 0.75$  compositions. Mean crystallite size of sintered materials showed that crystallites were in a Nano crystalline regime. It is then concluded, during mechanically alloyed sintering powder materials, solid-state reaction and crystallisation promoted formation of particles containing Nano crystallites. Microwave absorption data showed that materials with large amount of substituted Ba ion gives broad absorption profiles. Total substitution of La by Ba ions ( $x=1$ ) has significantly changed absorption profile. Smaller mean crystallite sizes indicated an increase in reflection loss value. In this report, empirical relationship between nanostructure and absorption profile of material is discussed.

### ABSTRACT

The macro texture of Nb<sub>3</sub>Sn superconductor was observed in order to identify the tendency of crystallographic orientation of such A15 compound. The Nb<sub>3</sub>Sn samples were prepared through the powder metallurgy process with the composition of 24at%Sn-76at%Nb. The well-blended Nb-Sn powder was consolidated by means of the uni-axial compression method, while the subsequent sintering was performed at T = 700°C for t = 96 hr. The macro texture of the sintered samples was measured using D8 Advance XRD Goniometer and the corresponding results were analyzed in the form of pole figures. Preliminary results indicate that the crystallographic orientations of Nb<sub>3</sub>Sn for both green compact and sintered samples show the strong textures in {112}-pole figures. The intensity of Nb<sub>3</sub>Sn textures decreases from green compact sample to sintered sample, probably due to the mechanism of recovery – recrystallisation following the Nb-Sn inter-diffusion process during sintering.

### ABSTRACT

Barium - Strontium Hexaferrite and Barium – Strontium Titanate are both well established materials which widely used respectively as permanent magnets and piezoelectric devices. As the properties are a structure sensitive, materials structure as well as crystal structure must be properly designed to meet a specific application. In this paper, we report our recent investigation on material structure analysis of  $Ba_{0.3}Sr_{0.7}Fe_{12}O_{19}$  and  $Ba_{0.7}Sr_{0.3}TiO_3$  composite system prepared by a mechanical alloying process to promote ferroic properties. The average of particle size for composites system was found initially increased to a large size of 9  $\mu m$  after mechanically milled for 30 hours and then start to decreased to smaller size of  $\sim 5 \mu m$  when the milling time was extended to 80 hours and showing trend toward further reduction in mean particle sizes. In the latter case, the XRD trace for milled powders showed broadened diffracted peaks pattern due to deformation during mechanically milling. After sintering at a temperature of 1050  $^{\circ}C$  much finer crystallites of 7-13 nm size in a dense pellet were observed. Hence, sintering to the milled particles has promoted formation of nanocrystal containing particles. The mean crystallite size for magnetic phase was about more than 350 times smaller than the mean particle size of composite particles. Finer crystallite sizes were found in  $B_3SF$  in which the mean was about 700 times smaller than the mean particle size. The magnetic and electric properties of the composite system are also discussed.

### ABSTRACT

The formation of barium hexaferrite, BaFe<sub>12</sub>O<sub>19</sub> single phase with nanosize crystalline is very important to get the best performance especially magnetic properties. The samples were prepared by sol gel method in citric acid-metal nitrates system. Hence the mole ratios of Ba<sup>2+</sup>/Fe<sup>3+</sup> were varied at 1:12 and 1:11.5 with pH of 7 in all cases using ammonia solution. The solution was then heated at 80-90°C for 3 to 4 hours. Then it was kept on a pre- heated oven at 150°C. The samples were then heat treated at 450°C for 24 hours. Sintering process was done at 850°C and 1000°C for 10 hours. Crystallite size was calculated by X-Ray Diffraction (XRD) peaks using scherrer formula. To confirm the formation of a single phase, XRD analyses were done by comparing the sample patterns with standard pattern. The peak shifting of pattern could be seen from XRD pattern using rocking curves at extreme certain 2θ. It was used MPS Magnet – Physik EP3 – Permagraph L to know magnetic characteristics. This method can produce BaFe<sub>12</sub>O<sub>19</sub> nanosize powder, 22-34 nm for crystallite size and 55.59-78.58 nm for particle size. A little difference in nanosize affects the peak shifting of XRD pattern significantly but shows a little difference in magnetic properties especially for samples at 850°C and 1000°C with mole ratio of 1:12 respectively. The well crystalline powder is formed at mole ratio of 1:11.5 at 850°C since it has the finest particle (55.59 nm) and crystalline (21 nm), the highest remanent magnetization (0.161 T) and the lowest intrinsic coercive (275.8 kA/m). It is also fitting exactly to the standard diffraction pattern with the highest value of best Figure of Merit (FoM), 90%. XRD peak position of this sample is almost same with XRD peak position of another sample with sinter temperature 1000°C at same mole ratio.

### ABSTRACT

Fe-Mn alloys in biomedical materials application are prospective to be developed because of their properties, such as biodegradable and compatible with MRI (Magnetic Resonance Imaging). Many researches were focused on degradable rate of this alloy in order to adjust with healing time process at about 12 months as coronary stent. Several methods were investigated to produce excellence properties for this application, such as addition of alloying elements and powder metallurgy with mechanical alloying (MA). In this study, carbon is added as an alloying element. Material compositions were set to the value of Fe-25%Mn-1%C and Fe-35%Mn-1%C with MA or Non-MA treatment. Specimens were compacted for 15 minutes and followed by sintering process in vacuum furnace. XRD pattern and Ferrite Scope test showed the effects of the addition of Carbon allowed to produce a material that is dominated by the austenite phase (99%) with manganese content lower than previous studies. This result could reduce the toxicity issue from Manganese content in alloy. MA treatment gave smaller particle size, lower porosity and reduce corrosion rate than alloy material that formed without MA treatment. This study offers an easier fabrication process and produces alloys with manganese content lower than previous studies and dominated by Austenite phase

## ABSTRACT

The Al-Cu/SiC composite was obtained by hot press (5 tons) method without addition element. The XRD pattern show specific pattern of Al-Cu/SiC composite with no other phases. The Al-Cu ingot without reinforcement has heterogeneous nucleation precipitates. However, the Al-Cu with reinforcement by SiC composite has smoother surface as indicating the nucleation less heterogeneous. Furthermore, the hardness of Al-Cu/SiC composite by ageing treatment has better quality.

## Keywords

*Al-Cu/SiC composite, hot press, XRD, heterogeneous nucleation, hardness*

## 1. INTRODUCTION

To date, metal matrix composite (MMC) is becoming potential candidate as structural material, automotive, aerospace.[1] MMC of Al-Cu/SiC are now claimed as possible solution as electronic packaging industry. Aluminium (Al) and Copper (Cu) reinforced by SiC has excellent thermo-physical properties such as low coefficient of thermal expansion (CTE), high thermal conductivity and improved mechanical properties such as higher specific strength, better wear resistance and specific modulus.[2,3]

The Al matrix composite are produced by casting route or powder metallurgy.[4] Nevertheless, the difficulties of casting is non wettability of the ceramic particles by liquid Al.[4] In order to improved the non wettability, Al matrix was coated by metals such as Ni and Cu.[5] Other also reported that the non wettability can be improved by adding surface active elements such as Mg into liquid Al or by preheating of the particles added into liquid Al.[4,5] However, the addition of Mg can reduce mechanical properties of the Al matrix.[2]

In this paper, we report the structure and mechanical properties of composite material of Al-Cu/SiC without any addition elements. The Al-Cu/SiC composite alloy has been prepared by using hot press method.

## 2. EXPERIMENTAL METHODS

Al-Cu ingot as the matrix with various Cu contents (3.8 wt%, 4.4 wt%, 4.9 wt%) were melted up to 1200°C for 30 minutes and cooled at room temperature. Al-Cu was cut and mixed with SiC powder. Vibration ball mill was performed in order to get smoother powder. Then, Al-Cu/SiC (10 wt%) composite were pressed by hot press (5 tons) at temperature 500°C for 10 minutes. Cooling process of the Al-Cu/SiC alloy was done by flowing water into mold porous. The next step was ageing by temperature 190 °C for 15 hours. The crystal structure and morphology were analyzed by using X-ray diffraction (XRD) and digital microscope. Furthermore, the mechanical properties of all composition of Al-Cu/SiC were characterized using hardness Vickers (HV).

## 3. RESULTS AND DISCUSSION

### 3.1 Phase identification and microstructure

In order to confirm phase of Al-Cu, the x-ray diffraction (XRD) has been performed. Figure 1 shows the XRD pattern of Al-Cu ingot with various Cu contents.

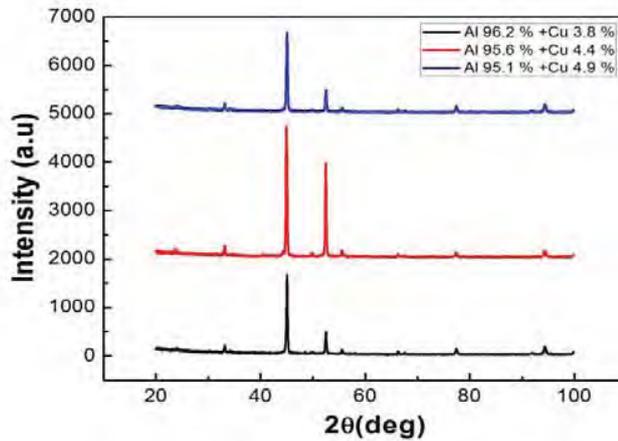

Figure 1: XRD patterns of Al-Cu ingot with various Cu contents were melted up to 1200°C for 30 minutes and cooled at room temperature

The XRD spectra shows the observed peaks at  $2\theta = 45^\circ$  and  $52^\circ$  corresponding to Al phase. Meanwhile, minor phase ( $Al_2Cu$  and  $Al_2O_3$ ) also observed eventhough the intensity low. It's indicates that the Al-Cu alloy was formed by casting process. The minor phase of  $Al_2Cu$  originates from precipitate atoms which diffuse into Al matrix during melting process. However, at cooling process, the precipitate atoms moveback to the grain boundary and the composite surface. Therefore, it can be understood that there is no other new phase forms in Al-Cu composite.

Figure 2 shows the XRD patterns of Al-Cu ingot, Al-Cu/SiC hot press, and Al-Cu/SiC hot press with ageing at temperature 190°C for 15 h. The XRD pattern observed that the highest peaks corresponding to Al phase. It's confirmed that the Al contents has dominant composition compare to other phase even after mixed with SiC. By ageing, the other peaks at  $2\theta = 78^\circ$  and  $95^\circ$  increased. It is predicted that by ageing, the orientation of structure of the Al matrix was changed.

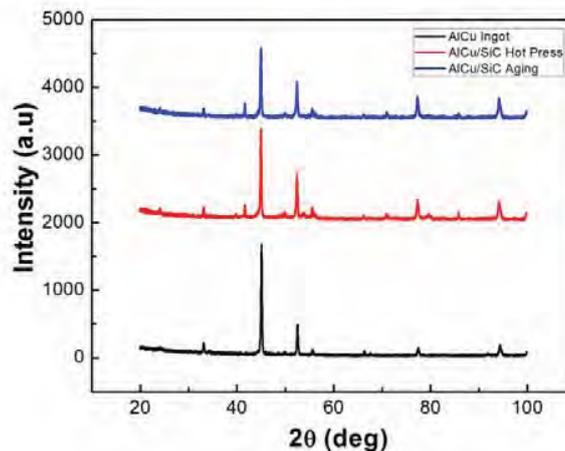

Figure 2: XRD patterns of Al-Cu ingot, Al-Cu/SiC hot press, and Al-Cu/SiC hot press with ageing at temperature 190°C for 15 h

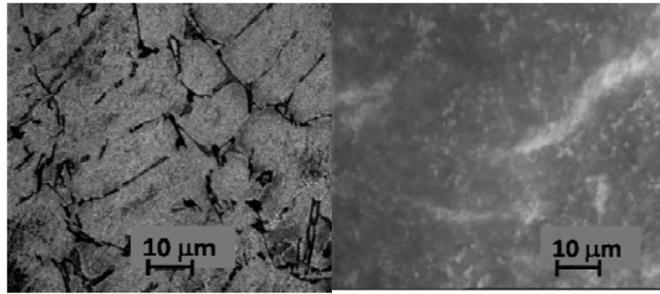

Figure 3: (a) Microstructure of Al-Cu ingot, (b) Microstructure of Al-Cu/SiC

Figure 3 (a) shows the morphology of the microstructure of Al-Cu ingot which melted at temperature 1200°C. It can be seen that the grains and grain boundary clearly observed. It is assumed that Al-Cu without reinforcement has greater dislocation density. As results, the dislocation provide heterogeneous nucleation of the precipitates. Nevertheless, figure 3 (b) shows the Al-Cu/SiC looks smoother compared to Al-Cu ingot. Its because the Al-Cu was reinforced significantly by SiC alloy composite.

### 3.2 Mechanical properties

Figure 4 shows the hardness Vicker (HV) value of Al-Cu ingot with various Cu contents which are melted up to 1200°C for 30 minutes and cooled at room temperature. The hardness of Al-Cu varies with distance and Cu contents. It can be assumed that during cooled process, the interface of the matrix interfaces has heterogeneous dislocation density which provide heterogeneous nucleation of precipitates. As results, the hardness of Al-Cu varies for each distance.

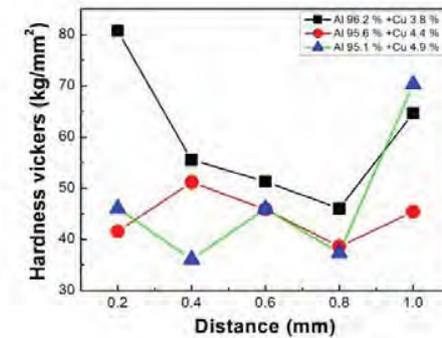

Figure 4: HV value of Al-Cu ingot with various Cu contents were melted up to 1200°C for 30 minutes and cooled at room temperature.

Figure 5 shows the HV of Al-Cu ingot, Al-Cu/SiC, and Al-Cu/SiC with ageing at temperature 190°C for 15 hours. The HV values confirm that the hardness of Al-Cu/SiC with ageing (temperature 190°C for 15 hours) has strongest value compared to the others.

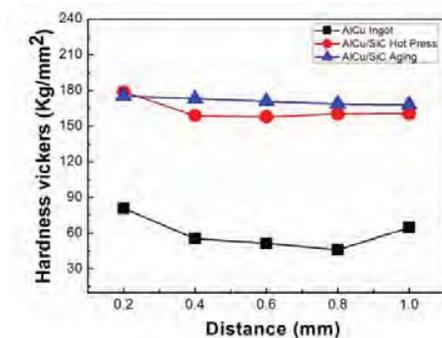

Figure 5: HV of Al-Cu ingot, Al-Cu/SiC hot press, and Al-Cu/SiC hot press with ageing at temperature 190°C for 15 h

Its predicted that reinforcement matrix composite of Al-Cu by SiC was improved by ageing treatment. Eventhough, the hardness improvement not significantly different with Al-Cu/SiC. It can be assumed that the volume fraction of SiC has significant effect on the ageing kinetics of Al-Cu alloy matrix in the cast composite.[6]

#### 4. CONCLUSION

In conclusions, the Al-Cu/SiC composite was obtained by hot press (5 tons) method without addition element. The XRD pattern show spesific pattern of Al-Cu/SiC composite with no other phases. The Al-Cu ingot without reinforcement has heterogeneous nucleation precipitates. However, the Al-Cu with reinforcement by SiC composite has smoother surface as indicating the nucleation less heterogeneous. Furthermore, the hardness of Al-Cu/SiC composite by ageing treatment has better quality.

### ABSTRACT

Nanotechnology is one of the key technology had been developed since in all fields including textile industries for medical, hygienic, and technical textiles. Particle size with nano had been indicated in particular for the application of controlled release material for functional textiles. TiO<sub>2</sub> nano powder has remarkable photo-catalytic and semiconductor as material for various advanced technology fields of application such as UV Protection. In this research the synthesis of TiO<sub>2</sub> nanoparticle and characterization had been conducted successfully by sol-gel method. The starch was used as a template to get nanoparticles structure. TiO<sub>2</sub> sol with narrow particle size distribution using TiCl<sub>4</sub> as the starting material. The sol was prepared by a process where HCl was added to a gel of hydrated titanium oxide to dissolve it. The effect of preparation parameters were investigated, by deionized water : HCl 1 M was slowly added to TiCl<sub>4</sub> at 5 °C. In this study the production of anatase or rutile TiO<sub>2</sub> nanostructured powder by forced hydrolysis of aqueous Ti (IV) chloride solution and concentration from 0,3, 0,5 then 1 M. TiO<sub>2</sub> sphere were fabricated by a facile and low – cost stable starch assisted by sol-gel method. Aqueous solution of starch was added and then heated in temperature 80°C and aqueous solution of ammonium hydroxide was added to adjust pH to 8. After aging period of time, the white precipitate was filtered and then calcined in temperature 500° C. The as-obtained samples were characterize, kjnhjd by SEM (Scanning Electron Microscope), UV-vis diffuse reflectance spectroscopy, X-Ray Diffraction (XRD) and Brunauer Emmett Teller (BET) analysis. The particle size is less than 100 nm and if it uses template particle TiO<sub>2</sub> more uniform distribution and spherical shape with particle size 170 – 200 nm. Crystallinity particle is 4 – 19 nm and the phase structure of anatase and rutile. The energy band gap semiconductor TiO<sub>2</sub> synthesis is 3.1 to 3.7 eV. Surface area without template starch 40.655 m<sup>2</sup>/g, with total for volume 0.278 cm<sup>3</sup>/g and pore size of 27 nm, and used template starch surface area 35.488m<sup>2</sup>/g with total for volume 0.196 cm<sup>3</sup>/g and pore size of 22 nm. Based on this research, the best a crystal phase for UV protection application is rutile phase.

### ABSTRACT

Synthesis of mesoporous silica from tetraethylorthosilicate (TEOS) by using sodium ricinoleic as a template and 3-aminopropyltrimethoxysilane (APMS) as a co-structure directing agents (CDSA) in a volume variation of acid addition has been carried out. Preparation of mesoporous silica was conducted in HCl 0.1 M at volume variations of 2 ml, 35 ml, 40 ml and 50 ml. In acid conditions, the amine groups of APMS will protonate, which will then interact electrostatically with the carboxylate groups from ricinoleic acid, while the methoxy groups from APMS will condense with the silanol groups from TEOS to form an end product of mesoporous silica. The reaction products were characterized by using X-ray diffractometer (XRD), Fourier transform infra-red spectrometer (FTIR), surface area analyzer (BET), scanning electron microscope (SEM), and transmission electron microscope (TEM). X-ray diffractograms of the products from all of the acid volume variation additions show broadening peaks indicating amorphous materials as a characteristic of mesoporous materials. Infrared spectra show that all of the products have Si-OH and Si-O-Si groups that are characteristics for mesoporous silica. Imaging results from SEM and TEM show morphology and particle size differences in accordance with the differences in volume variation of acid addition. Adsorption/desorption isotherm by using nitrogen at 77 K of the products from the addition of 2 ml of HCl show an isotherm Type II (adsorption on the surface layer) with irregular pore size distribution, whereas from the addition of 30 ml, 35 ml, 40 ml and 50 ml HCl show an isotherm Type IV with a hysteresis loop that is characteristic for mesoporous materials with a regular pore size distribution.

### ABSTRACT

Microencapsulation is a new breakthrough in the field of nanotechnology that can be used for various applications, in particular for the application of controlled release material for functional textiles which were added by certain active substances and gave effects when used such as fragrance and anti mosquito textile. In this research, the synthesis of silica-lavender microencapsulation for anti-mosquito textile had been conducted successfully via sol-gel emulsion process. Sodium silicate solution which was emulsified into the lavender oil as an active ingredient acted as oil phase and ethanol solution acted as water phase. The addition of chitosan as surfactant and polymer for encapsulation with starch as soft template affected the rod-structure formation of nanorod. SEM result showed the morphology of silica-lavender. The rod has the average diameter size of 0.042-0.206  $\mu\text{m}$ . The optimum result of rod-structure was obtained by adding 1% (v/v) of chitosan. FTIR analysis indicated the presence of absorbance peaks at wavenumber of 1411.89, 958.62, and 1078.2  $\text{cm}^{-1}$  respectively for C-H (alkanes), C-H (alkenes) and ester functional groups which indicated the lavender compound in silica-lavender. UV-Vis analysis showed the maximum absorbance at wavelength of lavender at 350 nm. The combination of morphology and chemical properties of silica-lavender modified by chitosan-starch made this material as a candidate material for application in functional textile.

### **ABSTRACT**

The purpose of this paper is to investigate an application of a piezoresistive microcantilever for gas sensor using a dynamic mode operation. The working principle of the microcantilever sensor is based on the measurement of microcantilever deflection or resonance frequency change due to the objects attached on the microcantilever surface. The measurement was performed by using Wheatstone bridge circuit, which is constructed by two piezoresistors in the microcantilever and two external resistors, in order to measure the resonance frequency shift of the microcantilever vibration. The result shows that the voltage of oscillation peak-to-peak from the output of Wheatstone bridge circuit, which represents the microcantilever vibrations, decreases with the time due to the gas detection. This occurs due to the resonance frequency shift caused by the addition of gas molecules mass on the microcantilever surface. This result indicates that the developed system can be used as gas sensor

### ABSTRACT

NiTi alloy is one of important materials in orthodontics. Shape memory effect of this material ensures the possibility to deliver highly desirable light forces for tooth movement. Unfortunately, NiTi has problem in the high amount content of Ni that can cause allergy or even risk of poisoning in the human body due to Ni ion released. To overcome this problem, several methods of coatings were performed to prevent the releasing of Ni ion. They were Electropolishing Pretreatment combined with Photo Electrochemical Oxidation, TiN Pack Cementite, Advanced Oxidation Process and Biomimetic Hydroxyapatite. The objective of this research was to analyze the effect of various coatings to the biocompatibility of orthodontic wire. Biocompatibility of coated NiTi wire was investigated through MTT assay using BHK-21 fibroblast cell in order to analyze the toxicity of each coating method. In addition, the surface roughness was determined using Atomic Force Microscope (AFM). Furthermore, the attachment and spreading of fibroblast cell were observed by Scanning Electron Microscope (SEM). The result was revealed that biomimetic HA coating has the highest cell viability percentage due to its surface morphology.

**Plenary 3****Microbial cell factories for the production of bio-fuels and bio-based chemicals from cellulosic materials****Akihiko Kondo***Department of Chemical Science and Engineering,**Graduate School of Engineering**Kobe University,**1-1 Rokkodai, Nada, Kobe 657-8501, Japan**Tel : +81-78-803-6196. Fax : +81-78-803-6196**E-mail : akondo@kobe-u.ac.jp*

To build an energy and material secure future, a next generation of renewable fuels and bio-based chemicals produced from lignocellulosic biomass is required. Consolidated bioprocessing (CBP), which integrates enzyme production, saccharification and fermentation into a single process, is a promising strategy for effective production of bio-based materials. As a key technology for the development of recombinant cellulolytic microbial strains, cell surface engineering, which enables the display through genetic engineering of various types of functional proteins on microbial cell surfaces without loss of their function, is a promising tool reducing the requirement for cellulase addition, as cellulases can be displayed on the microbial cell surface. The display of cellulolytic and hemicellulolytic enzymes on the yeast cell surface effectively hydrolyzed lignocellulosic materials (e.g. hydrothermally pretreated rice straw). High-titer and high-yield ethanol production was achieved by short-term liquefaction and fermentation of high-solid lignocellulose biomass using a yeast strain developed for the cell-surface display of fungal endoglucanase, cellobiohydrolase, and  $\beta$ -glucosidase. Also, rice straw hydrolysates were directly converted to ethanol by constructing a recombinant yeast that not only hydrolyzed hemicelluloses by codisplaying endoxylanase and  $\beta$ -xylosidase, and  $\beta$ -glucosidase but also assimilated xylose through the expression of xylose reductase, xylitol dehydrogenase, and xylulokinase in the cell. Regardless of the process used for the biomass hydrolysis, CBP-enabling microorganisms encounter a variety of toxic compounds released during biomass pretreatment that inhibit microbial growth and ethanol yield. Systems biology approaches including transcriptomics and metabolomics have been recently exploited to gain insight into the molecular and genetic traits involved in tolerance and adaptation to the fermentation inhibitors. A combination of a cell surface displayed enzyme system and an intracellular metabolic engineering system is a very effective approach to develop cells with novel fermentation ability for industrial applications. The technology will open up the various new applications of cell factories to the industrially important processes.

## Structure and Functional Mechanism of Small Heat Shock Proteins

Masafumi Yohda

Department of Biotechnology and Life Science, Tokyo University of Agriculture and Technology,

The small heat shock protein (sHsp), categorized into a class of molecular chaperones, binds and stabilizes denatured proteins for the purpose of preventing aggregation. Compared with other chaperones, the overall amino acid sequence homology among sHsps is rather low. Their common feature is the  $\alpha$ -crystallin domain, which is named after the  $\alpha$ -crystallin of the vertebrate eye lens(1). The  $\alpha$ -crystallin domain is flanked by a highly variable N-terminal region and a short, partially conserved C-terminal extension (2). The molecular mechanism of the chaperone function of sHsps resides in the oligomeric structure. The chaperone potential of sHsps is latent when they exist as large oligomeric structures under physiological conditions. At elevated temperatures, the equilibrium shifts to the dissociated state, and the hidden hydrophobic substrate-binding sites are exposed to express chaperone activity (3). In the presence of unfolded proteins, small oligomers form a large stable complex with unfolded proteins to protect against protein aggregation. As sHsps lack refolding activity, trapped polypeptides can be refolded with the assistance of ATP-dependent chaperones, such as Hsp70 and Hsp100 (4-7).

We have been studying the structure and function of sHsps of thermophilic archaea and a fission yeast, *Schizosaccharomyces pombe*. StHsp14.0, the sHsp of acidothermophilic archaeon *Sulfolobus tokodaii*, exists as a spherical 24meric oligomer with a diameter of 115 Å(8), and the oligomer dissociates to exhibit molecular chaperone function over 80°C(9). Mutant StHsp14.0s with the amino acid replacements in C-terminal IKI motif exhibited oligomer dissociation and protected citratesynthase from thermal aggregation at 50°C(10). We examined the temperature dependent oligomer dissociation and complex formation with denatured protein of StHsp14.0 variants by small angle X-ray scattering (SAXS)(11). The results suggest that a partially dissociated oligomer of StHsp14.0 protects a denatured protein from interacting with other molecules by surrounding it. Recently, we reported the oligomer architecture of SpHsp16.0 from *Schizosaccharomyces pombe* determined with X-ray crystallography and small angle X-ray scattering. Both results indicate that 16 monomers of SpHsp16.0 form an elongated sphere with the 422 symmetry (12). The result of temperature dependence of the oligomeric state of SpHsp16.0 investigated by SAXS indicates that the large oligomeric state is maintained at the heat stressed condition. Previously, we have shown that the interaction between an unfolded protein and SpHsp16.0 is transient (13). Recent our study has also shown that the interaction between an unfolded protein and TkHsp20.0, sHsp of hyperthermophilic archaeon, *Thermococcus* strain KS1, at the elevated temperature is transient (Manuscript in preparation). The captured protein was released and started to refold spontaneously at the lowered temperature. In addition, other chaperones captured unfolded proteins that were protected by TkHsp20.0 at the elevated temperatures and enhanced refolding of them in an ATP dependent manner.

Based on these results, I propose a model for the molecular chaperone function of sHsp. In the heat shock response, sHsp is the first aid chaperone to treat thermally damaged proteins. After exposure to heat shock conditions, the oligomer of sHsp partially dissociates to expose hydrophobic surface and protect thermally denatured proteins from aggregation. The interaction seems to be transient. Other chaperones that are expressed as the heat shock response capture the protected unfolded proteins for productive folding after the end of thermal stress.

### ABSTRACT

Dragon's blood is a resin exudated by rattan (*Daemonorops draco*) fruit, collected and traded by forest-surrounded communities and is an exportable commodity. However, the National Standardization Agency issued an Indonesia National Standard for dragon's blood designated three qualities, i.e. super, A, and B, based solely on physical characteristics and visual parameters. Some parameters are qualitative and some others need a tedious procedures for the determination. In this study, claims by the traders and laboratory tests based on the national standards were compared. In average, the match between SNI determination and the traders claim was only 50%. In determining resin content, this study revealed that acetone extract was more useful than that of diethyl ether for being not involving heat in the process and the yield was also linearly correlated with absorbance at 473 nm using a UV-visible spectroscopy. A rapid quantitative measurement for revising SNI parameters is proposed. Chemical markers in dragon's blood resin are flavan derivatives, i.e. dracorhodin and 3,4-dihydro-5-methoxy-6-methyl-2-phenyl-2H-1-benzopyran-7-ol.

### Keywords

Dracorhodin, dragon's blood, Indonesia National Standard, rattan-fruit resin, UV-vis spectrophotometer

### 1. INTRODUCTION

Dragon's blood, so called *getah jernang* in Indonesian, is exudated by rattan (*Daemonorops draco*) fruit and is specific of Indonesia, especially in Sumatera. This red-color substance gives significant income for the forest-surrounding communities, with the price ranges from 80-100USD/kg, depending on the quality. This commodity is used for dyes, crafts, and even for medicine for treating diarrhea, asthma, syphilis, reported as an aphrodisiac [1]. The substance falls into hard resin, shiny solid, transparent, amorphous, specific gravity of 1.18-1.20, low acid number, ester number approximately 140, melting point approximately 120 °C, soluble in alcohols, ether, partially dissolves in chloroform, ethyl acetate, carbon disulfide, and insoluble in water [2].

Chemical constituents and their bioactivities in dragon's blood have been reported [3]. The main constituents identified among others are dracorhodin, nordracorhodin, 5-methoxy-6-methylflavan-7-ol, nordracorubin, dracoalban; dracoresene; dracoresinotannol, and dammaradienol. However, the quantitative data are not reported, especially those regarding the classification of this commodity.

Badan Standardisasi Nasional (BSN, Indonesian Standardization Agency) categorizes dragon's blood into 3 qualities, namely, Super, A, and B [4]. The parameters are based on the range contents of moisture, ash, resin texture, melting point, impurities, and color (Table 1). These physical properties are very subjective in nature and are potential to inflict financial loss at the farmer side, which are usually having low bargain position in trading. This study aimed to provide quantitative and rapid measurement to designate the quality of dragon's blood.

Table 1 Specification of dragon's blood as stipulated in SNI 1671:2010

Parameter	Unit	Quality requirement		
		Super	A	Mutu B
Resin content (w/w)	%	Min. 80	Min. 60	Min. 25
Moisture content (w/w)	%	Max. 6	Max. 8	Max. 10
Impurities (w/w)	%	Max. 14	Max. 39	Max. 50
Ash content (w/w)	%	Max. 4	Max. 8	Max. 20
Melting point	°C	Min. 80	Min. 80	-
Color	-	Dark red	Pink	Pale red

## 2. METHODS

The experiment was initiated by comparing the quality between the requirements according to SNI [4] and claims by the traders. The second step was identifying chemical markers in the collected samples, and concluded by an attempt to provide rapid measurement of the chemical marker.

### 2.1 Materials

There were 8 samples collected from traders in Sumatera (5 samples from Jambi, 2 from Aceh, and 1 from Medan). There was no claim from trader in Medan regarding the quality of the samples. All samples, in the forms of lumps and powder, were obtained from *D. draco* species.

### 2.2 Quality Classification Based on Standard Procedures

According to SNI [4], resin content was determined by extracting 5 g materials in soxhlet apparatus using diethyl ether, and reported as w/w percentage. Ash content was based on gravimetric analysis after ashing and also reported as w/w percentage. Color quality was determined visually after dissolving 1 g of sample in 20 mL ethanol and spread on a white paper. Level of impurities was determined by dissolving 2 g sample in 10 mL toluene and weighed the dry residue retained on the dried filter paper. Moisture content was following AOAC [5] as well as for melting point determination. All determinations were in duplicates.

### 2.3 Acetone Extraction

Fine ground samples (5 g) was placed in beaker glass, macerated overnight in 50 mL acetone, and filtered. The filtrates from triplicate experiments were combined, concentrated, and evaporated to dryness. The dried red acetone extract was weighed to obtain the percent yield (w/w).

### 2.4 Chemical Identification

Gas chromatography-mass spectrophotometry (GCMS; Shimadzu) was used to identify the chemical constituents contained in the acetone extract. The analysis was carried out in the Center of Forensic Laboratory (Puslabfor), Jakarta. Electron impact ionization was equipped in the gas chromatograph GC-17A (Shimadzu) tandemed with mass spectrometer MS QP 5050A; capillary column DB-5 ms (J&W) (silica 30 m × 250 μm × 0.25 μm); column temperature was raised from 50 °C (0 minute) to 290 °C in the rate of 15 °C/minute; helium as the carrier gas at constant pressure 7.6411 psi, and data base of Wiley 7N 2008 version.

### 2.5 Color Intensity Measurement

Fine ground samples (1 g) were dissolved in 20 mL ethanol in beaker glass and diluted 200 times. The dilute solution was analyzed using ultraviolet-visible spectrophotometer at wavelength 473 nm. The measurements were conducted in duplicates.

## 3. RESULTS AND DISCUSSION

### 3.1 Discrepancies between Quality According to SNI 1 and Claims by The Traders

In average, the match between SNI determination and the claims from traders was 51.1% (Table 2). The lowest match (14.3%) was regarding resin content and the highest was dealing with color (85.7%). Resin content determination requires a tedious work. On the other side, even though the color parameter is relatively easy to determine, is still give some discrepancy. This fact emphasizes the need of quantitative and rapid method in revising the SNI 1671:2010.

Table 2. Quality of dragon's blood resin as determined by SNI parameters and claims by traders

Sample	Traders	SNI					
		Resin (%)	Moisture (%)	Impurities (%)	Ash content (%)	Melting point (°C)	Color
Jambi 1	B	B (37.0)	*B (17.0)	*B (55.2)	A (6.1)	-	B (Pale)
Jambi 2	Super	B (99.6)	B (9.3)	Super (12.6)	Super (0.8)	Super/A (71-73)	Super (Dark)
Jambi 3	Super	Super (95.2)	Super (4.7)	Super (9.8)	Super (0.7)	Super/A (82-91)	Super (Dark)
Jambi 4	Super	Super (92.6)	*B (12.7)	A (20.1)	Super (2.7)	Super/A (80-81)	Super (Dark)
Jambi 5	A	A (61.4)	B (9.0)	A (38.1)	A (4.5)	Super/A (81-84)	A (Pink)
Aceh 1	A	*B (8.1)	*B (11.6)	*B (89.6)	B (9.5)	-	Super (Dark)
Aceh 2	B	Super (81.7)	Super (2.3)	*B (76.7)	Super (0.7)	-	B (Pale)
Medan	-	B (50.9)	Super (4.5)	*B (57.8)	B (8.2)	Super/A (75-80)	A (Pink)
Percent match (%)		14.3	71.4	42.9	57.1	71.4	85.7

- = not measured; \* = poor, do not meet the specification; Super/A = can fall into Super or A quality; Numbers in brackets are average from 2 experimental data

### 3.2 Diethyl Ether Extract vs. Acetone Extract

SNI 1671:2010 requires diethyl ether for extracting resin in the dragon's blood. Diethyl ether is flammable and the 7-hour extraction needs a special apparatus. In practice, maceration using acetone was much easier and faster than the extraction using flammable diethyl ether in soxhlet apparatus. Figure 1 shows that acetone extraction consistently gave higher yield than that of diethyl ether. The correlation between qualities of dragon's blood based on SNI is also seen, however, transition between B and A, as well as between A and Super is not distinct. Pure methanol and methanol:water mixtures were also used in other studies (6, 7] with lower yield.

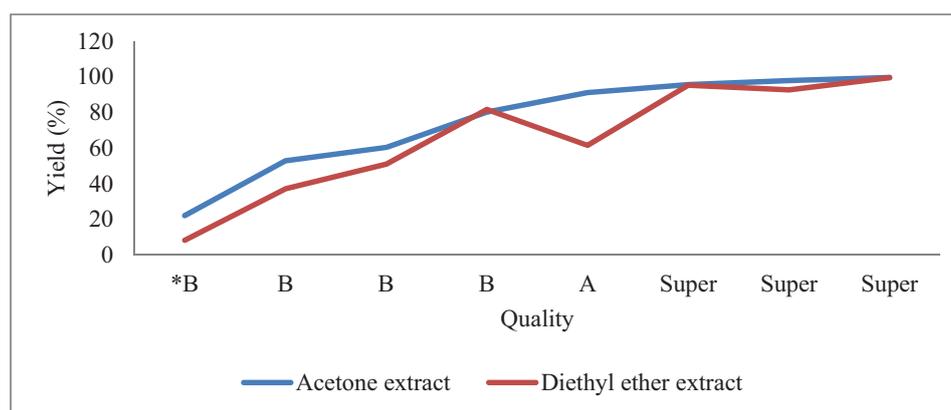

Figure 1. Linearity between acetone extract, diethyl ether extract, and quality of dragon's blood according to SNI 1671:2010

### 3.3 Chemical Markers in Dragon's Blood

Chemical constituents have been identified using GC-MS. There were 59 different compounds detected, however, only 7 that have similarity of higher than 80% as compared to the available database in Wiley 7N/2008 (Table 3). Dracorhodin and 3,4-dihydro-5-methoxy-6-methyl-2-phenyl-2H-1-benzopyran-7-ol are almost consistently detected in all samples, followed by 3,4-dihydro-5-methoxy-6-methyl-2-phenyl-2H-1-benzopyran-7-ol. The structure of these proposed chemical constituents are depicted in Figure 2.

Table 3. Chemical constituents detected by GCMS equipped with Wiley 7N/2008 database of each sample correspond to quality based on SNI 1671:2010

Compound	Aceh	Medan	Jambi	Jambi	Aceh	Jambi	Jambi	Jambi
	1		1	5	2	3	4	2
	*B	B	B	A	Super	Super	Super	Super
Dracorhodin	√	√	√	√	-	√	√	√
3,4-Dihydro-5-methoxy-6-methyl-2-phenyl-2H-1-benzopyran-7-ol	√	√	-	√	-	√	√	√
Trendione	√	√	-	-	-	√	√	-
Linoleic acid	√	√	√	-	√	-	-	-
2,6,10,14-Tetramethyl-pentadecane	-	-	-	-	-	√	√	√
4-(4-Ethylcyclohexyl)-1-pentyl-cyclohexene	√	√	-	-	√	-	-	-
7-Pentadecyne	√	√	-	-	√	-	-	-

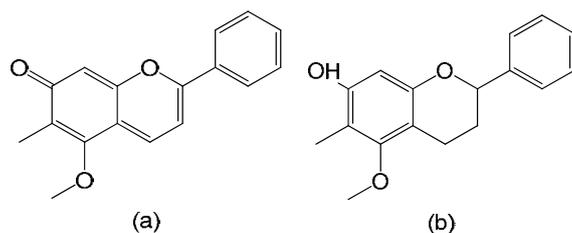

Figure 2. Chemical structures of dracorhodin (a) and 3,4-dihydro-5-methoxy-6-methyl-2-phenyl-2H-1-benzopyran-7-ol (b)

Dracorhodin has been reported in the literatures [8-10]. Some previous work also reported dracorhodin and its derivatives as dyes in art articles since 15<sup>th</sup> century [11]. Dracorhodin is claimed to be a derivative of anthocyanins, a natural dye in dragon's blood resin [12]. 3,4-Dihydro-5-methoxy-6-methyl-2-phenyl-2H-1-benzopyran-7-ol in this study is also detected in all samples that contain dracorhodin and never been appeared in the literature as a chemical marker of dragon's blood resin.

Dracorhodin was detected in all samples except in Aceh 2. There must be other red dyes in Aceh 2 sample and was not yet identified by the existing GCMS-Wiley 7N2008 data base. 7-Pentadecyne, linoleic acid, 4-(4-ethylcyclohexyl)-1-pentylcyclohexene, and (*E*)-9-octadecenoic acid detected in this particular sample were certainly not dyes. 1-Methoxy-2-(2-methoxycarbonyl-ethyl)-3,8-dimethyldipyrin-9-carbaldehyde was the highest constituent in Aceh 2 sample.

One rational approach to measure red dyes in dragon's blood is by combining constituents, i.e. dracorhodin and 3,4-dihydro-5-methoxy-6-methyl-2-phenyl-2H-1-benzopyran-7-ol. Quantitative data were obtained by multiplying areas of the GC chromatograms and the respective resin content (Table 4). There is also inconsistency between SNI qualities and the total content of these two chemical markers. The total content of these two markers is exactly consistent with the quality according to SNI that may be caused by other pigments that could not be identified by the analytical instrument being used. Nevertheless, content of red dyes seems to be more objectively followed in determining the quality of dragon's blood commodity.

Table 4. Dracorhodin and benzopyrene contents (in % w/w of resin) listed according to quality of dragon's blood

Sample	SNI based	Dracorhodin	3,4-Dihydro-5-methoxy-6-methyl-2-phenyl-2H-1-benzopyran-7-ol	Total
Aceh 2	B	-	-	-
Aceh 1	B	1.38	1.16	2.54

Medan	B	1.84	2.24	4.08
Jambi 4	Super	2.42	2.78	5.20
Jambi 3	Super	4.05	4.87	8.92
Jambi 1	B	3.08	5.86	8.94
Jambi 5	A	6.54	2.86	9.40
Jambi 2	Super	3.99	6.50	10.49

### 3.4 Rapid Measurement of The Chemical Markers

As previously mentioned, the acetone extract is correlated with the quality based on SNI. On the other hand, the total content of dracorhodin and 3,4-dihydro-5-methoxy-6-methyl-2-phenyl-2H-1-benzopyran-7-ol is not consistently increasing with the increasing quality of the resin. In our attempt to find a new method to expedite the measurement of quantitative parameters, ultraviolet-visible wavelength was indeed useful. It is interesting to note that the increasing acetone extract was positively correlated with the increasing absorbance at 473 nm, as well as the increasing the resin quality (Figure 3). Dracorhodin and its variants in different pH at 477 nm have been studied [12]. The workers also stated that dracorhodin is stable quinoid base and constitutes the major species at pH 4-7. This finding, based on the study of all equilibrium constants, implies that does not fit the commonly accepted definitions of anthocyanidin nor 3-deoxy-anthocyanidin.

One of the parameters in SNI is color intensity, which is easily measured using UV-visible spectroscopy. Extended double bonds in dracorhodin and 3,4-dihydro-5-methoxy-6-methyl-2-phenyl-2H-1-benzopyran-7-ol facilitated the rapid measurement in determining the quality rather than using GCMS. The acetone extraction must be able to capture all pigments in the material being study. However, absolute quantitative measurement requires pure compounds as has been developed [13]. Based on this experiment, a range of absorbance value can be proposed, namely for super quality, the absorbance shall be  $> 0.50$ , for A quality is  $0.20-0.49$ , and for B quality is  $<0.20$ .

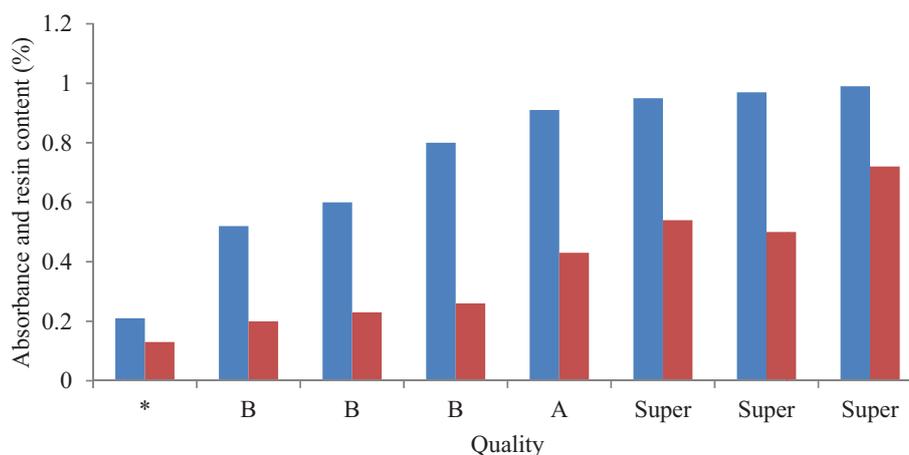

Figure 3 Correlation between resin content (■) and absorbance (■) of dragon's blood according to its quality

## 4. CONCLUSION

Chemical markers that have been confirmed contained in dragon's blood resin are dracorhodin and 3,4-dihydro-5-methoxy-6-methyl-2-phenyl-2H-1-benzopyran-7-ol. These are constituents that are extracted along with other pigments in acetone extract. Further, the absorbance of acetone extract at 473 nm can be proposed as a quantitative parameters stipulated in SNI. Acetone extraction is better than that of soxhlet extraction using diethyl ether and the value of absorbance is a quantitative method in replacing visual method in the SNI. Quantitative measurement using UV-Vis spectrophotometer requires pure forms of these two chemical markers.

## ACKNOWLEDGMENT

Funding came from the Directorate General of Higher Education, the Ministry of Education and Culture through grant *Kerja Sama Antarlembaga dan Perguruan Tinggi (313/SP2H/PL/ Dit.Litabmas/IX/2012)*. Appreciation goes to Mr. TK Waluyo for the samples.

### ABSTRACT

Acidogenic fermentation of palm oil mill effluent (POME) can serve as a precursor in a process for production of polyhydroxyalkanoates (PHA) since the produced volatile fatty acids (VFAs) are preferred precursor for PHA production. Acidogenic fermentation of POME was studied in a 2-L reactor with semi-continuous mode operation (once-a-day feeding and draw-off) for optimal volatile acid compositions. Main fermentation products were acetic acid, propionic acid and butyric acid. The results showed acetic acid, propionic acid, and butyric acid with concentrations are 2.79 g/L; 1.18 g/L, and 3.04 g/L, respectively. VFAs that serves as a precursor on PHA production. The result of feeding of synthetic of VFAs or VFAs from POME at the 20<sup>th</sup> and 40<sup>th</sup> in a batch show the concentrations DCW and PHA are 2.38 g/L and 0.74 (g PHA/g DCW) or 2.76 g/L and 0.74 (g PHA/g DCW), respectively.

### Keywords

*Palm oil mill effluent (POME), Volatile Fatty Acid (VFAs), acidogenic, Polyhydroxyalkanoate (PHA)*

### 1. INTRODUCTION

Indonesia is the world largest producer of palm oil [1]. The palm oil extraction from the fresh fruit bunches (FFB) of palm involves a number of processing procedures: sterilization, stripping, digestion, pressing, classification, purification and vacuum drying for which large quantities of water required [2]. The process of one tonne FFB needs about 1.5 m<sup>3</sup> of water, half of this amount ends up as palm oil mill effluent (POME) [2]. In the year 2011, the government is targeting production of FFB for about 35 tonnes/Ha/Y with an area of 7.8 million hectares of plantation, indicating more than 200 million tonnes of POME was generated from around 490 mills in Indonesia [3].

Wastewater treatment in the palm oil industry done by a multistage process that utilizes the pools open. The core component of this process is the biodegradation of organic waste. Anaerobic decomposition of organic matter decomposition compound includes a compound of organic acids and further broken down into gas and water. Methane is formed during wastewater treated in open ponds. Methane off the air will increase the threat of global warming, because methane in air will react with water to form carbon dioxide and water. Reactions that occur in the air causes the accumulation of methane gas and carbon dioxide as well. Methane and carbon dioxide gases are gases that contribute to the greenhouse effect causing global warming synergism [4].

POME has a high organic content (more than 20,000 ppm BOD) and non-toxic that could be as a carbon source in the fermentation system [5]. POME containing high levels of organic matter that could potentially contaminate the environment so that the necessary degradation of organic matter is greater POME substances are usually in complex forms that cannot be directly consumed or production other product such as polyhydroxyalkanoate (PHA).

There is a great potential to bioconvert POME to volatile fatty acids (VFAs), the followed by the recovery of acids for biosynthesis of PHA. On the other hand, species such as *Ralstonia eutropha* as a representative bacterium for PHA synthesis [6]. In a previous study, reported by Aznury [7, 8] the production of PHA with *Ralstonia eutropha* JMP 134 used VFAs POME as a precursor in batch and fed batch fermentations. The study is that effect of feeding time of VFAs POME affected of

DCW and PHA concentrations. In this paper, we present our result on effect of feeding time of VFAs POME on PHA production by *Ralstonia eutropha* JMP 134. It has been demonstrated that the composition of VFAs produced under acidogenic fermentation can be affected by environmental.

## 2. MATERIAL AND METHODS

### 2.1 Material

The main material used in the experiments was palm oil mill effluent (POME) taken from PT. Mitra Ogan South Sumatra.

#### 2.1.1 Media for *Ralstonia eutropha*

A mineral salts medium consisted of: 2.0 g/L  $(\text{NH}_4)_2\text{SO}_4$ ; 2.0 g/L  $\text{KH}_2\text{PO}_4$ , 0.6 g/L  $\text{Na}_2\text{HPO}_4$ , 0.2 g/L  $\text{MgSO}_4 \cdot 7\text{H}_2\text{O}$ ; 20 mg/L  $\text{CaCl}_2$ , 10 mL/L trace metal solution, 0.1 g/L yeast extract was used. Trace metal solution consisted of: 1.3 mg/L  $\text{ZnSO}_4 \cdot 7\text{H}_2\text{O}$ ; 0.2 mg/L  $\text{FeSO}_4 \cdot 7\text{H}_2\text{O}$ , 0.6 mg/L  $(\text{NH}_4)_6\text{Mo}_7\text{O}_{24} \cdot 4\text{H}_2\text{O}$  and 0.6 mg/L  $\text{H}_3\text{BO}_3$ . Glucose was used as a source of carbon with a concentration of 40 g/L as a medium for inoculums development and production media. Glucose, yeast extract, and salt solution were sterilized separately at 121°C and then mixed with the inoculation aseptically. As for the pH adjusted to about 7 using 2 N HCl or 2 N NaOH [9].

#### 2.1.2 The source of carbon, nitrogen, and VFAs

The medium used in the experiment were all the same, i.e 40 g/L as carbon source, with the initial volume of 5.2 L, and urea nitrogen from with a concentration of 2 g/L, then VFAs added at 20<sup>th</sup> and 40<sup>th</sup> hours with a volume of 1 L, respectively.

## 2.2 Methods

### 2.2.1 Anaerobic fermentation of POME

POME fermented with active anaerobic microbial seed. Active microbial seeds are added to the oil palm industry waste water with a ratio of 1 L: 4 L in a batch bioreactor with a volume of 8 liters. Anaerobic fermentation is taken and replaced with POME with a ratio of 1 L: 1 L per day. Then, POME fermented has distillation to get VFAs.

### 2.2.2 Analyses and VFAs and Glucose

The content of residual VFAs was determined and described in standard methods [12]. Organic acids and glucose were detected by HPLC (Agilent 1100 equipped with and RID detector, USA) with an Aminex HPX-87 column (300 mm x 7.8 mm, Biorad, USA) at a column temperature of 60 °C, and 0.0055 M  $\text{H}_2\text{SO}_4$  as mobile phase. The injection volume was 20  $\mu\text{l}$ . The eluted time for glucose, acetate, propionate and butyrate was at about 10.7, 15.6, 17.9 and 21.8 min, respectively.

### 2.2.3 Analyses of PHAs

Samples were collected at every 20 hour intervals during incubation and pH was measured using an Ecoscan Hand-held series pH meter (Eutech Instruments, Singapore). At 20<sup>th</sup> until 200<sup>th</sup> hours, 50 ml samples were collected to determine cell dry weights.

In determining the concentration of PHA, biopolymer contained in the cells extracted with the addition of sodium hypochlorite and chloroform on the cell as has been described by Jacquelin N. et al [10]. PHA dissolved in chloroform was analyzed by concentration crotonic acid conducted by Slepecky and Law [11].

### 2.2.4 Experimental Set-Up

The set-up consisted of two bench-scale reactors and a distillation equipment (Fig. 1). The acidogenic fermentation of POME was carried out in a batch reactor under anaerobic conditions.

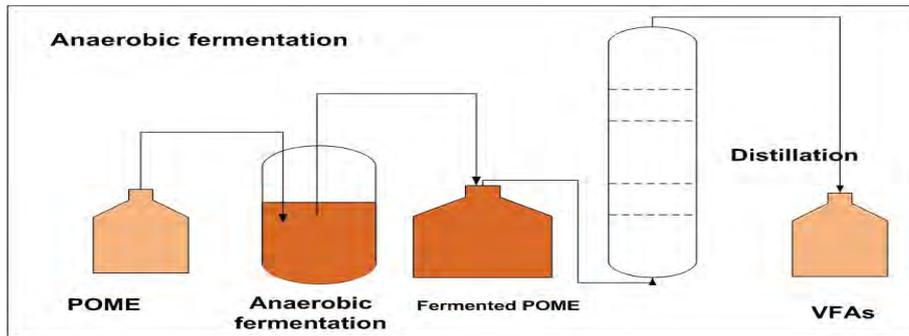

Figure 1: Process POME to VFAs Production

### 3. RESULTS AND DISCUSSION

#### 3.1 Anaerobic fermentation

The batch anaerobic fermentation was conducted to assess determine complexity organic compounds of POME that could be converted into VFAs. The main products produced from fermentation is VFAs. The results of measurements of VFAs shown in Figure 2. VFAs levels before treatment amounted to 8942.39 mg/L, after 1 day of fermentation increased to 10082.1 mg/L. In fermentation 2 and 3 days had concentration VFAs 9862.93 mg/L and 9766.49 mg/L, respectively. The longer the fermentation time will reduce levels of VFAs produced. The concentration of VFAs was 8978.46 mg/L on 4 days fermentation.

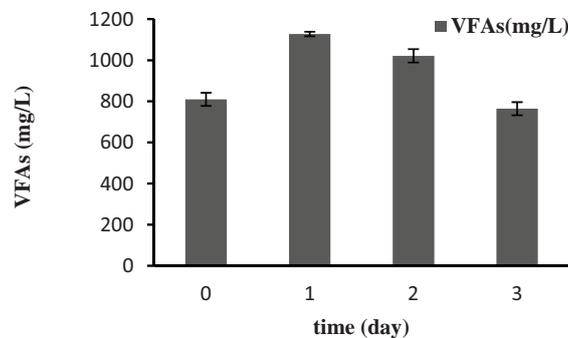

Figure 2: Concentration VFAs from fermented anaerobic POME

Anaerobic fermentation applied as a pretreatment to convert the organic acids into the various components of VFAs which increases the potential for producing PHA from wastewater [12]. Hydrolysis and acidogenesis were early stage to produce organic acids, such as acetic acid, propionic, and butyric which can be used for the synthesis of PHA. Hydrolysis of complex organic components in the POME more soluble compounds. Through the process of acidogenesis, the compound breaks down into VFAs and other monomers. Acidogenesis microbes can produce an acidic solution comprising a mixture of acetic acid and propionic acid or acetic acid and butyric acid [13].

Levels of acid produced in POME correlated with pH value. The results of pH shown in Figure 3, the pH of POME before fermentation was 4.48. The pH value decreased was 4.43 on 1 day fermentation. Fermentation for 2 days at pH values up to 4.67. For fermentation 3 and 4 days was an increase in pH to 4.71 and 4.82, respectively. This resulted in a pH value tends to increase when the fermentation time be longer.

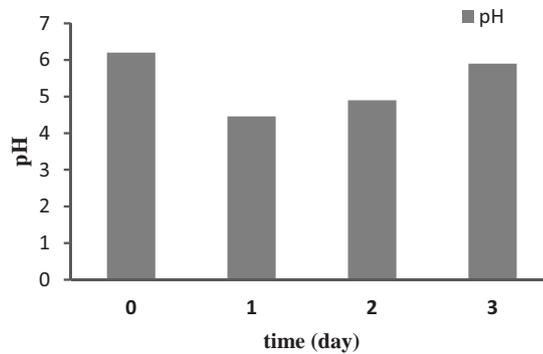

Figure 3: The change of pH with time from anaerobic fermentation

Data anaerobically fermented POME shows the time to produce the fermentation VFAs on the first day because of the acid produced is quite high, which is about 10000 mg/L or 10 g/L. VFAs concentrations used in these experiments is similar to the acid content 10.3 g/L in batch fermentation POME [14].

POME was also analyzed for total nitrogen content. Analysis of total nitrogen content using a Buchi (Buchi 412 scrubber, Buchi 435 digestion unit, Buchi 339 Distillation unit, Germany). Total nitrogen content of POME early, after fermented and fermented wastewater and distilled after each is 136.68 g/L, 183.07 g/L, and 0 g/L, respectively. The ratio of total nitrogen content can be seen in Figure 4.

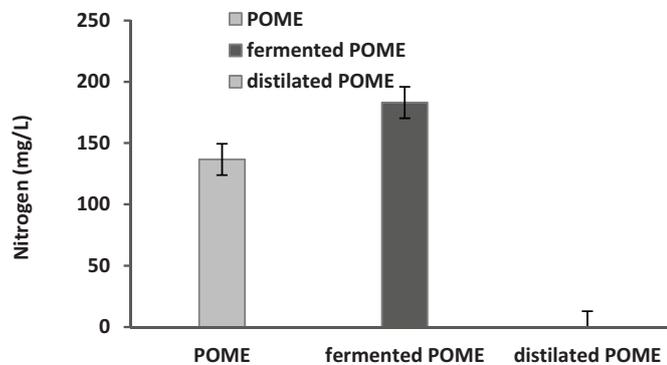

Figure 4: Comparison nitrogen content from POME, fermented POME, and distilled POME

POME has been distilled showed levels of total nitrogen was 0 g/L and containing VFAs. So later in the text will be written is the VFAs from POME. VFAs from POME will be used as a precursor on PHA production.

POME after fermented to start for distilled to obtain pure compounds VFAs. The results of this distillation analyzed using HPLC (Waters, USA) to determine the type and concentration acidic compounds by comparing the standard of acetic acid (JT Baker), propionate acid (Merck), and butyric acid (Sigma-Aldrich). Figure 5 showed concentration of acetic acid, propionate acid and butyric acid from POME, fermented POME, and distilled POME.

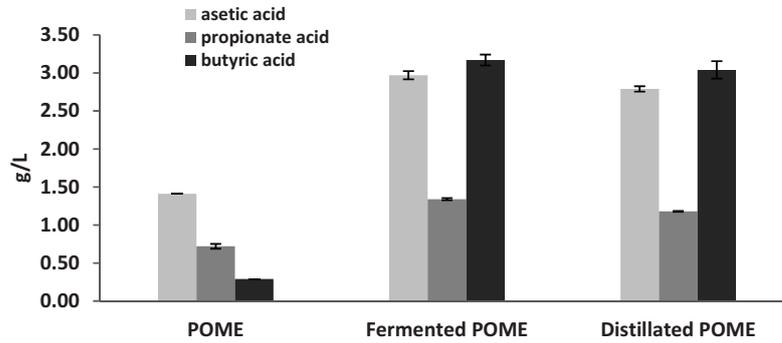

Figure 5: Comparison acetic acid, propionate acid, and butyric acid from POME, fermented POME, destilated POME

POME fermented anaerobic on VFAs production for 1 day and at pH 4.43. POME and fermented POME also contain other fatty acids such as citric acid, formic acid, and malonic acid, while for distillation POME had acetic acid, propionate acid and butyric acid. The results VFAs from POME had acetic acid, propionate acid and butyric acid that the concentration were 1.41 g/L; 0.72 g/L, and 0.29 g/L, respectively. While fermented POME produced acetic acid, propionate acid and butyric acid were 2.97 g/L; 1.34 g/L, and 3.17 g/L, respectively. Destilated POME produced acetic acid, propionate acid and butyric acid, were 2.79 g/L; 1.18 g/L, and 3.04 g/L, respectively. VFAs from destilated POME would used to feed as precursor of Synthetic VFAs on PHA production.

Hassan, et al [15] got the levels of concentration of VFAs from POME depending on the pH of the fermentation. Fermented POME at pH 4 got formic acid, acetic acid, and propionic acid with 1.4 g/L , 4.4 g/L , and 0.5 g/L, respectively. Then fermentation at pH 7 consisted acetic acid and propionic acid with concentration 6.6 g/L and 1.2 g/L, respectively [15].

### 3.2 Application: VFAs as precursor on PHA Production

VFAs from POME were added 1 liter in the batch fermentation at the 20<sup>th</sup> and 40<sup>th</sup> hours. Consumption of glucose, acetic acid, propionate acid, and butyric acid analyzed at the 0<sup>th</sup> to 200<sup>th</sup> hours. Figure 6 shows the cells to consume glucose and VFAs from POME. The concentration of glucose consumed by bacteria as source of growth at the 0<sup>th</sup> to 160<sup>th</sup> hours. Glucose concentration shows a very drastic decrease in the concentration from 20.77 g/L to 3 g/L at the 60<sup>th</sup> to 80<sup>th</sup> hours. The concentration of glucose decreased indicates that the cells require a source of the other substrates on PHA production.

VFAs consumption were an after adaptation phase at the 60<sup>th</sup> and 80<sup>th</sup> hour. The increase of consumption VFAs were need cell on PHA production. VFAs consumption ceased when glucose had also begun to run out can be seen at the 120<sup>th</sup> hour.

Butyric acid consumption was faster consumed than acetic acid and propionate acid by the cell. Effect of addition of VFAs as a precursor suggests that the ability of cells to consume each of the different acids. Effect of high concentrations VFAs will be inhibitory or toxic thus may result in a low growth rate and PHA content [16].

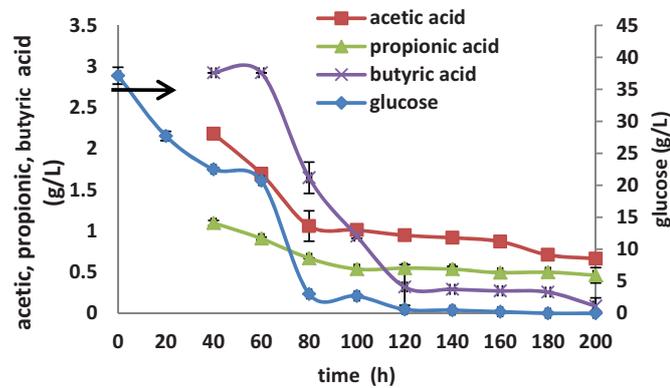

Figure 6. Effect of feeding time of precursor VFAs from POME in batch fermentation at the 20<sup>th</sup> and 40<sup>th</sup> of the consumption of glucose, acetic acid, propionate acid, and butyric acid.

Figure 7 shows concentration of DCW and PHA increased during the first reflected the cell growth at the 20<sup>th</sup> hour. VFAs from POME did not significantly affect the growth of bacteria due to the concentration of DCW at the 20<sup>th</sup> and 40<sup>th</sup> hours were 0.29 g/L and 0.4 g/L, respectively. VFAs had not inhibit cell on growth phase. While the highest number of DCW fermentation occurs in the 200<sup>th</sup> hour was 3.66 g/L. Graph the rate of cell growth has been through a phase when compared to static fermentation at the 160<sup>th</sup>, and 180<sup>th</sup> were 3.57 g/L, and 3.66 g/L, respectively. So the increase ranged only from 0.09 g. A small increase was indicates that the cell has experienced a static phase.

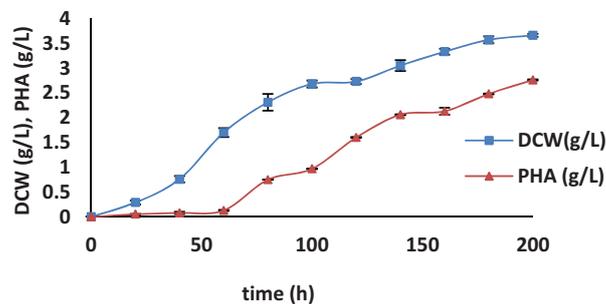

Figure 7. Effect of feeding time of precursor VFAs from POME at the 20<sup>th</sup> and 40<sup>th</sup> hours on production of DCW and PHA

The highest concentration and content of PHAs were 2.76 g/L and 0.75 (g PHA/g DCW) at the 200<sup>th</sup> hour. PHAs were also the rate of increase began to decline from from 160<sup>th</sup> to 200<sup>th</sup> hours and ranged from 0.28 to 0.35. PHAs content in the cell begins to decline or already depolymerization by cells for energy. The cells harvest to produce PHA at the 200<sup>th</sup> hour.

#### 4. CONCLUSION

Acidogenic fermentation of POME in batch resulted in VFAs production. With the condition applied in 1 day and at pH 4.43 the main fermentation products were acetic acid, propionate acid and butyric acid. The composition and concentration of POME acetic acid, propionate acid and butyric acid, were 2.79 g/L; 1.18 g/L, and 3.04 g/L, respectively. For the used VFAs from POME as a precursor in batch and fed batch fermentations. The result of feeding of synthetic of VFAs or VFAs from POME at the 20<sup>th</sup> and 40<sup>th</sup> in a batch show the concentrations DCW and PHA are 2.38 g/L and 0.74 (g PHA/g DCW) or 2.76 g/L and 0.74 (g PHA/g DCW), respectively. The application for this research was that effect of feeding of VFAs from POME affected on DCW and PHA concentrations.

### ABSTRACT

One of the cultivation failure reasons of *Jatropha curcas* Linn (JcL) in Indonesia was only recommended for Crude *Jatropha* Oil (CJO) production which is processed into biodiesel. CJO is only 17-25% of dry seeds weight, while the waste residue is called seed cake. Another waste is dried capsule husk (DH-JcL) about 30-80% of fresh fruit weight and sludge CJO (S-JCO) about 2-5% of the CJO. S-CJO was unutilized which is bad for the ecological when disposal. The research objective was utilization of S-CJO waste for bio-refinery and improvement productivity of biogas made from DH-JcL. The study was conducted at the research garden of PT Bumimas Ekapersada, Bekasi, West Java in November - December 2012. A liter one-stage digester was compiled completely randomized design (CRD) with three replications in water bath on 32°C. The materials are DH-JcL of JatroMas cultivars in toxic category which was mixed with sludge S-CJO as co-substrate about 10% and water in 1:8. Observation variables were biogas production volume (water displacement method), pH and temperature in the outlet slurry. The preliminary study concludes that S-CJO appropriate as co-substrate DH-JcL. It can increase the biogas productivity with feed in less than 10% of S-CJO per day.

Biogas , co-digestion, capsule husk, sludge crude *jatropha* oil, *Jatropha curcas* Linn.

**This paper is published in International Journal of Technology (IJTech)**

This waste pineapple juice is no value for foods, and industrial chemical products. At the present time, the local markets are negligible for waste pineapple juice. Biomass or biological material <sup>[3]</sup> can be used for the production of several products, namely; (1) Fuel and energy such as bioethanol, methanol, fuel oil; (2) Biochemicals such as activated carbon, oxy fuel additive, furfural (3) Fatty and acetic acid, industrial surfactants, and agricultural chemicals, (4) Biomaterials.

## 1.2 The research problem

There is a lot of waste pineapple juice as food waste material has been known, but it is not fully developed and implemented to produce foods and industrial chemicals. A problem of flow rate of waste pineapple juice as substrate and inoculum concentration of *Saccharomyces cerevisiae* in the immobilized cell bioreactor of *Saccharomyces cerevisiae* into ethanol production is not developed and implemented into a large scale. Scaleup of batch bioreactor for an aerobic fermentation of acetic acid is not fully developed and implemented. One of the problems is the bioconversion of a low grade ethanol of about 6 % into acetic acid product. The price of ethanol concentration of about 6% is cheaper than the price of acetic acid product. Acetic acid is a low volume but a high price, on the other hand ethanol is a high volume but a low price

## 3. The objective

The first **objective** is to study immobilization cell bioreactor of *Saccharomyces cerevisiae* inoculum of 2.5%, 5%, 7.5%, and 10% by volume, respectively in the waste pineapple juice as a substrate into ethanol product and the second objective is to study the effect of temperature of 25°C, 30°C, 35°C, 40°C and inoculum concentration of *Acetobacter aceti* of 2.5%, 5%, and 10% by volume, respectively in the ethanol fermentation by *Acetobacter aceti* into acetic acid product. The third objective is to study a verbal model of scale up of a batch bioreactor for acetic acid fermentation in terms of impeller speed N and impeller diameter D.

## 1.4 The benefit

The **benefit** of this research is to increase the additional income for the pineapple farmers in rural areas, and to utilize waste pineapple juice for chemical product of ethanol and acetic acid in order to eliminate waste pineapple juice and finally acetic acid product can be used for food condiments, to increase food flavour, to preserve foods in order to get ecologically sound technologies and good environmental condition. Scale-up of immobilized cell bioreactor of *Saccharomyces cerevisiae* for ethanol production and a batch bioreactor for aerobic fermentation of acetic acid can be used for a large scale operation.

## 1.5 The original finding of this research

The original finding of this research is the approach in the immobilized cell bioreactor of *Saccharomyces cerevisiae* by supported with an insoluble material of pressed solid waste of pineapple fibre and flow rate of substrate in order to cut fermentation time course of ethanol production by *Saccharomyces cerevisiae* inoculum and it can be used for the innovation process and equipment design. The other original findings of this research are the determination of constant for the design of batch bioreactor and it can be used for the process design of innovation process and equipment in the acetic acid fermentation.

## 2. MATERIALS AND METHODS

### 2.1 Preparation of *Saccharomyces cerevisiae*

*Saccharomyces cerevisiae* preparation starts from reaction tubes with pure culture on sterile agar medium in incubator, thus, inoculum was prepared as a step by step employing increasing volume. The initial inoculation from a stock culture of *Saccharomyces cerevisiae*, require the transfer of approximately of 0.5 % to 5%. Scale up of seed culture of *Saccharomyces cerevisiae* from a reaction tube into a erlenmeyer flask of 100 mL scale into a bigger scale was done.

### 2.2 Substrate of waste pineapple juice

Solid waste of pineapple was washed by the wet cleaning method in order to remove all contaminants and it was ground in order to achieve the desired size of solid waste of pineapple. Waste pineapple juice was added by water in the ratio of 1:1 and then this mixture was ground in order to obtain slurry of waste pineapple juice and this slurry was separated by filtration method by a hydraulic press in order to get filtrate and a fine fibre of cellulose solid waste. Filtrate can acts a substrate of ethanol fermentation and a fine fibre of cellulose solid waste may be packed in a column of an immobilized cell bioreactor. Sugar concentration of filtrate is 10.54%. Sugar sources for ethanol fermentation can be obtained from three sources, namely; 57,7 g sugar from 500 g solid waste of pineapple and the addition of 15% sugar is 450 g that is derived from 3,000 mL filtrate and finally, the addition of 10% sugar in the 300 mL of *Saccharomyces cerevisiae* inoculum is 30 g, so that the total amount of sugar is 532.7 g sugar in the 3,000 mL substrate for ethanol fermentation.

This filtrate as a substrate of carbon sources for an immobilized cell bioreactor of *Saccharomyces cerevisiae*. Figure 1 can be shown that binding of an immobilized cell bioreactor of *Saccharomyces cerevisiae* to a fine fibre of cellulose solid waste in the glass column of bioreactor can be used for ethanol production. Immobilized cell bioreactor consists of a glass column with a double glass wall where inside a glass column of bioreactor containing a fine fibre of cellulose solid waste as a supporting material, and outside of a glass bioreactor containing warm water of about 30°C from a water bath thermostat and circulated warm water from a water bath thermostat at temperature of 30°C in order to keep a constant temperature of 27°C inside of a glass column of bioreactor. The total a fine fibre of cellulose solid waste of 500 gram put inside a glass column of bioreactor number 5 in figure 1 and the total volume of substrate of 3,000 mL in the storage tank number 10 in figure 1. A glass column of bioreactor containing of 500 gram a small and a fine fibre of solid waste can act as to bind enzyme of *Saccharomyces cerevisiae* inoculum. Binding of enzyme that is derived from *Saccharomyces cerevisiae* to the small and a fine fibre of solid waste inside a glass column of bioreactor may be by adsorption method.

Fermentation was done as a semi continuous followed by fresh substrate of filtrate and inoculum and finally recycling of outgoing result from a glass column of bioreactor by a circulating pump from a glass column of bioreactor until the desired ethanol product.

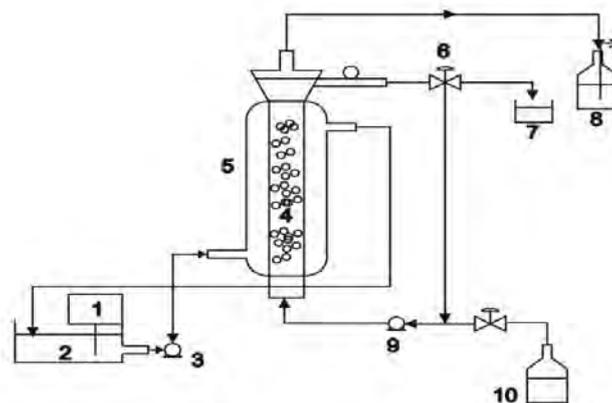

Figure 1: Completely mixed of an immobilized cell bioreactor of *Saccharomyces cerevisiae* with a fine fibre of solid waste in a glass column of bioreactor for ethanol production.

Remarks ;

1. Thermostat to keep a constant temperature,
2. Warm water at temperature of 30°C,
3. Warm water pump to circulate warm water,
4. Supported a fine fibre of solid waste,
5. A glass column of bioreactor,
6. Circulating valve,
7. Sample of ethanol collection,

8. Rinser,
9. Pump for substrate and *Saccharomyces cerevisiae*, and
10. Storage tank of substrate and *Saccharomyces cerevisiae* inoculum.

### 2.3 Preparation of *Acetobacter aceti* inoculum

Slope of a reaction tube containing medium of bacto pepton of 0.30%, dextrose of 2.5%, yeast extract of 0.50%,  $MgSO_4 \cdot 7H_2O$  of 0.02 %,  $KH_2PO_4$  of 0.10% and bacto agar of 1.5 %. Those ingredients were diluted in the sterilized water, heated, entered into a reaction tube of 5 mL volume and finally this reaction tubes were sterilized by using an autoclave at  $121^\circ C @ 20$  minutes.

### 2.4 Medium of liquid for ethanol fermentation into acetic acid

This medium containing medium of bacto pepton of 0.30%, dextrose of 0.50 %, yeast extract of 0.50%,  $MgSO_4 \cdot 7H_2O$  of 0.02%,  $KH_2PO_4$  of 0.10%. Those ingredients were diluted in the sterilized water with a total volume of 300 mL or according to the needs and it was sterilized in the autoclave at  $121^\circ C @ 20$  minutes and after that it was cooled at a room temperature. One ose of needle of *Acetobacter aceti* at the reaction tube into medium of liquid of 300 mL and then this liquid medium incubated at  $30^\circ C @ 24$  hours and after that this medium was homogenized by water bath shaker at  $30^\circ C @ 48$  hours. This inoculum can be used for the next ethanol fermentation by *Acetobacter aceti* into acetic acid.

### 2.5 Substrate of ethanol fermentation by *Acetobacter aceti* into acetic acid product

Ethanol of 6.02% (w/w) can be used as a substrate of aerobic fermentation by *Acetobacter aceti* into acetic acid product. The total volume of ethanol as a substrate of 300 mL.

### 2.6 Chemical analysis

Chemical analysis was done in terms of pH value, sugar, ethanol and acetic acid concentrations.

### 2.7 Microbiological analysis

Microbiological analysis was done in terms of total *Acetobacter aceti* by the total plate count method.

## 3. RESULTS AND DISCUSSION

### 3.1 Result of ethanol production

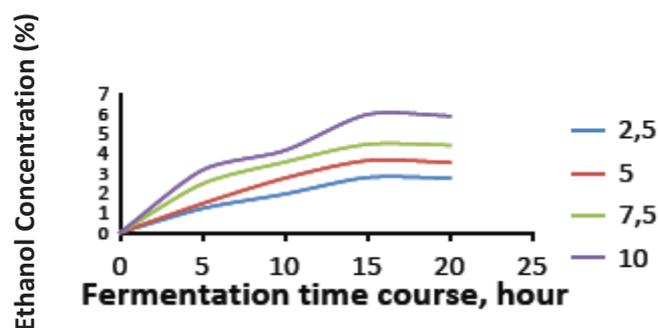

Figure 1: The effect of *Saccharomyces cerevisiae* inoculum in the immobilized cell bioreactor containing filtrate in the ethanol production

From figure 1 can be shown that the higher the *Saccharomyces cerevisiae* inoculum, the higher the ethanol concentration, because of the higher total cell

### 3.2 Result of acetic acid production

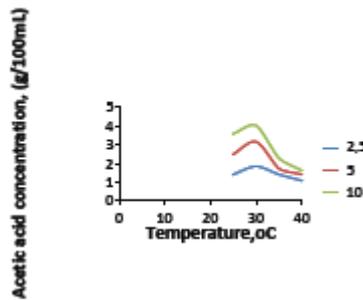

Figure 2: The effect of temperature and *Acetobacter aceti* inoculum concentration in the batch fermentation of ethanol by *Acetobacter aceti* into acetic acid production.

The fermentation medium was sterilized at 60°C@ 15 minutes to kill the residue of *Saccharomyces cerevisiae*. The sterilized fermentation medium was added by glucose of 0.5 -0.7 g/L, ammonium of 20 mg/L, phosphate of 120 mg/L and magnesium of 5 mg/L. Aerobic fermentation of 300 mL ethanol by *Acetobacter aceti* was carried out at the water bath shaker completed with a thermostat and agitation rate of 200 rpm followed by the parameters of temperature of 25°C, 30°C, 35°C, 40°C, respectively and *Acetobacter aceti* inoculum concentration of 2.5%, 5% and 10% by volume and aeration rate of 0.18 vvm in order to produce acetic acid product. The function of water bath thermostat is to keep a constant temperature. Figure 2 can be shown that the higher the temperature of about 25°C to 30°C, the higher the acetic acid concentration. The higher the temperature of 35°C, the decrease in acetic acid concentration and also the higher the temperature of 40°C, the decrease in acetic acid concentration. The temperature of 25°C to 30°C and *Acetobacter aceti* inoculum of 10% were optimal condition for the conversion of ethanol by *Acetobacter aceti* into acetic acid of 4.03 g/100 mL.

In the aerobic fermentation of ethanol by *Acetobacter aceti* mechanisms can be divided into three different kinetic patterns, namely; (1) microbial growth without product formation, (2) microbial growth associated with product formation, and (3) product formation without microbial growth<sup>[7][8][9][10]</sup>. Kinetic of microbial growth of *A. aceti* and product of acetic acid formation can be expressed as follows:

$$dC_x/dt = k_x \Phi C_x \quad (1)$$

$$dC_p/dt = k_{p1} \Phi C_x + k_{p2} (1-\Phi) C_x \quad (2)$$

where  $C_x$  = *Acetobacter aceti* concentration,  $t$  = fermentation time course,  $C_p$  = acetic acid concentration,  $k_x$  = the growth rate of *A. aceti* constant,  $\Phi$  = the coefficient of growth activity,  $k_{p1}$  and  $k_{p2}$  are the production rate constants (per hour).

### 3.3 Scale up of bioreactor

#### 3.3.1 Scale –up

Scale-up of a glass column of bioreactor for ethanol production can be done by scale up ratio that means the ratio of the bigger size or scale 2 divided by the small a glass coulumn of bioreactor or scale 1. In this cell immobilized bioreactor of *Saccharomyces cerevisiae* that product yield of ethanol depend on flow rate of a mixture substrate and inoculum. Therefore, scale up of this a glass column of bioreactor was done in terms of samll flow rate into large flow rate of a mixture of substrate and inoculum.

#### 3.3.2 Scale–up of impeller speed $N$ and impeller diameter $D$ in a batch bioreactor

Scale-up ratio =  $\frac{\text{large scale}}{\text{small scale}}$ . This example is the calculation of small bioreactor with  $N_1$  = impeller speed and  $D_1$  = impeller diameter will be scale-up into large bioreactor with  $N_2$  = impeller speed and  $D_2$  = impeller diameter.

$$N_2^3 D_2^2 = N_1^3 D_1^2 \quad (3)$$

$$N_2 = N_1 \left( \frac{D_2}{D_1} \right)^{\frac{-2}{3}} \quad (4)$$

Table 1: Scale up of the relationship between the impeller speed  $N$  and impeller diameter  $D$  in the bioreactor for ethanol fermentation by *Acetobacter aceti* into acetic acid product at the condition of temperature  $30^{\circ}\text{C}$ , impeller speeds of 100 rpm based on constant power per substrate volume.

$N_1$	$N_2$	$\left(\frac{D_2}{D_1}\right)^{\frac{2}{3}}$
100	34,20	5
00	21,54	10
100	13,57	20
100	10,36	30
100	8,55	40
100	7,37	50

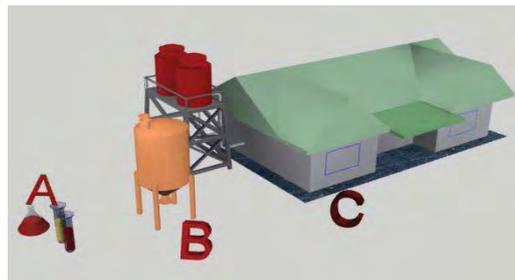

Figure 3. Transfer of scale up from the laboratory scale (A) into pilot plant (B) and finally to industrial scale (C)

#### 4. CONCLUSIONS

1. The approaches for using immobilized cell bioreactor of *Saccharomyces cerevisiae* and substrate with a fine fibre of pine apple solid waste in a glass column of bioreactor for ethanol production are to cut fermentation time course of 2 weeks into 15 hours and simple operation.
2. Scale up of a glass column of bioreactor can acts as an immobilized cell bioreactor for ethanol production depend on flow rate of substrate and inoculum concentraions.
3. The optimum of *Saccharomyces cerevisiae* inoculum is 10% at the fermentation time course of 15 hours in order to produce ethanol concentration of 6.02%.w/w.
4. The optimum condition of etahnol fermentataion by *Acetobacter aceti* were considered optimal, namely; temperature of  $30^{\circ}\text{C}$ , and *Acetobacter aceti* inoculum concentration of 10% , agiatation rate 200 rpm, aeration rate of 0.18 vvm produced the acetic acid concentration of 4.03%.
5. The innovation process and immobilized cell bioreactor of *Saccahromyces cerevisiae* can be used as basis scale up operation.
6. This research results will be one of inputs in the vertical transfer of technology of bioconversion of waste pineapple into ethanol and acetic acid for small and medium scales of ethanol and acetic acid industries.
7. Scale-up of impeller speed  $N$  and impeller diameter  $D$  in a batch bioreactor can be used for other related aerobic fermentation.

#### ACKNOWLEDGEMENT

The authors acknowledge support from the Department of Chemical Engineering, Faculty of Industrial Technology, and Research Institute (LPPM), Parahyangan Catholic University, Bandung, Indonesia made this research result can be presented in The 13<sup>th</sup> International Conference on Quality In Reserach from 25 -28 June 2013, Yogyakarta.

# Cellulase from *Bacillus* sp. BPPT CC RK 2 for Saccharifying Process using Pulp and Paper Industry Sludge

Siswa Setyahadi

*Center for Bioindustrial Technology, Agency for the Assessment and Application of Technology.*

## ABSTRACT

*Cellulose is the most abundant polymer in nature and can be converted into sugar molecules with enzymatic reaction. Paper sludge is lignocellulosic biomass. Lignocellulosic biomass represents the largest renewable resources of potentially fermentable carbohydrates. Cellulase enzyme was used for the process of decomposition of ligno-cellulose into saccharides.*

*In this study, the cellulase enzyme produced by *Bacillus* sp. BPPT CC RK2 on natural substrates (rice bran and coconut water). Among pre treatment tested, saccharification percentage was highest in paper sludge after alkaline pre treatment with NaOH at 24 hours.*

*Pre-treatment of lignocellulose opened the structure and removes secondary bonds between glucose chains. The maximum amount of percentage saccharification was accomplished within 96 hours of incubation. The process of paper sludge saccharification is done by variation of the concentration of the enzyme with activity unit 6,12,18 unit and variation of the concentration of substrate 25,50,100,150 and 200 mg. The best results were obtained from the concentration of the enzyme activity 12 units and substrate as 100 mg. pH and temperature optimum was 5.5 and 37°C. Analysis of the final product saccharification was identified by thin layer chromatography. Maltose was found to end product of saccharification process.*

## Keywords

*Cellulase, Paper Sludge, *Bacillus* sp. BPPT CC RK2, Saccharification.*

## 1. INTRODUCTION

The continuously increasing population of Earth is rising a new challenge for biotechnology: supplementation of mankind with commodity products from renewable resources, instead of fossil based ones. Biotechnology producing commodity products should aim to be responsive to societal needs for sustainable resource utilisation and improved environmental quality. As raw materials are often dominant factors in determining the price of commodity products, renewable materials available at large scale are required as feedstock. In addition, these renewable sources are geographically more evenly distributed than fossil fuels; therefore the products will be domestic and provide security of supply. Plant biomass represents a renewable raw material available at large quantity. These feedstocks are mostly built up of lignocelluloses, and their carbohydrate polymer fraction is a brilliant raw material for biotechnology. Utilisation of lignocelluloses as feedstock would make new challenges for biotechnology, such as overcoming the recalcitrance of cellulosic biomass and product diversification. Most agricultural crops have been optimised for producing starch (rather than biomass) over many centuries and as already touched upon; plants have evolved to successfully resist microbial degradation. Reducing production and especially conversion costs through plant genetic engineering is believed to be able to significantly improve the potential for plant biofuel production [1].

Fifty percent of the total biomass of the world is expected to come from lignocellulose, and will produce lignocellulosic waste as much as 10-50 billion tons per year. Lignocellulosic waste accumulates every year and cause pollution problems. Lignocellulosic waste can be converted into simple sugars by hydrolysis, so as to reduce the amount of pollution [2].

Lignocellulosic wastes from paper manufacturing contains 60-70% cellulose, 10-20% hemicellulose and 5-10% lignin. The efficient utilisation of lignocelluloses requires the fractionation and separate utilisation of these components, fermenting the carbohydrate fractions to ethanol or other valuable products, and use lignin as solid fuel. The processing of lignocellulosic biomass to ethanol proceeds through a series of operations. The first step is the pretreatment to overcome the natural resistance of plant materials to biological breakdown. The primary function of pretreatment is to open up the lignocellulose's complex structure, so that it becomes accessible for the enzymes. There are several pretreatment methods, such as chemical, physical, biological ones, and combination of these. During acid catalysed steam pretreatment hemicelluloses are partially hydrolysed and solubilised, therefore separation of liquid and solid fraction gives an opportunity of a separate utilisation of hemicellulose sugars. Additionally, fermentation inhibitors formed during pretreatment are also removed with this step. The separated liquid fraction can then be utilised in enzyme production, yeast propagation steps, or converted to products, such as ethanol or biogas.

Plant cell walls are highly recalcitrant to degradation, both microbially and mechanically, and one of the main challenges is concerned with enzymatic conversion of cellulosic plant biomass into fermentable sugars[3][4].

To address this challenge of efficiently hydrolysing cell walls into fermentable sugars - also known as saccharification - two key aspects of cellulosic bioethanol production have been improved upon: Pretreatment and enzyme optimisation. Pretreatment is a balancing act that involves unlocking the cell wall structure without forming inhibitors, which affect hydrolysis and/or fermentation [5].

Being an insoluble and highly heterogeneous substrate, cellulosic materials pose several challenges in enzymatic conversion. However, recent years have shown important advances in understanding, improving and producing synergistic cellulases [6][7].

Currently sewage sludge in the paper industry is still a problem that has not been resolved. Therefore, the required solutions by utilizing the potential of the sludge waste, requiring the availability of technology. Waste management through the use of a management action appropriate, given that change the characteristics of the waste into materials that are not harmful and toxic substances can even transform into high-value products.

Pulp and Paper Industry Sludge is the largest solid waste stream produced by the “pulp and paper industry.” It is an attractive feedstock for emergent technologies that are based on the processing of cellulosic biomass. Disposing of Paper Sludge in landfill or by incineration creates environmental problems, and legislative trends in many countries are restricting the amount and types of materials that are permitted to be disposed of by landfill. In Indonesia, paper sludge is generally of 1-3% by weight of the product for an integrated pulp and paper industry, while for industries that use virgin paper pulp, sewage sludge generated ranged from 0.6 to 0.7% by weight of the product and paper industries that use natural raw waste paper around 0.8 to 1.2% by weight of the product.

Pulp and Paper Industry Sludge consists of 24.5% lignocelluloses (90% cellulose and 10% hemicellulose), 10.5% clay, and 65% water. More than 40% of clay is composed of kaolin and silica. Other minerals such as Si, Ti, Al, Fe, Mn, Na, and K are also present. Some Pulp and Paper Industry Sludge materials also contain non glucan carbohydrate (xylan and mannan). Incineration and on-site landfills used for Pulp and Paper Industry Sludge disposal are running out of storage space and are becoming an environmental concern. Another possible way to utilize Pulp and Paper Industry Sludge based on its high content of polysaccharides (mainly cellulose), it can be further processed to produce cellulase, which can be utilized again to hydrolysis Pulp and Paper Industry Sludge enzymatically [8].

Microorganisms have been used for saccharification of lignocellulosic wastes such as *Aspergillus oryzae* [9] reducing sugar produced 7.53 mg/ml with 9.03% saccharification. *Cellulomonas* sp. [10] with *Acacia auriculiformis* Cunn leaves as a substrate produced reducing sugar of 4.5 g / L.

This study aims to utilize paper sludge into sugar derivatives using cellulase enzymes from *Bacillus* sp. BPPTCC RK2 for saccharifying process.

## 2. MATERIAL AND METHODS

### 2.1. Raw Material.

The Pulp and Paper Industry Sludge (PPIS) was collected from a primary clarifier sludge dewatering process of the production of used paper contained 65% water, 10.5% clay, and 24.5% organic material on a weight basis. Dry PPIS contained 60% organic material consisting of cellulose and hemicellulose.

### 2.2. Microorganism

*Bacillus* sp. BPPTCC RK 2 was isolated from termite body and found in Serpong, Banten. The strain is not identified yet but selection this strain using screening *Bacillus* method.

### 2.3. Inoculum Preparation

A loopful of culture from the nutrient agar slant was transferred to 5 mL of LB (Luria Broth) media. The culture was grown at 37°C with 150 rpm for 24 h. 2% of the culture inoculum was transferred to 250mL Erlenmeyer flask containing 50mL of cellulolytic medium described below. The pH of the medium was adjusted to 7.0 using 1N NaOH before autoclaving. All the experiments were performed in duplicate. The culture broth after 36 h of incubation was centrifuged at 10,000 g for 10min at 4°C to separate the cells. The cell-free supernatant was analyzed for enzyme activity and protein concentration.

### 2.4. Cellulase Production Media And Cultivations

The fermentation medium for *Bacillus* sp. BPPTCC RK2 consisted (per liter) of 10 g Bacto-peptone, 5 g of yeast extract, 10 g NaCl and added 0,5% CMC (pH 7.0). The medium was sterilized at 121°C for 15 min. The inoculated medium was incubated at 37°C for 48 h. The production medium was agitated at 150 rpm for better aeration and growth of the organism. Crude

enzyme preparation was obtained from the supernatant after centrifugation of the broth culture at 5000g for 20 mins and was examined for the total protein content and cellulase activity.

### 2.5. Pretreatment Of Substrates:

The raw substrates were sun dried individually to reduce the moisture content and then crushed into bits. Then the substrates were soaked individually in 1% sodium hydroxide solution (NaOH) in the ratio 1: 10 (substrate: solution) for two hours at room temperature and autoclaved at 121°C for one hour. The treated substrates were then filtered and washed with distilled water until the wash water become neutral [11][12] then dried overnight at 60°C. The dried substrates were packed in polypropylene bags until use.

### 2.6. Cellulase Assay

Cellulase activity was determined by estimating the reducing sugar produced during enzymatic reaction by dinitro salicylic acid (DNS). One milliliter of the enzyme solution was mixed with 0.5% of CMC and incubated at 37°C for 15 min to perform the enzyme substrate reaction. The contents were cooled and 1 ml of DNS was added and heated at 90°C for 5–15 min till slight reddish brown was developed. The contents were cooled and 1 ml of potassium sodium tartrate was added. The absorbency of the contents was measured at 540 nm against reaction mixture prepared using distilled water as blank [13]. One unit of cellulase activity has been taken as the amount of the enzyme required to liberate one micromole of the reducing groups per min as glucose equivalent.

### 2.7. Protein Content

The amount of protein was estimated by Bradford method [14] using Bovine Serum Albumin (BSA) as a standard according to the instruction manual of Quick Start Bradford Protein Assay.

## 3. RESULT

Saccharification process is being derived cellulase processing sugar. The products fermentation on saccharification process indicated by the percent (%) saccharification and sugars produced. One that affects the process of saccharification is the concentration of enzyme and substrate.

To determine the value of percent saccharification, it must first be known reducing sugar content samples. Measurement of glucose level reduction is done by DNS method [13]. 3,5 - dinitrosalisilat acid (DNS) is an aromatic compound that reacts with a reducing sugar samples that have free aldehyde or ketone group to form complex color 3-amino-5 dinitro salicylic acid which can be detected by UV-vis spectrometer at a wavelength of 540 nm [15].

Variations in substrate pretreatment were compared between the treated substrate (pretreatment) and the substrate without treatment (untreatment). Pretreatment process done to change the structure and size of lignocellulosic materials by breaking down and removing lignin content and hemicellulosa, damaging the crystalline structure of cellulose and increase the porosity of the material [16]. Destruction of the cellulose crystal structure will facilitate the disintegration of cellulose to glucose. Furthermore, hemicellulose will help break down into simple sugars such as glucose, galactose, mannose, hexoses, pentoses, xylose and arabinose [17]. The process is done by alkaline pretreatment using NaOH.

Tabel 1: Various incubation time and pretreatment substrate on % saccharification

Incubation time	24 h	48 h	72 h	96 h	120 h
Sample	% Saccharification				
Untreatment	0	0,8154	0,6762	0,2138	0
Pretreatment 6 hours	0,358	0,4325	0,5817	1,1783	1,1783
Pretreatment 12 hours	0,6265	0,7458	0,8353	1,1932	0,9546
Pretreatment 24 hours	1,1485	1,2678	1,417	1,76	1,3722
Pretreatment 36 hours	1,0292	1,1783	1,2976	1,6258	1,3126

From tabel 1 shows that the highest percent saccharification obtained on substrates with substrate pretreatment than without pretreatment process. NaOH can break ester bonds and glycosidic and break down lignin. With the opening of this bond will allow the enzyme to break down cellulose and hemicellulos [18]. It can be shown that by doing pretreatment, saccharification produced greater than untreatment. Percent of Saccharification largest found in samples taken pretreatment for 24 hours is as much as 1.79% with incubation time of 96 hours.

From the table above shows the length of incubation time lead decline in value of percent saccharification, this is because the enzymes used not purely so that the possibility of sugar produced can be turned into other products, for example ethanol [19].

On the variation of the substrate concentration results obtained highest percent saccharification of 1.01%. From the results can be seen that the percent saccharification increased from the lowest substrate concentration of 25 mg and reached the highest value at a concentration of 100 mg. Once the optimum point, the value of percent saccharification decreased. This is because if the substrate concentration was varied, the initial reaction increases until it reaches a maximum and finally decreased. With the increasing concentration of the substrate can be seen in the chart saccharification decreased, it is because of the limited amount of enzyme [20].

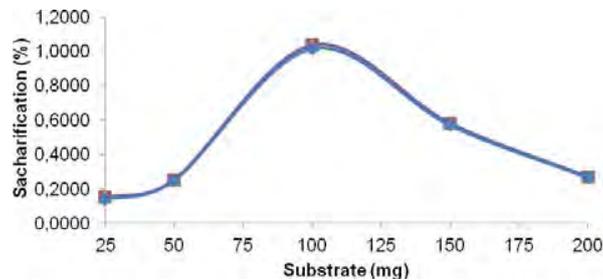

Figure 1: Effect substrate on % saccharification

On the effect of variations in the concentration of the enzyme, showed the highest percent saccharification of 1.80% on Unit enzim12 activity.

Enzymes are catalysts that can speed up the rate of a reaction without participating in the reaction. Enzyme reaction rate influences a variety of factors such as substrate concentration, enzyme concentration, pH, temperature, and inhibitors. Substrate concentration affect the rate of reaction, as more substrate there is the more the bonding that occurs between the enzyme and the substrate.

The product of the reaction between the substrate and enzyme are depended on the condition of the concentration of enzyme and substrate. At the enzyme concentration increases while the fixed substrate concentration, enzyme concentration or number of molecules is lower than the amount that will be catalyzed substrate molecule, the product will be proportional to the amount of substrate converted by enzymes into products.

Saccharification process of pulp and paper industry sludge processing using commercial enzymes and blank (substrate waste paper processing without the addition of cellulase enzymes *Bacillus sp* CC RK2 BPPT) was done.

Tabel 2: Comparison between enzyme commercial and cellulase *Bacillus sp* BPPT CC RK2 on % saccharification

Sampel	Reduction sugar content (mg/ml)	Saccharification (%)
Enzim selulase <i>Bacillus sp</i> BPPT CC RK2	0,4022	1,80
Commercial Enzyme	0,0033	0,0033
Blank (without enzyme)	0	0

Commercial enzyme has optimum conditions at pH 4.5 to 5.5, and a temperature of 55 to 60°C. The process of saccharification followed the optimum conditions of the enzyme, ie pH 5.5 and 60 °C. The substrate used was the result of waste as much as 100 mg pretreatment with NaOH for 24 hours, and the concentration of enzyme used as much as 15.04 units / mg. In the process of saccharification blank, 100 mg of substrate pretreatment with NaOH results for 24 hours plus citrate buffer pH 5.5 and then incubated at 37 °C.

From the results shown that the process of saccharification of PPIS by using the enzyme cellulase *Bacillus sp* CC RK2 BPPT has highest sugar reduction and percent saccharification. This shows that the value of percent saccharification using cellulase enzyme produced from *Bacillus sp*. BPPT CC RK2 is much higher than the commercial enzyme and blank.

After knowing the value of percent saccharification, further identification of the type of sugar used thin layer chromatography comparison with standard sugars using glucose, Xylosa, arabinose, Galactose, Maltose, and Sucrose a concentration of 5 mg / ml. Since this type of sugar saccharification process was not originally known, then spotted various sugar standard comparators to identify the type of sugar produced from saccharification process.

TLC can be used for compound identification standard. Parameters used in the TLC for identification is Rf. If the two compounds identical will have the same Rf value as measured on the same TLC conditions.

Rf values of the ratio between the sample and the reference standard were spotted sugar seen that the value of Rf sample is 0.32 cm, the approximate value of Rf maltose is 0.33 cm, so that based on the analysis of thin-layer chromatography, the final product is expected to contain Maltose.

Note : S= Succrose; A= Arabinose; Ga= Galactose; X= Xylose; M= Maltose; G=Glukose; Su= Sampel; B= Blank (without enzyme)

## ACKNOWLEDGMENT

### ABSTRACT

Polymer poly (1-vinyl-1,2,4-triazole) have been synthesized via free radical polymerization using the monomer 1-vinyl-1,2,4-triazole and the initiator azobisisobutyronitrile (AIBN) in toluene as solvent. Proton conducting membranes were prepared by adding nitrilotri (methyl triphosphonic acid) as a dopant into a solution of poly (1-vinyl-1,2,4-triazole) at various molar ratios. The mixture was cast in polished poly (tetrafluoroethylene), PTFE plates and the solvent was evaporated carefully at temperatures of 50 °C for 12 hours. Interaction between the polymer and the dopants have been studied through; FTIR spectrum, thermogravimetric analysis (TG), glass transition temperature using DSC and proton conductivity of membranes made using dielectric-impedance analyzer Novocontrol. Proton conductive membranes with molar ratio of 0.25 was obtained proton conductivity of  $8.52 \times 10^{-4}$  S/cm at 150 °C.

# Adsorption of Lead (II) and Copper (II) Ions on Rice Husk Activated Carbon Under Sonication

Muhammad Zakir

Laboratory of Physical Chemistry, Hasanuddin University  
Kampus Tamalanrea 90245, Makassar  
E-mail: muhammadzakir@gmail.com

## ABSTRACT

The effect of sonication on the adsorption of  $Pb^{2+}$  and  $Cu^{2+}$  ions on rice husk activated carbon has been conducted. This study was aimed to removal of  $Pb^{2+}$  and  $Cu^{2+}$  ions from aqueous solution by activated carbon under the influence of sonication. Surface characteristics of activated carbon showed that rice husk based activated carbon prepared at  $400^{\circ}C$  and treated with  $ZnCl_2$  10% has better properties compared to the others prepared with difference conditions. The value of Langmuir model constant,  $b$ , for  $Cu^{2+}$  ion adsorption is -0.0362 (absence of sonication) and 0.1105 (presence of sonication), and for  $Pb^{2+}$  ion adsorption is -5.1508 (absence of sonication) and 1.0745 (presence of sonication). Those values suggest that ultrasonic irradiation positively affects the affinity of  $Pb^{2+}$  and  $Cu^{2+}$  ions towards the adsorbent. Maximum adsorption capacities increase in the presence of sonication. This can be seen on the value of  $a_m$ , Langmuir constant which represents the maximum adsorption capacity of adsorbent. The values of  $a_m$  for  $Cu^{2+}$  and  $Pb^{2+}$  adsorption changed from 1.0464 mg/g (absence) to 6.2775 mg/g (presence) and from 9.7561 mg/g (absence) to 16.5017 mg/g (presence), respectively. Those values suggest an increase in the adsorption capacity of activated carbon under sonication.

## Keywords

Activated carbon, rice husk, adsorption affinity, maximum adsorption capacity, ultrasound

## 1. INTRODUCTION

Environmental pollution due to the disposal of heavy metals and organic pollutants has been causing serious concern for the last few years [1-2]. Heavy metals are non-degradable to harmless end products, unlike organic pollutants, the majority of which are probably biodegradable. Heavy metals are toxic to aquatic ecosystems even in relatively low concentrations. Heavy metals, which are toxic to human beings and ecological environments, include chromium (Cr), copper (Cu), lead (Pb), and mercury (Hg), etc. These metals might be assimilated, stored and concentrated by human body, causing erythrocyte destruction, nausea, salivation, diarrhea, muscular cramps, renal degradation, chronic pulmonary problems and skeletal deformity [3-7].

Lead, which has been used by man for years, can be regarded as an important environmental contaminant. All compounds containing lead are considered as cumulative poisons that affect the gastrointestinal track, nervous system and sometimes both. The sources of lead in water are the effluents of processing industries, storage batteries, insecticides, plastic water pipes, food, beverages, ointments and medicinal concoctions for flavoring and sweetening. Environmental pollution due to copper is originated from mining, printed circuits, metallurgical, fiber production, pipe corrosion and metal plating industries. The other sources of copper pollution are industries of paper and pulp, petroleum refining and wood preserving. Agricultural activities such as fertilizers, fungicidal sprays and animal wastes can cause also copper pollution in water resources [3-7].

Removal of toxic or heavy metals from aqueous solutions can be carried out through several methods, such as chemical precipitation, membrane filtration, ion exchange, biosorption and adsorption [4]. Among those removal techniques of toxic or heavy metals, adsorption is the preferred method and gives the best results as it can be used to remove various types of toxic materials [1-7]. Commercial Activated Carbon (CAC) is the most widely employed adsorbent for the removal of toxic metals due to its effectiveness and high adsorption capacity; however, its use is still limited because of high operating costs. The need for regeneration and difficulty of separation from the wastewater after use are also major concerns associated with CAC. Many researchers have focused on finding non-conventional alternative adsorbents to reduce the cost of pollution treatment. Low-cost adsorbents are generally referred to non-hazardous waste produced from industry, agriculture, and biosorbents. Several lists and reviews of these types of adsorbent for pollutant removal have been made [1-2, 4]. In addition, the use of agricultural waste as adsorbent has attracted some researchers because: (1) it is available abundantly; (2) most of the types of agriculture waste are readily to be utilized and do not need a complex pretreatment step or activation process before applications; (3)

regeneration of these adsorbents may not be necessary (unlike CAC, where regeneration is essential); and (4) less maintenance and supervision are required for the operation of the adsorption process [8-15]. However, use of these cheap alternatives for pollutant treatment is still limited because both insufficient documentation in real wastewater systems and the necessity of post-usage disposal. The employment of rice husk waste for the treatment of wastewater is a win-win strategy because it does not only convert the waste into a helpful material but it also prevents on-site burning of the waste, saves on disposal costs, and reduce CO<sub>2</sub> emission [1-4, 8-9]. Disadvantage of biosorbents, that is often found, is the relatively low adsorbing capacity. However, in some cases, the adsorption capacity can be improved by activation, surface modification, and sonication. The use of activated carbons from plant materials is also often suffered from the low adsorption rate because of their microporous structures and long diffusion path through solid particles of adsorbents [16-18].

The effect of sonication has been studied to exhibit several effects in solid-liquid systems such as the increase of mass transfer rate, the enhancement of the surface area by many micro-cracks formation on the surface of solid and the clean-up of solid particle surfaces [19-28]. The effect of ultrasound on the adsorption/desorption processes has been previously studied and some controversial effects have been found [16, 20-23]. Nevertheless, there is less information in the literature about the removal of heavy metal ions from aqueous solution by adsorption under the influence of ultrasonic irradiation [20-23].

The objectives of the current study was aimed to removal of Cu(II) and Pb(II) ions from an aqueous solution by adsorption onto the activated carbon obtained from rice husk under the influence of sonication. The models of Cu(II) and Pb(II) adsorption will be evaluated to observe the effects of ultrasound on the adsorption of both metals onto the rice husk based activated carbon, and finally to choose optimal adsorption condition.

## 2. MATERIALS AND METHODS

*Materials:* Rice husk (*Oryza satyfum* L.) was supplied from the south part of South Sulawesi (Bontomaero, Kecamatan Bajeng, Kabupaten Gowa). Fresh rice husk were washed several times with distilled water for the removal of surface impurities, dried at 100°C overnight (6h), crushed by a hammer mill and simultaneously carbonized in a muffle furnace at 300 and 400 C for 2h. Carbonized rice husk was then immersed into ZnCl<sub>2</sub> (10%w/v) for 24h. Afterwards, the granular activated carbon was washed three times with distilled water, dried at 110 C for 24h and stored in desiccators. Copper(II) acetate and lead(II)acetate, analytical reagent grade, were purchased from Merck Co. Distilled water was used to prepare aqueous solutions of copper(II) acetate and lead(II)acetate.

*Material characterization:* Surface characteristics of adsorbents were determined by Scanning Electron Microscope (SEM) (JEOL, JSM6510). Crystallinity analysis was carried out through X-Ray Diffraction method (XRD) (Shimadzu, XRD6000). Specific surface area, total pores volume, and pores size distribution were determined by N<sub>2</sub> adsorption method in a Gas Sorption Analyzer (Quantachrome, Autosorb iQ-MP).

*Experimental set-up of sonication:* The set-up consisted of an ultrasonic cleaner (Elmasonic S40H; total nominal power: 250 W; and internal dimensions: 300 x 220 x 155 mm), operating at 40 kHz frequency. The cleaner was filled with distilled water up to 1/3 of its volume (about 3.5 l). The temperature was controlled and maintained by water circulating from a thermostated bath by means of a pump. An Erlenmeyer flask (250 ml) used as adsorption vessel was fixed on a swinger (90 oscillations per minute). The copper(II) acetate and lead(II)acetate solutions (100 ml) and the adsorbent (1.0 g) were put into the flask fixed on the swinger.

*Adsorption experiments:* In these experiments, the initial copper(II) acetate and lead(II)acetate concentrations were in the range between 2 and 50 mg/l. In a preliminary equilibrium test under silent conditions applying the smallest (2 mg/l) and the highest (50 mol/l) copper(II) acetate and lead(II) acetate concentrations, it was established that the equilibrium was reached after 2 h. For sure, all equilibrium experiments lasted 3 h. After establishing equilibrium, a sample was taken from the flask and was centrifuged (1500 rpm for 5 min) for the removal of adsorbent particles. The Cu(II) and Pb(II) concentrations in the supernatant were measured by *Atomic Absorption Spectrophotometer* (AAS) Bulk Scientific Model 205VGP. The amount of Cu(II) and Pb(II) ions adsorbed was calculated from the mass balance equation (Equation 1).

$$q = \frac{(C_0 - C)V}{m_a} \quad (1)$$

Where q is the amount of ions adsorbed at time t; C<sub>0</sub> and C are the initial ions concentration and the ions concentration at time t, respectively; V is the volume of solution (=100 ml); and m<sub>a</sub> is the amount of adsorbent (=1.0 g). For each sample, the ion concentrations were measured in triplicate and the mean value was used as the equilibrium one.

### 3. RESULTS AND DISCUSSION

*Characterization of rice husk based activated carbon (RHAC):* The activated carbon prepared from rice husk by carbonization at elevated temperature (300C and 400C) and salt impregnation ( $ZnCl_2$ ; 10% w/v) for 24 h was characterized by standard methods (Table 1 and Figure 1). The highest specific surface area of RHAC was obtained at carbonization at 400C i.e. 284,963  $m^2/g$ , and the total pore volume was 4,670E-01 cc/g. The active groups were formed due to the dissolution of many chemical bonds initially present in the rice husk through prolonged carbonization at elevated temperature. Immersion of RHAC into  $ZnCl_2$  10% solution for 24h has increased the specific surface area and total pore volume. Based on the SEM results, the surface structure of RHAC (carbonization at 400C and activation with  $ZnCl_2$ ; 10% w/v) has a layered structure and pieces of pores compared to the other RHAC (Fig. 2). Activation can increase the number of pores as can be seen from Fig. 2(a) and 2(b), respectively. The number of pores is available more in Fig. 2(a) than 2(b). This explanation can also be connected to information from the specific surface area and total pore volume, where RHAC produced and activated at 400 C has the highest value of both parameters. Activation can also increase the values of specific surface area from 38,248  $m^2/g$  to 115,282  $m^2/g$ , and from 55,074  $m^2/g$  to 284,963  $m^2/g$  at 300 C and 400 C of activation, respectively.

Table 1: Specific surface area, pores radius and total pores volume of activated carbon. 300 A and 400 A were activated by  $ZnCl_2$  (10% w/v) at 300C and 400C, respectively. 300 TA and 400 TA means without activation at the same temperature.

No	Sample name	Specific surface area ( $m^2/g$ )	Pore radius ( $\text{\AA}$ )	Total pore volume (cc/g)
1	300 TA	38,248	1,735E+01	3,318E-02
2	300 A	<b>115,282</b>	1,821E+01	1,050E-01
3	400 TA	55,074	8,040E+01	2,214E-01
4	400 A	<b>284,963</b>	3,278E+01	<b>4,670E-01</b>

Table 2: Parameters of adsorption isotherms and linear correlation coefficient of both presence and absence of ultrasonic irradiation experiments.

Isotherm	Parameter	Absence ( $Cu^{2+}$ )	Presence ( $Cu^{2+}$ )	Absence ( $Pb^{2+}$ )	Presence ( $Pb^{2+}$ )
Langmuir	$a_m (q_{max})$	1,0464	6,2775	9,7561	16,5017
	b (adsorption affinity)	-0,0362	0,1105	-5,1508	1,0745
	R	<b>0,7612</b>	<b>0,9906</b>	<b>0,9988</b>	<b>0,9927</b>
Freundlich	$k_F$ (adsorption capacity)	10,4372	2,0086	7,1717	9,4595
	n (adsorption intensity)	-2,6385	4,3497	13,1926	8,4459
	R	0,5614	0,9054	0,7864	0,7972

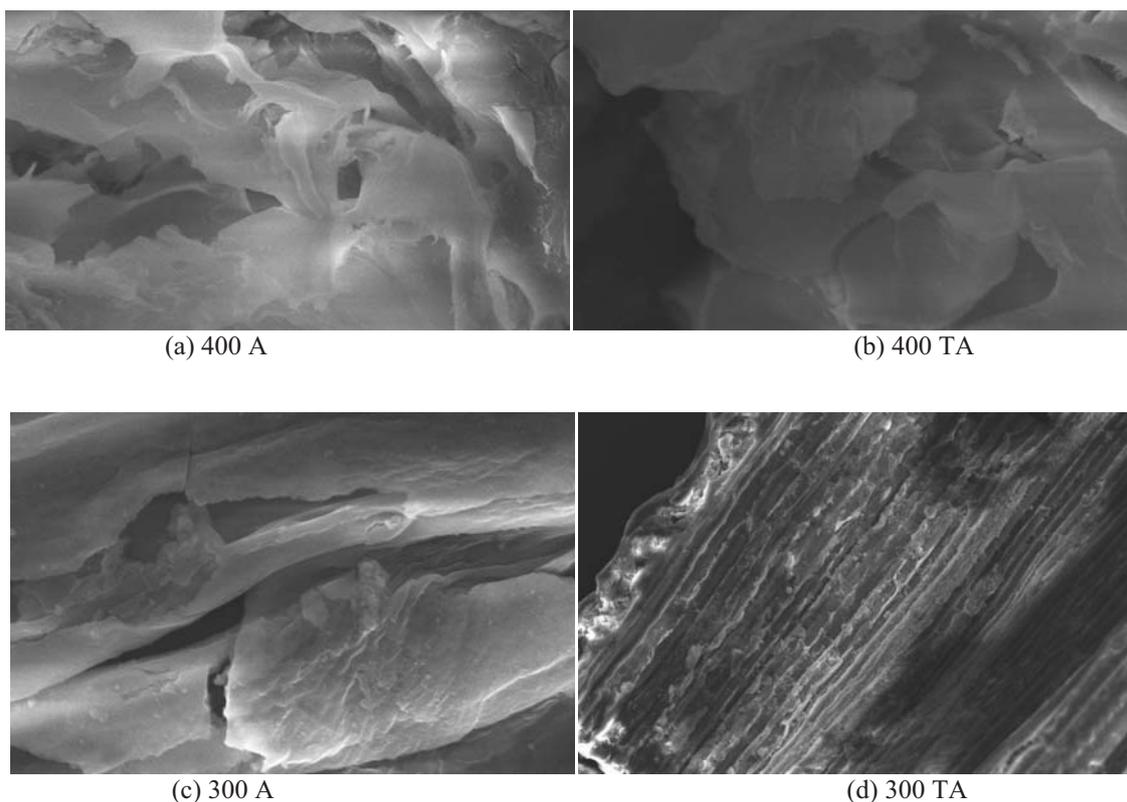

Figure 1: Surface characteristics of adsorbent determined by Scanning Electron Microscope (SEM). 300 A and 400 A were activated by  $ZnCl_2$  (10% w/v) at 300C and 400C, respectively. 300 TA and 400 TA means without activation at the same temperatue.

In addition, as seen from Fig. 2, both adsorption isotherms for both metals are non-linear and seem to approach to the maximum values, except Pb(II) adsorption under sonication. Indication from the shape of the curves can be understood that several well-known models reported in the literature could be employed to explain the adsorption isotherms. Both Langmuir and Freundlich models are the most frequently used isotherms for adsorption studies [3-7, 10-16]. The Langmuir model can be applied to homogeneous sorption, where the sorption of each molecule is carried out onto monolayer surface and has equal sorption activation energy. The Freundlich model is an empiric isotherm model in nature. In this study, both adsorption isotherms were used to model the relationships between the amount of Cu(II) and Pb(II) ions adsorbed onto RHAC and its equilibrium concentration in solution in the absence and the presence of ultrasonic irradiation. Table 2 shows parameters of both adsorption isotherm models that were obtained in the presence and absence of ultrasonic irradiation. Nevertheless, when the Langmuir isotherm model was utilized in our experimental data, this model better fits both in the presence of ultrasound and its absence than with the Freundlich isotherm model. This can be seen in Table 2 when the corresponding linear correlation coefficients (R) are compared. The higher R-value for the Langmuir isotherm model than for the Freundlich isotherm model might be caused by homogeneous distribution of active sites of RHAC surface as it was explained in the case of Cu(II) ions removal by activated carbon from hazelnut shells under sonication [16].

The Langmuir constants  $a_m$  and  $b$  as well as the Freundlich constants  $k_F$  and  $n$  are also shown in Table 2. The Langmuir adsorption constant  $b$  defines the ratio of adsorption and desorption rate constants and is related to the free energy of adsorption. Its value represents the affinity of Cu(II) and Pb(II) ions to the adsorbent. When both values are compared, the values of  $b$  for the silent and the ultrasound-assisted adsorption, it can be concluded that ultrasound positively affected the affinity of Cu(II) and Pb(II) ions to the granular activated carbon as it was previously found for the adsorption of Cu(II) ions by activated carbon of hazelnut shell under sonication [16].

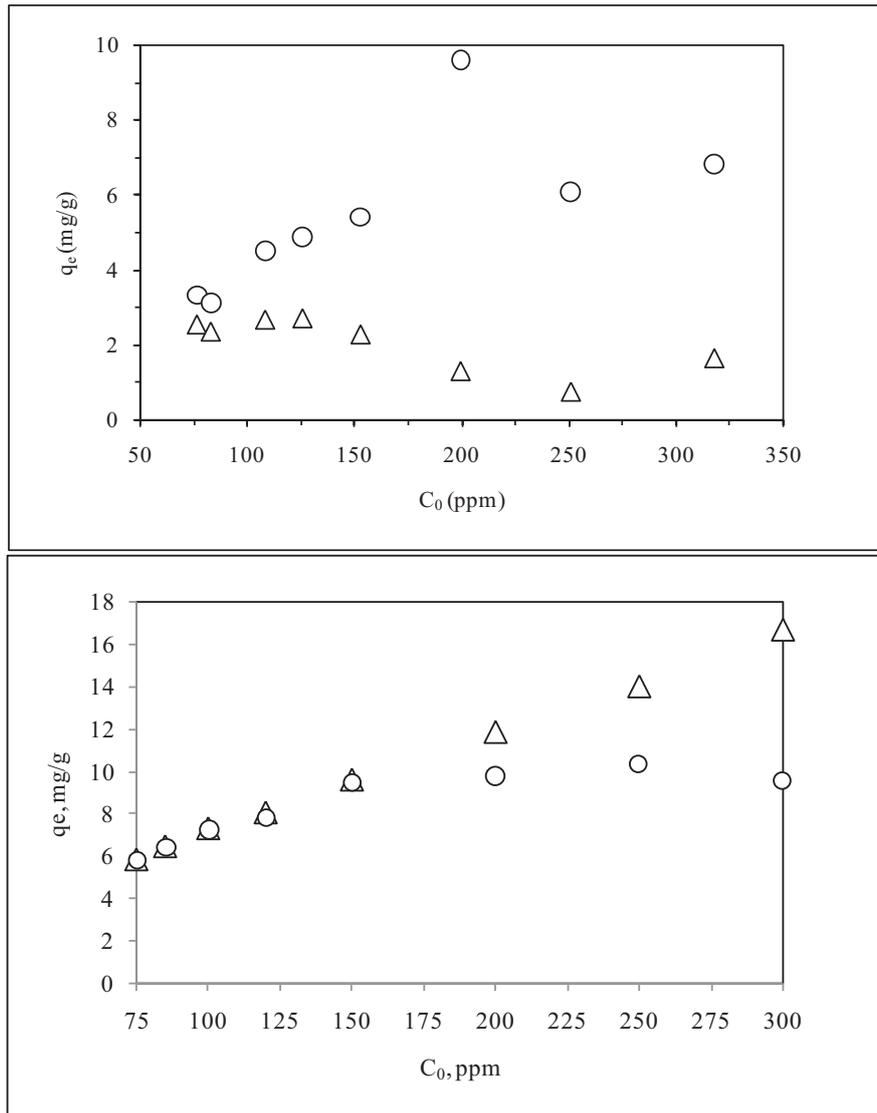

Figure 2. Adsorption isotherms of (upper)  $Cu^{2+}$  ions and (lower)  $Pb^{2+}$  ions on rice husk based activated carbon (O = presence of sonication, Δ = absence of sonication).

The difference conclusion was withdrawn from values of the Freundlich constant  $k_F$ , related to the adsorption capacity. The increase of  $k_F$  was only observed in adsorption of  $Pb(II)$  ions under sonication, while in the case of  $Cu(II)$  ions adsorption, sonication was decreasing the adsorption capacity of RHAC. The corresponding linear correlation coefficients (R) of  $Cu(II)$  adsorption in the absence of sonication, however, is lower than the presence of sonication. The adsorption capacity of  $Cu(II)$  ions by activated carbon of hazelnut shell was also greater in the presence of ultrasound than in the silent conditions [16]. This can be attributed to the cavitation effects which can increase the capability of the porous particle structure for  $Cu(II)$  and  $Pb(II)$  ions adsorption and/or the appearance of new sites of sorption by disruption of sorbent particles [16-28].

Maximum adsorption capacities for removal of  $Cu(II)$  and  $Pb(II)$  ions from aqueous solution by the granular activated carbon achieved in silent and ultrasound-assisted adsorption are 1.0464, 6.2775, 9.7561 and 16.5017 mg/g (calculated from the Langmuir isotherm model), respectively. Those values are much higher than that reported for the activated carbon obtained by steam activation of hazelnut shells under sonication [16]. This might be attributed to the specific surface area of the granular activated carbon of rice husk used in the present experiment.

## 5. CONCLUSION

Surface characteristics of RHAC prepared at 400C then impregnated with ZnCl<sub>2</sub> 10% are better than the other activated carbon prepared with the other conditions. When the values of *b* for the silent and the ultrasound-assisted adsorption are compared, it can be concluded that ultrasound positively affected the affinity of Cu(II) and Pb(II) ions to the surface of RHAC. The values for Cu<sup>2+</sup> adsorption are 1.0464 mg/g and 6.2775 mg/g for the absence and presence of sonication, respectively, which suggests an increase (83%) in the adsorption capacity of activated carbon due to the ultrasonic irradiation. The values for Pb<sup>2+</sup> adsorption are 9.7561 mg/g and 16.5017 mg/g for the absence and presence of sonication, respectively, which also suggests an increase (41%) in the adsorption capacity of activated carbon due to the ultrasonic irradiation. Langmuir adsorption isotherm model is better fits than the Freundlich model based on the values of corresponding linear correlation coefficients (R), both in the presence and absence of ultrasonic irradiation.

## ABSTRACT

Activated carbon is the most commonly used adsorbent for wastewater treatment and water purifications. The main characteristics of activated carbon are its high surface area and high adsorption capacity with certain adsorbates. In this work, activated carbons were synthesized using banana peel wastes. The samples were activated chemically using zinc chloride as the activating agent. These samples were then activated at 600 °C in nitrogen flow respectively. The activated carbons were characterized by Scanning Electron Microscopy (SEM) and nitrogen adsorption at 77 K. Results indicated that activation processes improved the uptake of methylene blue (MB) with respect to adsorption results obtained for raw precursors. Overall, activated carbons obtained from banana peel wastes showed good performance for the removal of MB dyes. The activated carbon prepared from banana peel wastes exhibits good surface characteristics and porosity properties. This indicates that banana peel can be one of a promising precursor for the production of commercial activated carbon.

## Keywords

Activated carbons, dyes, banana peel, chemical activation

## 1. INTRODUCTION

Recently, adsorption has shown to be one of well-established and cheap pollutant removal process among other purification techniques. From various type of adsorbents, activated carbons (ACs) are one of the most popular for both liquid and gas purification [1] since they own unique properties such as porous structure, high specific surface areas and large adsorption capacities. The surface properties of ACs are determined by both the precursor material and the method used for their synthesis [2–4]. On the other hand the adsorption capacity is highly dependent on its specific surface area, pore size distribution and surface functional groups, with the latter affecting their behaviour during interaction with polar, non-polar, anionic and cationic adsorbates [5].

A main drawback in the application of ACs, in commercial scale, is the production cost. In the last years, a lot of research has been concentrated on the utilisation of new carbon precursors, cheap and abundant with great valorisation potential, such as agricultural residues and waste biomass [6,7]. A variety of starting materials have been already used for the preparation of AC, such as jackfruit peel, orange peel, coconut shell, nut-shells, bituminous coal, coffee ground etc [8-12].

One method to prepare such kind of carbon material is the chemical activation route that might improve the pore structure with tunable structural characteristics. This method involves the impregnation of the carbon precursor by a chemical agent, usually  $H_2SO_4$ ,  $H_3PO_4$  or  $ZnCl_2$ , and then followed by the heat-treatment at moderate temperatures (673–873 K). From the available activating agents, Zinc chloride is preferably used for the activation of lignocellulosic materials as it causes the decomposition of the cellulose structure and, on carbonization, causes dehydration process that results in charring and aromatization of the carbon structure and formation of the pore structure [13].

The focus of the research is to investigate the adsorption potential of banana peel-based activated carbon for methylene dye based on the fact that the banana peel is a very abundant waste in Indonesia and never exploited for commercial use. Methylene blue (MB) was selected in this study because it has a very strong adsorptive capability on the solids and is often serves as a model compound for removing organic contaminants and colored bodies from aqueous solutions. The kinetic data and equilibrium data of adsorption studies were then examined to understand the adsorption mechanism of the dye molecules onto the activated carbon.

## 2. EXPERIMENTALS

### 2.1 Preparations of activated carbons

Raw material (banana peel) used for preparation of activated carbon was collected locally, washed, dried, crushed to desired mesh size of +100/-200. The raw material was then carbonized at 450°C under nitrogen atmosphere for 1 h (first pyrolysis). A certain amount of produced char then was soaked with zinc chloride (ZnCl<sub>2</sub>) at various impregnation ratio of 1:1, 2:1, 4:1, 1:2 and 1:4 (ZnCl<sub>2</sub> pellets: char). The mixture was dehydrated in an oven overnight at 105 °C; then pyrolysed in a furnace under nitrogen flow (second pyrolysis) to a final temperature of 450°C and activated for 1 h. Once the final temperature was reached, the gas flow was switched to carbon dioxide and activation was continued for 2 h. The activated product was then cooled to room temperature under nitrogen flow and washed with deionized water to remove remaining chemical. Textural characterization of the activated carbon (AC) was carried out by N<sub>2</sub> adsorption at 77K. The BET (N<sub>2</sub>, 77K) is the most usual standard procedure used when characterizing an activated carbon. The morphology of carbon samples was observed using scanning electron microscope and its elemental compositions was estimated by Energy Dispersive x Ray (EDX) Spectroscopy.

### 2.2 Analysis of methylene blue

Methylene blue (MB) was used as an adsorbate and was not purified prior to use. Double distilled water was employed for preparing all the solutions and reagents. The concentration of methylene blue in the supernatant solution after and before adsorption was determined using a double beam UV spectrophotometer (Shimadzu, Japan). It was found that the calibration curve was very reproducible and linear over the concentration range used in this work.

### 2.3 Batch equilibrium studies

Adsorption isotherms were performed in a set of Erlenmeyer flasks (250 ml) where solutions of dye (200 ml) with different initial concentrations were placed in these flasks. Equal mass of 0.5 g of particle size activated carbon was added to dye solutions and kept in an isothermal shaker (30 °C) for 48 h to reach equilibrium of the solid-solution mixture. The pH was adjusted to 7 by adding either few drops of diluted hydrochloric acid or sodium hydroxide. The flasks were then removed from the shaker and the final concentration of dye in the solution was analyzed. The samples were filtered prior to analysis in order to minimize interference of the carbon fines with the analysis. Each experiment was duplicated under identical conditions. The amount of adsorption at equilibrium,  $q_e$  (mg g<sup>-1</sup>), was calculated by:

$$q = \frac{(C_0 - C_e)V}{W} \quad (1)$$

where  $C_0$  and  $C_e$  (mg l<sup>-1</sup>) are the liquid-phase concentrations of dye at initial and equilibrium, respectively.  $V$  is the volume of the solution (l), and  $W$  is the mass of dry adsorbent used (g).

### 2.4 Batch kinetic studies

The procedures of kinetic experiments were basically identical to those of equilibrium tests. The aqueous samples were taken at preset time intervals, and the concentrations of dye were similarly measured. The amount of adsorption at time  $t$ ,  $q_t$  (mg g<sup>-1</sup>), was calculated by:

$$q = \frac{(C_0 - C_t)V}{W} \quad (2)$$

where  $C_0$  and  $C_t$  (mg l<sup>-1</sup>) are the liquid-phase concentrations of dye at initial and any time  $t$ , respectively.  $V$  is the volume of the solution (l), and  $W$  is the mass of dry adsorbent used (g).

## 3. RESULTS AND DISCUSSION

### 3.1. Structural and morphological characteristics of the activated carbons

Figure 1 shows the SEM images indicating the differences in the external surfaces of the carbon samples produced by various impregnation ratio. It can be observed from the SEM that all samples contain porous structure and, in general, exhibits an uneven distribution of particle sizes. The activation procedure caused a significant structural change.

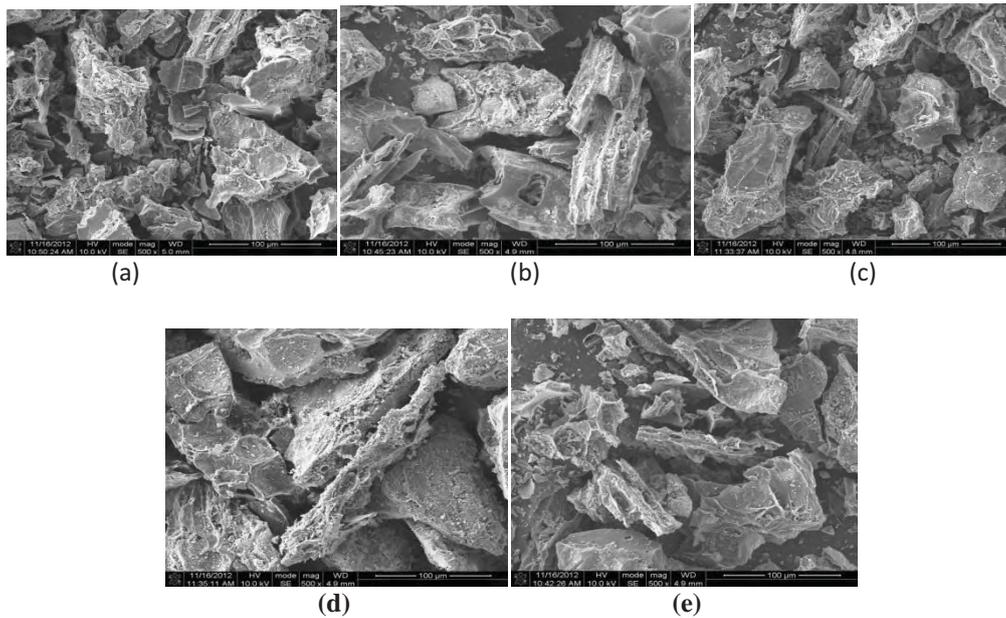

Figure 1: SEM images of activated carbons produced by various impregnation ratio (banana powder :  $ZnCl_2$  : (a) 1:1 (b) 1:2 (c) 1:4 (d) 2:1 (e) 4:1

The  $N_2$  adsorption–desorption isotherms as shown in Fig.21 are usually used to determine the surface area of the banana peel based activated carbons. The isotherm of carbon samples exhibits type I characteristics exhibited by a well-defined plateau, according to IUPAC classification, which confirms its microporosity. An obvious hysteresis loop for the samples is detected between the relative pressures ( $P/P_0$ ) of 0.45 to 1.

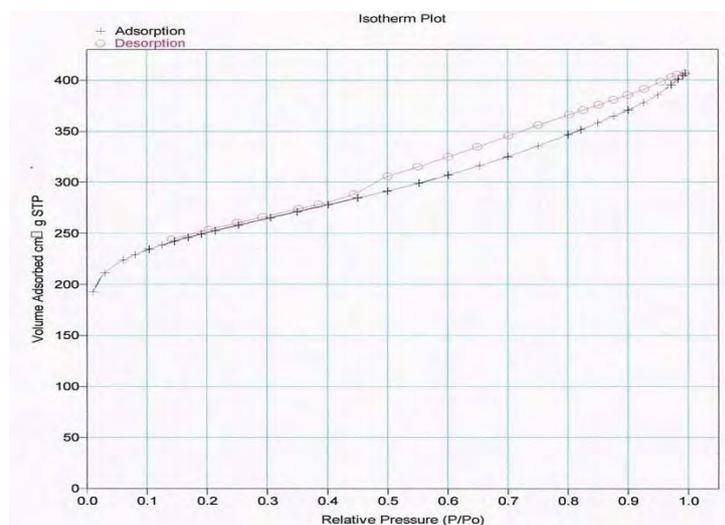

Figure 2: Adsorption/Desorption Isotherm of  $N_2$  gas on the banana peel based activated carbons

Table 1 summarizes the textural properties of the carbon samples obtained by various impregnation ratio. It can be seen that the highest surface is shown by the sample activated at ratio of 4:1. It seems that higher ratio of impregnation leads to the higher surface area generated during activation process using  $ZnCl_2$ .

Table 1: Textural characteristics of banana peel based activated carbons

Samples	Impregnation ratio (banana powder: ZnCl <sub>2</sub> )	BET Surface Area (m <sup>2</sup> /g)
1	1:1	553.66
2	1:2	555.75
3	1:4	601.54
4	2:1	612.78
5	4:1	632.65

### 3.2 Adsorption isotherm of batch adsorption of MB onto the banana peel based activated carbons

The adsorption isotherm shows the distribution of adsorption molecules between the liquid phase and the solid phase when the adsorption process reaches an equilibrium state. The analysis of the isotherm data by fitting them to different isotherm models is an important step to find the suitable model that can be used for design purpose [17]. Fig. 3 typically shows the adsorption isotherms of MB dye on the activated carbon. Adsorption isotherm is basically important to describe how solutes interact with adsorbents, and is critical in optimizing the use of adsorbents.

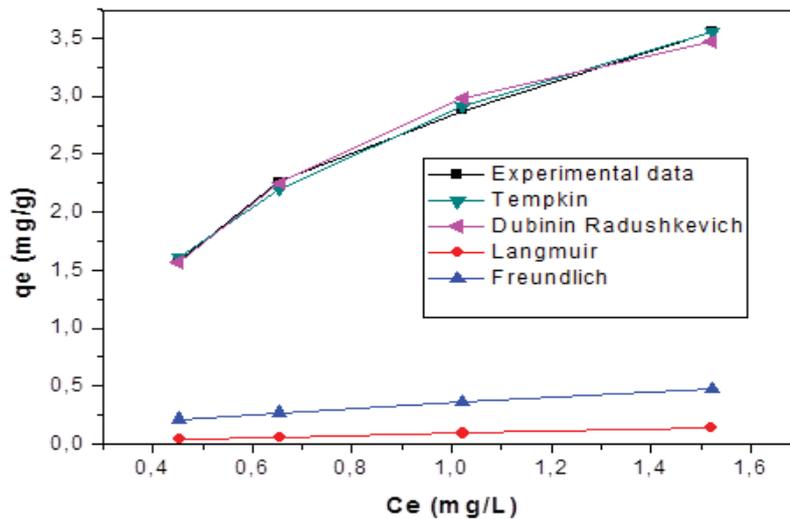

Figure 3: Equilibrium adsorption isotherm of methylene blue onto activated carbon

Adsorption isotherm study is carried out on the four type of isotherms, Langmuir, Freundlich, Tempkin and Dubinin Radushkevich model. The applicability of the isotherm equation is compared by judging the correlation coefficients.

#### 3.2.1 Langmuir adsorption

Langmuir isotherm assumes monolayer adsorption onto a surface containing a finite number of adsorption sites of uniform strategies of adsorption with no transmigration of adsorbate in the plane of surface [14]. The linear form of Langmuir's isotherm model is given by the following equation:

$$\frac{C_e}{q_e} = \frac{1}{q_0 b} + \frac{1}{q_0} C_e \quad (3)$$

where  $C_e$  is the equilibrium concentration of the adsorbate (MB) (mg/l),  $q_e$  the amount of adsorbate adsorbed per unit mass of adsorbate (mg g<sup>-1</sup>), and  $q_0$  and  $b$  are Langmuir constants related to adsorption capacity and rate of adsorption, respectively. When  $C_e/q_e$  was plotted against  $C_e$ , straight line with slope  $1/q_0$  was obtained. The Langmuir constants ' $b$ ' and ' $q_0$ ' were calculated from this isotherm and their values are given in Table 2.

Table 2: Langmuir, Freundlich, Tempkin dan Dubinin R isotherm constants for MB

Langmuir		Tempkin	
q <sub>o</sub> (mg/g)	7.168	β	1.606
b (L/mg)	0.657	α	6.014
R <sup>2</sup>	0.974	R <sup>2</sup>	0.997
Freundlich		Dubinin-Radushkevich	
n	1.527	K (mol <sup>2</sup> .J <sup>2</sup> )	1.129 x 10 <sup>-7</sup>
K <sub>f</sub>	0.358	Q <sub>m</sub> (mg/g)	4.166
R <sup>2</sup>	0.977	R <sup>2</sup>	0.994
		E (J/mol)	2104.26

The essential characteristics of the Langmuir isotherm can be expressed in terms of a dimensionless equilibrium parameter ( $R_L$ ) [14], which is defined by:

$$R_L = \frac{1}{1 + bC_0} \quad (4)$$

where  $b$  is the Langmuir constant and  $C_0$  the highest dye concentration ( $\text{mg l}^{-1}$ ). The value of  $R_L$  indicates the type of the isotherm to be either unfavorable ( $R_L > 1$ ), linear ( $R_L = 1$ ), favorable ( $0 < R_L < 1$ ) or irreversible ( $R_L = 0$ ). Value of  $R_L$  was found to be less than 1 and confirmed that the activated carbon is favorable for adsorption of MB dye under conditions used in this study.

### 3.2.2 Freundlich adsorption

While, Freundlich isotherm model assumes heterogeneous surface energies, in which the energy term in Langmuir equation varies as a function of the surface coverage [14]. As implied, its derivation is characterized by a uniform distribution of binding energies (up to some maximum binding energy). The well-known logarithmic form of Freundlich model is given by the following equation:

$$\ln(q_e) = \ln(K_F) + \frac{1}{n} \ln(C_e) \quad (5)$$

where  $q_e$  is the amount adsorbed at equilibrium ( $\text{mg g}^{-1}$ ),  $C_e$  the equilibrium concentration of the adsorbate (MB) and  $K_F$  and  $n$  are Freundlich constants,  $n$  giving an indication of how favorable the adsorption process and  $K_F$  ( $\text{mg g}^{-1} (\text{l mg}^{-1})^n$ ) is the adsorption capacity of the adsorbent.  $K_F$  can be defined as the adsorption or distribution coefficient and represents the quantity of dye adsorbed onto activated carbon adsorbent for a unit equilibrium concentration. The slope  $1/n$  ranging between 0 and 1, is a measure of adsorption intensity or surface heterogeneity, becoming more heterogeneous as its value gets closer to zero [14]. A value for  $1/n$  below one indicates a normal Langmuir isotherm while  $1/n$  above one is indicative of cooperative adsorption [14]. The Freundlich constant is given on Table 2.

### 3.2.3 Tempkin adsorption

Tempkin isotherm contains a factor that explicitly taking into the account of adsorbent-adsorbate interactions. By ignoring the extremely low and large value of concentrations, the model assumes that heat of adsorption (function of temperature) of all molecules in the layer would decrease linearly rather than logarithmic with coverage [14]. The Tempkin isotherm has been used in the following linearized form:

$$q_e = \beta \ln(\alpha) + \beta \ln(C_e) \quad (6)$$

The adsorption data can be analyzed according to Eq. (13). A plot of  $q_e$  versus  $\ln C_e$  enables the determination of the constants A and B.

### 3.2.4 Dubinin Radushkevich (D-R) adsorption

The D-R model, which does not assume a homogeneous surface or a constant adsorption potential as the Langmuir model, was also used to test the experimental data. It was applied to distinguish between physical and chemical adsorption of MB. The following form of D-R model is used :

$$\ln(q_e) = \ln(q_m) - K \varepsilon^2 \quad (7)$$

Where K = coefficient related to the mean free energy of adsorption ( $\text{mol}^2/\text{J}^2$ ) and  $\varepsilon$  = Polanyi potential [ $\text{J}/\text{mol}$ ] , which is equal to  $RT \ln(1+1/C_e)$  where R = gas constant ( $8.314 \text{ J}\cdot\text{mol}^{-1}\cdot\text{K}^{-1}$ ); and T = temperature (K)]. The values of constants  $q_m$  and  $\beta$  thus obtained from linear regression, along with the error functions, are given in Table 2.. Therefore, in all the cases, the D-R equation represented the most fit to experimental data than the other isotherm equations. The constant  $\beta$  gives an idea of the mean sorption energy, E, which is defined as the free energy transfer of 1 mol of solute from infinity of the surface of the sorbent and can be calculated using the relationship :

$$E = \frac{1}{\sqrt{2K}} \quad (8)$$

The magnitude of E was less than  $8 \text{ kJ}\cdot\text{mol}^{-1}$  indicating that the adsorption mechanism was physical adsorption.

### 3.3. Adsorption Kinetics

Two kinetic models such as pseudo-first-order and pseudo-second-order kinetic were applied for the experimental results. The pseudo-first-order kinetic model proposed by Lagergren and Svenska [15] was usually used to predict sorption kinetic and was defined as:

$$\ln(q_e - q_t) = \ln(q_e) - k_1 t \quad (9)$$

where  $q_e$  and  $q_t$ (mg/g) are the amounts of adsorbate adsorbed at equilibrium and at any time,  $t$  (h), respectively and  $k_1$  (1/h) is the adsorption rate constant.

The pseudo-second-order equation [12] is expressed by :

$$\frac{t}{q_t} = \frac{1}{k_2 q_e^2} + \frac{t}{q_e} \quad (10)$$

where  $k_2$  (g/mg h) is the rate constant of second-order adsorption.

The values of all constants  $R^2$  obtained from the plots for adsorption of MB dye on the adsorbent at  $25^\circ\text{C}$  are reported in Table 3. It was observed that the  $R^2$  values obtained for the pseudo-second-order model was higher than that of first order model. This shows that the adsorption of MB dye on the adsorbent follows a pseudo second-order kinetic model.

Table 3: Adsorption kinetic models and their parameters

Models	Parameters	Values
1st Order	$k_1$	0.012
	$q_e$	2.339
	$R^2$	0.892
2nd Order	$k_1$	0.009
	$q_e$	3.826
	$R^2$	0,989

## 4. CONCLUSIONS

The present investigation showed that banana peel can be effectively used as a raw material for the preparation of activated carbon for the removal of methylene blue dye from aqueous solution. Methylene blue is found to adsorb strongly on the surface of activated carbon. Adsorption behaviour is described by a Dubinin Radushkevich type isotherm. Kinetic data follows pseudo second-order kinetic model.

### ABSTRACT

In recent years, there have been many methods developed to synthesize Zinc Oxide (ZnO) nanoparticles. Nevertheless, a simple yet cheap method to prepare single crystal with high purity nano ZnO was still yet to be established. In this research, nano Zinc oxide (ZnO) was prepared by sol-gel method. The pH variation effect to the resulting ZnO product was also observed.  $(\text{CH}_3\text{COOH})_2\text{Zn}\cdot 2\text{H}_2\text{O}$  powder and NaOH solution were used as precursors. NaOH solution was added to  $(\text{CH}_3\text{COOH})_2\text{Zn}\cdot 2\text{H}_2\text{O}$  solution by titration until colloids with different pH were obtained, then precipitates of nano ZnO were formed. From the precipitation profile, it can be observed that increasing pH led to shortened precipitation time, which also means increasing particle size. It was also further confirmed that particle size at pH 7 and pH 12 was 1.3 nm and 73.8 nm, respectively. XRD profile showed that increasing pH led to increasing purity of nano ZnO: 42.9%, 62.2%, 64.7%, and 100% at pH 7, pH 8, pH 10, and pH 12, respectively. To conclude, nano ZnO synthesized by Sol-Gel method was highly affected by pH of the working solution. Increasing pH led to increasing particle size, however led to higher purity of nano ZnO produced.

### Keywords

*Nano ZnO; sol-gel; pH variation*

### 1. INTRODUCTION

Zinc Oxide (ZnO) ceramics have gained much attention due to their distinct properties and characteristics. ZnO ceramics in various forms are used extensively in electronic applications, such as LED, sensor, or solar cells [1]. In recent years, it has also been found that ZnO can be used in other potential applications like photocatalysis and anti-bacterial substance, thus making them exciting commodities for industries [2].

At the same time, nanotechnology becomes much more popular nowadays. Scientists believe that by engineering material size into nanoscale, there will be an enhancement on properties of the material. In many literatures, it can also be learned that nano ZnO offers better performance compared to that of in bulk size [3].

There have been many methods to synthesize nano ZnO. Some of the widely used methods are, for instance, Chemical vapor deposition (CVD), dip coating, or mechanical alloying [4,5,6]. Those methods have their own advantages and disadvantages. For example, CVD and dip coating, they can produce nano ZnO with high purity, however high growth temperature is needed in their system. Also, the preparation scheme is quite complex and can be very expensive [7]. Mechanical alloying is another interesting method where it can synthesize nano ZnO in relatively simple manner [8]. Nevertheless, to date, there has been no reports on mechanical alloying method that can yield pure nano ZnO. Another possible method is sol-gel method. The good

thing about this method is that, it is relatively simple and cheap in process, and it does not need to be treated in high growth temperature [9]. However, to date, there is still a little knowledge on the effect of pH variation on sol-gel working solution, also whether high purity of nano ZnO can be achieved by this method.

In this research, nano ZnO was synthesized by sol-gel method, in an attempt to find the optimum condition to produce single crystal ZnO with relatively small size. The pH condition would be varied for this optimization process.

## 2. EXPERIMENTAL PROCEDURE

4.39 gram  $(\text{CH}_3\text{COOH})_2\text{Zn}\cdot 2\text{H}_2\text{O}$  (Merck) powder was dissolved in 100 mL methanol. It was then sonicated at 750 Watt for 30 minutes to obtain homogenous solution of 0.2 M. Separately, 1.0 M NaOH was dissolved in 500 mL distilled water. After that, optimization for titration was conducted to find the optimum condition of the time, temperature, and stirring speed.

The optimized condition was used for titration of NaOH solution dropped to  $(\text{CH}_3\text{COOH})_2\text{Zn}\cdot 2\text{H}_2\text{O}$  solution. Titration was continued until 5 pH variations were obtained: pH 7, pH 8, pH 9, pH 10, pH 11, and pH 12. After the color of the solution become milky white, the solution was sonicated for another 30 minutes. It was then idled for several days to observe the precipitation of nano ZnO in the solution.

After the precipitation could be clearly seen through, solution was centrifuged at 3000 rpm for 30 minutes. The supernatant was then removed, and the precipitation which contains nano ZnO was obtained. Nano ZnO precipitates was first treated in  $80^\circ\text{C}$  oven to remove the remaining water. Finally, nano ZnO was grinded with mortar to be shaped into powder.

To find out the particle size, Particle Size Analyzer (Delsa<sup>TM</sup> Nano C Beckman Coulter) was used. Briefly, nano ZnO was dissolved in distilled water in 1:10 concentration. It was then stirred until ZnO suspension in water was formed. 1 mL of the suspension was then tested to obtain the average particle size.

The solution was then centrifuged, and the supernatant was removed to obtain the nano ZnO. Finally, nano ZnO powder was achieved after heat treatment at  $80^\circ\text{C}$ . The X-ray diffraction (XRD) pattern of the final ZnO nanoparticles was obtained with Cu K $\alpha$  radiation (Shimadzu, Japan). The peak positions and relative intensities were characterized by comparison with the Joint Committee for Powder Diffraction Standards (JCPDS). Williamson-Hall plot was used to analyze the crystal size at different pH.

The preparation scheme was shown in Figure 1.

## 3. RESULTS AND DISCUSSIONS

The time for nano ZnO to precipitate from solution was observed. It can be seen from Figure 2 that time to precipitate decreased over increasing pH. The range from pH 7 condition which needed 72 hours to pH 12 condition which needed only 120 minutes to precipitate showed that pH plays a very significant role in sol-gel experiment.

One of the prominent characteristics of nanoparticles are that they tend to float in solution and they need much longer time to be precipitated inasmuch as the gravitation force exerting them is very small, or even almost negligible [10]. It was hypothesized that by varying the pH condition, the size of the particle obtained would also be varied, and this would affect the precipitation profile of the ZnO nanoparticles.

To test above hypotheses, size of the particles at lower and upper pH (pH 7 and pH 12) were measured by PSA machine. Results showed that the size of nanoparticles at pH 7 and pH 12 were 1,3 nm and 73,8 nm, respectively. It is in agreement with hypotheses above that as pH of the solution increased, the size of the nanoparticle increased as well.

Finally, XRD graph in Figure 4 gave us information about the elements of the particles formed at pH 7, 8, 10 and 12. From the graph, it can be inferred that the purity of nano ZnO produced increased as pH increased. Only at pH 12 the 100% ZnO without any contaminants or mixture with other compounds were obtained. The quantitative data of ZnO purity at pH 7, 8, 10, and 12 was as follows: 42.9%, 62.2%, 64.7%, and 100%, respectively.

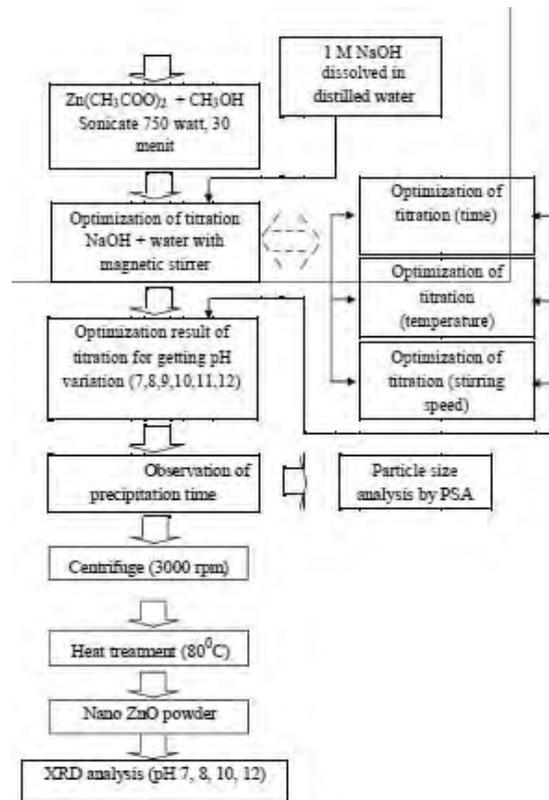

Figure 1: Experiment Scheme

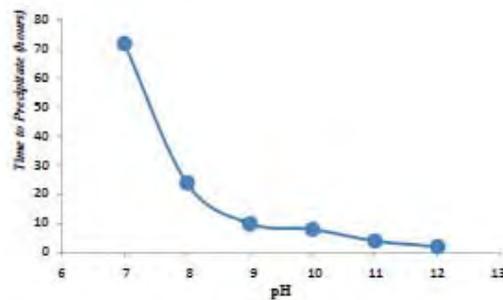

Figure 2: The graph of precipitation time over pH of working solution

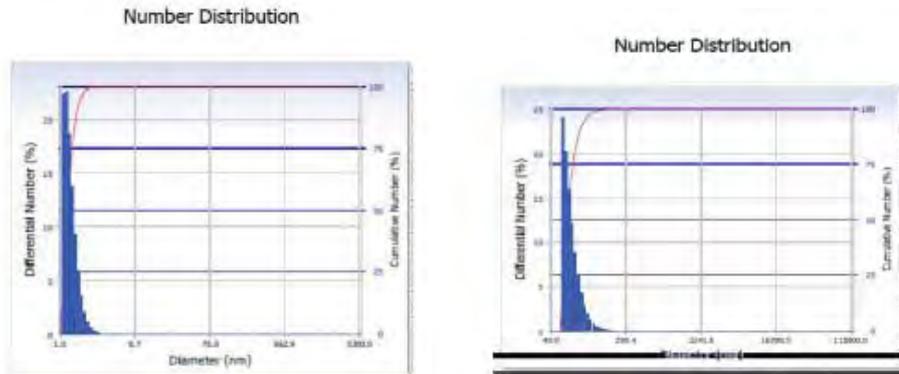

Figure 3: Size distribution of ZnO nanoparticle at pH 7 (top) and pH 12 (bottom)

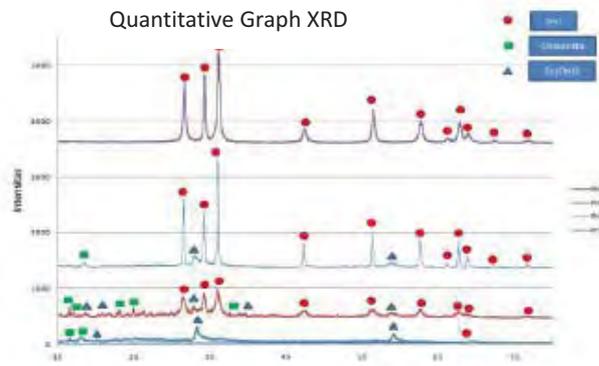

Figure 4: XRD graph of nano ZnO at pH 7, pH 8, pH 10, and pH 12

This phenomenon was well explained by Sunandan, *et al.* that the growth of ZnO is normally enhanced in basic medium. The final growth of ZnO depends upon the competition between growth and etching [10]. The size became significantly bigger at basic condition maybe because high purity ZnO nanoparticles tend to bind each other and agglomerate. In lower pH, although the particle was much smaller in size, the ZnO obtained was still in mixture with other compounds, such as  $\text{CH}_3\text{COONa}$  and  $\text{Zn}(\text{OH})_2$ , therefore they tend to be separated, hence each has small size. Interestingly, at pH 7 there was almost no ZnO particles could be observed. It can be understood that at pH 7, the growth of ZnO was suppressed. It can be predicted that at pH lower than 7, there might be no ZnO produced by sol-gel method using protocol implemented in this research.

Another interesting finding was observed from measurement of crystal size using Williamson-Hall plot analysis as shown in Table 1. From those data, it can be seen by comparing the particle size (before heat treatment) and crystal size (after heat treatment), there was a tendency for the particle to grow in size. This might be due to recrystallization happened due to heat treatment effect. Nevertheless, it can be deduced that the size increment was not significant.

Table 1: Crystal size analyzed by williamson-hall plot

pH	Crystal size (nm)
7	10,94±0,99
8	17,44±5,36
10	38,27±2,14
12	74,04±41,77

#### 4. CONCLUSIONS

Nano ZnO was synthesized successfully from precursor  $(\text{CH}_3\text{COOH})_2\text{Zn}\cdot 2\text{H}_2\text{O}$  and NaOH. pH of the working solution was varied to see the different resulting nano ZnO produced. Nano ZnO precipitation time increased over increasing pH, while the size of the nanoparticle also increased over increasing pH. The XRD data showed that from pH 7 to pH 12, there was significant improvement of the nano ZnO purity. Interestingly, 100% purity of nano ZnO could be obtained at pH 12. This research showed that pH condition in sol-gel reaction plays a very significant role to control the characteristics of nano ZnO produced.

### ABSTRACT

Zinc Oxide (ZnO) possesses high tendency to agglomerate in dispersion system, thus making it difficult to be stable. This research is intended to find out the effect of addition of polyelectrolyte Polyacrylic Acid (PAA) to improve the stability of nano ZnO dispersion. Two parameters that will be observed here are particle size and zeta potential. 5% nano ZnO was dispersed with different condition of stirring (1 hour and 5 hour) with different concentration of PAA (0.5%, 1% dan 3%) also with different temperature (27°C and 57°C). Results showed that in all conditions, PAA addition gave significant effect in particle size and zeta potential, compared to control without PAA addition. Most optimum condition for PAA addition was obtained on PAA addition of 0.5%, 1 hour stirring duration and temperature of 57°C with particle size in range of 193.4 – 253.8 nm and zeta potential of -74.86 mV. From all results and discussions, it can be concluded that PAA addition could improve the stability of nano ZnO dispersion.

### Keywords

*ZnO; Dispersion stability; Particle size; Zeta Potential*

### 1. INTRODUCTION

In recent years, Nano *Zinc oxide* (ZnO) was used in enormous applications, such as photocatalysis [1], coating [2], food packaging [3], and many more. One of the way of utilization of nano ZnO is by dispersing it in the solution. However, nano ZnO is not stable in the solution, and possesses high tendency for agglomeration.

One of the mostly used dispersion solution for nano ZnO is ethanol. Nevertheless, ethanol is easily vaporized, flammable, and poisonous, thus making it limited in this application [4]. On the other hand, water can also be used as a dispersion media for nano ZnO. Water is safe, though is difficult to obtain stable dispersion. In some researches, it was found that Nano ZnO agglomerated much faster in water than in ethanol [1].

The stability of the dispersion can be controlled by adding electrolyte in the form of surfactants or polymers [5]. Polyelectrolyte is a type of polymer that has many charges surrounding its surface and has electrolytic characteristics [6,7]. This charged polymeric chain has an essential role to decide dispersion system's stability. In this research, the dispersion stability of nano ZnO in water will be studied by adding polyelectrolyte Polyacrylic acid (PAA) that hypothesized to be able to neutralize excessive cations in the dispersion system. The effect of PAA concentration, stirring time, and stirring temperature will also be studied. Two parameters that will be analyzed are particle size and zeta potential.

## 2. EXPERIMENTAL PROCEDURE

Materials used in this experiment are Zinc Oxide (Nanotech Indonesia Ltd.), and Polyacrylic acid (Foton Prima Perkasa Ltd.).

ZnO was first analyzed by Scanning Electron Microscopy (SEM) (JEOL) with 10,000 and 20,000 times magnification. ZnO was then dispersed in distilled water, with or without PAA addition. 5% ZnO was dispersed in distilled water and stirred using magnetic stirrer in 700 rpm. Concentration of PAA, stirring time, and stirring temperature were varied as follows: 0.5%, 1%, and 3%; 1 hour and 5 hour; 27°C and 57°C, respectively.

The particle size and zeta potential of dispersed ZnO was then analyzed by Particle Size Analyzer (Delsa™ Nano C Beckman Coulter) and Zeta Potential Analyzer (Delsa™ Nano C Beckman Coulter), respectively.

## 3. RESULTS AND DISCUSSIONS

From the SEM image of nano ZnO shown in figure 1, particle size of nano ZnO can be obtained by manual observation. The particle size was predicted to be in range of 142.8 – 809.2 nm as shown in Figure 2. This particle size can be assumed as the real particle size of nano ZnO.

The complete data of particle size and zeta potential at varied PAA concentration, stirring time, and stirring temperature is shown in Table 1.

Particle size in dispersed ZnO in water without PAA addition has minimum particle size at 1 hour stirring time at 57°C, which is in range of 3.758 nm – 13.049 nm. Physically, stirring time and stirring temperature did not give significant effect towards ZnO particle size in control group (without PAA addition).

The ZnO particle size in PAA added group has relatively smaller size compared to those without PAA addition, and much nearer to predicted real size of ZnO as analyzed earlier by SEM. It can be inferred that PAA can improve the stability of the dispersion system, most likely due to its ability to neutralize excessive positive charges in the dispersion system, which also relates to particle size of ZnO. The complete graph of the effect of PAA addition to ZnO particle size can be seen in Figure 3.

As shown in figure 3, PAA addition, stirring time, and stirring temperature have significant effects towards ZnO particle size. Generally, by increasing the PAA concentration, the ZnO particle size became relatively smaller, also prolonged stirring time tends to make particle size smaller. However, this phenomenon only occurred during stirring temperature of 27°C. Increasing stirring temperature can give an effect towards decreasing particle size, nevertheless, still, most significant variable that affects the particle size is PAA addition. 3% PAA addition is much more effective to obtain particle size with narrow distribution. Meanwhile, ZnO particle size with PAA addition that has smallest particle size was obtained at 1% PAA addition, stirring time of 5 hours and stirring temperature of 57°C, which led to size of 88.3 nm – 350.5 nm.

The graph of effect of PAA addition to ZnO zeta potential is shown in Figure 4. ZnO without PAA addition could not be analyzed by Zeta Potential Analyzer because during the characterization, the light scattering intensity was not enough for measurement.

Figure 4 shows that as the PAA added more and more, the zeta potential of ZnO will shift towards positive axis. This zeta potential increase made the dispersion system becomes unstable, close to  $\pm 30$  mV that is usually considered as the limit of dispersion stability. In the other words, increasing PAA concentration leads to decreasing ZnO stability. The highest ZnO dispersion stability was obtained at PAA addition of 0.5% with 5 hour stirring time and at stirring temperature of 27°C, which gave the zeta potential of -76.06 mV. At the very last, the correlation of zeta potential and particle size of nano ZnO can be observed in figure 5. It can be inferred that generally, increasing zeta potential leads to decreasing ZnO particle size. Also, it can be concluded that the most optimum sample of all experiments, which compromises the particle size and zeta potential value was obtained at PAA addition of 0.5% with stirring time of 1 hour and at 57°C which gave the zeta potential value of -74.86 mV and particle size with narrow range of 193.4 – 253.8 nm.

## 4. CONCLUSIONS

Based on results above, it can be concluded that the predicted real size of ZnO in this experiment is 142.8 nm – 809.2 nm as characterized by SEM. PAA addition that gave smallest particle size was obtained PAA addition of 1% with 5 hour stirring time at 57°C, with size range of 88.3 nm – 350.5 nm. The ZnO dispersion with highest stability was obtained at PAA addition of 0.5% with 5 hour stirring time at 27°C, which gave the zeta potential value of -76.06 mV. While the most optimum that compromises the particle size and zeta potential of ZnO was obtained at PAA addition of 0.5% with 1 hour

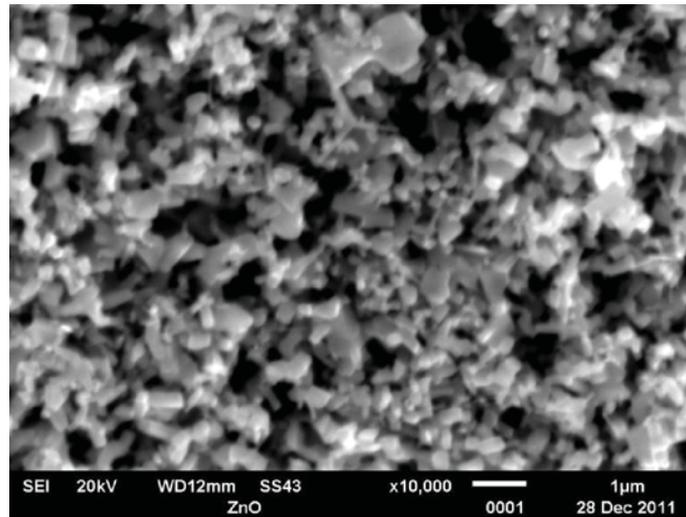

stirring time at 570C, with particle size in range of 193.4 nm – 253.8 nm. At the very last, PAA addition in ZnO dispersion was proven to be able to improve the system's stability significantly.

## ABSTRACT

The objective of this research is the application of a phenomenological kinetic model to the analysis associated with measuring the carbon formed using a thermobalance. The Ni-Cu-Al catalyst was prepared using the co-precipitation method and then calcined at 800°C. Direct decomposition of the methane reaction was performed in a 15 mm quartz thermobalance reactor at atmospheric pressure in the temperature range of 500-750°C. The reaction mechanism and the identification of rate-controlling steps were attempted in the present study following the mechanism proposed by Snoeck et al. Methane adsorption on the catalyst surface was identified as the limiting step for the reaction rate when activation energy was 67.76 kJ/mol and the frequency factor of decomposition was  $5.15 \times 10^{18}$ . Results also demonstrate that there was catalyst deactivation during the reaction due to deposits of carbon on the catalyst surface, and it was therefore considered in the kinetics model with the order of decay rate being first. This result would be valid for reaction temperatures of 500 - 750 °C. At 500-600 °C, deactivation was rapid and led to a complete loss of catalyst activity. The second process that dominated above 650 °C involved a slow decrease in the decomposition rate.

## Keywords

*Deactivation, Kinetic model, Ni-Cu-Al catalyst, Thermo balance*

## 1. INTRODUCTION

Natural gas (methane) in Indonesia is directly used for fuel consumption or export with selling value lower than domestic. Advanced processing of methane is expected to increase its economical value. Methane could be processed into more valuable products, such as nanocarbons and hydrogen. There are some methane manufacturing processes developed to produce both products with great benefit. One alternative to produce nanocarbons and hydrogen economically and simultaneously is by using methane catalytic decomposition as follows  $CH_4 \rightarrow C + 2H_2$   $\Delta H = +75 \text{ kJ/mol}$  [1].

Carbon nanotubes (CNTs) are tubular carbon molecules with superior mechanical, chemical, optical, and electrical properties. These unique properties make CNTs potentially valuable for hydrogen storage, superconducting, drug delivery, and other end-use applications. Catalytic decomposition of methane is a promising method for producing hydrogen and CNTs simultaneously. In the future, this process represents a potential alternative to infuse small-scale natural gas reserves with methane as their main component in order to produce high value products, i.e., hydrogen as an energy source for the future and carbon nanotubes, which have many applications. This kind of energy may also prevent the formation of greenhouse gases that contribute to global warming. [2, 3]

According to Snoeck et al. and Rahman et al. [4, 5], the catalytic decomposition of methane proceeds through four steps (for a nickel catalyst): surface reaction, dissolution/segregation, diffusion of carbon through nickel, and precipitation/dissolution of carbon. Surface reactions involve the adsorption of methane, followed by a series of dehydrogenation steps, and finally hydrogen desorption. The dehydrogenation steps are followed by the dissolution/segregation of carbon into the Ni. After dissolution/segregation, the carbon dissolved in the nickel particle at the front end diffuses to the rear interior of the particle

(i.e., metal/carbon filament interface). Opinion is divided concerning the driving force for the bulk diffusion of carbon through the metal particle.

To carry out the catalytic decomposition of methane, many researchers have measured the conversion of methane while others have measured the production of hydrogen [5]. Research has been conducted on the kinetics of catalytic decomposition of methane, but studies have been limited to fluidized bed reactors and fixed bed reactors [2, 3]. Other experimental studies have been performed to gain a better understanding of the kinetics of methane decomposition. The majority of the studies focused on the reaction mechanisms and identification of primary decomposition products [6].

Catalytic activity can be measured in various ways depending on the chosen approach. Some researchers have measured the catalytic activity of 16.4% wt Ni/SiO<sub>2</sub> by measuring the conversion of diluted CH<sub>4</sub> streams (20% CH<sub>4</sub> + 80% He) in connection with time-on-stream (min) in a fixed-bed, plug-flow reactor at 550 °C [5]. Others have been monitoring the outlet concentration of hydrogen as a function of reactor temperature in the range of 500-750 °C using different combinations of catalysts in a plug-flow reactor [5, 7]. Another method utilizes a thermobalance to obtain the level of methane cracked by monitoring the mass gain with time. This method appears to overcome the problem of space limitations that interfere with the fixed-bed technique for measuring the activity, as discussed by several researchers [5]. Therefore, we selected the thermobalance for this study. In this research, an intrinsic kinetics study of catalytic decomposition of methane was performed on the Ni-Cu-Al catalyst with a microkinetics analysis method, in which the reaction rate is determined by the reaction mechanism.

## 2. EXPERIMENTAL

Methane decomposition experiments were conducted in a thermobalance. At atmospheric pressure, the thermobalance can operate up to 1100 °C. The system consists of three main sections: the hardware [Sartorius T-214 S micro balance, data acquisition, furnace, gas chromatography with thermal conductivity detector (Shimadzu GC-8A)]; the software (electronic components and displays); and the external flow, pressure, and temperature controllers. The loading and unloading of the sample was accomplished by opening the sample holder and lowering the furnace. The temperature inside the reaction chamber was measured and controlled by a 1/8-inch Chromel–Alumel thermocouple located just inside the sample holder. The sensitivity of the balance was 100 µg, the data were recorded at thermobalance reached constant.

The catalyst used for catalytic decomposition of methane was prepared by the coprecipitation method with a molar ratio of 2:1:1 for Ni:Cu:Al. An aqueous solution of nitrates salts, which include nickel nitrate hexahydrate, copper nitrate trihydrate, and aluminum nitrate nonahydrate from Merck, was used. After stirring 1 h at about 50°C, the solution was dissolved with sodium carbonate at the rate of 10ml/min until it reach the desired pH. The viscous solution was then stirred for another 1 h at the same temperature and left to age overnight. The precipitate was filtered out and washed with deionized water in order to remove ammonium nitrate; washing was repeated five times. Wetcake was then dried at 120°C for 5 h in a vacuum furnace and calcined at 800°C for 5 h in an atmospheric furnace.

### Activity Measurement

The specific rate of carbon formation,  $r'_C$ , relative to the initial amount of nickel in the catalyst is defined as follows [5]:

$$r'_C = \frac{\text{rate formation of carbon (g}_C/\text{min)}}{\text{Mass of Ni (g}_{Ni})} \quad (1)$$

$$= \frac{1}{W_{Ni}} \frac{dm}{dt} \left( \frac{g_C}{g_{Ni} \cdot \text{min}} \right) \quad (2)$$

where  $W_{Ni}$  is the mass of nickel in the catalyst ( $g_{Ni}$ ),  $t$  is the time on stream (min) and  $m$  is the mass gain as recorded by the balance ( $g_C$ ).

The activity is defined as [5]:

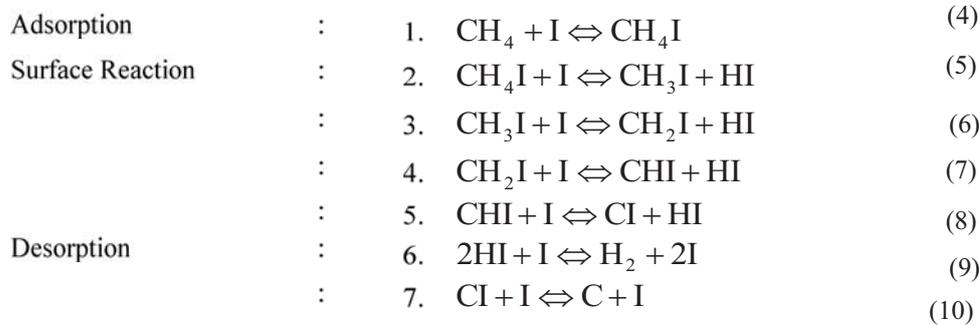

$$a = \frac{r'_{C(t)}}{r'_{C(\max)}} \quad (3)$$

Where  $r'_{C(\max)}$  is the maximum specific rate, usually occurring at the early stage of the cracking reaction.

### 3. RESULTS AND DISCUSSION

#### 3.1 Intrinsic Kinetic Model and Estimation of Parameter

The reaction mechanism and identification of rate-controlling steps were attempted in the present study following the mechanism model for methane decomposition proposed by Snoeck et al. [4], which is outlined below.

The Langmuir-Hinshelwood-Hougen-Watson model was chosen as the intrinsic kinetic model for the reaction. This model is based on the assumption that each stage of the reaction mechanism model can be the rate limiting step (RLS).

Surface concentrations of methane and hydrogen can be replaced by partial pressure respectively by the Langmuir isotherm, so that:  $[CH_4] = P_{CH_4}$  and  $[H_2] = P_{H_2}$ . The following rate equation is derived for the mechanism:

$$r_{C,M} = \frac{k_M^+ \cdot K_{CH_4} \cdot p_{CH_4} - \frac{k_M^- \cdot K_H^2 \cdot K_C}{K_3 \cdot K_4 \cdot K_5} \cdot [c_{Ni,T}] \cdot p_{H_2}^2}{\left( 1 + K_C \cdot [c_{Ni,T}] + K_H^{1/2} \cdot \left( 1 + \frac{K_C \cdot [c_{Ni,T}]}{K_5} \right) \cdot p_{H_2}^{1/2} + \frac{K_H \cdot K_C \cdot [c_{Ni,T}]}{K_4 \cdot K_5} \cdot p_{H_2} + \frac{K_H^{3/2} \cdot K_C \cdot [c_{Ni,T}]}{K_3 \cdot K_4 \cdot K_5} \cdot p_{H_2}^{3/2} + K_{CH_4} \cdot p_{CH_4} \right)^2} \quad (11)$$

Where,  $r_{C,M}$  is Rate of carbon filament formation by the methane cracking (g/gNi min);  $k_M^+$  and  $k_M^-$  are Rate coefficients of the forward and the reverse reaction of the rate-determining step; K is symbol used for equilibrium coefficients and  $p_i$  is partial pressure of component i.

When the surface concentrations of H-I, CH-I and CH<sub>2</sub>-I are negligible, the rate equation is simplified to :

$$r_{C,M} = \frac{k_M^+ K_{CH_4} p_{CH_4} - \frac{k_M^- K_C K_H^{1/2}}{K_3 K_4 K_5 / K_H^{3/2}} \cdot [c_{Ni,T}] \cdot p_{H_2}^2}{\left( 1 + K_C \cdot [c_{Ni,T}] + \frac{K_C \cdot [c_{Ni,T}]}{K_3 K_4 K_5 / K_H^{3/2}} p_{H_2}^{3/2} + K_{CH_4} p_{CH_4} \right)^2} \quad (12)$$

Where :  $k_M^- = k_M^+ \cdot K_H^{1/2}$   
 $K_r' = K_r / K_H^{3/2} = K_3 \cdot K_4 \cdot K_5 / K_H^{3/2}$  and equation (12) into

$$r_{C,M} = \frac{k_M^+ \cdot K_{CH_4} \cdot p_{CH_4} - \frac{k_M^-}{K_r'} \cdot K_C \cdot [c_{Ni,T}] \cdot p_{H_2}^2}{\left( 1 + K_C \cdot [c_{Ni,T}] + \frac{1}{K_r'} \cdot K_C \cdot [c_{Ni,T}] \cdot p_{H_2}^{3/2} + K_{CH_4} \cdot p_{CH_4} \right)^2} \quad (13)$$

It is assumed that the concentration of carbon dissolved in nickel is almost uniform (uniform) across the Ni particles and equal to the concentration of carbon on the catalyst support. This implies that the closure of the surface by carbon occurs constantly [10, 11], so  $[c_{Ni,T}] \approx [c_{Ni,r}] \approx [c_{Ni,sat}]$ . Assumptions  $K_C \cdot [c_{Ni,T}]$  can be combined with the coefficient  $K_r'$  so

$K_r'' = K_r' / (K_C \cdot [c_{Ni,T}]) = K_r' / (K_C \cdot [c_{Ni,T}])$ . Dividing the numerator and denominator by  $(1 + K_C \cdot [c_{Ni,T}])$  and incorporating this group in the other parameters leads to the following simplified form for the rate equation:

$$r_{C,M} = r_{CH_4} = \frac{k_M^+ \cdot K_{CH_4} \cdot p_{CH_4} - \frac{k_M^-}{K_r''} \cdot p_{H_2}^2}{\left(1 + \frac{1}{K_r''} \cdot p_{H_2}^{3/2} + K_{CH_4} \cdot p_{CH_4}\right)^2}$$

Thus, seven kinetic models were obtained that represent the rate-limiting steps of this mechanism: Model 1 is the adsorption model; Model 2 represents the first step of hydrogenation in the surface reaction; Models 3-5 are the second, third, and fourth steps of hydrogenation in the surface reaction; Model 6 represents hydrogen desorption; and Model 7 represents carbon desorption [12].

The best kinetic model is closer to the line equation  $Y = X$ . In addition, kinetic models are close to the line equation  $Y = X$  on Figure 1 will be the rate-limiting step reaction. From the statistical point of view and calculation of error percentages for the seven models [12] for all of the reaction temperatures, we observed that Model 1, the adsorption model, had the higher  $R^2$  value and the lowest error percentage. Thus, Model 1 is the most representative model, statistically, based on the reaction rate equation of carbon growth via methane catalytic decomposition.

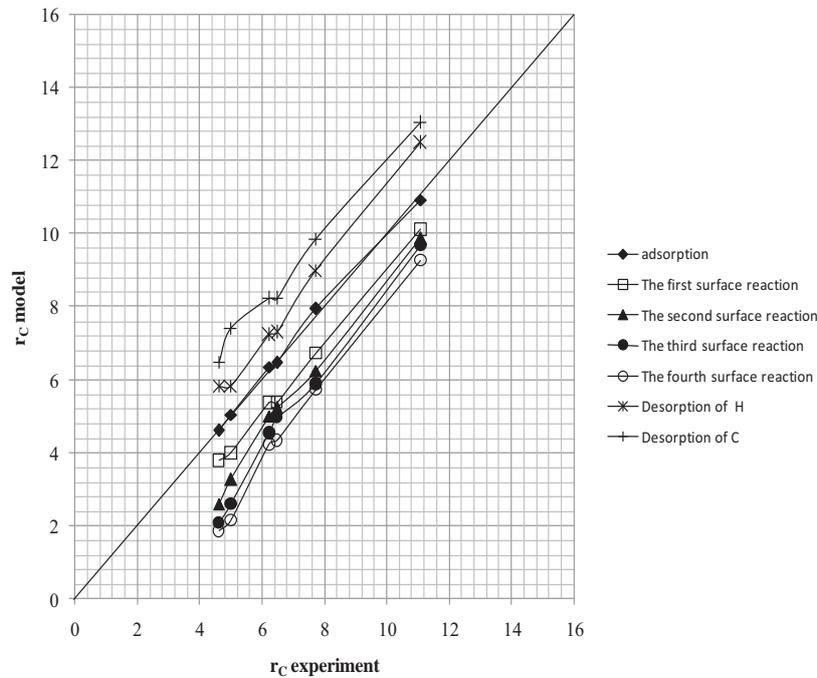

Figure 1: Rate of Carbon Growth,  $r'_C$  (experiment) vs.  $r'_C$  (model)

The kinetics equation for methane catalytic decomposition with adsorption as the reaction rate-limiting step is as follows. This result would be valid for reaction temperatures of 500-750 °C. Then, the determination of the activation energy is conducted by using Arrhenius equation as follows:

$$\ln\left(\frac{k}{T}\right) = \ln A - \frac{E_a}{R} \left(\frac{1}{T}\right) \quad (15)$$

The applicability of Eq. (12) is tested by plotting  $\ln\left(\frac{k}{T}\right)$  vs  $\left(\frac{1}{T}\right)$  as in Figure 1. If the plot is linear, where the slope of the plot is  $E_a/R$ , then  $E_a$  value can be calculated. An Arrhenius plot of the deactivation methane decomposition rates is given in Figure 2. Fitting the data with a straight line, we calculated activation energy of about 67.76 kJ/mol and the frequency factor of  $5.15 \times 10^{18} \text{ s}^{-1}$ .

The Ea value obtained from this calculation is between the energy activation value in several reported literatures, i.e. 60 – 236 kJ/mol. In addition, this value is similar to the results obtained with the value of 60 kJ/mol for the adsorption step ( $\text{CH}_4 + \text{I} \rightarrow \text{CH}_4\text{I}$ ) [11] where I is the active site. This supports the view that the adsorption model step may be rate-determining, at least in the early stage of the decomposition process.

The resultant parameter estimates were subjected to a statistical analysis and checked with the statistical test from the L-H type intrinsic kinetic model [6]. Normally, this model is suitable for application when  $\rho^2 > 0.9$ ,  $F > 10F_T$  [6].  $\rho^2$  is the key parameter, calculated by:

$$\rho^2 = 1 - \frac{\sum_{i=1}^M (y_{i,e} - y_{i,c})^2}{\sum_{i=1}^M y_{i,e}^2} \quad (16)$$

where M is the number of experiments,  $y_{i,e}$  is specific mass gain of experimental data, and  $y_{i,c}$  is the specific mass gain of simulation value.

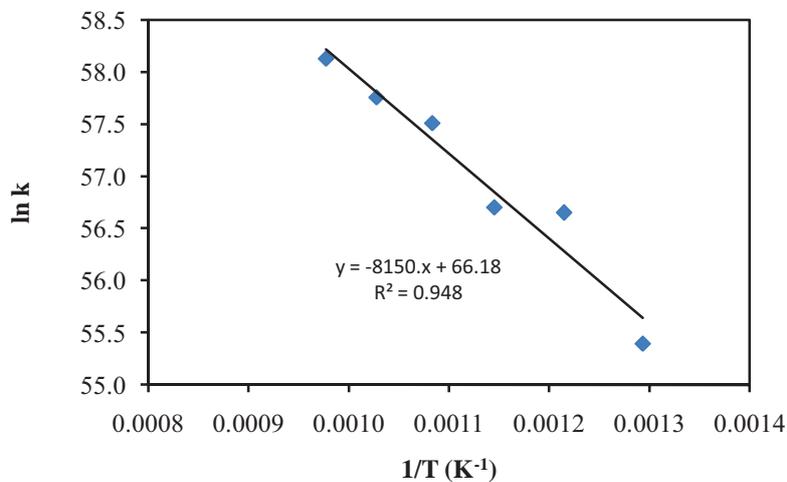

Figure 2: Arrhenius plot for the maximum specific rate of carbon formation

F is the proportion of the regression sum of the mean square to residual error sum of the mean square,  $F_T$  is a value of F Table corresponding to 5% significant level, and  $M_p$  is the number of parameters in the equation of models shown below.

$$F = \frac{\left[ \frac{\sum_{i=1}^M y_{i,e}^2}{M} - \frac{\sum_{i=1}^M (y_{i,e} - y_{i,c})^2}{M} \right] / M_p}{\frac{\sum_{i=1}^M (y_{i,e} - y_{i,c})^2}{(M - M_p)}} \quad (17)$$

The values calculated by the Langmuir-Hinshelwood intrinsic kinetic model agree with the experiment results for Model 1. The average relative errors of the specific mass gain for each temperature in Model 1 are 1.13 % and 3.96 %, respectively.

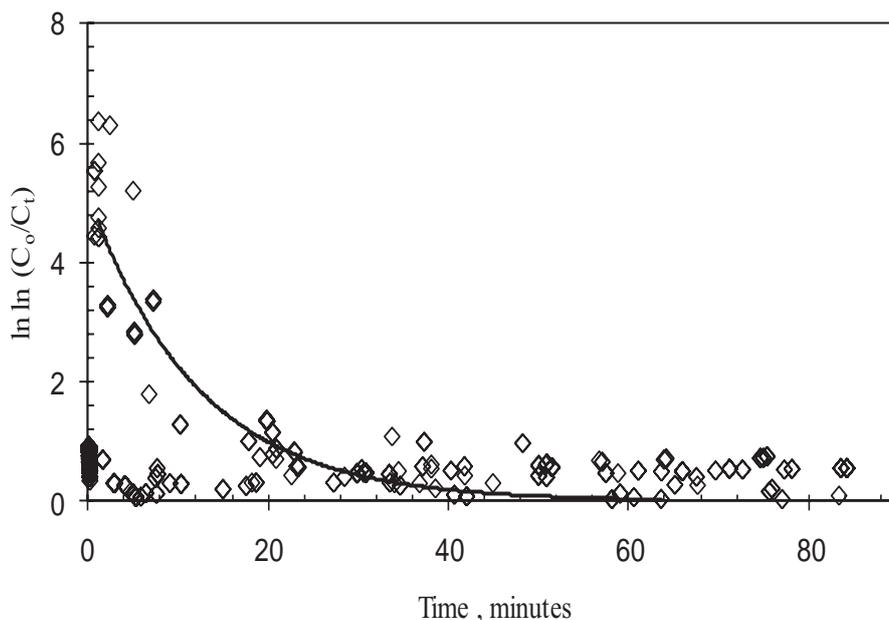

### 3.2 Catalyst Deactivation

The main causes of catalyst deactivation are fouling by encapsulating coke, sintering (or thermal aging), and poisoning [13]. Therefore, the deactivation rate,  $r_d = -\frac{da}{dt}$ , must be described according to an appropriate deactivation kinetic model related to the deactivation cause [13, 14]. Thus, if the formation of encapsulating coke is partially reversible, the catalyst does not suffer complete deactivation, maintaining a residual level of activity at steady state [6]. As shown in Figure 3, the profile corresponds with Empirical Decay Laws from Fogler [14], where the catalyst activity decreases as the function of time due to the presence of catalyst decay (deactivation of catalyst).

Profile of the graphic in this research more to exponential which is the characterization of first order reaction. The bigger the deactivation reaction order, the greater the decrease in the reaction rate because catalyst deactivation will decrease significantly.

The exponential data enables the first deactivation reaction order, where  $a(t)$  value can be obtained by using Eq. (18) as follows [14], where  $\beta_1$  is reaction order.

$$a = e^{\beta_1 t} \quad (18)$$

**Figure 3** Profile of time versus  $\ln \ln(C_{c,t}/C_{c,i})$

Deactivation mechanism is due to the encapsulation of metal particles by carbon layers of graphite. Through EXAFS and Mössbauer Spectroscopies, Shah et. al., 2001, said that in the form of encapsulation, the catalyst remains in a state of the metal. It is postulated that the metallic catalyst deactivated not due to poisoning or a change in surface structure but was isolated from  $\text{CH}_4$  by encapsulation and could not catalyze the decomposition of methane.

## 7. CONCLUSION

The following conclusions summarize findings from this research is the reaction kinetics equation model of methane catalytic decomposition with adsorption as the reaction rate limiting step is more accurate than the equation model with surface reaction and desorption as reaction rate limiting step. The activation energy required is 67.76 kJ/mol with frequency factor of  $5.15 \times 10^{18}$ . Based on the result of this research, the catalyst deactivation during the reaction due to deposits of carbon on the catalyst surface, and it was therefore considered in the kinetics model with the order of decay rate being first.

### **ABSTRACT**

*This study brings out a disinfection process of bacteria *Escherichia coli* using hydrodynamic cavitation method. The method used different contactors, orifice plate and venturi injector. The experiment result shows that orifice plate with initial concentration of  $10^4$  CFU/mL has decreased into 0 CFU/mL after 20 minutes, while venturi injector has decreased into 0 CFU/mL after 30 minutes. The orifice plate gave a better, more effective and faster disinfection than the venturi injector.*

## ABSTRACT

Conventional biomass stoves, which currently use direct combustion of biomass pellets or briquettes, have still a problem of emitting much higher CO gas emission compared to LPG stoves at the level of 100's ppm. These values are well above the minimum allowable CO gas emission of 25 ppm and therefore the emission is not safe for the stove users.

In this research, a biomass-gas stove was designed using a method of *top-lit updraft gasification* where the combustion of pyrolysis gas evolving from the bed of rubber wood pellets by adding secondary air occurs at the top of the stove. The primary air is delivered upward the bed, while the secondary air flows through the annulus of the stove and bends horizontally towards a series of holes at the top of the stove. This research has an objective to obtain optimum value of flowrate ratio of the secondary air to the primary air (air flow ratio) where the stove produces minimum emission of CO and maximum thermal efficiency. The ratio was varied at 2.44, 6.29, 13.43, and 20.6.

This work concluded that the lowest CO emission and the highest average flame temperature occur at the air flow ratio of 6.29, while the highest thermal efficiency at 2.44.

## Keywords

*Rubber wood pellets, biomass-gas stove, top-lit updraft gasification, CO emission, pyrolysis*

## 1. INTRODUCTION

Indonesia has abundant potential of biomass waste, which is currently not utilised massively. The production of the waste is estimated to reach 123.5 million tons per year and is equivalent to 1,455.97 million GJ/year. The main resources are rice waste of 705 million GJ/year, rubber plantation waste of 46.45 million GJ/year, bagasse waste of 70.65 million GJ/year, palm plantation waste of 247.15 million GJ/year, and coconut plantation waste of 162.3 million GJ [1-2]. If the biomass waste is directly burnt as solid fuels for stoves in the forms of briquettes or pellets, CO emission resulting from the combustion is expected to be high, well above the minimum allowable CO emission of 25 ppm [3]. This occurs due to heat absorption by solid fuels through conduction during the combustion causing the surface temperature of briquettes or pellets to drop and consequently increasing CO emission. This condition encourages the research on the biomass waste fuel which utilises its gas phase to allow the combustion to produce low CO emission. This may be substantiated by pyrolysing the solid biomass waste to produce biomass gas and burning the gas. This is expected to produce much lower CO emission similar to that produced by LPG stoves.

The combustion occurs due to oxidation reactions between gases (CO, H<sub>2</sub>, CH<sub>4</sub> and hydrocarbons) produced by pyrolysis of the biomass material. This pyrolysis is carried out in limited air environment and combustion uses a separate flow of air. The air used for pyrolysis is usually termed as primary air, whereas that for combustion secondary air. This pyrolysis is usually called oxidative pyrolysis. Senneca *et al* [4] found that this type of pyrolysis results in much higher weight loss of solid fuels at certain range of temperature compared to the loss using inert-gas pyrolysis. The pyrolysis is initiated by heat radiation of the gas combustion at the top of the pellet bed. The gas produced by oxidative pyrolysis may subsequently be completely oxidised to produce CO<sub>2</sub> and H<sub>2</sub>O [5][6]. Stoves utilising gas produced by oxidative pyrolysis of biomass material as a fuel is usually called biomass-gas stoves. Figure 1 describes the schematic diagram of the stove. Fuel, in the current research of rubber wood pellets, is ignited at the top of the pellet bed. The ignition forms flaming pyrolysis front which moves downward. During its passage, the biomass pellets are pyrolysed (gasified) from the top to the bottom of the fixed bed [7]. Primary air is supplied from the bottom of the pellet bed at strictly limited amount to sustain flaming pyrolysis front. Biomass gas produced moves upward and after mixing with the secondary air supplied radially from the top side of the stove, it burns over the top of the fixed bed with high heat release. The gasification process is entirely autothermal and does not need any external heat. Part of the pellet bed left behind by flaming pyrolysis front forms biochar after releasing biomass gas. The char may be oxidised by

remaining oxygen from the flaming pyrolysis front to form  $\text{CO}_2$  [8].  $\text{CO}_2$  and  $\text{H}_2\text{O}$  produced in the flaming pyrolysis front may react with biochar to form gases  $\text{CO}$  and  $\text{H}_2$  [7]. The pyrolysis-combustion of biomass material using this method was first introduced by using a principle of *top-lit updraft (TLUD) gasification* by Reed [9].

The present research is aimed to investigate the  $\text{CO}$  emission resulting from the combustion of the gas phase of the pyrolysis products of rubber wood pellets and the stove efficiency subject to the variation of ratio of the secondary to primary air flowrates. Although some researches relating to the  $\text{CO}$  emission has been conducted, but in general the emission figures were published in terms of grams as cumulative emissions [9]. None present in terms of the ppm during the combustion. Effect of  $\text{CO}$  emission to human being depends on the concentration of  $\text{CO}$  emission in ppm and the duration to which the human being is exposed [10]. Besides, the  $\text{CO}$  emission may also depend on the type of biomass used as fuel because different biomass types have different compositions of cellulose, hemicellulose and lignin part of which under pyrolysis environment will decompose to volatile matter and subsequently to smaller molecules [11]. The threshold  $\text{CO}$  emission stipulated by Ministry of Workforce Indonesia is 25 ppm. According to the result of proximate analysis by Energy Technology centre, BPPT, the content of volatile matter of the rubber wood sample was 68.32%. This gives indication that the rubber wood if used as fuel in TLUD stove will produce much volatile matter and therefore it is potential for biomass-gas stove.

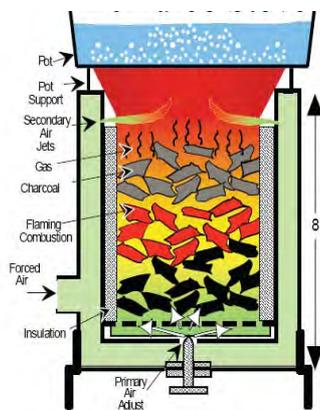

Figure 1a: Schematic description of TLUD stove [8].

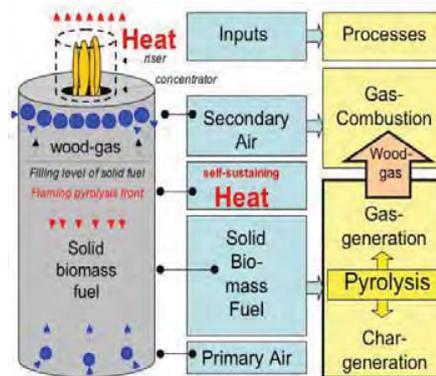

Figure 1b: Mechanisms of biomass pellet pyrolysis and wood gas combustion [9].

## 2. EXPERIMENT

The experiment consists of biomass pellet preparation, and biomass pellet pyrolysis and combustion. Rubber wood pellets were prepared by first grinding the rubber wood branches to powder, drying the powder to reach moisture content of 10%. Subsequently, the dry powder was moulded to form pellets. During the pyrolysis-combustion, measurements of  $\text{CO}$  emission and flame temperature were conducted. Main measurement tools used were biomass-gas stove where the pyrolysis-combustion of pellets was undertaken, some thermocouples type K, a temperature data logger to log data of flame temperature, a gas analyzer to measure  $\text{CO}$  concentration in flue gas, and an anemometer to measure velocity of air to the primary and secondary air blowers, and a water pot of 17cm diameter. The water pot was used for determination of the stove thermal efficiency using water boiling test method. Pellets made of rubber wood were of cylindrical shape with 1.5cm diameter and 3cm length.

The stove prepared has inside diameter of 15cm and height of 58cm (see Figure 2). These sizes were to accommodate the loading of rubber wood pellet of 1.4 kg. The stove consists of 2 concentric cylinders with an annulus in between the cylinders. The pellets were laid in the inner cylinder of the stove. Through the annulus, the secondary air is flowing to fulfil the need for the combustion of wood-gas produced by the pyrolysis. The construction material is made of mild steel. The outer side of the stove was lined with ceramic fibre and enclosed with an aluminium plate. A grate of stainless steel 314 was installed at the lower side of the stove to support the pellet bed to resist corrosion. Two centrifugal blowers have been used to deliver primary and secondary air respectively (see Figure 2). The first blower has diameter of 2 inches and input electricity ampere of 1A, while the second blower 2.5 inches and input ampere of 1.6A. The primary air was delivered to the base of the bed, while the secondary air flowed through the annulus of the stove and bent towards a series of holes at the circumference of the top of the stove. This design allows the crossflow between pyrolysis gas and combustion air, which intensifies mixing. For each run, the stove used 1.4 kg of the pellets and primary air flowrate set about  $0.0038 \text{ m}^3/\text{sec}$ . The ratio of the secondary air to the primary air flowrates (air flow ratio) as the free variabel for this experiment was varied at 2.44, 6.29, 13.43 and 20.6 and its effect on

flame temperature, CO emission and thermal efficiency were observed. The measurements of CO emission, flame temperature and water temperature in the water boiling test were carried out simultaneously.

Figure 2: Fabricated biomass-gas stove for experiment with 2 blowers for primary air and secondary air respectively.

### 3. RESULTS AND DISCUSSION

#### 3.1. Flame temperature and CO emission

Figure 3 shows that at the air flow ratio equal to 2.44, the flame temperature is nearly constant during the course of the combustion. At this ratio, the use of the secondary air to oxidise the pyrolysis gas is limited and may be not sufficient (see Table 1). As a result, the concentration of CO as an indicator of the incomplete combustion is high as described in Figure 4. The heat radiated from the combustion flame to the flaming pyrolysis front to enhance the pyrolysis may be not high due to low temperature driving force between both flames. This weakens the rate of pyrolysis and consequently, the rate of pyrolysis gas production is low and the pyrolysis-combustion lasts longer to produce and oxidise all the pyrolysis gas compared to that at higher air flow ratios. This also affects the CO emission, where its level of emission is high at low flame temperature (see Figure 4) [10]. At higher air flow ratio of 6.29, Figure 3 shows that most of the time, the flame temperature is higher than that at air flow ratio of 2.44. This may happen due to more complete oxidation as a result of sufficient supply of secondary air. In terms of the CO emission, this favours the low production of CO as described by Figure 4 and achieves the lowest average CO emission (see Table 1). Due to higher temperature driving force between combustion flame and flaming pyrolysis front at the air flow ratio of 6.29, the pyrolysis may occur at higher temperature and lasts shorter.

Pyrolysis-combustion operation at air flow ratio of 13.43 where the supply of the secondary air is higher than that at flow ratio of 6.29 exhibits opposite trend compared to the trend if the air flow ratio is increased from 2.44 to 6.29. The flame temperature is lower (see Figure 3) and consequently the CO emission during the course of the pyrolysis-combustion is higher (see Figure 4) and its average value is also higher (see Table 1). This may happen due to excessive supply of the secondary air which cools the combustion flame. The temperature driving force between combustion flame and pyrolysis flame is lower at the air flow ratio of 13.43 and thus extending the pyrolysis time as shown in Figure 3.

At the air flow ratio of 20.6, at times after 9 minutes, the flame temperature is lower than that at air flow ratio of 13.43 as expected due to excessive supply of the secondary air to the combustion flame. However, at times before 9 minutes, the flame temperature is slightly higher than that at air flow ratio of 13.43. The temperature fluctuation at the air flow ratio of 13.43 at initial stage of pyrolysis-combustion operation where the position of the thermocouples was kept at the combustion flame indicates that there may be non-uniformity of the secondary air supply because the secondary air inlet at the base of the stove is at one side of the stove. Consequently, this creates non-uniformity of the secondary air supply and forms lacking and excess air regions in the combustion flame front. The regions where the air supply is lacking form soot which intensifies radiation heat transfer [10]. At higher air flow ratio of 20.6, which means higher secondary air supply, turbulence inside the annulus becomes more rigorous and results in redistribution of inlet flow of the secondary air across the circumference of the top side of the stove [12]. As a result, the inlet flow is more uniform and flame temperature at this ratio is relatively unchanged from time to time. This also causes the portion of heat radiation is less than that at the air flow ratio of 13.43. The less flame temperature at initial stage of the combustion using the air flow ratio of 13.43 is due to non-uniformity preheating of the secondary air in the annulus. With the time proceeds, the wider region of the pellet bed with higher temperature allows expansion of the preheated

secondary air and intensified turbulence which gives effect similar to that which happens in the case of the air flow ratio of 20.4 where the flame temperature is less turbulent (see Figure 3). This comparison between flame temperature profile for the combustion using the air flow ratio of 13.43 and that of 20.6 gives consequences on the CO emission profile of both air flow ratio. At initial stage of the combustion, the CO emission at the air flow ratio of 13.43 is higher than that at the ratio of 20.6. Contrary to that, at later stage of the combustion, the CO emission at air flow ratio of 13.43 is less than that at the ratio of 20.6 (see Figure 4).

Table 1. shows that the average CO concentration in the flue gas reaches the minimum value, i.e. 14 ppm, when the air flow ratio was set 6.29. This implies that using controlled air flows both of primary air and secondary air, we can make the stove healthy to the users in domestic kitchens because the CO emission can be kept low. However, the stove fabricated for this experiment is considered too high to be practical, so the next research should be directed to fabricate a shorter stove with longer operation to suit the needs in the kitchens.

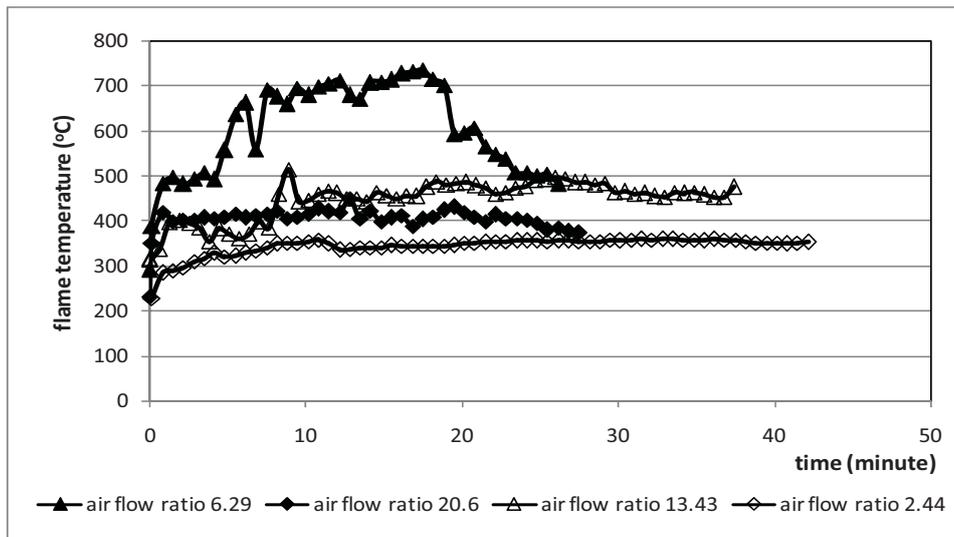

Figure 3: Flame temperature measured during the course of the combustion

Table 1. Average CO emission, maximum flame temperature and maximum water temperature at different values of ratio of secondary air to primary air flowrates (air flow ratio)

Primary air flow rate (m <sup>3</sup> /s)	Secondary air flow rate (m <sup>3</sup> /s)	Air flow ratio	Average CO emission (ppm)	Maximum flame temperature (°C)	Maximum water temperature (°C)
0.00038	0.0024	6.29	14	739.3	87.1
0.00038	0.0078	20.6	29	441.7	86.4
0.00035	0.0047	13.43	32	516.8	96.0
0.00038	0.00093	2.44	52	360.8	133.0

### 3.2. Stove thermal efficiency

Thermal efficiency is calculated using the following equation

$$\eta = \frac{M \times c_{p1} \times (T_b - T_a) + M_1 \times c_{p2} \times (T_b - T_a) + M_2 \times H_L}{H_c \times W} \quad (1)$$

where  $M$  is the initial mass of water in the water pot,  $M_1$  is the mass of the water pot,  $C_{p1}$  is the heat capacity of water,  $C_{p2}$  is the heat capacity of the water pot,  $M_2$  is the mass of evaporated water,  $H_L$  is the latent heat of evaporation,  $H_c$  is the high heating value of the rubber wood (3771 cal/gram),  $W$  is the mass of the rubber wood pellets in the stove,  $T_a$  is the initial temperature of the water in the water pot and  $T_b$  is the end temperature of the water in the water pot before the water is evaporated at constant temperature. The values of the thermal efficiency for all runs based on varied air flow ratio are shown in Table 2.

The highest efficiency (58.05%) is achieved by the stove using air flow ratio of 2.44. Even though in average the flame temperature at this ratio is low, insufficient supply of the secondary air forms soot particles in large number. These particles make the emissivity of the flame high which favours the heat radiation from the combustion flame to the base of water pot. In turns, this heat radiation intensifies the heat transfer to the water in the water pot and therefore the water temperature. Because the lack of secondary air supply uniformly occurs across the circumference of the top of the stove, the water temperature is higher than those measured at other air flow ratios (see Figure 5). In terms of the efficiency, this is desired, but as far as the CO emission is concerned, the stove at this ratio is not favourable because it produces high CO emission with the average value of 52 ppm (see Table 1).

The highest thermal efficiency (56.98%) with appropriate CO emission of 32 ppm in average is achieved at air flow ratio of 13.43. This is slightly higher than that achieved by the ratio of 6.29, i.e. 52.8% though the maximum flame temperature at the ratio of 13.43 was lower, i.e. 516.8°C. As discussed previously in Section 6.1 there may be non-uniformity of the secondary air supply on the circumference of top of the stove which exerts the formation of soot at circumferential positions where the air primary flow is low indicated visually by the yellow flame and intensifies heat radiation [10]. The high thermal efficiency was the result of the combined effect of heat convection and radiation, but at the ratio of 13.43, the heat radiation seems more predominant which intensifies the water temperature above the water temperature measured at the air flow ratio of 6.29 (see Figure 5). At the air flow ratio of 20.6, as discussed in Section 3.1, due to the uniformity of the secondary air supply across the circumference of the top of the stove, the soot formation can be lessened and the combustion flame is engulfed with excessive air. As a result, the thermal efficiency at this ratio is less than that at the ratio of 13.43 (see Table 2).

Table 2. Thermal efficiency at different values of ratio of secondary air to primary air flowrates (air flow ratio)

Air flow ratio	Thermal efficiency (%)	Maximum flame temperature (°C)
6.29	52.8	739.3
20.6	36.32	441.7
13.43	56.98	516.8
2.44	58.05	360.8

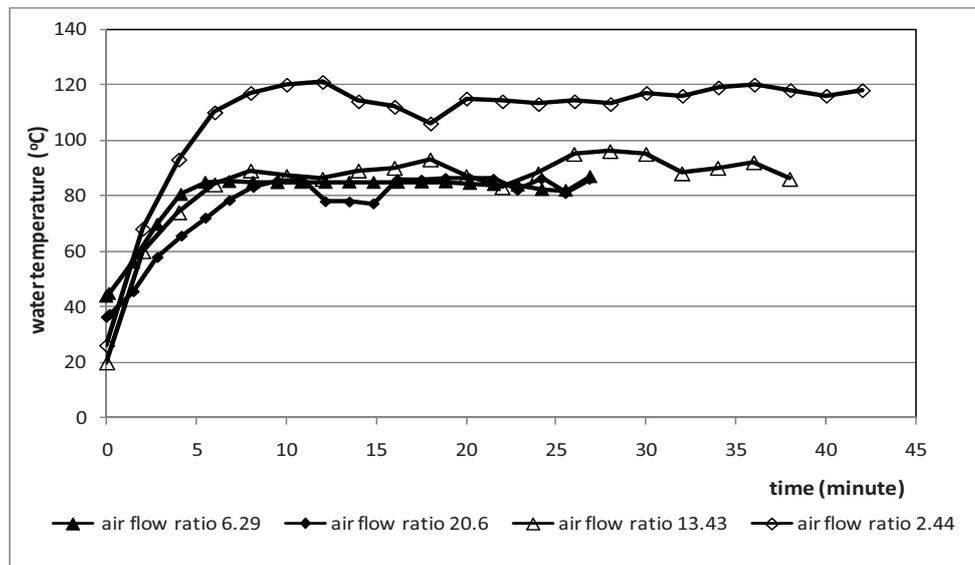

Figure 5: Water temperature measured during the course of the combustion

#### 4. CONCLUSIONS

This experiment gives some conclusions as follows:

1. The stove operating with air flow ratio of 6.29 results in the lowest CO emission which reaches 14 ppm in average.
2. The stove operating with air flow ratio of 6.29 results in the highest average flame temperature which reaches the peak temperature of 739°C.
3. The stove operating with air flow ratio of 2.44 results in the highest efficiency of 58.05%.
4. It seems that by exploiting a condition where the formation of soot is intensified, the thermal efficiency may be improved.

### ABSTRACT

Processing of crude *Jatropha* oil (CJO) for biodiesel produced waste, one of them was capsule husk about 30-80% weight of the *Jatropha curcas* Linn (JcL) fruit. Utilization of dried capsule husk (DH-JcL) for organic fertilizer directly was not recommended due to high C/N ratio value (40-69). Fermentation process could be solved these problems. This paper reports the study of culture enrichment to increase microbes present on JcL substrate with some additives. The study was conducted at the research garden of PT Bumimas Ekapersada, Bekasi, West Java in November - December 2012 using DH-JcL of JatroMas cultivars in toxic category as material. There were three variable, they were the control, 3% urea and 5% CJO as additive. Observation variables were biogas production volume, pH and temperature in the effluent. The results showed that effluent pH average about 5 and daily average biogas production showed that 56.64, 43.13 and 32.63 cc biogas/g VS for 3% urea, 5% CJO and the control respectively. The study concluded that urea and CJO was appropriate as additive for culture enrichment due to they could increase the biogas production of DH-JcL with the best result was achieved by 3% urea as additive.

### Keywords

Biogas, capsule husk, *Jatropha curcas* Linn, urea, Crude *Jatropha* Oil (CJO)

## 1. INTRODUCTION

*Jatropha curcas* Linn (JcL) was believed as biofuel crops renewable energy. In the other side, the facts show that the process of making Crude *Jatropha* Oil [CJO – Oil] (the biodiesel raw materials) were not environmental friendly. There are a number of waste, namely sludge CJO (S-CJO), seed cake (*Jatropha curcas* press cake, *Jatropha curcas* defatted waste), and capsule husk (*Jatropha* fruit coat, fruit husk, hulls, shell, fruit shell, peel, fruit encapsulation) that were stacked in the field and / or thrown into the river. Stacking JcL waste on land would have negative impact on global warming due to greenhouse gases (GHG). Similarly with discharging to rivers would pollute the environment, one of them was negative impacts on fish life. As an agricultural waste for recycling soil nutrients and minerals, JcL seed cake (SC-JcL) was used as organic fertilizer [1, 2].

However capsule husk (DH-JcL) was not recommended as organic fertilizer with direct application (fresh). The quality standards of organic fertilizer according to the Minister of Agriculture number 28/Permentan/OT.140/2/2009 said that C/N ratio for organic fertilizer was 15-25, whereas the DH-JcL C/N ratio was 40-69 [3]. Fermentation is one of the threatment to reduce the C/N ratio. Anaerobic fermentation is more efficient than aerobic, besides producing organic fertilizer (solid and liquid), it will produce gaseous bio-fuels, namely biogas.

SC-JcL was also recommended as biogas substrate due to the biogas production was made from seed cake higher than cow dung [4, 5], but DH-JcL utilization as substrate having a number of constraints. DH-JcL float as biogas substrate due to its density is relatively low, so the fermentation process was imperfect. DH-JcL residual fibers fermentation also clogs at the inlet and outlet of biogas digester [6, 7]. DH-JcL does not suitable as biogas substrate due to slow degradation [8, 9]. DH-JcL volume is relatively large which is about 30-80% of the weight of fresh fruits [10, 11] or 8-15% of the dry weight [12]. In consideration to increase revenue of JcL farmer and to push JcL development as biodiesel feedstock, the series of study has been done which use DH-JcL as biogas substrate. The study was conducted in the laboratory and field scale with 6 m<sup>3</sup> digester capacity [3, 13]. The series of studies were expected to push the development of two bio-fuels types, biogas and non-edible oil-based biodiesel.

This paper reports one part of the series to increase the biogas production from DH-JcL with enrichment culture which conducted by increasing number of existed microbial at the waste by adding some of the required microbial nutrients for growth [14]. One of required biogas substrate is contains the C/N ratio of 16-25 [15] or 20-30 [16, 17] or 25-32 [18]. Based on these requirements, DH-JcL with the C/N ratio of 40-69 [3] was not suitable as a substrate. On the substrate with high C/N ratio (low nitrogen) will occur reduce biomass growth and reduce degradation [18], unstable pH and easy of pH decreasing [19], imperfect conversion of carbon to methane which indicated by high CO<sub>2</sub> of biogas content [19, 20, 21], and insufficient microbial growth for methane production [22]. Urea was suggested as nitrogen source [23, 24]. Using 0.04-6% urea result positive impacts in single substrate cassava tubers, rice straw, cattle dung and / or substrate mixtures of meal waste, mixture of chicken feces and corn stalks, wood ash and poultry droppings, cattle slurry and pressed sugar cane stalk [25, 26, 27]. Another study proposed that 3% urea was better than 6% [28, 29]. Culture enrichment action is also called co-digestion technology which is different types of wastes are treated together [30, 31]. Because of urea is not waste and it is deliberately added to substrate for increasing the biogas production, it is called as additive [32, 33, 34, 35] or supplement [36, 37] or amendment [38]. Mixtures substrate is identical with enrichment culture because it adds co-substrate for nutrient addition in the substrate. Some of study suggest a number of studies on the co-digestion positive impacts [36, 39]. The materials are rich in fat, can help to improve the quality and quantity of the biogas [40, 41, 42, 43, 44, 45]. Related JcL and CJO, a preliminary study reported that DH-JcL and 10% S-CJO as a co-digestion can increase biogas production [46].

## 2. METHODS

The preliminary study was conducted at the research garden of PT Bumimas Ekapersada, Bekasi, West Java in November - December 2012. On this laboratory scale, a liter glass laboratory digester was used as one-stage digester which was compiled completely randomized design (CRD) with three replications in water bath on 32 °C as in Figure 1. The materials are DH-JcL of JatroMas cultivars in toxic category as substrate which mixed with water in 1: 8 as the control treatment. The 1<sup>st</sup> treatment was using 3% urea (w/w) and the 2<sup>nd</sup> was using 5% CJO (w/w) as additives. As the starter was used semi-artificial inoculum [47] from the DH-JcL digester slurry. Hydraulic retention time was set for five weeks. Every day 4 g DH-JcL and 32 cc water as a feed was added and removed from the digester based on draw and fill method [48]. Observation variable were biogas production volume (water displacement method) [49], pH (pH meter) and temperature (digital thermometer) in the effluent.

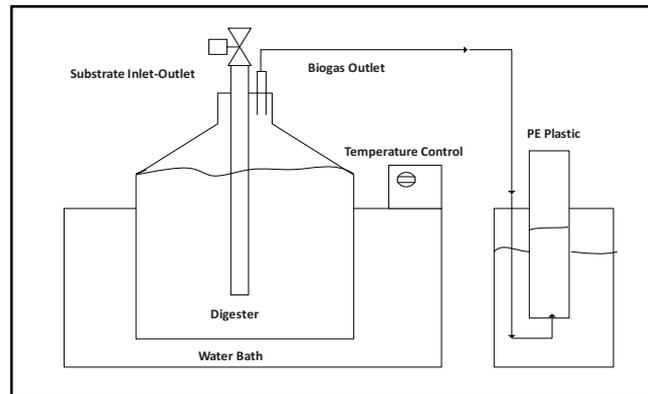

Figure 1: Schematic Research Digester

### 3. RESULTS AND DISCUSSION

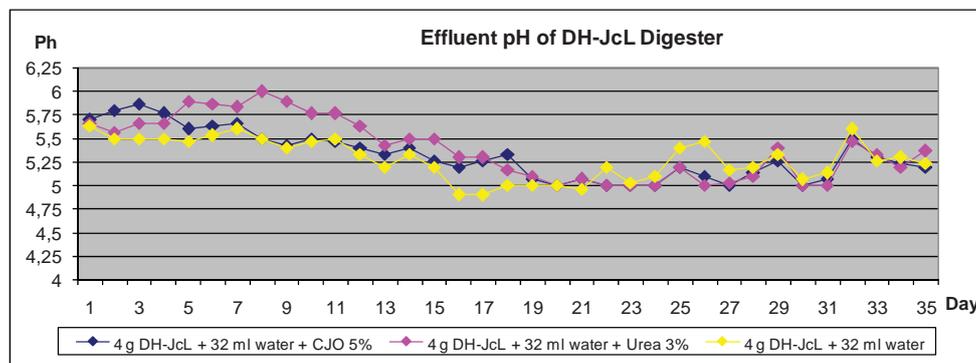

Figure 2: pH curves of DH-JcL digester effluent with three treatments

Observations of 3rd pH treatment for 5 weeks were presented in Figure 2. Figure 2 shows that the average pH in the effluent with three treatments tended to decrease from 2<sup>nd</sup> week to 5<sup>th</sup> week. The average pH for five weeks, the treatment 1 (CJO as an additive), treatment 2 (urea as an additive), and controls were 5.32, 5.43 and 5.23 respectively. These data support previous studies which showed pH at one stage DH-JcL digester is not ideal conditions for biogas microbial growth, especially methanogenic bacteria [46]. Optimal pH for methanogenic bacteria is 6.7 to 7.5 [40], so pH conditions in Figure 2 was marginal category [50]. This is one issue on utilization DH-JcL substrate due to DH-JcL properties is very high buffering capacity such as another JcL waste (SC-JcL) [46]. The pH average of urea treatment was relatively higher than the others, especially in 5<sup>th</sup> – 17<sup>th</sup> day. It was similarly with the pH average of CJO treatment in 2<sup>nd</sup> – 5<sup>th</sup> day. These data indicate that urea and CJO able to provide better conditions than the controls. The daily production average of biogas on weekly recapitulated was shown in Table 1.

Table 1. Daily biogas production (cc/g VS) of DH-JcL digester with three treatments

Treatment	1 <sup>st</sup> week	2 <sup>nd</sup> week	3 <sup>rd</sup> week	4 <sup>th</sup> week	5 <sup>th</sup> week	Average
5% CJO	81.40	29.53	51.11	31.57	22.03	43.13
3% Urea	106.77	46.19	59.82	41.27	29.15	56.64
Control	52.24	21.96	21.2	35.97	31.8	32.63

Table 1 shows that the urea treatment produces the highest number of biogas production average at 56.64 cc/g VS. At weekly biogas production details, it appears that the urea treatment is always the highest except at 5<sup>th</sup> week. CJO treatment generate 2<sup>nd</sup> rank of production average at 43.13 cc/g VS. CJO additives were able to produce biogas in 2<sup>nd</sup> rank, especially in 1<sup>st</sup> – 3<sup>rd</sup>

week. The data in Table 1 support the Figure 2, the urea treatment pH effect of biogas production is relatively higher than the others. The nitrogen addition through urea as enrichment culture action is useful to add nutrients for microbial growth which impacting for increase biogas production. The same conclusions were obtained at Sri Lanka in the urea treatment of rice straw which decrease C/N ratio from 80 to 30 [33]. The high C/N ratio has negative impact on the protein formation which needed for microbial growth due to the low nitrogen in the substrate [40].

Table 1 shows that the CJO treatment is the 2<sup>nd</sup> rank of the biogas average production, especially in the 3<sup>rd</sup> week which producing two times higher than the control. It has similarity with the addition of 5% fish oil which will double the biogas productions from manure or sewage sludge [45] and the addition of 5% oil bleaching earth (which has high lipids content) in hog manure substrate [44]. The correlation graph between biogas methane content and carbon chain length reveals that the higher C atoms in the substrate, then the higher the methane content of the biogas substrate [51]. Lipids C<sub>57</sub>H<sub>104</sub>O<sub>6</sub> potentially CH<sub>4</sub> yield on 1.014 l/g VS with CH<sub>4</sub> levels at 70% was compared to the potentially CH<sub>4</sub> of Carbohydrate C<sub>6</sub>H<sub>10</sub>O<sub>5</sub> on 0.415 l/g VS with CH<sub>4</sub> levels at 50% [43]. Fats will produce biogas on 1300 l/kg TS with CH<sub>4</sub> levels at 72% was compared to the carbohydrate that produces 746 l/kg TS with CH<sub>4</sub> levels at 50% [52]. Typical gas compositions for carbohydrate feeds are 55% methane and 45% carbon dioxide, while the gas contains as much as 75% methane for fats [53].

However, there are problems such as reduction in daily average biogas production. Daily biogas production is decrease from the 1<sup>st</sup> week to the 5<sup>th</sup> week with CJO, urea, and control treatment on 72.94%, 72.70%, and 39.15% respectively. Production decrease on additive treatment is greater than control. This is presumably due to the enrichment culture treatment impact to the accumulation of organic acids. The accumulation will form a weak acid buffer that will cause the pH became lower as shown in Figure 2. It show that the additive urea and CJO are more stimulate the development of fermentative bacteria which not balanced by the rate of growth and development of methanogenic bacteria. With fats, the hydrolysis (the first stage of biogas fermentation) proceeds more rapidly with increasing emulsification (bioavailability), so that the acetogenesis (third stage of biogas fermentation) is limiting [40]. Addition of urea in cattle dung digesters at various organic loadings has been reported to be beneficial but has certain limitations, i.e. continuous addition of urea leads to decrease in biogas production and also ammonia toxicity [54]. pH decrease affects to the majority of methanogenic bacteria, are very sensitive with low pH, will die [55]. At pH < 6.5, only one genus of methanogenic bacteria (from 7 genus of methanogenic bacteria) is able to life namely Methanosarcina [40]. This affects the biogas production decreased from week to week as shown in Table 1. Further examination Figure 1 and Table 1 indicate other problems of DH-JcL substrate as shown on Table 2.

Table 2. pH values and daily biogas production (cc/g VS) average of DH-JcL digester with three treatments in the 1<sup>st</sup> week

Treatment	pH	Biogas Production
5% CJO	5.71	81.4
3% Urea	5.73	106.77
Control	5.63	52.44

Table 2 shows that the observed pH and average daily production in the first week. pH values show flat at about 5, but the average biogas productions show relatively different. The urea treatment produces biogas at 2.03 times higher than the control in average. It show that, the pH value is not the appropriate properties for monitoring biogas fermentation especially for those containing highly buffered substrates such as agricultural wastes [50, 56.57, 58].

#### 4. CONCLUSION

This preliminary study concluded that 3% urea (w/w) and 5% CJO (w/w) was able to used as additives due to it could increase the biogas production of DH-JcL for each 132% and 173%. More research/study is needed to solve the decrease in the biogas production of DH-JcL as a result of the organic acids accumulation. At the other side, it was taken a cheap and easy way tool to monitor the biogas fermentation process as a replacement or companion of pH values.

## ABSTRACT

Nitrous oxide (N<sub>2</sub>O) gives highest contribution in global warming and also categorized as a dangerous gas. Removal of N<sub>2</sub>O could be achieved by biofilter technology. Activated Lampung Natural Zeolite was utilized as filter media because of its high porosity. As comparison, activated carbon was also utilized due to its great surface area. *Nitrobacter winogradskyi* was used to reduce N<sub>2</sub>O into harmless gas N<sub>2</sub>. This research aims to study the effect of bacteria culture addition in biofiltration and to determine the optimum operation condition by adjusting concentration of synthetic nutrient solution to 0.37%, 0.31%, 0.27%, 0.23%, 0.21% weight wt/wt and initial pH of media to pH 4, 5, 6, 7, 8. Concentration of synthetic nutrient solution studied because aerobic microorganisms need nutrients for growth as energy source and oxygen or growth substrate. Initial pH of media studied because optimum pH affects bacteria growth speed hence affects pollutant removal efficiency. In this experiment, biofilter was operated for 24 hours with gas concentration was 15000 ppm N<sub>2</sub>O in air and gas flow rate was maintained at 88 cc/minute. Removal efficiency optimum achieved by 0.31% (wt/wt) and initial pH 7 for both filter media. From BET and TPC, activated carbon has better capability for biofiltration media than natural zeolite.

## Keywords

Biofilter, Natural Zeolite, Activated Carbon, Nitrous oxide, *Nitrobacter winogradskyi*

## 1. INTRODUCTION

N<sub>2</sub>O has a significant role in causing global warming, where biggest contribution given by agricultural by-product, also biomass burning and land use. Although emission from N<sub>2</sub>O gas is lower than CO<sub>2</sub>, however N<sub>2</sub>O gas could absorb heat 320 times stronger than CO<sub>2</sub> in atmosphere [1]. Beside that, N<sub>2</sub>O gas could stay longer in atmosphere and more stable than CO<sub>2</sub> or CH<sub>4</sub> gas [2].

Biofilter is reactor in which pollutant air stream is passed through a porous packed bed on which a mixed culture of pollutant-degrading organism grow in a biofilm on the surface of a media [3]. The benefit of biofilter compared to other methods are low investment cost, stable if operated in relative long time, and has high degradation ability of pollutant gas, and could convert a mixed of organic and inorganic into harmless oxidation product [4].

In this research natural zeolite was chosen as filter media because its stable structure and high porosity [5]. Activated Carbon was utilized as filter media due to wide surface area and high adsorption [6]. Beside that, *Nitrobacter winogradskyi* was used to oxidize N<sub>2</sub>O into harmless N<sub>2</sub> [7].

This research studied biofiltration ability of nitrous oxide pollutant by *Nitrobacter winogradskyi* bacteria on natural zeolite and activated carbon as inoculated filter media with adjusting operation condition which was synthetic nutrient solution and initial pH of media. This research also studied the effect of *Nitrobacter winogradskyi* inoculation to pollutant degradation ability, and growth of *Nitrobacter winogradskyi* along preparation and biofiltration. The main goal of this research is to determine better biofiltration media between natural zeolite and activated carbon on N<sub>2</sub>O removal, from its function as filter media and microbes growth media.

## 2. METHODOLOGY

### 2.1 Inoculum Preparation

Preparation of bacteria culture consist of culture of bacteria on agar, broth, and synthetic media, include inoculation of bacteria into natural zeolite. Synthetic nutrition is useful as source of carbon and inorganic nutrition for bacteria along biofiltration and as source of moisture content for filter media [8]. Synthetic media composition for *Nitrobacter winogradskyi* [9] are NaNO<sub>2</sub> (1

gram), NaCl (0.3 gram),  $K_2HPO_4$  (0.5 gram),  $MgSO_4 \cdot 7H_2O$  (0.5 gram),  $MnCl_2$  (0.02 gram),  $FeSO_4$  (0.005 gram) in aquadest (1 liter). Inoculation of biofilter media with adapted microbial aggregates greatly reduces adaptation time of biofilter [10].

## 2.2 Lampung Natural Zeolite Activation

Natural zeolite used in this research was clinoptilolite from CV Mina Tama, Bandar Lampung, Indonesia which trade name is ZKK (Zeo Kap Kan) and particle size is P-4 range 5-7.5 mm. Zeolite activated by water vapour removal and dealumination using HF. Dealumination could increase porosity and adsorption capacity, also extend adsorber life [11].

## 2.3 Activated Carbon Reactivation

Activated carbon used in this research was from CV Sari Hikmah Nusantara, Depok, Jawa Barat, Indonesia which particle size is  $\pm 4$  mm. Activated carbon reactivated by water vapour removal.

## 2.4 Biofiltration Experiment

Biofilter system used in this experiment had been used by Utami et al. [2009] with addition of *mass-flow regulator* and *thermo-hygro meter* installation on biofilter column as shown in Figure 1.

Biofilter equipment used was laboratory scale equipment with height 120 cm, outer radius 4 cm, and column thickness 0.325 cm. *Down-flow mode* stream used to increase control of moisture content [13]. Concentration of  $N_2O$  gas was 15000 ppm in the air and flow rate was 88 cc/minute. Biofiltration was run with *batch* system for 24 hours. Gas was flowed through filter media which had been inoculated by bacteria.  $N_2O$  gas then will be adsorbed by biofilm and filter media will be oxidized by bacteria which live inside that biofilm. Mass of filter media used was 4 kg for height of filter media inside column achieved 100 cm.

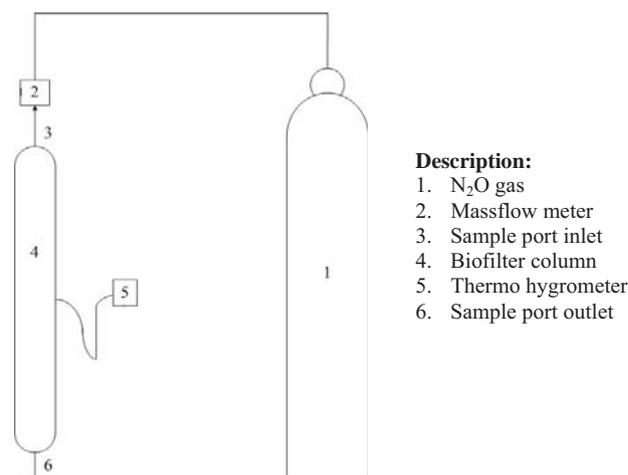

Figure 1: Schematic diagram of biofilter

## 2.5 Analytical Method

Concentration of inlet and outlet gas from biofilter column analyzed using Gas Chromatography (GC). Temperature and moisture content of filter media monitored using *thermo-hygro meter*. Amount of bacteria counted using Total Plate Count (TPC) method. Morphology of filter media analyzed using Scanning Electron Microscopy (SEM) and Field Emission Scanning Electron Microscopy (FESEM).

## 3. RESULT AND DISCUSSION

### 3.1 Biofilter Performance Test in Reducing $N_2O$

In this research, one of the factors that influence biofiltration is amount of nutrient. Aerobic microorganism needs nutrient for growth in addition to oxygen and an energy source or growth substrate. The inlet gas contaminant, referred to as the substrate, is usually both the microbe's energy and carbon source for building cellular material [14].

In the other hand, initial pH of media was also studied because optimum pH affects bacteria growth speed hence affects pollutant removal efficiency [15]. Beside that, ideal pH of filter media depends on reduced pollutant and characteristic of bacteria ecosystem [16].

Variation of concentration of synthetic nutrient solution used is 0,37%, 0,31%, 0,27%, 0,23%, 0,21% (w/w). Variation of initial pH of media used is 4, 5, 6, 7, 8. The effect of concentration of synthetic nutrient solution and initial pH of media variation can be obtained at removal efficiency.

For concentration of synthetic nutrient solution variation, highest average of removal efficiency for 24 hours achieved by 0.31% (wt/wt) concentration of nutrient solution for both media. Therefore, 0.31% (wt/wt) was optimum concentration of nutrient solution for biofilter system in this experiment.

In the other hand, for initial pH of media, highest average of removal efficiency for 24 hours achieved by initial pH 7 for both media. Therefore, initial pH 7 was optimum initial pH for biofilter system in this experiment. This was appropriate with optimum pH for biological activity is around 7 [17], where a near neutral pH provides widest spectrum of bacterial activity [18].

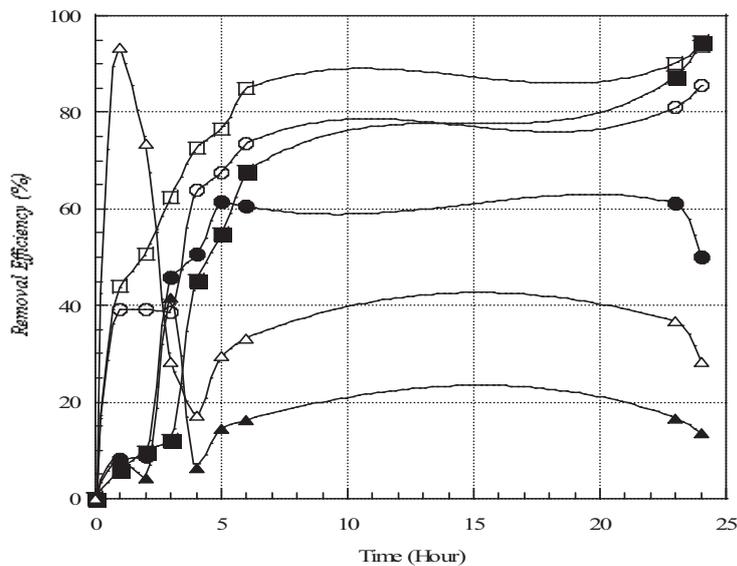

Figure 2. N<sub>2</sub>O Removal Efficiency (RE) at 0,31% (wt/wt) concentration of synthetic nutrient solution using natural zeolite (●) and activated carbon (○); and at initial pH media 7 using natural zeolite (■) and activated carbon (□); and without microbes inoculation using (▲) natural zeolite and (△) activated carbon

Curve in Figure 2 shows that pollutant removal efficiency in the earlier hours were low because microbes exposed to new environment may require adaptation time before they start vigorous biodegradation [19]. Figure 2 also show effect of microbes inoculation to pollutant degradation ability. Adsorption process on filter media without microbes inoculation in the earlier hours were still unstable due to start-up phase [20]. Inoculation of bacteria succeeded increasing average of removal efficiency in all variations. Hence, inoculation of bacteria is one of important parameter in determining biofiltration performance. This was because in the biofiltration system, the pollutant are removed due to biological degradation rather than physical straining. Once the pollutant are adsorbed on the biofilm or dissolved in the water layer surrounding the biofilm, the contaminants are adsorbed and biodegraded by microbes in the biofilm, pollutant may also be adsorbed at the surface of the packing [3].

Table 1: Average and Optimum Removal Efficiency of N<sub>2</sub>O by Biofiltration Media Inoculated by *Nitrobacter winogradskyi* with Optimum Operation Condition of Synthetic Media

Removal Efficiency (%)	Concentration of Synthetic Nutrient Solution 0,31% (wt/wt)		Initial pH 7	
	Lampung Natural Zeolite	Activated Carbon	Lampung Natural Zeolite	Activated Carbon
Average	61.1	43.6	47.29	71.89
Optimum	61.5	85.7	94.73	93.8

Table 1 shows that the optimum removal efficiency in biofiltration using Lampung Natural Zeolite media reached 61.5% with 0.31% (wt/wt) concentration of nutrient solution, whereas the optimum removal efficiency in biofiltration using Activated

Carbon reach 85.7% in the same concentration. Both of the media reached the optimum removal efficiency at the same solution concentration. This indicates that 0.31% (wt/wt) concentration of synthetic nutrient solution is the sufficient concentrations that needed by bacteria to reduce N<sub>2</sub>O to get the optimum performance of the biofiltration process. In addition, the concentration of 0.31% (wt/wt) is the suitable conditions for bacteria to reproduce and obtain nutrients.

Moreover, Table 1 also shows the optimum initial pH of media for Lampung Natural Zeolite and Activated Carbon is same which is initial pH 7. This happened because both experiments use the same *Nitrobacter winogradskyi* as degrading microbes. Optimum removal efficiency of N<sub>2</sub>O gas difference is not significant, both have a high value. However, the average value for Activated Carbon is higher than Lampung Natural Zeolite. This is because adsorption at the beginning of biofiltration using activated carbon is better than natural zeolite due to larger surface area as mentioned in Table 2 from BET analysis. Based on Zilli et al. (2003) and Kim et al. (2002), the high pollutant removal in the early stage was mainly due to adsorption onto filter media and mass transfer into aqueous phase, but not due to biodegradation activity of microbes [21, 22].

Table 2: Biofiltration Media Characterization

Parameter	Lampung Natural Zeolite	Activated Carbon
Surface Area (m <sup>2</sup> /g)	1.207 × 10 <sup>2</sup>	2.578 × 10 <sup>2</sup>
Pore Volume (cc/g)	1.810 × 10 <sup>-1</sup>	1.580 × 10 <sup>-1</sup>
Pore Size (Å)	2.999 × 10 <sup>1</sup>	1.226 × 10 <sup>1</sup>

### 3.2 Bacteria Growth Test Result

TPC analyzed by Health and Environmental Engineering Laboratorium, Civil Engineering Department, Engineering Faculty of Universitas Indonesia. TPC analysis in Tabel 3 shows that there were quite significant decreasing of bacteria population in both media media after biofiltration due to lack of synthetic nutrition supply that needed by bacteria to keep growing and oxidizing pollutant. Based on Fu et al. (2011), It is needed to design biofilter system with spray nozzle installation at the top of biofilter column which useful to provide nutrition for bacteria hence microbes population could be kept along biofiltration [23].

Table 3: Amount of Bacteria (CFU/mL) in Biofiltration Media during Preparation and Running

Sampling Time	Concentration of Synthetic Nutrient Solution 0,31% (wt/wt)		Initial pH 7	
	Lampung Natural Zeolite	Activated Carbon	Lampung Natural Zeolite	Activated Carbon
At 0 hour incubation at synthetic media	2.5 × 10 <sup>7</sup>	12 × 10 <sup>8</sup>	3 × 10 <sup>13</sup>	26 × 10 <sup>9</sup>
After 48 hour incubation at synthetic media	1.64 × 10 <sup>9</sup>	5 × 10 <sup>11</sup>	2.2 × 10 <sup>12</sup>	49 × 10 <sup>10</sup>
Before biofiltration	1.85 × 10 <sup>12</sup>	121 × 10 <sup>12</sup>	2.5 × 10 <sup>14</sup>	22 × 10 <sup>12</sup>
After biofiltration	5.25 × 10 <sup>10</sup>	24 × 10 <sup>11</sup>	20 × 10 <sup>11</sup>	45.5 × 10 <sup>10</sup>

Table 4: Amount of Bacteria (CFU/mL) in Biofiltration Media during Incubation in Synthetic Media

Incubation Time (Hour)	Lampung Natural Zeolite	Activated Carbon
t = 0	3 × 10 <sup>4</sup>	1.1 × 10 <sup>6</sup>
t = 24	3.3 × 10 <sup>5</sup>	3.3 × 10 <sup>6</sup>
t = 48	3.8 × 10 <sup>6</sup>	4.2 × 10 <sup>7</sup>
t = 72	4 × 10 <sup>7</sup>	8 × 10 <sup>8</sup>

TPC (Total Plate Count) also done to determine colony of microbes which attached on surface of natural zeolite and activated carbon when being incubated in synthetic media during 0, 24, 48, and 72 hours. Based on TPC result shown on Table 4, activated carbon has 10<sup>1</sup> CFU/mL greater amount of bacteria than natural zeolite. This means activated carbon is more favorable as growth media for *Nitrobacter winogradskyi* than natural zeolite. It is predicted due to its large surface area, hence activated carbon could adsorb more water, then increase its moisture level. Park (2009) stated that microbes grow excellent on wet surface [24].

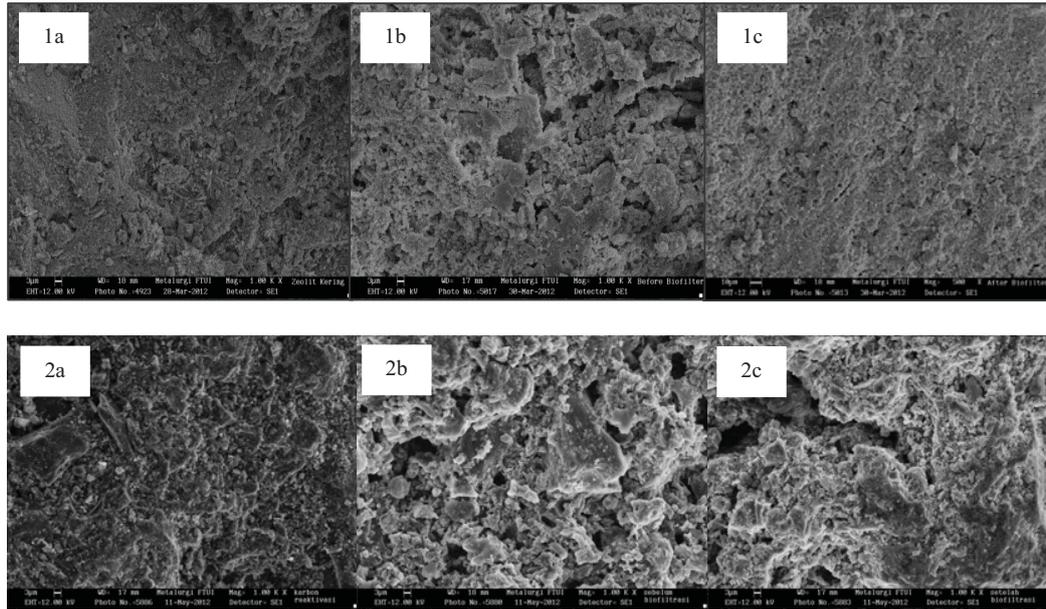

Figure 5. Morphology of biofiltration media on (1) Lampung Natural Zeolite and (2) Activated Carbon surface using SEM: (a) zeolite without bacteria inoculation, (b) before biofiltration, and (c) after biofiltration

Scanning Electron Microscope (SEM) test did to support TPC data that function to see the morphological change on filter media due to bacteria growth. SEM analyzed with 1000 times of magnification by Test Laboratorium, Metallurgical and Material Engineering, Engineering Faculty of Universitas Indonesia. SEM result in Figure 5 shows that biofilms grow thicker along biofiltration. Nevertheless, biofilm thickness was not equal with increasing amount of microbes population. This was due to biofilm accumulation is affected by presence of substrate concentration and product metabolism, also by biomass [25, 26]. Beside that, there was inactive biofilm because of decreasing of microbes population along biofiltration. However based on GC result, increasing of pollutant removal efficiency happened along biofiltration for 24 hours operation. It was predicted that plenty of active fraction and specific surface on biofilm were available.

Figure 6 shows morphology of biofiltration media that analyzed by Field Emission Scanning Electron Microscope (FESEM). FESEM could produce clearer image and has high resolution until 1.5 nm which is 3 until 6 times better than conventional SEM. From FESEM image, it is shown that microbes were attached on both biofiltration media which marked by red circle.

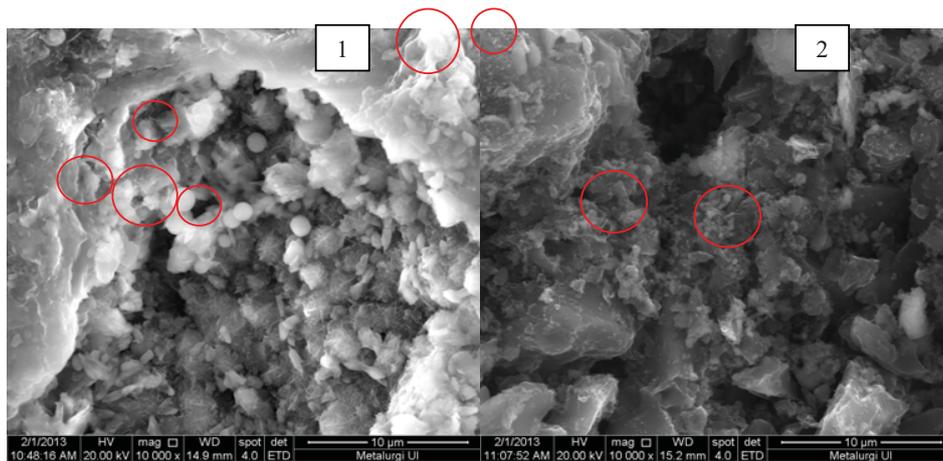

Figure 6. Morphology of biofiltration media on (1) Lampung Natural Zeolite and (2) Activated Carbon using FESEM after incubated for 72 hours in synthetic media

#### 4. CONCLUSION

Optimum concentration of synthetic nutrient solution was 31% (wt/wt) and optimum initial pH of media was 7 for both Lampung Natural Zeolite and Activated Carbon. Optimum *Removal Efficiency* at 31% (wt/wt) concentration of synthetic nutrient solution for Lampung Natural Zeolite was 61.5% with average was 61.1% for 24 hours operation; for Activated Carbon was 85.7% with average was 43.6% of 24 hours operation. Optimum *Removal Efficiency* at initial pH 7 for Lampung Natural Zeolite was 94.73% with average was 47.29% for 24 hours operation; for Activated Carbon was 93.8% with average was 71.89% of 24 hours operation. Bacteria inoculation increased *Removal Efficiency*. BET shows that activated carbon has 2.14 larger surface area than natural zeolite. TPC shows that activated carbon has  $10^1$  CFU/mL greater amount of bacteria than natural zeolite. Hence, activated carbon has better capability as biofiltration media than natural zeolite in reducing  $N_2O$  and inoculated by *Nitrobacter winogradskyi*.

### ABSTRACT

*Chlorella vulgaris* is one species of microalgae which has a lipid content of 10.2% so it becomes one of raw material in biodiesel production. In biodiesel production, there are many kind of reactions that can be used. The first reaction is esterification reaction and the second reaction is transesterification reaction. Sometimes, people use esterification then followed by transesterification. Each of reactions give different yield and the oxidative stability of biodiesel. Therefore, we need to find which reaction can give the highest yield of biodiesel and the best oxidative stability. In this study, lipid microalgae were synthesized by two methods which are esterification-transesterification reaction method and transesterification reaction method. Esterification-transesterification reaction method produces biodiesel about 76.43% and contains 63.25% saturated methyl esters. The transesterification reaction method can produce about 85.5% with saturated methyl esters composition is 60.25%. Saturated methyl esters composition indicates the oxidative stability of biodiesel. So, transesterification reaction method can produces higher biodiesel but has lower oxidative stability compared to esterification-transesterification reaction method.

### Keywords

*Chlorella vulgaris* , biodiesel, esterification-transesterification reaction, transesterification reaction.

### 1. INTRODUCTION

Nowadays, fossil fuel still becomes main energy source for people in the world. It makes many new problems such as the issue that fossil fuel can't fulfill the need of energy in the next time, the price is increasing time by time, and fossil fuel can release CO<sub>2</sub> to atmosphere which causes global warming. Based on those problems, the new energy sources must be developed soon. One kind of new energy source is biodiesel. Biodiesel is fuel that made from vegetable oil or animal lipid which has character like diesel oil. Biodiesel can be made by transesterification or esterification reaction with acid or base catalyst. Biodiesel is renewable energy and it can be made from many sources like corn, soybean, sunflower seed, microalgae, etc.

Microalgae is used as raw material for biodiesel for some reasons. The first reason is microalgae has high lipid content. The second reason is microalgae is not an edible plant so it won't make new problem like famine. The third reason is microalgae easy to be grown in Indonesia. Microalgae *Chlorella vulgaris* has attracted attention of many researchers as a potential raw material for biodiesel due to the high content of lipid. *Chlorella vulgaris* has an average lipid content of 10.2% [1] with lipid productivity is 11.2 to 40.0 mg/L/day [2]. Biodiesel from microalgae is the third generation from biofuel [3].

Many research has done to find the best condition to make biodiesel from microalgae because there are many factors may effect it [4,5,6,7,8]. One of them is the reaction used in biodiesel production. In biodiesel production, there are many kind of reactions that can be used. The first reaction is esterification reaction and the second reaction is transesterification reaction. Sometimes, people use esterification then followed by transesterification. Each of reactions give different yield and the

oxidative stability of biodiesel. Therefore, we need to find which reaction can give the highest yield of biodiesel and the best oxidative stability.

## 2. MATERIAL AND METHODS

This research has been done in Bioprocess Laboratory, Department of Chemical Engineering University of Indonesia. The type of microalgae that is used was domestic microalga, *Chlorella vulgaris*, which cultivated in Walne medium. After cultivated for 204 hours, *Chlorella vulgaris* is separated from its medium using centrifugation method. After that the cake is taken and dried in oven at 60°C. Dried microalgae then extracted by Soxhlet method using n-Hexane at 80°C for 6 to 8 hours. After that, the lipid extracted is dried in oven at 100°C. The Soxhlet's apparatus can be seen in Figure 1 below.

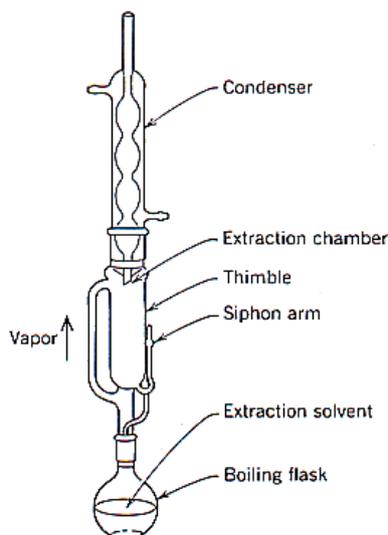

Figure 1: The Soxhlet's apparatus

In this study, the lipid of microalgae were synthesized by two methods. The first one is esterification with methanol and acid catalyst ( $\text{H}_2\text{SO}_4$ ) at 55°C for 1 hour then followed by transesterification with methanol and alkaline catalyst (KOH) at 55°C for 1 hour. The second method directly performed transesterification with methanol and acid catalyst at a temperature of 90°C for 40 minutes. In esterification-transesterification reaction method, molar ratio for lipid to methanol is 1:600 with the amount of  $\text{H}_2\text{SO}_4$  is 1 ml and KOH is 0.01 grams. For transesterification reaction method, the number of methanol is 3.7 ml and  $\text{H}_2\text{SO}_4$  is 0.3 ml. The apparatus for the reaction can be seen in Figure 2 below.

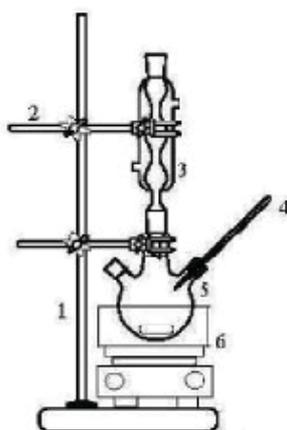

Figure 2: The apparatus for biodiesel reaction

The content of Fatty Acid Methyl Esters (FAME) produced in this study is measured using Gas Chromatography-Mass Spectroscopy (GC-MS). Beside that, the yield of biodiesel produced is measured also.

### 3. RESULTS AND DISCUSSION

The first result that will be discussed in this study is the yield of biodiesel produced from esterification-transesterification reaction method compared to transesterification reaction method. The result is shown in Figure 3 below.

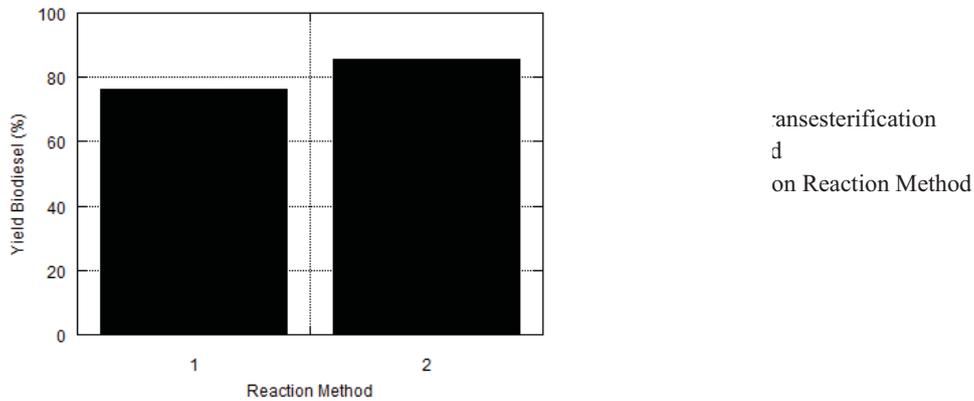

Figure 3: Yield biodiesel between esterification-transesterification reaction and transesterification reaction

Figure 3 show the comparison between two kind of reaction used in biodiesel production. The first bar is esterification-transesterification reaction method and the second bar is transesterification reaction method. Esterification-transesterification reaction method produce the yield of biodiesel about 76.43% compared to the lipid content before reaction. The second reaction method (transesterification) can produce biodiesel about 85.5% of biodiesel produced. From that result, we can conclude that transesterification reaction method may give higher biodiesel yield than esterification-transesterification reaction method. Beside that, transesterification reaction method provide shorter biodiesel production time.

The second result from this study is composition of fatty acid methyl ester. The composition of methyl esters from biodiesel are different depend on the method used. The composition of methyl esters from that two methods is shown in Table 1 and Table 2 below. Table 1 is composition of methyl esters from esterification-transesterification reaction method and Table 2 is composition of methyl esters from transesterification reaction method.

Table 1: Composition of methyl esters from esterification-transesterification reaction method

Composition	Amount (%)
Myristic acid methyl ester	1.55
Palmitic acid methyl ester	57.75
Stearic acid methyl ester	4.22
Oleic acid methyl ester	33.26
Linoleic acid methyl ester	3.22

Table 2: Composition of methyl esters from esterification-transesterification reaction method

Composition	Amount (%)
Methyl 12-methyltetradecanoate	0.76
Palmitic acid methyl ester	56.34
Palmitoleic acid methyl ester	1.55
9,12-hexadecadienoic acid methyl ester	2.95
4,7,10-hexadecatrienoic acid methyl ester	1.22
Heptadecanoic acid methyl ester	0.7
7-hexadecenoic acid methyl ester	1.90
Stearic acid methyl ester	3.21
Linoleic acid methyl ester	25.79
9,12,15-octadecatrienoic acid methyl ester	1.88
11-octadecenoic acid methyl ester	3.72

The comparison of methyl ester composition from esterification-transesterification reaction method and transesterification method can be seen in Table 3 below.

Table 3: Comparison of fatty acid composition from two transesterification methods

Composition	Amount (%)	
	First Method	Second Method
Myristic acid methyl ester	1.55	-
Methyl 12-methyltetradecanoate	-	0.76
Palmitic acid methyl ester	<b>57.75</b>	<b>56.34</b>
Palmitoleic acid methyl ester	-	1.55
9,12-hexadecadienoic acid methyl ester	-	2.95
4,7,10-hexadecatrienoic acid methyl ester	-	1.22
Heptadecanoic acid methyl ester	-	0.7
7-hexadecenoic acid methyl ester	-	1.90
Stearic acid methyl ester	4.22	3.21
Oleic acid methyl ester	33.26	-
Linoleic acid methyl ester	3.22	25.79
Linolenic acid methyl ester	-	1.88
11-octadecenoic acid methyl ester	-	3.72

From Table 4 we can see that palmitic acid methyl ester is the biggest amount of fatty acid methyl ester from biodiesel produced in two different methods. Palmitic acid is main fatty acid in *Chlorophyceae* microalgae [9]. From those fatty acid methyl esters composition, only myristic acid methyl ester, palmitic acid methyl ester, heptadecanoic acid methyl ester, and stearic acid methyl ester included into saturated methyl ester. So, it can be calculated that the esterification-transesterification reaction method contain 63.52% saturated methyl ester and the transesterification reaction method contain 60.25% saturated methyl ester. Shortly, the comparison of saturated fatty acid methyl ester composition in biodiesel produced from those two methods can be seen in Figure 4 below.

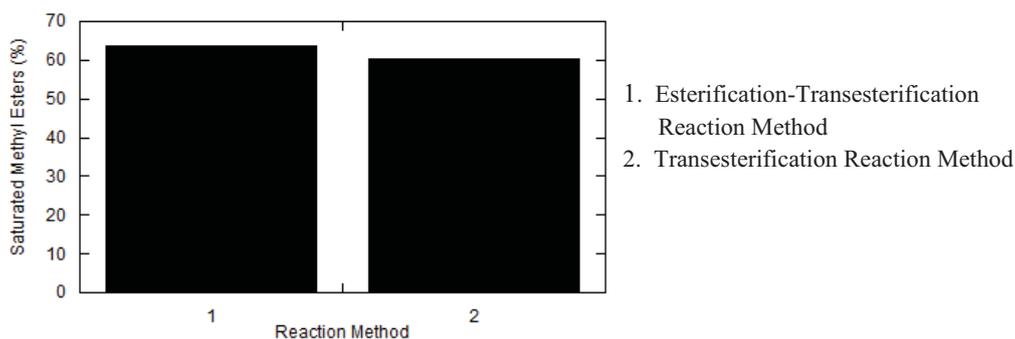

Figure 4: Saturated methyl esters composition between esterification-transesterification reaction and transesterification reaction

Figure 4 is the comparison between two kind of reaction used in biodiesel production. The first bar is esterification-transesterification reaction method and the second bar is transesterification reaction method. Esterification-transesterification reaction method produce the saturated methyl esters about 63.52%. The second reaction method contain saturated methyl esters about 60.25%. The higher saturated methyl esters composition indicates higher oxidative stability. So, we can conclude that esterification-transesterification method provides higher oxidative stability [9].

#### 4. CONCLUSION

From this study, we can conclude that esterification-transesterification reaction method needs more time compared to transesterification reaction method. Esterification-transesterification reaction method produces lower yield of biodiesel but has higher oxidative stability compared to the other reaction method. Higher oxidative stability comes from higher number of saturated methyl ester content in biodiesel.

### ABSTRACT

*Minimizing the natural gas leak along the pipeline is the primary key for pipeline network reliability. There are various methods for the detection of leaks. These methods have been established, but its use is very dependent on the system of each pipeline network. The method used in this study is based on the material balance in some segments of pipeline. The calculation will be performed by pipeline software to identify the amount of gas leaks. In order to confirm the gas leaks, the leak detection method were conducted with some variation in size and location of the leak. The best method considering the response time and low false alarm will be evaluated and selected.*

### Keywords:

*Gas leak, leak detection, pipeline*

### 1. INTRODUCTION

The use of natural gas in Indonesia each year is increasing. Based on data from the year of 2010, the energy consumption for natural gas in industry ranked second or 28.86% from total industrial energy consumption (Syahrial, 2011). Natural gas reserves in Indonesia based on data from the Department of Energy and Mineral Resources in 2010 amounted to 152.89 TCF (Department ESDM, 2010). With the high oil prices, then it is the time for the industry to be able to fully utilize the use of natural gas for fulfilling the energy demand.

Utilization of natural gas is not without obstacles. The unequal distribution of development in Indonesia with the majority of the natural gas reserves away from the center of industry (Figure 1), is a challenge that must be faced. In order to cope with these conditions, the development of infrastructure to support the distribution of natural gas should be increased. One tangible manifestation of infrastructure development, there is now a transmission pipeline linking South Sumatra West.

This transmission pipelines are now in operation with a total capacity of about  $\pm 600$  MMSCFD, given the importance of these networks will require reliable protection system. One thing that is avoided in the operation of the pipeline is a leak. The impact of natural gas leaks other than the economic impact can also cause loss of life and environmental damage. Although natural gas is released into the atmosphere does not burn, the impact caused by methane emissions 21 times greater than CO<sub>2</sub> (Speight, 2007).

In Canada cause of gas leak (Alberta EUB Report, 2006) such as construction damage, earth movement, corrosion, joint failure, overpressure, and damage by others/<sup>3rd</sup> party. Total natural gas leak that occurred was 1.326 cases with a total length of 235.592 km pipeline. In Europe during the year 1970-2007 have been cases of leakage of 1.172 cases with the leakage frequency of 0.11 per 1000 km (EGIG, 2008).

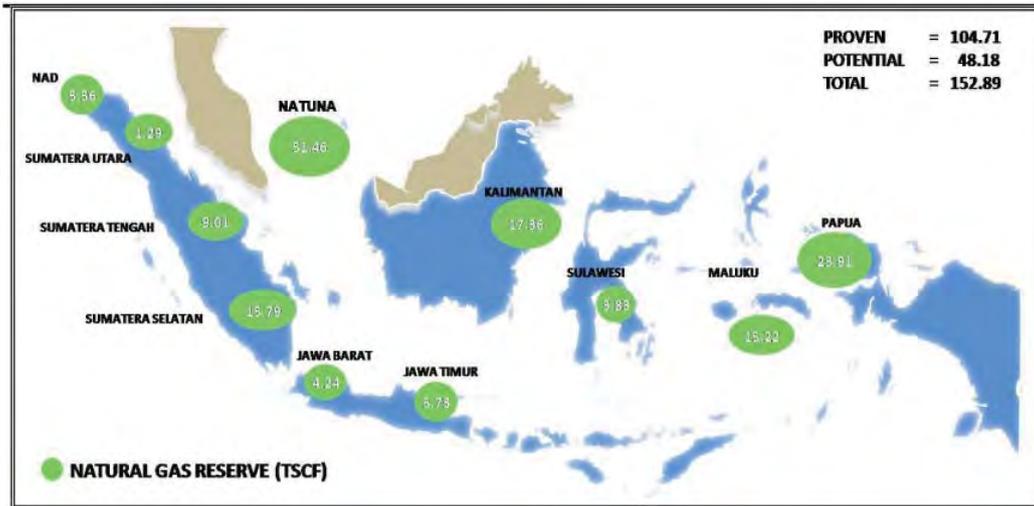

Figure 1: Natural Gas Resources in Indonesia

In order to detect the gas leak, there must be a system that can identify the event of a pipeline leak. Several kinds of methods have been invented and implemented throughout the piping network in the world. The available methods can be categorized as a hardware-based methods, software-based method, and non-technical method (Pal-Stevan Murfay, 2012). In this paper focused on software-based method by mass balance and pressure monitoring. The two methods were chosen because of low cost and can be applied to existing transmission pipelines.

## 2. MATERIALS AND METHOD

In this study, simulated leak in the pipe is done by using the PIPELINE STUDIO. PIPELINE STUDIO will calculate operating conditions that occur per time step with a leak at the pipe wall that has a different size and location. The results of the simulation PIPELINE STUDIO will then be analyzed by the Mass Balance Method and Pressure Monitoring.

### 2.1 Mass Balance Methods

In the steady state condition, the mass entry ( $M_{in}$ ) of pipes that do not leak will be balanced by the mass exit of the pipe ( $M_{out}$ ). In general, the mass difference in and out should be balanced by changes in inventory in the ( $M_{pipe}$ ), so:

$$M_{in} - M_{out} = \frac{dM_{pipe}}{dt} \quad (1)$$

If there is no leak, theoretically mass in the pipe depends on the result of multiplying the volume density of the product pipeline. Which are both a function of temperature and pressure, and density is also a function of the composition of the product. If there is an imbalance in the mass balance is calculated, the amount of mass that is leaking can be described as:

$$\Delta M_{leak} = \Delta M_{in} - \Delta M_{out} - \Delta M_{pipe} \quad (2)$$

### 2.2 Pressure Monitoring

If a leak occurs, the pressure in the pipeline will fall by an amount  $\Delta P$  (Geiger, 2006). With the use of pressure transmitter that has been installed, using statistical analysis of the presence of a leak is declared when the mean value of the pressure measurements decreased.

### 2.3 Pipeline System

The pipeline that used for this paper is real life 196 km long pipeline and has a circular uniform outside diameter of 36 inch and inside diameter of 34.75 inch. The pipeline only have pressure transmitters and flow meters at the upstream and downstream of the pipe. For the simulation, there are three different locations for the leak which is at 49 km, 98 km, and 147 km from the upstream. The size of the leak that simulated are 1 inch and 5 inch at each of the location. The composition of the natural gas is given in Tables 1. The flow through this pipeline is 400 MMSCFD.

Table 1: Natural Gas Composition

Component	Mole Percentage
Methane	91.514
Ethane	2.8313
Propane	0.7511
i-Butane	0.2098
n-Butane	0.1966
i-Pentane	0.0933
n-Pentane	0.0545
n-Hexane	0.1074
Nitrogen	0.2293
Carbon Dioxide	4.0084
Water	0.0039
Sulfur	0.0003

### 3. RESULT AND DISCUSSION

The pipeline model is first run in steady state condition, where the simulated result are compared to the real data from the instrumentation. After the model in PIPELINE STUDIO give result exactly the same as the real data, then the simulations are divided into six categories:

- The leak had a diameter of 1 inch and at 49 km from the upstream.
- The leak had a diameter of 5 inch and at 49 km from the upstream.
- The leak had a diameter of 1 inch and at 98 km from the upstream.
- The leak had a diameter of 5 inch and at 98 km from the upstream.
- The leak had a diameter of 1 inch and at 147 km from the upstream.
- The leak had a diameter of 5 inch and at 147 km from the upstream.

From the result of the simulation, pressure and the flow then to be counted using equation (2) for mass balance and a linear statistic approach for the pressure monitoring. The simulation time step is minutely with interval until 1440 minutes. The leak are assumed to be happened at time step 675 until 1440.

Figures 2 to 4 show the pressure profile for diameter of leak 1 inch at different location. From the graphic we can see that the leak happen at the vertical line and in an hour it change the pressure 3 psia. This simulation are based on that there is no change in flow at the inlet and outlet which is hold constant at 400 MMSCFD. With the same flow, Figures 5 to 7 show the pressure profile for diameter of leak 5 inch. There is significance change in pressure drop, for an hour it is already drop from 943 psia to 878 psia or the pressure drop is 65 psia/hour. From Figures 2 to 7 we also can see that the pressure drop happen at the closes pressure transmitter first.

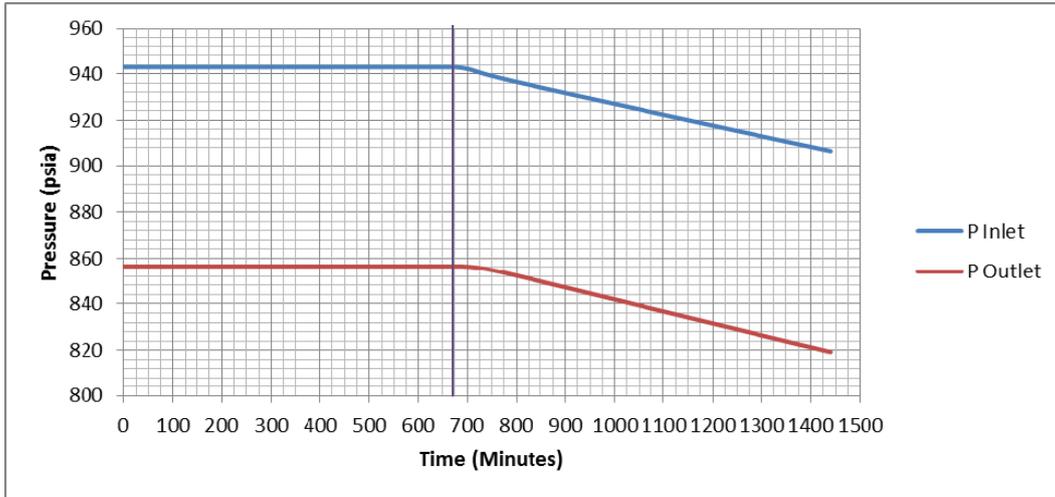

Figure 2: Pressure Profile for 1 inch leak at 49 km

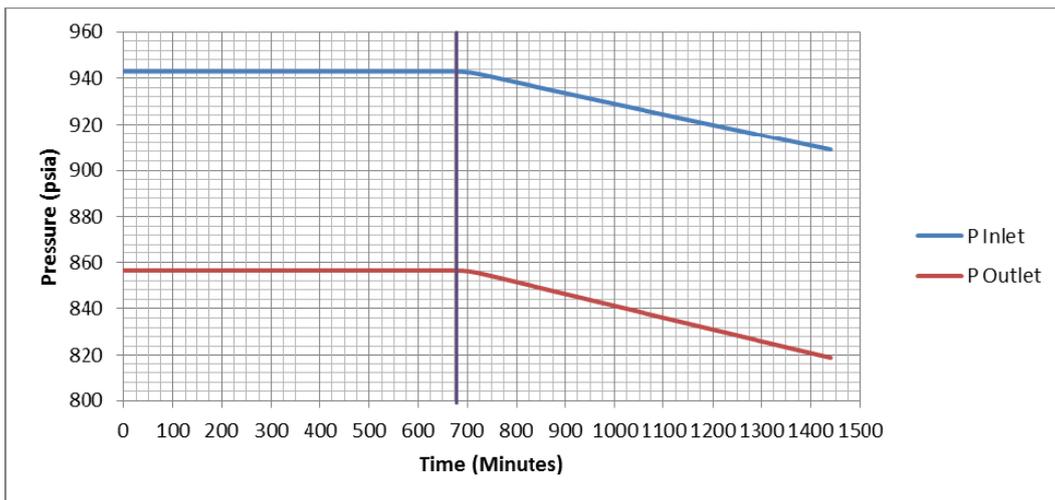

Figure 3: Pressure Profile for 1 inch leak at 98 km

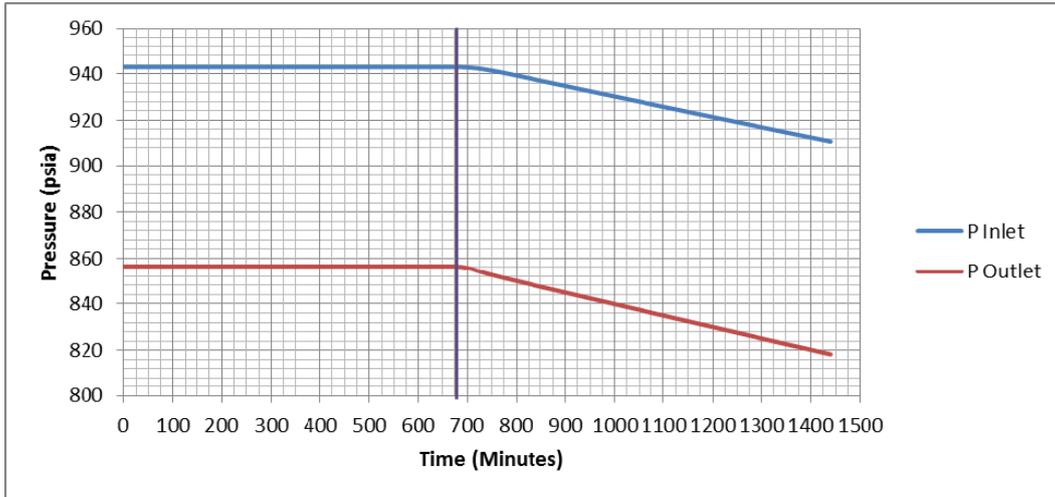

Figure 4: Pressure Profile for 1 inch leak at 147 km

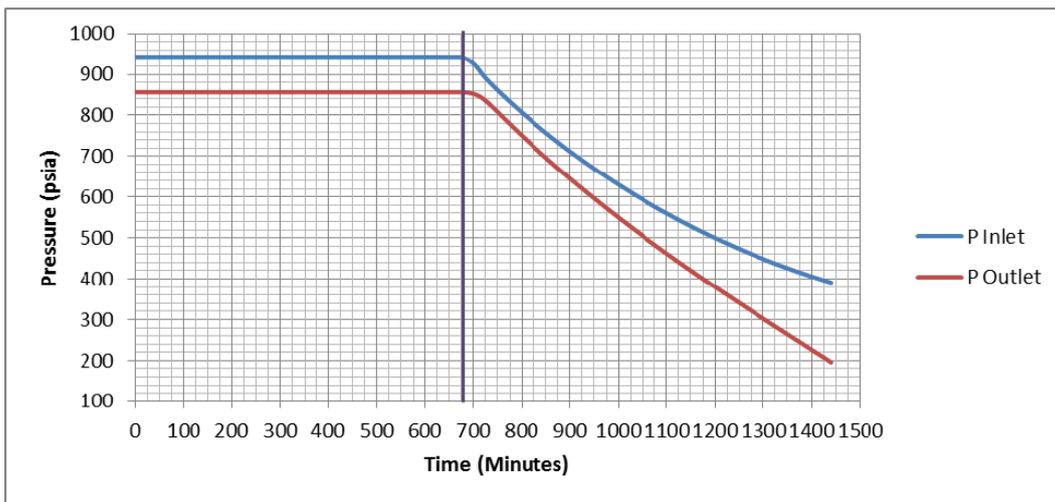

Figure 5: Pressure Profile for 5 inch leak at 49 km

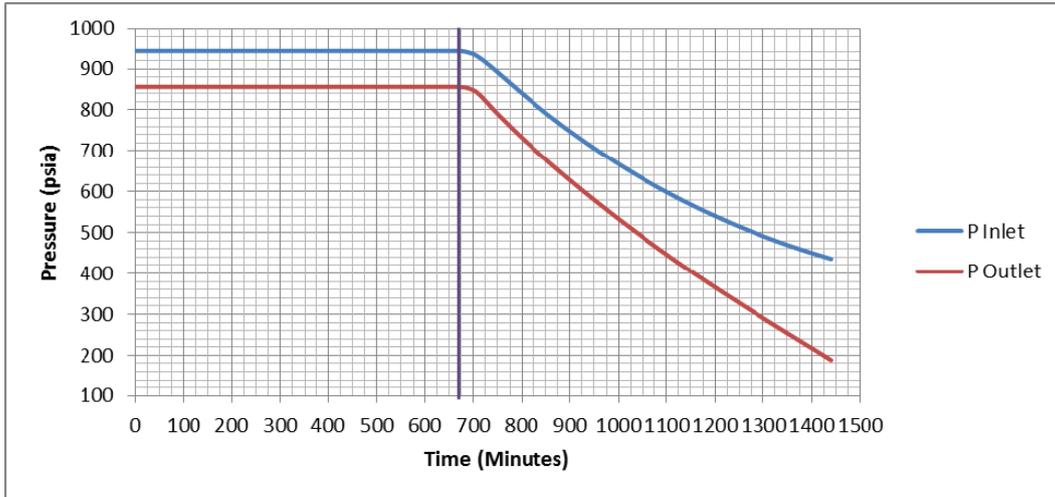

Figure 6: Pressure Profile for 5 inch leak at 98 km

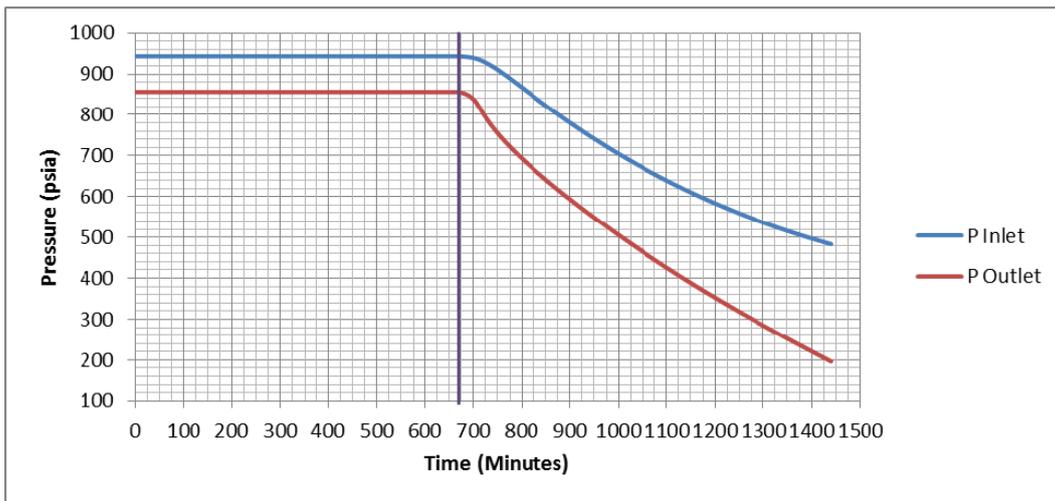

Figure 7: Pressure Profile for 5 inch leak at 147 km

Table 2: Mass Balance Estimated Leak

Leak Location (kilometer)	Leak Size (inch)	Magnitude of leak simulated (MMSCFH)	Estimated Leak Magnitude (MMSCFH)	% Error	Delay in Leak detection time (Minutes)
49	1	1.06	0.87	-17.82	30
49	5	22.33	19.51	-12.62	15
98	1	1.04	0.86	-17.32	30
98	5	21.84	19.22	-12.00	15
147	1	1.01	0.84	-17.12	30
147	5	20.50	18.29	-10.77	15

Using equation (2) the estimated leak magnitude are counted and compared to the simulated leak at each location and size. We can see that with the mass balance methods the average error for the leak magnitude is -14.61%. From the simulation the

change in the pipeline inventory are the only indication for the leak, it is happen because there is no change in flow at the inlet and outlet of the pipeline systems.

#### 4. CONCLUSION

In this study, it was found that the pressure point analysis is not recommended for the leakage smaller than 1 inch. The change of the pressure is small ( 3 psia/hour) which is under normal operation the change of the pressure barely noticed because at transient state it is normal to have such a change. But to be more discussed is the effect of location of the pressure transmitter. This study is based on the real condition of the pipeline systems were the pressure transmitter only attached at the inlet and outlet of the pipe (196 km in distance). With this method the location of the leak can be estimated from the pressure transmitter that change first, then the group of pipeline patrol can be sent from the closes location. Although not given the exact location of the leak but it is good enough for the pipeline patrol to reduce its search range..

The mass balance methods were quite accurate in terms of giving the estimated leak size and leak detection time. But with this method the location of the leak can't be determined. Further study is needed to combine this two methods and given the better leak detection methods.

## ABSTRACT

A Multiple Model Predictive Control (MMPC) is now widely used for controlling nonlinear multivariable process. The MMPC consists of some linear MPCs or called local MPCs. Representative Model Predictive Control (RMPC) can be used for determining some models which are able to represent whole operating point. In this paper, the application of RMPC on proposing some models for MMPC is described. The result shows improvement of controller's performance than the single MPC. For the change of bottom composition set point from 0.01 to 0.05 the use of MPC2.3.5 is recommended, and for the 0.01 to 0.1 change, the MPC4.5.8 is recommended.

## Keywords

*Representative Model Predictive Control (RMPC), Multi Model Predictive Control (MMPC), distillation column control, Column A*

## 1. INTRODUCTION

Distillation column is the most common unit operation in the chemical industry. It is an important unit for separation process in chemical industries [1]. A distillation column especially used to get products with highest purity, beside to separate multicomponent mixtures such as crude oil. To separate crude oil used an atmospheric distillation column, firstly. Furthermore, distillate products (up products of the atmospheric distillation column) separated again using a hydrocarbon distillation column such as a depropanizer or a debutanizer to get an LPG product. Whereas, the bottom products (residue) separated by a vacuum distillation column. Distillation systems also used to separate a mixture from non-mixture substances and for materials that sensitive with temperature, such as aromatic substances in atsiri oil.

For many years, dynamics and control of distillation processes have become one of the important issues among process system engineers and researchers. The distillation process itself is a nonlinear multiple-input multiple-output system with strong inherent interactions, and significantly sensitive to exogenous disturbances.<sup>[2]</sup>

Nonlinear MPC (NMPC) has been developed to overcome distillation column control problems. However, the scope of NMPC application is typically much smaller than that of linear MPC applications. This is likely due to the computational and modeling complexity of NMPC algorithms<sup>[3, 4]</sup>. Multiple MPC is the alternative solution to solve this problem. MMPC consists of some linear models that represent the whole operating point of CV (controlled variable). This structure is based on the identification of different models in order to optimize the prediction on each step involved in the computation of the cost function<sup>[5]</sup>. The utilization of MMPC algorithm needs the identification of local linear models which represent the whole operating point of CV<sup>[6]</sup>.

Those local linear models are called local MPCs or Representative MPC (RMPC). The research about RMPC algorithm application has been done by using ten models (local MPCs). The best three local MPCs are proposed to be used in MMPC. A caution of choosing the local MPCs is needed because of the distinctness of each local MPC's response<sup>[7]</sup>. In this paper, the application of RMPC on proposing some models for MMPC is described.

## 2. DISTILLATION COLUMN MODEL

Distillation column model to be used is based on fundamental model names Column A which is developed by Skogestad. Column A has 40 theoretical stages and separates binary mixture with relative volatility 1.5 to products with 99% purity. The dynamic model of distillation column uses the following assumptions: binary mixture; constant pressure; constant relative volatility; equilibrium on all stages; total condenser; constant molar flows; no vapor holdup; linearized liquid dynamics, but effect of vapor flow ("K2"-effect) is included. These assumptions may seem restrictive, but they capture the main effects important for dynamics and control (except for the assumption about constant pressure)<sup>[1]</sup>.

Manipulated variables are reflux flow and boil up flow (LV-configuration). Controlled variables are overhead product mole fraction ( $y_D$ ) and bottom product mole fraction ( $x_B$ ). In the whole experiment the top concentration will be measured and used in state estimation but the controller will not attempt to regulate it directly. It will vary as needed to regulate the bottom concentration. A typical two product distillation column is shown in Figure 1.

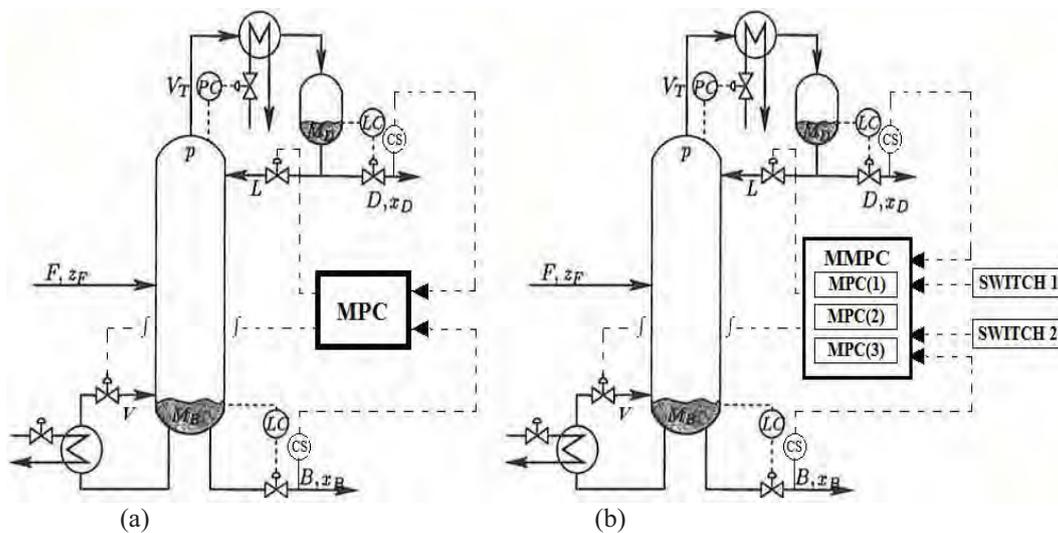

Figure 1. Typical simple distillation column controlled with LV-configuration using: (a) MPC and (b) MMPC

## 3. SYSTEM IDENTIFICATION

System identification is done by pulsing each controller output at each level of operation. This affects both measured process variables. System identification is done by increasing reflux flow  $L$  with constant boil up flow  $V$  and increasing  $V$  with constant  $L$ . Each controller output to measured process variable pair is a sub-process. In this experiment there are four sub-processes:  $L$  to  $y_D$ ,  $L$  to  $x_B$ ,  $V$  to  $y_D$ , and  $V$  to  $x_B$ .

This experiment yields FOPDT model parameters ( $K_p, \tau_p$ , and  $\theta_p$ ) as shown in Table 1. The FOPDT model parameters are then used in the non-adaptive DMC tuning equations<sup>[8]</sup> for obtaining MPC tuning parameters as shown in Table 2.

Table 1. FOPDT Model Parameters

	L to y1	L to y2	V to y1	V to y2

P	66	50	36	29
M	26	20	15	13

#### 4. SINGLE MPC FOR NONLINEAR PROCESS

To obtain the local MPCs to be used in MMPC, firstly Column A is controlled by single MPC. It uses one local model for the whole operating points. There are two schemes of bottom concentration set point changes. First is moderate set point changes i.e. 0.01 to 0.05. In this scheme, PI controller can be used although gives unstable response when the controlled variable reaches 0.05. This scheme will be called scenario 1 for the rest of the paper. Local MPCs are chosen based on their Integral Absolute Error (IAE) values which are less than PI controller's IAE value, 0.4437. The response of  $x_B$  given by PI controller is shown in Figure 2.

The second set point changes is from 0.01 to 0.1 where PI controller can not be used anymore. This scheme will be called scenario 2 for the rest of the paper. Because PI controller can not be used as comparison basis, the five best local MPCs, with the least IAE, will be chosen.

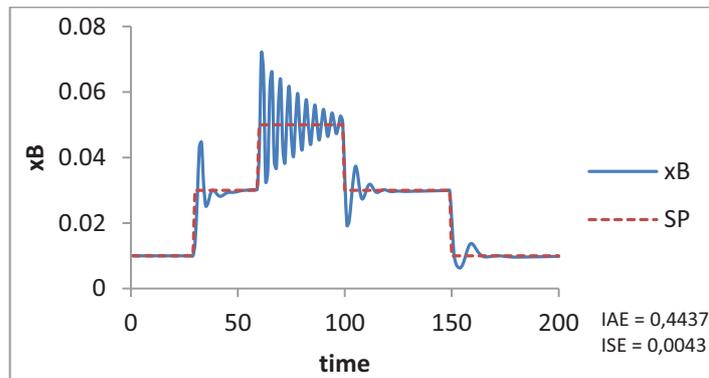

Figure 2: PI Controller Performance on Scenario 1

Ten local models are tested, they are in the operating point of 0.01 (called as MPC1) to 0.1 (called as MPC10). Column A controlled by single MPC uses MPC tuning parameters as shown in Table 2 with an addition of one set of parameters which actually yields less IAE values in response than IAE given by parameters of non-adaptive DMC tuning. The parameter set is  $T_s=0.1$ ;  $P=12$ ;  $M=2$ . By using this set of parameters, 9 out of 10 models give less IAE values than others, except for MPC1.

Table 3 and Table 4 show IAE values for each single MPC in each parameter for scenario 1 and scenario 2 respectively. For scenario 1, local MPCs chosen for MMPC are MPC2, MPC3, MPC4, MPC5, and MPC6. For scenario 2, MPC4, MPC5, MPC6, MPC7, and MPC8 are chosen. The differences of the best model between the two scenarios show that single MPC represents its operation range.

Table .: Integral Absolute Error of Single MPC at Scenario 1

Controller	Ts = 0.72 P = 66 M = 26	Ts = 0.53 P = 50 M = 20	Ts = 0.36 P = 36 M = 15	Ts = 0.29 P = 29 M = 13	Ts = 0.1 P = 12 M = 2
PI	0.4437				
MPC1	0.9587	0.8361	0.7920	0.7029	1.2259

## 5. MULTIPLE MPC FOR NONLINEAR PROCESS

The models used in MMPC are the local MPCs proposed in the section above. The two scenarios of set point changes will be tested in this experiment. There are 5 local MPCs for each scenario. They will be combined each other to obtain MMPC consists of only two and three models. The more models we use in MMPC do not guarantee the better response. That is because each model has an error. The utilization of many models yields greater error. Besides, MMPC with too many models is not practical because of the difficulty in handling those models.

We also have to consider the operating range where each model will perform. How we switch one model to another will affect the response. It shows that setting the right models in the right operating range is important.

Combination of MPC2, MPC3, and MPC5 (MPC2.3.5) gives the best response for scenario 1 with IAE 0.2296 and ISE 0.0015. This response is obtained at switch specification 0.02 and 0.04. It means when measured CV values < 0.02, system is controlled by MPC2, when  $0.02 \leq CV < 0.04$ , system is controlled by MPC3, and when  $CV \geq 0.04$ , system is controlled by MPC5.

Figure 3 shows that MPC2.3.5 has a combined characteristic of single MPCs which performs in their regions. At the low region, MMPC has MPC2 characteristic which is better than MPC3 and MPC5. At the middle region, MMPC gives response like MPC3 and at the high region it is like MPC5.

For the scenario 2, MPC4.5.8 gives the best response with IAE 0.5528 and ISE 0.0076 which is obtained at switch specification 0.02 and 0.09. Same as those on scenario 1, here are the switches from one model to another based on the changes of measured CV. Comparison between single MPC and MMPC for scenario 2 is shown in Figure 4.

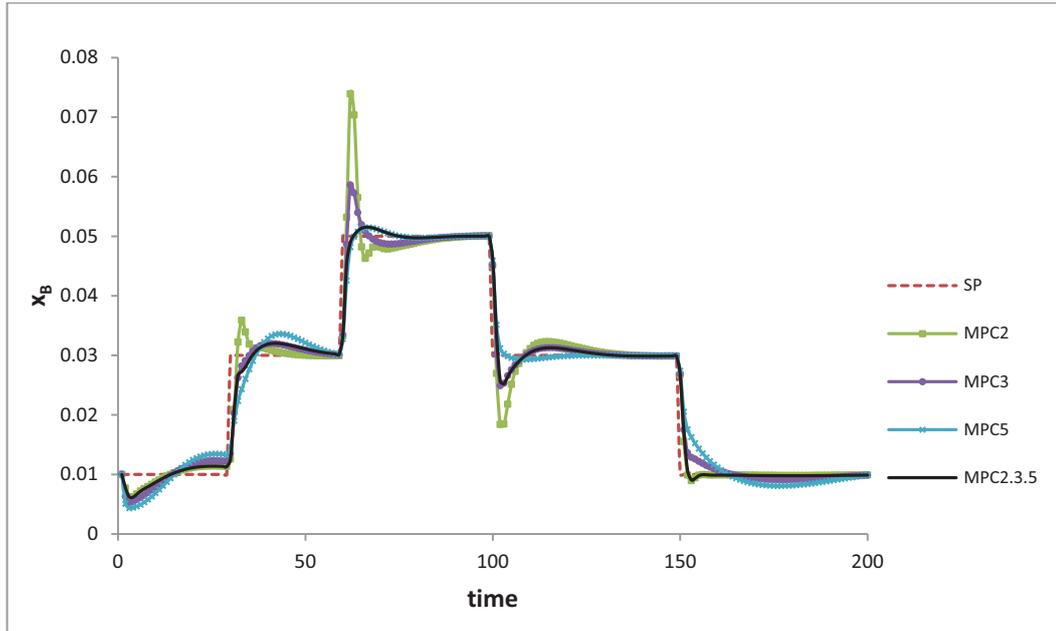

Figure 3: Comparison of MPC2, MPC3, MPC5, and MPC2.3.5

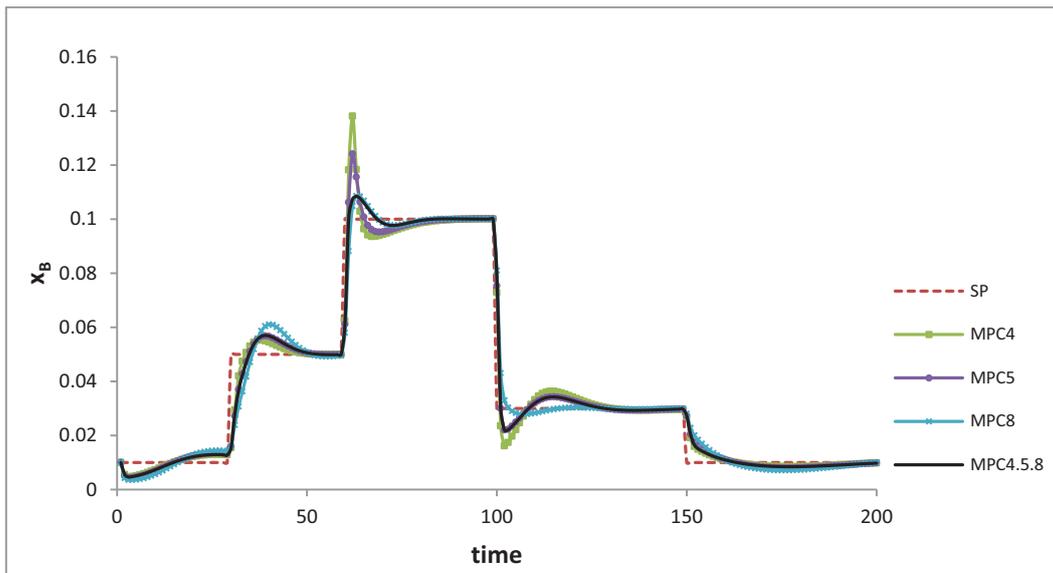

Figure 4: Comparison of MPC4, MPC5, MPC8, and MPC4.5.8

What we have to consider is the combination of local MPCs must be able to cover the overall set point changes. To obtain the best MMPC, it must consist of local MPCs operating at the lowest, middle, and highest region of the overall set point changes. And then, determining the right switch specification is by observing each local MPC's response then deciding the operating region where it performs best.

Eventhough determining the best MMPC, models combination and switch specifications, needs a careful experiment, in average MMPCs give better response than single MPC. Table 5 shows comparison of PI controller's, MPC's, and MMPC's IAE and ISEfor scenario 1 and scenario 2.

One of the implementation of MMPC in industry is propane/butane splitter<sup>[6]</sup>. The controlled outputs are the temperature at the first stage of the top section of the distillation column and the percentage of propane in the bottom stream. The manipulated inputs are the flow rate of hot oil to the reboiler and the reflux flow rate to the top of the column. The feed flow rate and the temperature of the hot oil stream are measured disturbances to the controller. A conventional MPC controller based on a single

linear model for the output prediction had been in operation for several years showing a poor performance. Output  $y_1$  was maintained satisfactorily inside its range, but the width of the reference range corresponding to this output had to be kept larger than desired. For output  $y_2$ ; the closed-loop response was not satisfactory since this output remained outside its reference range for most of the time in which the system was observed. The MMPC presented a performance significantly better than the conventional single MPC controller. Output  $y_1$  only needs narrower reference range and output  $y_2$  remained inside its reference range. Step change in each CV's set point yields good responses too. The use of MMPC has been operating successfully for more than a year in the refinery of Cubatão, Brazil.

Table 5: Comparison of PI controller's, MPC's, and MMPC's IAE and ISE

Scenario 1			Scenario 2		
Controller	IAE	ISE	Controller	IAE	ISE
PI	0.4437		PI	not converged	
MPC3	0.2947	0.0018	MPC6	0.6114	0.0083
MPC2.3.4	0.2309	0.0015	MPC4.5.6	0.5687	0.0078
MPC2.3.5	0.2296	0.0015	MPC4.5.7	0.557	0.0076
MPC2.3.6	0.2349	0.0015	MPC4.5.8	0.5528	0.0076
MPC2.4.5	0.2383	0.0016	MPC4.6.7	0.5608	0.008
MPC2.4.6	0.2402	0.0016	MPC4.6.8	0.5581	0.0081
MPC2.5.6	0.2457	0.0017	MPC4.7.8	0.5678	0.0078
MPC3.4.5	0.2759	0.0016	MPC5.6.7	0.5797	0.0078
MPC3.4.6	0.2774	0.0016	MPC5.6.8	0.5776	0.0078
MPC3.5.6	0.2792	0.0016	MPC5.7.8	0.5798	0.0079
MPC4.5.6	0.3166	0.0019	MPC6.7.8	0.5997	0.0084

## 6. CONCLUSION

The use of MMPC based on RMPC gives better response than single MPC. What you have to consider are the models' ability to cover the whole set point changes, the combination of the models used, and the switch specification of MMPC.

## ABSTRACT

Government has spent much budget for fuel subsidy when it is compared with other component of state budget. Monitoring, tracking and control systems are required to record fuel purchases for each type of motor vehicle in distribution location per area. It will ultimately create a system of verification and validation the distribution of certain type of fuel based on Integrated Information Technology related to quota of subsidized fuel in each region. Distribution of fuel subsidy can be supervised properly by these systems. The concept of supervision and control of distribution are carried through method of recording daily transaction and tracking retail outlets through front end devices. It will be installed in each dispenser equipment of filling stations gasoline and diesel fuel with a computer data acquisition card reader and electronic data capture. By this way, it has result in total saving for gasoline 1 393 030 kL and for diesel fuel 32 557 616 kL with a total amount 33 950 646 kL in 2011. If state budget subsidy is assumed to be Rp2000,- per liter, total saving can reach Rp 67 901 000 000,-. When total saving by supervision and control of subsidized fuel is compared with amount of budget monitoring and control of Rp 23 467 000 000,- the system can save state budget amounting of Rp 44 434 000 000,-.

## 1. INTRODUCTION

Current demand of fuel subsidy in Indonesia is increasing which can be seen from budget of fuel subsidy every year. Government spends fund on fuel subsidy in accordance with amount of fuel subsidized consumed. This value is quite high compared with other components of expenditure especially for post-crisis of finance and economic in 1997-1998. Along with increase of fuel consumption and motor vehicle, they cause allocation of fuel subsidy increasing. The government has made various efforts in the form of limiting subsidy and saving fuel consumption. They are expected to be able to limit subsidy to certain groups. Hence, number of fuel subsidy in budget can reflect actual needs of subsidized object. Although arrangement of user of subsidized fuel is clear, but its application is not easy. There are still parties which do not have right to consume subsidized fuel such as large industries and rich people. In addition, subsidized fuel is smuggled out of country since fuel price in overseas is more expensive than fuel price in the country.

## 2. RESEARCH METHODOLOGY

### 2.1 Preliminary Data Collection and Implementation Preparation

Initial data processing and identification of problems are directed to mapping of main issues which have become cause of each problem that exists in distribution of subsidized fuel especially gasoline and diesel fuel in the following ways.

1. Initial data processing with statistical method related to realization of distribution of subsidized fuel typed gasoline and diesel fuel in entire territory of Indonesia. This data was taken from Regulatory Body of Oil and Gas Downstream (BPH Migas) to calculate distribution of allocation of subsidized fuel typed gasoline and diesel fuel in entire territory of Indonesia.
2. Indepth Interview with Provincial Government (Dipenda) at 33 provinces.
3. Indepth Interview with Central institution and relevant stakeholders such as Pertamina (Persero), DPP Hiswana Gas which represent network of filling stations, and Ministry of Finance related to verification of realization of distribution of subsidized fuel which is paid to Business Entity.
4. Preliminary data which is processed to conduct statistical analysis of use of gasoline and diesel fuel is recapitulation of number of motor vehicle in 2008 from National Police Headquarter and allocation of quota distribution of subsidized fuel typed gasoline and diesel fuel 2007-2008 from BPH Migas.

## 2.2 Data Processing of Motor Vehicles on Implementation Area

Initial data processing of motor vehicle in Province of Riau Region was conducted by Coordination Meeting between BPH Migas and Riau Islands Police related to data integration of motor vehicle. It was processed and synchronized into database of motor vehicle in system data center.

## 2.3 Arrangement of Strategic Plan of Development and Implementation System

In arranging strategic plan of development, a utilization of information systems of setting management and monitoring national consumed fuel will be implemented via some strategies.

1. Coordination meeting with 33 Provincial Government to seek input on social impact that will be resulted from implementing system in each province.
2. In depth interview related to mapping of the Management Information System (MIS) infrastructure especially MIS and its association with administration system and tax registration of motor vehicle (DIPENDA).
3. In depth interview was also conducted to map MIS infrastructure of online banking services and network infrastructure between bank and merchant.

## 2.4 Development of Technical Cooperation Inter-Institution and Socialization

Development of technical cooperation inter-institution is needed to integrate authority of relevant institution and synchronization of inter-system information through Limited Coordination Meeting and Overall Coordination Meeting to socialize Management Information System Regulation and Supervision of National Fuel Volume Usage.

1. BPH Migas – Ministry of Home Affair: Obtaining support of implementation of activities from Ministry of Home Affair to be forwarded to Provincial Government of Riau and ranks below it.
2. BPH Migas – National Police Headquarter: Acquisition support of implementation of activities from National Police Headquarter to be forwarded to Police Area and institutions under it.
3. BPH Migas - Provincial Government and DIPENDA of Riau: Acquisition of technical cooperation to integrate system and data.
4. BPH Migas-Bintan, Tanjungpinang, and Pemko Government: Technical Cooperation inter-institution to implement activities by survey, socialization and implementation of system.

## 2.5 Design of System Monitoring and Control of Subsidized Fuel for Transportation

Strategy to control the volume of subsidized fuel typed Gasoline and Diesel Fuel is conducted through five approaches.

1. Policy Approach Tool & Support: Data Center for Regulatory and Supervisory against National Fuel Usage.
2. Supervision Authority approach inherent in BPH Migas Authority against subsidized fuel distribution.  
 Tool & Support:  
 Monitoring System of Fuel Distribution at filling station, Integration System of Local Government - BPH Migas.
3. Approach To Data - Know Your Customer.  
 Tool & Support:  
 Integration System, Consumer Identification with Control Card Program.
4. Territorial Approach and System Integration - Local Government Development.  
 Tool & Support:  
 Arrangement of system utilization and development per territorial based Provision of Commercial Business Area and Distribution of Specific Types of fuel.
5. TAPPER (Tapping, Processing, and Reporting) System Tests.  
 Tool & Support:  
 Technical cooperation among sectors, community support, the readiness of information system infrastructure.

Table 1: Tapper Methodology (Tapping, Processing and Reporting)

SYSTEM	DEVICE	OUTPUT
<b>Customer identification</b>	Motor Vehicle Database Identification of Control Card on vehicle (Barcode sticker)	Database users of premium subsidized fuel and diesel oil..
<b>Tapping</b> Record transaction activity at point of handover . Namely distribution of fuel transaction at filling station and recording transaction of subsidized fuel in each dispenser.	Front end device: Card reader GPRS	recording logbook data through computer of filling stations to network access center  Transaction volume data recording the purchase of subsidized fuel for each vehicle Processing
<b>Processing</b> Processing the data sent / taken from front end devices at each filling	Network access center	transaction data processing

SYSTEM	DEVICE	OUTPUT
station		
<b>Reporting</b> Report of recording transaction at each filling station and volume of subsidized fuel usage per vehicle type	data center of volume regulation and supervision of national fuel	Report of distribution of fuel realization per filling stations

### 2.6 Projection of Total Vehicle Fuel Typed Gasoline and Diesel Fuel Users in Riau Province.

Based on data obtained from Riau Islands Police Units in 2008 about data population and number of vehicles in Riau, projected number of vehicles is drawn up until 2015. The number of vehicles through 2015 is projected using population data in 2008. Projection calculation is done because the population has a correlation or strong relationship with number of vehicles.

#### Projected Number of Vehicles Typed Gasoline Fuel

Statistically, number of vehicles using gasoline has population correlation of 0.99 with P-value 0.00 ( $\alpha \leq 5\%$ ). Population has strong and direct relationship with number of vehicles.

Data of number of vehicles and population is used to calculate proportion of number of vehicles per population in 2008 [1,2]. The calculation of number of vehicles in 2009-2015 is multiplying proportion of those with population from 2009-2015. Total population in 2009 - 2015 is projected until 2015. Projected population in 2009 up to 2015 was calculated using population growth data 2000-2008 [3].

$$\text{Total population (n)} = \text{Number of residents (n-1)} + (\text{growth rate (n-1)} \times \text{Number of residents (n)}) \quad (1)$$

Assumptions: population growth rate is same every year.

$$\text{Number of vehicles (n)} = (\text{number of vehicles (n-1)} / \text{population (n-1)}) \times \text{population (n)} \quad (2)$$

$$\text{Number of vehicles (n)} = \text{proportion of number of vehicles per year} \times \text{number of population (n)} \quad (3)$$

With n = 2009, ..., 2015

Assumption: proportion of number of vehicles and number of people per year used is same.

#### Projected Number of Vehicles Typed Diesel Fuel

It is almost the same projection with number of vehicles typed gasoline fuel. Statistically, number of vehicles using diesel fuel and population has value of 0.93 with correlation value P-value 0.00 ( $\alpha \leq 5\%$ ). The population has strong and direct relationship with number of vehicles.

Data of number of vehicles and population is used to calculate proportion of number of vehicles per population in 2008 [1,2]. So calculation of number of vehicles in 2009-2015 is multiplying proportion of those with populations from 2009 until 2015. Total population in 2009-2015 is projected until 2015. Projected population in 2009 up to 2015 was calculated using population growth data 2000-2008 [3].

$$\text{Total population (n)} = \text{Number of residents (n-1)} + (\text{growth rate (n-1)} \times \text{Number of residents (n-1)}) \quad (4)$$

Assumptions: population growth rate is same every year.

$$\text{Number of vehicles (n)} = (\text{number of vehicles (n-1)} / \text{population (n-1)}) \times \text{population (n)} \quad (5)$$

$$\text{Number of vehicles (n)} = \text{proportion of number of vehicles per year} \times \text{number of population (n)} \quad (6)$$

With n = 2009, ..., 2015 ;

Assumption: proportion of number of vehicles and number of people per year used is same.

### 2.8 Calculation of Quota Allocation of Gasoline and Diesel Fuel in Riau Province

Specified quota allocation of gasoline and diesel fuel in Riau Province in 2006 through 2008 based on data from BPH Migas is shown below.

Table 2: Allocation of Premium 2006 to 2008 in the Riau Islands Province [4]

City	Allocation per Year (kL)					
	2006		2007		2008	
	Premium	Diesel	Premium	Diesel	Premium	Diesel
Batam	124,712	88,060	114,369	75,450	124,539	88,060

City	Allocation per Year (kL)					
	2006		2007		2008	
	Premium	Diesel	Premium	Diesel	Premium	Diesel
Karimun	9,953	6,995	6,975	6,928	9,939	6,995
Bintan	19,233	35,981	17,148	30,226	19,206	35,981
Natuna	5,337	7,661	3,547	5,129	5,329	7,661
Lingga	3,871	8,189	299	1,747	3,866	8,189
Tanjung Pinang	29,014	27,640	20,963	20,487	28,974	27,640
Total	192,120	174,526	163,301	139,967	191,853	174,526

### Projection of Quota Allocation of Gasoline in Riau Province

Projection need of gasoline volume quotas for the next 7 years is conducted by using data quota volume of gasoline in 2008 and data on number of vehicles in 2008 in particular types of private cars and motorcycles.

$$\text{Proportion (n)} = \text{Volume of the needs of gasoline (n)} / \text{number of vehicles gasoline users (n)} \quad (7)$$

$$\text{Projection (n)} = \text{proportion of quota gasoline per vehicle} \times \text{estimated number of vehicles (n)} \quad (8)$$

With n = 2009, ..., 2015

Assumption: the proportion of the quota volume needs premium per vehicle is the same every year

### Projection of Quota Allocation of Diesel Fuel in Riau Province

Projected need for quota volume of diesel fuel for seven years into the future is done using data quota volume of diesel fuel in 2008 and data of number of vehicles in 2008 in particular types of trucks, buses and large cars.

$$\text{Proportion (n)} = \text{Volume of diesel fuel demand (n)} / \text{number of vehicle Diesel Fuel users (n)} \quad (9)$$

$$\text{Projection (n)} = \text{proportion quota diesel demand per vehicle} \times \text{estimated number of vehicles (n)} \quad (10)$$

With n = 2009, ..., 2015

Assumption: proportion of quota volume of diesel fuel demand per vehicle is same every year

## 3. RESULTS AND DISCUSSION

Based on results of the calculation of projected proportion of number of vehicles per population in 2008, projected number of users of gasoline vehicles in 2009 to 2015 is obtained.

Table 3: Projected Number of Vehicles Table Gasoline up to 2015 Users

City	Year (Unit)						
	2009	2010	2011	2012	2013	2014	2015
Batam	1,519,076	1,716,556	1,939,708	2,191,870	2,476,813	2,798,798	3,162,642
Karimun	42,800	48,364	54,651	61,755	69,784	78,856	89,107
City	Year (Unit)						
	2009	2010	2011	2012	2013	2014	2015
Bintan	30,140	34,058	38,485	43,489	49,142	55,531	62,749
Natuna	3,499	3,954	4,468	5,049	5,705	6,447	7,285
Lingga	9,031	10,205	11,531	13,030	14,724	16,638	18,801
Tanjung Pinang	17,966	20,302	22,916	25,924	29,294	33,102	37,405
Total	1,622,512	1,833,439	2,071,759	2,341,117	2,645,462	2,989,372	3,377,989

Based on results of projected proportion of number of vehicles per population in 2008, projected number of users of diesel fuel in vehicles from 2009 to 2015 is obtained.

Table 4: Projected Number of Users Diesel Vehicles up to 2015

City	Year (Unit)						
	2009	2010	2011	2012	2013	2014	2015
Batam	17,683	19,981	22,579	25,514	28,831	32,579	36,814
Karimun	1,052	1,189	1,343	1,518	1,715	1,938	2,190
Bintan	836	945	1,067	1,206	1,363	1,540	1,740
Natuna	33	37	42	48	54	61	69
Lingga	99	112	127	143	162	183	206
Tanjung Pinang	7,793	8,806	9,950	11,244	12,706	14,358	16,224
Total	27,496	31,070	35,108	39,673	44,831	50,659	57,243

From data above, calculation data on number of vehicles that consumes fuel typed gasoline and diesel fuel in 2011 is obtained.

Table 5: Total Control Card and Barcode Stickers Used

No	City	Amount of Vehicle for Control Card and Barcode Stickers	
		Gasoline	Diesel
1	Bintan	38,485	1,067
2	Tanjung Pinang	22,916	9,950
Total		61,401	11,017
Grand Total		72,418	

Number of vehicles reflects number of control cards and barcode stickers that will be distributed to all vehicle owners and users of gasoline and diesel fuel on Bintan Island in 2011. To facilitate process of calculating cost of control cards and barcode stickers and prepare control cards and barcode sticker backup, number of control cards and barcode sticker is rounded up to 75,000 units. Cost for research can be calculated by calculation of Rp.23,467,710,200.

Based on Equation 7 and Equation 8, projected quota of gasoline fuel need for 2009 until 2015 is obtained.

Table 6: Projected Allocation of Gasoline in Riau Province

City	Year (kL)						
	2009	2010	2011	2012	2013	2014	2015
Batam	131,433.840	148,520.240	167,827.880	189,645.500	214,299.420	242,158.340	273,638.920

Total	182,255.030	205,948.170	232,721.430	262,975.220	297,161.990	335,793.060	379,446.150

Results of these projections will be used to determine amount of quota as a reference in order to determining effectiveness of monitoring subsidized gasoline and diesel fuel of transportation sector on Bintan Island using control cards and barcode stickers. Based on data projected number of vehicles up to 2015, it can be calculated value of monitoring results and diesel fuel in district of Tanjung Pinang in 2011 which data is obtained from projected number of vehicles in 2011 multiplied by percentage of vehicles based on data from Tanjung Pinang City Police. Next assumption is that average volume of fuel use per day and number multiplied by number of vehicles. Total volume of fuel usage for all vehicles in district of Tanjung Pinang can be obtained. Total volume of fuel usage for all types of vehicles in district of Tanjung Pinang is multiplied by 365 days. Volume of use of all vehicles in district of Tanjung Pinang for 1 year, volume of fuel usage for one year compared with projected Quota Volume Fuel Year 2011 for Tanjung Pinang can be obtained to get difference in volume of subsidized fuel that can be saved. Difference in volume of subsidized fuel can be saved multiplied by assumed amount of government subsidy per liter in 2011. It is assumed that amount of subsidy amounting to Rp.2,000 per liter. Value of monitoring result and diesel fuel compared to projected data volume quota need of gasoline and diesel fuel in Riau Province until 2015 shows comparison between projected results with results of monitoring in 2011 at Tanjung Pinang.

Table 8: Saved Subsidy Fuel Typed Gasoline of Tanjung Pinang

Vehicle Type	Percentage (%)	Amount of Vehicle	Assumption of Gasoline Usage Average per Day (L)	Total Assumption of Gasoline Usage per Day (L)	Total Assumption of Gasoline Usage per Year (kL)	Quota in 2011 (kL)	Deviation (kL)	Assumption of Subsidy (Rp/L)	Saved Subsidy (Rp)
Motorcycle	87	19,928	3	59,783	21,820.890	40,709.620	687.926	2,000	1,375,851,936

	Grand Total	6,350,474.517		12,700,949,033,136	

#### 4. CONCLUSIONS

The use of subsidized gasoline and diesel fuel of transportation sector in Bintan Island using control card and barcode sticker results data difference between number of vehicle users of gasoline and diesel fuel with use of volume fuel data. This indicates a distribution of subsidized fuel that is not on target especially for diesel fuel. Thus, the surveillance system needs to be applied immediately and control the use of subsidized gasoline and diesel fuel for transportation sector on Bintan Island with Full Card and Barcode to reduce the number of these differences. In turn, the fuel subsidy fraud can be minimized.

Yield of saving by monitoring and controlling the use of subsidized fuel for transportation sector on Bintan Island with Control Card and Barcode in 2011 is 1,393.030 kL for gasoline and diesel of 32,557.616 kL. Total yield of saving is 33,950.646 kL. If the state budget subsidy is assumed to be Rp.2000 per liter, the total saving that can be reached is Rp. 67,901,291,146,

If the result of saving of the supervision and control of the use of subsidized fuel is compared with the amount of budget monitoring and control of Rp.23,467,710,200, the system can save the state budget amounting to Rp.44,433,580,936. In that case, the system of supervision and control of fuel subsidies should be immediately applied with strong legal basis.

With the implementation of monitoring system of subsidized gasoline and diesel fuel for transportation sector using control cards and barcode, monitoring distribution of subsidized fuel at filling station can be supervised and unsupervised distribution level of dealer to users which are entitled in accordance with applicable regulations.

### ABSTRACT

Adsorption is one of the techniques that can be used in many applications in industrial processes, such as for separations, water treatments, and gas storages. The key success in the application of adsorption method is the selection of the adsorbent. Depending on the specific application, total surface area and the pore size of the adsorbent are the most important parameters in the selection of the adsorbent. Activated carbon has been a long pronounced as an excellent candidate adsorbent for separation purposes as well as gas storage (adsorptive storage). This research aims are to produce activated carbon from bamboo as the raw materials. Bamboo plants was selected as a raw material because it contains a fair amount of carbon (47.6%) and also available in almost many places in Indonesia. Moreover, unlike coals as main sources of activated carbon, bamboo can be considered as renewable natural resources. In this research, activation method is controlled by variation of activating agent,  $H_3PO_4$  and KOH with mass ratio of activating agent/carbon mass: 1/1, 2/1, and 3/1. The temperature of activation are varied at 600°C, 700°C, and 800°C for 30 and 60 minutes. The results shows that the highest surface area of 781  $m^2/g$  is obtained by activation using  $H_3PO_4$  with a mass ratio of activating agent/carbon mass 3/1 at temperature of activation of 700°C, for 60 minutes. Meanwhile, activation using KOH results in 824,83  $m^2/g$  obtained by activation at 800°C for 30 minutes. For comparison, the study produces activated carbon by physical activation method conducted at 700°C for 60 minutes and the surface area of activated carbon obtained is 291  $m^2/g$ .

### INTRODUCTION

Even today, the refined edible oils are mainly used as feedstocks for biodiesel and this causes an increase in the price of edible oils. The side-stream products, such as soapstocks, acid oils and deodorized distillates, obtained during edible oil refining have been suggested for use as alternative feedstocks for biodiesel. Especially, the crude oils of palm and rice bran have a high content of free fatty acid and, hence the amount of acid oils generated is large, about 10-15 wt% of refined oil output. There are a little industrial uses for acid oils such as ink, but most acid oils are burned out as waste. However, there exists no commercially realizable process for biodiesel production from acid oils.

The purpose of this research is to construct a simple and economical production process of high quality biodiesel from waste acid oils using the ion-exchange resins as catalysts and adsorbent.

### MATERIALS AND METHODS

The acid oil, donated by the rice bran oil company, consisted of about 95 wt% of free fatty acids and 5 wt% of acylglycerols. Figure 1 shows a schematic diagram and photograph of our production process. Two water-jacketed columns were individually packed with the cation-exchange resin, Diaion PK208LH, and the anion-exchange resin, Diaion PA306S, respectively, and connected in series. The temperature of each column was kept constant at 50 °C. The mixed solution at the stoichiometric molar ratio of methanol to the total fatty acid residue in the oil was supplied to the bottom of the first column at the constant flow rate. The effluent from the process was analyzed to check the quality of biodiesel.

### RESULTS AND DISCUSSION

Table 1 shows the analytical result of standard tests for biodiesel quality of product without purification except for removing residual methanol by evaporation. The contents of FAME and residual reactants were fully satisfied with the standard values. This indicated that free fatty acids and mono-, di-, and tri-glycerides were converted to biodiesel by esterification and transesterification with cation- and anion-exchange resin catalysts, respectively. The contents of byproducts also met the standard low values without downstream purification processes to remove them. This was because the by-products, water and glycerol were adsorbed on the anion-exchange resin and the effluent was free from them. Other properties for contaminants and fuel properties were found to be satisfied with the standards.

Figure 2 shows the photographs of the feed oil and the effluents from the first and second columns at room temperature. The feed oil was liquefied by the esterification through the first column. The dark brown pigment was removed by the adsorption through the second column.

### CONCLUSION

The simple process permitted the economical production of high quality biodiesel from the waste acid oils without complicated downstream purification process.

## ABSTRACT

Electricity consumption of the world had come up because of the rapid development of technology that uses electrical energy such as cellular phones or computers. Hence, research to complement the shortage of electricity continues to be done. Microbial Fuel Cell (MFC) provides new opportunities for sustainable energy production from fuel that is biodegradable, and can reduce the compound substrate, even from wastewater. Single chamber MFC reactor without ion exchange membrane with tempeh industry wastewater as substrate used in this experiment. We used graphite electrode as an electron mediator and grow biofilm in the anode for 3 weeks (precolonization anode) then compared it with clean anode system. Soy bean husk is added as biomass in substrate for second variation. Optimum electricity production obtained from clean anode without addition of soy bean skin system. Power density obtained was 1009,34 mW/m<sup>2</sup> when using wastewater model and 44,62 x 10<sup>-2</sup> mW/m<sup>2</sup> when using industry tempeh wastewater.

## Keywords

*Microbial Fuel Cell (MFC), single-chamber reactor, biofilm, biomass, wastewater of tempeh industry.*

## 1. INTRODUCTION

World consumption of the electrical energy is increasing every year because of the rapid development of technology and consumerism. The high electricity demand is not matched by availability of primary fuel, ie fossil fuels. This limitation requires creativity of researchers to be able to find alternative fuels that can producing electrical energy. Interesting alternative comes from the fuel cell. Contrary to the reaction of electrolysis, fuel cells reacting hydrogen and oxygen to produce water and electricity. In fact the use of hydrogen as an alternative fuel less than optimal in terms of cost.

Research to reduce the limitations of fuel cells continues. The abundance of bacteria is the original idea of the invention MFC (Microbial Fuel Cell) which is the development of fuel cell technology. MFC is a device that uses bacteria to generate electricity from organic and non-organic compounds [1]. MFC provides new opportunities for sustainable energy production with fuel that is biodegradable and can reduce the compound substrate [2]. MFC is comprised of anode, cathode and electrolyte. The main principle is the microbial activity in the liquid medium in the anode compartment. Microbial activity can produce organic component containing hydrogen elements such as ethanol, methanol, or methane gas that can be used to produce electrons and electrical current. This research will use a single-chamber reactor design MFC as the single-chamber reactor produces a higher power density than two-chamber [3]. Ion-exchange membranes are not used in the reactor design. Ion exchange membrane serves to prevent the diffusion of oxygen from the cathode into the anode and allow proton transfer occurs from the anode compartment into the cathode compartment [3]. According to Liu *et al.* (n.d), ion-exchange membrane will make the rate of removal of COD in waste slower and will reduce power density generated by the system [3]. Industry tempeh wastewater is used as the substrate in this system. Liquid waste of industry tempeh contains nutrients of nitrogen, phosphorus, and organic materials such as carbohydrates, vitamins, and proteins that act as nutrients for bacteria [4]. The use of waste as a substrate without the addition of bacteria can provide two benefits at once, which saves the cost of purchasing expensive bacteria and reduce the cost of wastewater treatment industry tempeh.

## 2. METHOD

Industry tempeh wastewater was taken from tempe manufacture located in the Lio village, Depok. Materials and tools used in the experiment originated from the Bioprocess Laboratory and Basic Chemistry Laboratory Department of Chemical

Engineering UI. Voltage is measured using digital multimeter (Sanwa Electric Instrument co., Ltd cd 771) and current is measured using analog microampere (Yokogawa Electric Works. Ltd, tipe 2011b9000em class 1.0, Singapore).

### 2.1. Electrolysis Tools Preparation

Electrodes used in this study are graphite electrodes that are relatively inexpensive, simple, and has a specific surface area [5]. Graphite electrode immersed in a solution of 1 M HCl for 1 day and then rinsed using distilled water. After that, the electrodes immersed again in 1 M NaOH solution for 1 day and then rinsed again using distilled water. Electrode preparation aims to regenerate the electrode and removes metal contamination and organic materials [5].

### 2.2. Substrate and Electrolyte Preparation

Industry tempeh wastewater is used as the substrate in this system, but to get an ideal system, we made a model of liquid waste. To make a model of liquid waste, boiling 200 grams of soy beans (*Glycine max*) by as much as 500mL of water (ratio 1:2.5;w/v) for 15 minutes. This is done through the process of boiling soy in tempeh industry, with the ratio of 3:5 (w/v) [6]. Then the temperature of boiling water left in place until normal ( $\pm 28^{\circ}\text{C}$ ), followed by filtering the cooking water, so it will get the effluent model and then peeled soy beans to be used as biomass.

### 2.3. MFC Configurations

For starting the experiment, we have to preparation the tools. First, set an electrode in the reactor then connected it to the cable and resistor. This is for anode part. Then we set another electrode to the hole side reactor and connected it to cable and resistor. This is for cathode part. Then we connected the two cables and then we will connect it to multimeter.

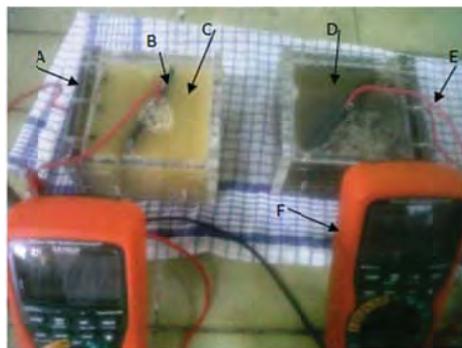

Figure 1: The scheme of MFC reactor.

(A) cathode, (B) anode, (C) industry tempeh wastewater, (D) liquid waste model, (E) cable or external circuit (F) multimeter.

### 2.4. MFC Experiments

MFC experiments performed with 2 variations which are variations pretreatment anode and the addition of biomass variations. Variations pretreatment anode is done by comparing the MFC system with clean anode and pre-colonized anode. Pre-colonized anode is the anode that permit biofilms or bacterial colonies growth in their surface. Pre-colonized done by immersing the anode in the anaerobic system for 3 weeks by refreshing the new waste every week. Biofilms that grow on the anode surface is expected to be a catalyst towards the transfer of electrons from bacteria to the anode. Researchers Yang, Jia and Liu [7] have explained that the presence of biofilm on the anode can reduce the diffusion of oxygen into the compartment so that it will reduce the potential for oxidation-reduction reactions that can raise coulombic efficiency and power generated by the system. Biofilm in the pre-colonized anode also can speed up the lag phase of bacteria compared to clean anode [8].

The experiment was continued by adding biomass to the MFC system with clean anodes and pre-colonized anode and compare them with systems that are not given additional biomass. Biomass in the form of soybean husk is used as an additional substrate. Soybean husk is expected to be a nutrient for bacterial metabolism to increase electricity production. MFC system with additional substrate can produce electricity up to twice compared to using only waste [6].

### 2.5. Analysis and Calculations

Of the MFC experiments, the data obtained in the form of currents and voltages. Power density ( $\text{mW}/\text{m}^2$ ) is the power generated per unit area of the electrode and is calculated using the equation:

$$\text{Power density (mW/m}^2\text{)} = \frac{I \times V}{A} \quad (1)$$

I (mA) is the electrical current, V (V) is voltage and A (m<sup>2</sup>) is the electrode surface area.

### 3. RESULT AND DISCUSSION

#### 3.1. Effect of Pre-colonized Anode

MFC performance in the variation of anode pretreatment can be seen from Figure 2, the system of pre-colonized anode had a shorter lag phase than the system with clean anode, respectively 37 hours and 41 hours. Microbial lag phase are influenced by the size of the inoculum, the time required for physical or stress recovery when inoculation, the time required for the synthesis of important coenzymes, and the time required to synthesize new enzymes for metabolism of substrates present in the growth media [10]. Both systems, clean anode and pre-colonized anode, have the same size of inoculums and medium with the possibility of same bacterial colonies and nutrients, so that we can conclude the differences are because of microbial adaptation speed for synthesizing new enzymes and their ability for recovery from stress.

At the peak of each electricity production pre-colonized anode is smaller than the clean anode. Power density was 3.20 mW/m<sup>2</sup> for pre-colonized anode and 1009.34 mW/m<sup>2</sup> for clean anode. The thickness of the biofilm on the pre-colonized anode reduced after the system starts up (microbial analysis), it showed the process of bacteria release from the anode surface into the liquid medium (desorption), so we can conclude that the electricity production of pre-colonized anode system was measured during the desorption process and clean anode occurs when bacteria start forming biofilms. Research conducted by Reimers and *et al* [8] showed similar results to electricity production in this system. A total of 6 pieces of anode and cathode electrodes were inoculated using sea water for 25 days before the system starts and the other electrode pair left clean. Results of research conducted indicate clean electrode has a strong current compared to the other electrode. System with clean electrodes can produce current up to 9 mA, while the maximum current of pre-colonized anode was 5 mA.

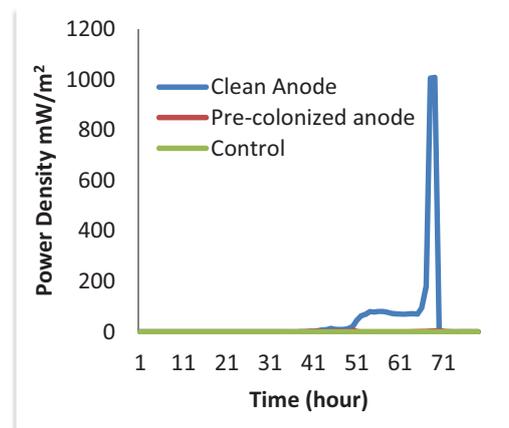

Figure 2: Electricity Production in Variation of Pretreatment Anode

#### 3.2. The Use of Biomass as a Substrate Addition

Biomass in the form of soybean husk researched by the systems of clean anode and pre-colonized anode. The result is a system with the added of biomass in the clean anode system generating electricity smaller than the system without the addition of biomass, respectively 3.32 mW/m<sup>2</sup> and 1009.34 mW/m<sup>2</sup> (Figure 3), while the pre-colonized anode system produces more electricity than when biomass added to the system, respectively 45.75 mW/m<sup>2</sup> and 3.20 mW/m<sup>2</sup> (Figure 4). Electron transfer from the bacteria into the anode to produce an electric current needed space for bacteria to make the shift easily, but the presence of soybean husk that satisfies both MFC systems can complicate the process of electron transfer, especially for planktonic bacteria in the clean anode system. Reduction of electron transfer due to the soybean husk will make the electrons are captured by the anode to produce electricity is not maximal. Pre-colonized anode system has had a bacterial system that stick to the anode surface (biofilm) that electron transfer is not reduced by the presence of soybean husk in the reactor. Pre-colonized anode system given positive results for the electricity generated in the addition of biomass. It is proved that the soybean husk can be an additional substrate in the MFC system to increase the production of electricity, but its use must be adapted to the system created to maximize their function.

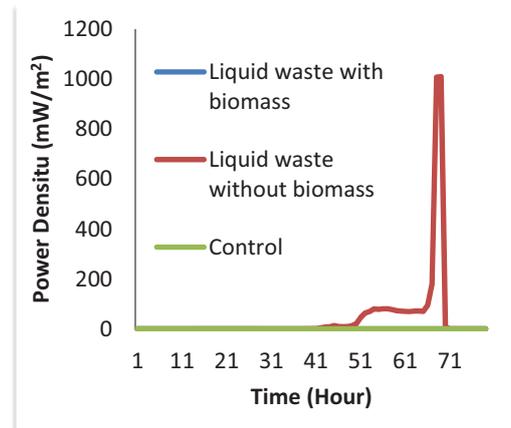

Figure 3: Electricity Production in Variation of Adding Biomass in the Clean Anode System

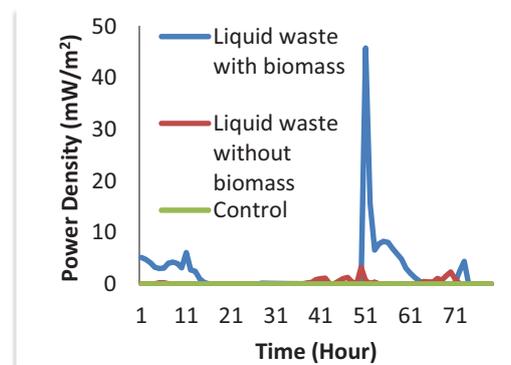

Figure 4: Electricity Production in Variation of Adding Biomass in the Pre-colonized Anode System

### 3.3. The Use of Industry Tempeh Wastewater as a Substrate

The results of the maximum power of the two variations then operated using industry tempeh wastewater substrate. Electricity generated at the industry tempeh wastewater is  $44.62 \times 10^{-2} \text{ mW/m}^2$  (Figure 5). Electricity production is lower due to several things, such as industry tempeh wastewater viscosity, contamination, and nitrate content in industry tempeh wastewater. Viscosity of industry tempeh wastewater will reduce power production due to the reduction of oxygen diffusion from the cathode towards the MFC system [6] and the magnitude of the resistance in the MFC system [3]. Contamination that occurred in the excess of the boiling process and from other area of the factory can bring new colonies. The presence of other bacteria colonies in industry tempeh wastewater can work synergistically or antagonist. Antagonist properties of a colony of bacteria that live in the same medium can lead to competition, especially if the bacteria are fighting over the same source of nutrients for survival [9]. This competition will lead to a limitation in the growth of these bacteria, thus affecting the metabolism of the bacteria will also be affect electricity production [11]. Large nitrate content in industrial soybean wastewater also affects electricity production in MFC system. Nitrate will act as an electron acceptor, so the electricity generation not only captured by oxygen but also by nitrate which will make the electricity generation is not maximal [6].

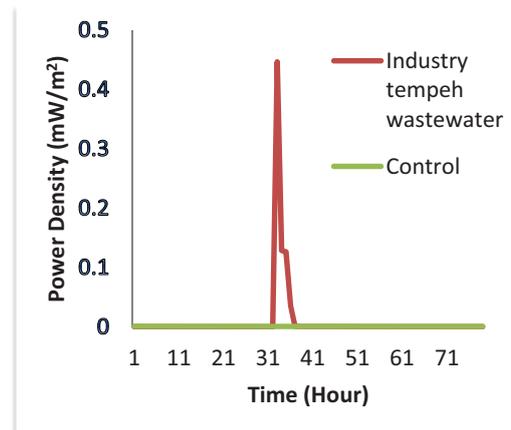

Figure 5: Electricity Production Industry Tempeh Wastewater

### 3.4. Microbial Analysis

The growth of bacterial cells in the model wastewater was observed by looking at the increase of cell based on Optical Density (OD) techniques in the incubation time [12]. OD method is done by measuring the absorbance using a spectrophotometer at a wavelength of 600 nm. Based on experiments conducted, it was found the growth curve as shown in Figure 6.

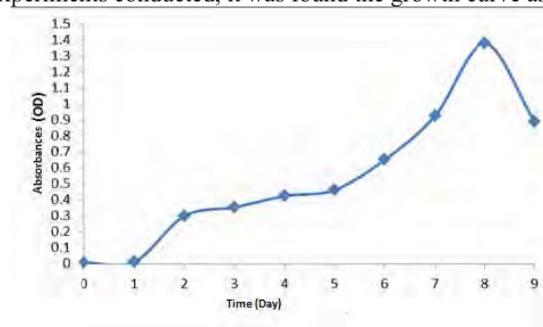

Figure 6: Bacterial Growth Curve in the Liquid Waste Model

Bacteria that grow on the medium of liquid waste is then allowed to grow to form a biofilm on the anode surface before the system starts (pre-colonized), so the analysis was also performed on the biofilm morphology. Attachment of bacteria to solid surfaces is the beginning of biofilm formation that occurs naturally in order to survive in adverse conditions, such as nutrient limitation or because of competition to get the same nutrients [9]. Bacteria that form biofilms has better resistance to chemicals, drought, and nutrient limitation compared with its planktonic cells [9].

Attachment occurs when organic material adsorbed on the wet anode surface. Pile of organic material on the surface of the anode will attract bacteria come in and stick to the surface to get nutrients. Bacteria that grow on the anode surface produce Extracellular Polymeric Substances (EPS) which content matrix that forming biofilm. Matrix formed from extracellular protein complex, sugars and bacterial cells, as well as conductive nanowires that can facilitate the conduction electrons [12]. When abundance bacteria come, they will form microcolony [13]. The last process is the development and spread of biofilms in all parts of the surface [13]. Bacteria that have been adsorbed can still move toward the liquid phase when the availability of nutrients in the liquid phase more than those on solid surfaces [13].

Based on the analysis of biofilm morphology (Figure 7), communities of bacteria that grow on the surface of the anode in wastewater tempeh model were spherical or coccus-shaped bacteria. Transfer of electrons from bacteria to the surface of the anode has 3 ways, there are through pili, through the outer membrane of the bacterial cell (cytochrome), through a redox mediator [3]. Redox mediator can be obtained from the addition of chemicals and the results of bacterial excretion [3]. This study does not add electron mediator MFC system, the community of bacteria attached to the surface of the anode also lacked pili (Figure 7), and the electricity generated by the experiment will go down when the bacteria undergo desorption phase. So, we can be concluded that the mechanism of electron transfer is likely to occur towards the anode bacteria through the outer cell membrane protein (cytochrome). The mechanism of transfer through the cytochrome can only happen if the microbes in

contact with the anode, so if more microbes are contacted with the anode, the electron transfer will be higher. In other words, the transfer of electrons increases with increasing surface area covering the biofilm anode.

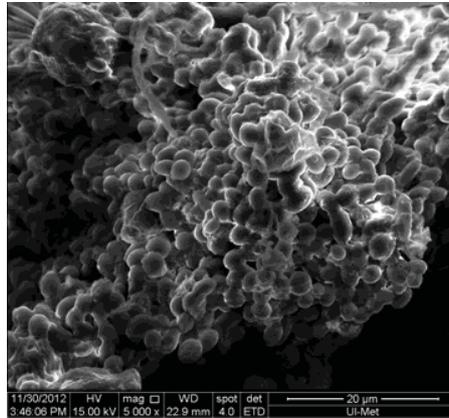

Figure 7: Biofilm Morphology in The Anode

The thickness of the bacteria was also obtained from the SEM test. The results obtained showed that biofilms grown on electrodes without the addition of biomass has a thickness smaller than biofilms grown in the system are added biomass (Figure 8). Biofilms were grown using natural substrate of liquid waste only has a thickness of between 127.8 µm - 176 µm, while the biofilm prepared by the addition of soybean husk as an additional substrate thickness ranged from 473 µm - 684 µm. Greater thickness in the MFC system with the addition of biomass showed positive results of soy husk as an additional substrate for bacteria. Soybean husk is proven to increase the metabolism of the bacteria to form colonies more on the anode surface.

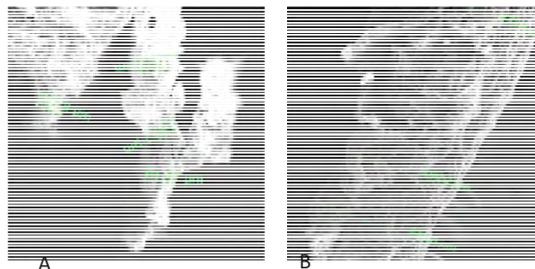

Figure 8: Differences of Thickness Before Incubation in the Substrate Variation with 100 Magnified.  
 (A) Biofilm without adding biomass (B) biofilm with adding biomass.

After the incubation is complete biofilm retested using SEM to determine the changes that occur. Based on the test results obtained from SEM the thickness after the system starts getting reduced (Figure 9). Originally biofilm on a system that was not given additional biomass has a thickness in the range of 127.8 µm - 176 µm and turned into a range of 19.55 µm - 44.8 µm after incubation process is completed and the biofilm biomass system provided additional thickness is reduced from the range of 473 µm - 684 µm to 163.4 µm range - 245.5 µm.

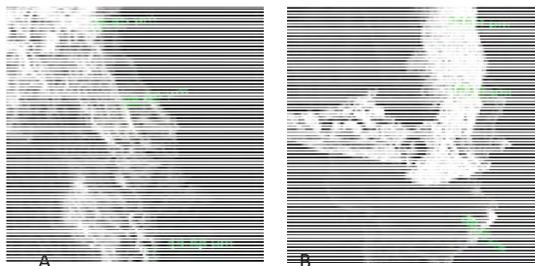

Figure 9: Differences of Thickness After Incubation in the Substrate Variation with 100xMagnified.  
 (A) Biofilm without adding biomass (B) biofilm with adding biomass.

Replacement of liquid waste at the pre-colonized anode system before electrical measurements will cause nutrients in the liquid phase into more than at the anode surface. An abundance of nutrients in the liquid phase resulting in bacterial defense system does not require any form of forming biofilm on the anode surface, so that the bacteria will make the release from the biofilm system into a liquid phase (desorption). This is what causes the thickness of the biofilm on the electrode decreased after incubation. In addition, bacteria in the biofilm system can fulfill their own nutritional needed. They will eat the dead cell in the system to still alive, so that the thickness of biofilm will decrease as the number of death bacteria on the system [9].

#### 4. CONCLUSION

Single-chamber MFC with clean anode systems without the addition of biomass produces the maximum power among other systems, which is 1009.34 mW/m<sup>2</sup>. Soybean husk has a pretty good ability to increase the production of electricity. Biomass is added to the pre-colonized anode system generating power density of 45.75 mW/m<sup>2</sup>, while the pre-colonized anode system without biomass has power density as 3.20 mW/m<sup>2</sup>. The use of industry tempeh wastewater produced power density as 44.62x10<sup>-2</sup> mW/m<sup>2</sup>.

### ABSTRACT

One of future research on National Research Agenda for renewable energy development is bioethanol development from lignocellulosic material. The problem in increase of ethanol production from lignocellulosic material includes bagasse is how to convert integrat polysaccharide to monosaccharide using specific enzymes. Integrated conversion including how to convert cellulose, hemicellulose and cellubiose, which is caused by partial hydrolysis of cellulose to glucose. The other phenomena, the existence of lignin in bagasse makes difficult to access enzyme in converting polysaccharide to monosaccharide. It causes ethanol production is not optimal.

This upstream bioethanol process simulation aim to optimize process production cost and the simulation can be modified to any variation of method in the process in bioethanol production to compare the effectivity of each variation. Acid hydrolization is applied in this process design, the acid will crack the polimer of cellulose and fermented by yeast which contain *S.cereviseae*. The source data in the simulation are obtained from the previous researches that have relation with the process.

Bagasse-based bio-ethanol yield in this process of 23:27%. With a capacity of 1.081 tons / yr bagasse prices and \$ 20 / ton, the importance of the sale price of \$ 2.4/kg. The production cost per year \$ 1.24/kg, IRR = 14:14%. From the sensitivity analysis, the variable selling price of bioethanol is the most sensitive variable.

## Waste Processing Equipment for Small Industries Based on Ozone and Ultraviolet-C

### ABSTRACT

Conventional Waste Water Processing equipment for small industrial technology is expensive and difficult to operate. This study was made to find a low-cost waste water treatment system that can be made small in size and easy to operate. Research using ozone and ultraviolet light showed excellent possibilities to build a waste processing unit suitable for small industries. Preliminary research has shown that the ability of Ozone and Ultraviolet-C (UV-C) to oxidize poly-azo sulfonated pigment (black ink inkjet printer) tens of thousands of times more powerful than the ability of the oxygen gas. Applied research is to treat waste laboratory provides the ability to reduce the value of Biological Oxygen Demand (BOD) and the value of Chemical Oxygen Demand (COD) is excellent. Furthermore, the results of the study made a laboratory waste processing equipment. The result is a waste processing equipment that looks simple, compact, can be developed and operated at a low cost, and very likely apply to small industrial and household waste that has high value on BOD and COD.

### Keywords

*Waste Water, Waste Water Processing equipment, Ozone, ultraviolet-C (UV-C), small industries.*

### 1. INTRODUCTION

A major problem in the treatment of industrial waste household and small industrial waste processing unit is priced relatively high and the way the operation that requires certain skills. The problems should be solved or small industrial activities and cottage industries in Indonesia will not process the waste generated from their activities. One possible waste treatment system that's cheap and easy to operate is based on ozone treatment system combined with ultraviolet-C light. Unfortunately, this waste processing unit, not yet available in small sizes. The smallest treatment unit using ozon-ultraviolet process can be found in 'five star' hotel activities.

On the other hand, technology-based provider of drinking water reverse osmosis process, also provides ultraviolet light and ozone generator for sterilization system. That is, the availability of spare parts to set up a waste processing unit for household and small industries . As the reactor, can be used poly vinyl chloride (PVC) pipe. It is recommended to use a high-quality PVC. At this experiment, the spare parts used are UV-C lamps 6 Watts, ozone generator 15 Watt with capacity of 0.45 grams per hour, and Wavin brand PVC with diameter 4 inches.

Having been studied the oxidation power of UV-Ozon to oxidize sulfonated poliaz black pigment. This study conducted aeration experiment on black ink solution of ink jet printer based on sulfonated poliaz pigment. The aeration proses was conducted by three treatments. The first aeration treatment was done with air. The aeration process on the second treatment

was done with air which was flowed through ozon generator. Then, the third treatment of the aeration process was conducted with air which was flowed through ozon generator and shone by UV-C light. The aeration process used air without ozon could not fade the colour ink, so it indicated that sulfonazied pigment poliazo could not be oxidized with air. On the other hand, the aeration process used with the mixture of air and ozon could increase the oxidation power up to multiple ten times. If it used UV-C light, the air's oxidation power mixed with the oxon would increase much higher. The ability of Ozone and Ultraviolet-C (UV-C) to oxidize poliazo sulfonated pigment (black ink inkjet printer) tens of thousands of times more powerful than the ability of the oxygen gas. In subsequent experiments, ozone and ultraviolet-C rays are combined to form a small reactor to treat wastewater from a laboratory study at the Academy of Chemical Analysis Bogor. The reactor showed excellent performance in the lower values of Biological Oxygen Demand (BOD) and Chemical Oxygen Demand (COD). The results of this research into the basic planning of waste treatment equipment that is simple and inexpensive for small industries or home industries.

At the end of the study is to create an industrial waste treatment reactor design small and cottage industries. This design should be equipped with waste water pH control unit for inlet and sediment filter unit for outlet. Initial experiments have given satisfactory results. The problem that remains is to adjust the size of the equipment with the load of the wastewater .

## 2. THE EXPERIMENT

### 2.1. Preliminary Experiment

The first experiment using three measuring glass as a reactor with a capacity of 2000 mL. Prepared three measuring glass. The three pieces measuring glass filled with 1800 ml of black ink solvent ink-jet-based poly-azo sulfonated with concentrations of 0.1%. Also prepared three ozone reactor. The first ozone generators, only the air pump activated , while the ozone generating unit is deactivated by cut off the electrical wire. The first measuring glass supplied air without ozone. The second measuring glass supplied air from ozone generators but not shone by ultraviolet-C light. Only a third measuring cup presented to the ultraviolet-C light . The first experimental equipment can be seen in Figure 1

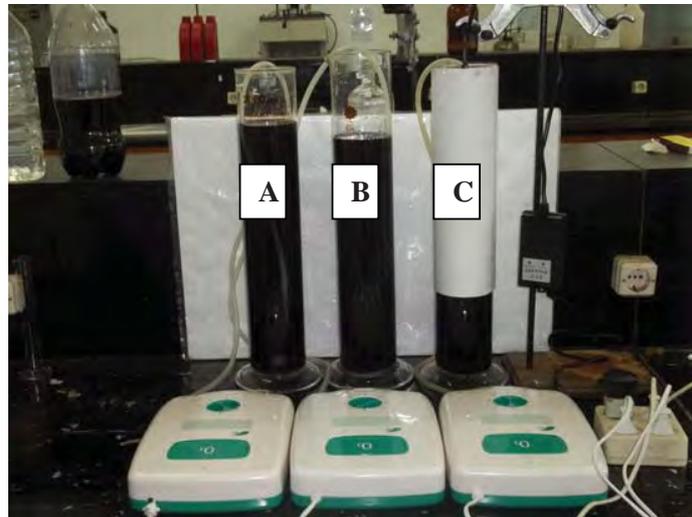

Figure 1: The first experimental equipment

The ultraviolet-C is a very dangerous light, so the third measuring glass (on the right), covered by aluminum foil and carton. The ultraviolet-C lamp used in this experiment is the small one use in ordinary reverse osmosis for home appliance. The power consumption is 6 watt with two peak of radiation at 253.7 nm (90%) and 185.0 nm (10%). The ozone generator also from ordinary reverse osmosis for home appliance with 13 watt power consumption equal to 0.4 g ozone per hour.[1] Physical appearance of these two main components can be seen in Figure 2A and 2B.

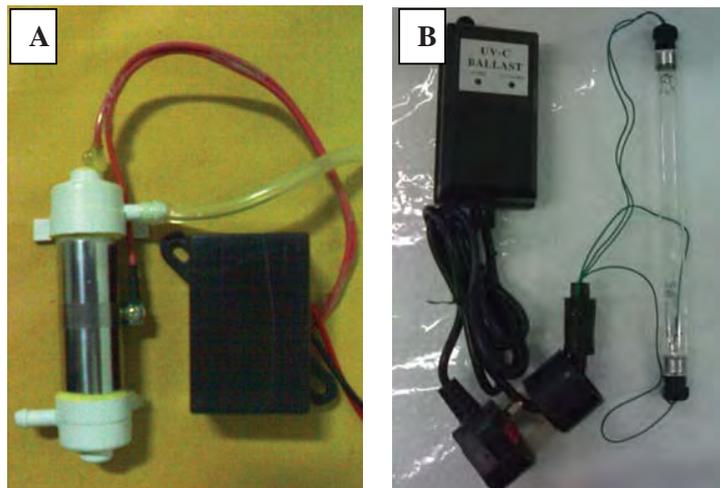

Figure 2 A: Ozone Generator and 2B. Ultraviolet Lamp

## 2.2. Second Experiment

In the second experiment, the process is run in a reactor made from Poli-vinyl Chloride Pipe. The inlet and the outlet use 0,125 inch connector. Air diffuser is made from a ceramic filter. Experiment processes perform by flowing 50 liter educational laboratory waste water through the reactor. The speed of flow relatively low i.e. about 0.5 liter per minute. The set of ultraviolet lamp and the ceramic air diffuser can be seen on Figure 3.

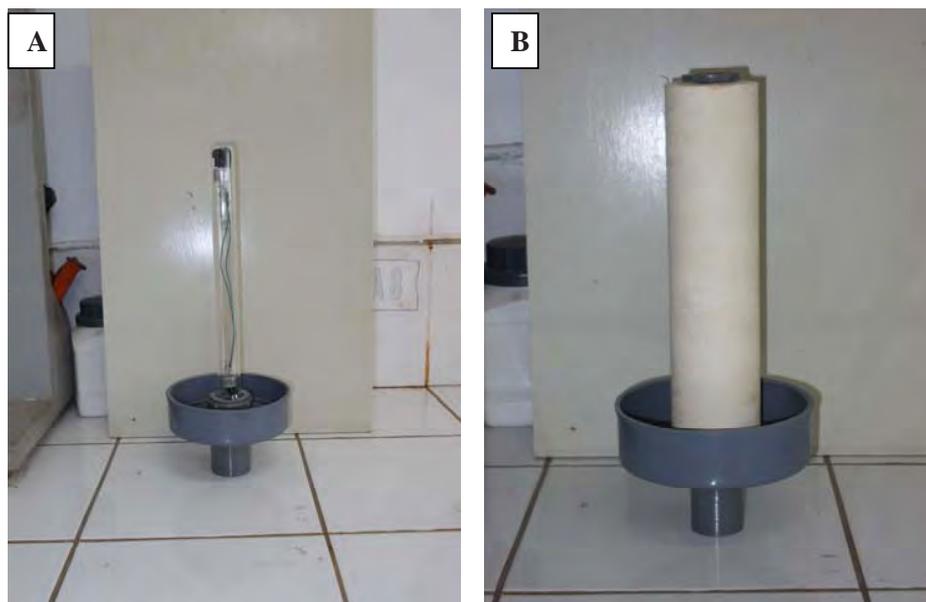

Figure 3: A Ultraviolet Lamp. B. Air Diffuser

In the reactor configuration, air diffuser placed in the bottom and the ultraviolet lamp on the top of the reactor. The reactor placed upright. Inlet placed in the bottom and outlet placed in the top. Inlet connected to reservoir of waste water with 19 liter (5 gallons) capacity. Outlet connected to a sediment filter. Treated water collected to a second 19 liter bottle. All of the experiments configuration (minus bottle) can be seen on Figure 4.

Figure 4: Complete Experimental Configuration.

### 3. RESULT AND DISCUSSION

#### 3.1. Preliminary Experiment

##### 3.1.1. Results

The first step of the experiment showed an extremely fast oxidation process on measuring glass, air flow and exposed to ozone and ultraviolet light. Comparison of black ink color density poly-azo sulfonated pigment measuring glass in the third, after a process lasting for 3 (three) hours, can be seen in Figure 5. While the color density measurement results, using color comparison method Nessler provide data as listed in Table 1.

### 3.1.2. Discussion

Ozone, O<sub>3</sub>, also called tri-oxygen, is tri-atomic molecule consisting of three oxygen atoms. This material is allotropi oxygen is extremely unstable when compared with in-atomic allotropi (O<sub>2</sub>). In the lower atmosphere, ozone is a pollutant air with damaging effects the respiratory system of animals and will burn sensitive plants. In the upper layers of the atmosphere, where ozone even at low concentrations is very useful to avoid damaging ultraviolet rays, preventing it from reaching the earth's surface [1]

Ozone can be made using ozone generators, the most popular being used in almost every industry that uses ozone is the charge corona-discharge method, using the discharge tube. This method changes the oxygen in the air to produce ozone and nitrogen oxides as a by-product. As a result, if used moderately moist air, will also be produced nitric acid. Two ozone generators are widely used vacuum ultraviolet ozone generator (V-UV, vacuum ultra-violet). This method uses a light source that produces narrow-spectrum ultraviolet light and short berlamdha, as produced by the sun. Vacuum ultraviolet rays from the sun is what keep the ozone layer in the atmosphere in order to stay there. This method produces ozone at concentrations of about 0.5% or lower and it takes a relatively longer exposure. Another method is the technique of cold plasma. In this method, pure oxygen is exposed to a plasma generated by dielectric barrier discharge of. Diatomic oxygen will break down into single atoms that then recombine to form ozone triplet. This method requires pure oxygen gas as a feedstock and produces a maximum concentration of about 5% ozone. In the process of making these ozone, oxygen allotropi also produced a short-lived, but more reactive than ozone as O<sub>4</sub>, O<sub>5</sub>, O<sub>6</sub>, O<sub>7</sub>, and so on. [2]. These experiments using vacuum ultraviolet ozone generators techniques. That is, the use of ultraviolet-C reactor, will strengthen the formation of ozone produced by the generator. This condition causes an increase in the use of ozone reactivity.

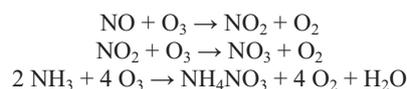

## 3.2. Second Experiment

### 3.2.1. Results

Experiments using ozone and ultraviolet-C reactor to treat laboratory waste of academy of chemical analysis Bogor, obtained as the following results ∴ COD value dropped from about 750 ppm to about 10 ppm. In this experiment it was observed that the production of waste water is not constant while the processing is constant. To adjust with fluctuations in the wastewater stream, need to complete the waste treatment unit with the container receptacle.

### 3.2.2. Discussion

Ozone is able to destroy and oxidize micro-organisms such as fungi, bacteria, and viruses. Ozone molecules that have reacted return to form oxygen gas. Ozone not only destroys micro-organisms, but also destroy the cosmetic ingredients, urine, cream, and oil. [3]. Ozone is also able to oxidize most metals and metal compounds. That can not be oxidized by ozone are gold, platinum, and iridium. Ozone can also oxidize NO to NO<sub>2</sub> gas and further oxidize NO<sub>2</sub> to NO<sub>3</sub> follow the following equation:

Ozone does not react with ammonium salts, but oxidize ammonia to Ammonium Nitrate  
 Ozone reacts with carbon to form carbon dioxide, even at room temperature

Reaction with sulfur compounds (sulfur)

Ozone oxidize sulfides to sulfates. For example, Pb (II) Sulfide oxidized to Pb (2) Sulfate:

Sulfuric acid can be produced from ozone, water and elemental sulfur or sulfur dioxide

In the gas phase, ozone reacts with sulfide to form sulfur dioxide Hidrigen:

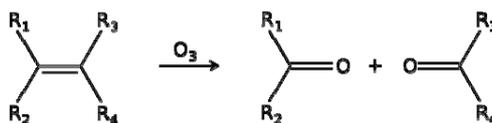

If the above reactions occur in the water, the two reactions will occur simultaneously, one producing elemental sulfur, and other produce sulfuric acid.

#### Reaction with alkenes and alkynes

Alkenes can be cleaved by oxidation by ozone, producing alcohols, aldehydes, ketones, and carboxylic acids, depending on the reaction of the two stage

Usually ozonolysis process carried out in dichloro-methane solution at a temperature of -78°C. After cleavage and rearrangement process, will form a ozonide-organic. By the end of the reaction is reductive, (eg Zn in acetic acid or dimethyl-sulfide), will produce ketones and aldehydes. By the end of the oxidative reactions (eg in water or alcohol, air-hydrogen peroxide), will be formed carboxylic acids. [1]

#### Other reactions

All (three) atoms in the molecule of ozone can react, as the reaction with tin (II) chloride with hydrochloric acid and ozone:

Perchlorate iodine can be made by treating iodine dissolved in anhydrous perchloric acid with ozone:

## 4. CONCLUSION

Experiments using ozone and ultraviolet-C reactor to treat laboratory waste of academy of chemical analysis Bogor, obtained as the following results: Chemical Oxygen Demand value dropped from about 750 ppm to about 10 ppm. The reactor showed excellent performance in the lower values of Biological Oxygen Demand (BOD) and Chemical Oxygen Demand (COD). The result is a waste processing equipment that looks simple, compact, can be developed and operated at a low cost, and very likely apply to small industrial and household waste that has high value on BOD and COD

## 5. RECOMENDATION

In this experiment, it was observed that the production of waste water is not constant while the processing is constant. To adjust with fluctuations in the wastewater stream, need to complete the waste treatment unit with the container receptacle.

## ABSTRACT

The synthetic dyes are a refractory and poisonous material. Most of industrial textile today used the synthetic dyes that can be dangerous to the environment because of the colored wastewater produced from their processes. This study concentrates on the application of Advanced Oxidation Processes (AOPs) for synthetic dyes wastewater treatment. Photocatalysis process as one of AOPs was applied for the degradation of organic content of synthetic dyes wastewater. The reactive dye, C.I. Reactive Red 2 (RR 2) was used as the organic pollutant model at the concentration of 100 mg/l. The TiO<sub>2</sub> concentration of 0.05-0.4 g/ml was used as the photocatalyst. The bulk and nano-size of TiO<sub>2</sub> were coating on the PET plastic and the degradation of organic content was examined in the term of color and COD within 0-12 hrs under solar irradiation. By using 0.4 g/ml of bulk TiO<sub>2</sub>, the color degradation of 88% and COD removal of 46% was achieved. Furthermore, by using 0.4 g/ml of nano-size TiO<sub>2</sub>, the enhancement of color degradation and COD removal was observed, that is 98% and 56%, respectively.

## Keywords

*Advanced Oxidation Processes (AOPs), Dyes wastewater, Synthetic dyes, Photocatalysis process, Solar irradiation*

## 1. INTRODUCTION

Annually, textile industries produce a large volume of colored dye effluents which are toxic and non-biodegradable. The color of the effluent released into the water bodies has become a serious environmental problem. This situation was indicated by a lot of minimization and remediation programs around the world has become as one of the most important environmental tasks associated to this area.

Because of the refractory nature of the color of synthetic dyes, conventional biological treatment processes are ineffective, and adsorption and coagulation practices result in secondary pollution[1]. On the other hand, a more promising technology based on advanced oxidation processes (AOPs) has been studied widely for decolorization and degradation of textile dyes. Among the AOPs method, heterogeneous photocatalysis using UVilluminated Titanium dioxide (TiO<sub>2</sub>) semiconductor has received great attention due to its ability to degrade a number of organic and inorganic pollutants [2, 3]. Although TiO<sub>2</sub> suspensions yield higher reaction rates, the use of photocatalyst coated on material surfaces is necessary because the need for separation of TiO<sub>2</sub> from the reacted solutions can be avoided and they would allow application of photocatalysis. By using the sunlight solar photocatalysis has been an intensive area of research [4-6], where the use of large area TiO<sub>2</sub>-coated surfaces is very important.

Nano-scale semiconductors, for instance TiO<sub>2</sub> particles, have a higher surface area-to-volume ratio than their equivalent bulk, and thus allow for greater photon absorption on the photocatalyst surface. Moreover, recombination of the electron hole pair within the semiconductor particle is drastically reduced as particle size decreases. With decreasing particles size of semiconductor to nanometer-scale, the band gap energy greatly increased, which in turn led to higher redox potentials in the system. Therefore, the nano-scale semiconductor is expected to have higher photocatalytic activity than its bulk [7, 8]. Many study have also reported various methods to apply TiO<sub>2</sub> coating on various substrates[9]. TiO<sub>2</sub> was immobilized on ceramic [10], fiber glass[11], sand[12], rigid support (glass, quartz, and stainless steel)[13], pebbles [14], activated carbon[15], polystyrene beads[16], zeolites[17], and acrylic plastic [18]. The TiO<sub>2</sub> immobilized substrates have been successfully used for the photocatalytic degradation of several organic pollutants. However, to the best of our knowledge, the use of thermoplastic polymer resin such as Polyethylene terephthalate (PET) plastic has been limited reported. In the present study the TiO<sub>2</sub>-coated PET plastic was prepared by using the bulk and the nano particle of TiO<sub>2</sub>. Photocatalytic degradation of reactive dye using TiO<sub>2</sub>-coated PET plastic and solar irradiation was investigated.

Reactive dyes have been recognized as the most environmental problematic compounds in textile dye effluents [19, 20]. Research on textile effluent degradation has focused on fiber reactive dyes [21] for the several reasons. First, reactive dyes are a class of dyes with high application rate in the textile industry due to their reactivity with fibers and their color stability [22].

Second, reactive dyes represent an integral market share (almost 45% of all textile dyes produced annually belong to the fiber reactive class). Third, these dyes have low fixation rates, which results in highly colored spent dye-baths whose treatment is insufficient in conventional wastewater treatment plants [23]. Fourth, of special concern is the reactive dyeing process, where on average of 10 times more water is consumed for preparation, dyeing, washing and rinsing stages than for dyeing with other dye types.

Table 1: Properties of C.I. Reactive Red 2

Dye	C.I. Reactive Red 2
Chemical formula	$C_{19}H_{10}Cl_2N_6Na_2O_7S_2$
Molecular weight (g/mol)	615
C.I. number	
$\lambda_{max}$ (nm)	18200
	538

In this study, one of synthetic textile dyes, C.I. Reactive Red 2 (RR2) selected as a model pollutant. The chemical formula and some properties of the reactive dye are presented in Table 1. This type of dye was selected for current study since the chemical structure is known and the dye is frequently being applied for the dyeing of traditional cotton cloth in Indonesia.

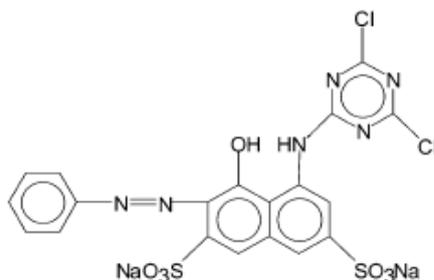

Figure. 1. Chemical structure of C.I. Reactive Red 2

The chemical structure of C.I. Reactive Red 2 can be illustrated in Fig. 1. A dye concentration of 100 mg/l was selected in the present study as previously reported [24-26] because the effluents originating from the cotton and polyamide dyeing factories are usually in the range of 10-200 mg/l and at this concentration the COD value is more than 150 mg/l, beyond the environmental quality standard of industrial wastewater effluent in Indonesia.

The use of solar energy to initiate the photodegradation of some organic pollutants, such as textile effluents, has been widely reported [27]. Although solar energy is a free, renewable and environmentally friendly energy source, it is not widely used in tropical countries like Indonesia. The objective of the research is to study the degradation of C.I. Reactive Red 2 by using the  $TiO_2$ -coated PET plastic under solar irradiation in the term of color and COD degradation.

## 2. MATERIALS AND METHOD

The synthetic dye wastewater was prepared by using C.I Reactive Red 2 (RR 2) obtained from FajarSetia Dyestuff in Jakarta and was used without further purification. The RR2 concentration was varied between 25-110 mg/l. The  $TiO_2$  anatase powder (bulk) and  $TiO_2$ anatase nano-powder were received from Sigma–Aldrich. Solvent (acetone) and adhesive was found from the chemical store.

The coating process was accomplished by mixing the  $TiO_2$ catalyst with acetone in the 300 ml beaker glass. The catalyst concentration was varied from 0 to 0.4 g/ml. The certain amount of catalyst was dissolved in 10 ml of acetone until a homogeneous solution recognized. Add the cyanoacrylate adhesive to the solution and stir slowly, followed by putting the PET plastic then stir until the thick solution obtained. Take the coated PET plastic immediately and place in the room air. Allow the PET plastic dry in the room temperature.

The solarphotocatalytic degradation was carried out in batch operation in a cylinder glass type of reactor. The reactor capacity is 300 ml with 7 cm of inside diameter and 9 cm of height. RR2 dye solution was prepared in distilled water, within the concentration of 25-100 mg/l For every experiment performed, the reactor was initially loaded with 250 ml of RR2 aqueous solution, after putting  $TiO_2$ -coated PET plastic, the color and COD degradation were observed every 3 hrs between 9 am and 3 pm under the sunlight for 2 days. The reactor was retained in the dark place when the experiment pending.

The TiO<sub>2</sub> particles catalysts were characterized by X-ray diffraction (XRD) and scanning electron microscope (SEM). The crystalline phases were determined using an X-ray diffractometer measurement (PC-APD Philip) with Cu tube anode, operated at 40 kV and 30 mA. A Scanning Electron Microscope (SEM), JEOL SEM-330 JAPAN was used to examine the surface morphology of TiO<sub>2</sub> coated PET plastic. Color degradation was measured by HACH Spectrophotometer and COD degradation was determined by titrimetric method. Degradation percentage of dye is defined as follows:

$$\text{Color degradation percentage} = ((C_o - C_t) / C_o) \times 100\% \quad (1)$$

Where  $C_o$  (mg/l) is the initial concentration of dye, and  $C_t$  (mg/l) is the concentration of dye at reaction time  $t$ (hr). The degradation of COD is represented by (2):

$$\text{COD degradation percentage} = ((COD_o - COD_t) / COD_o) \times 100\% \quad (2)$$

Where  $COD_o$  (mg/l) is the initial concentration of COD, and  $COD_t$  (mg/l) is the concentration of COD at reaction time  $t$ (hr).

### 3. RESULTS AND DISCUSSION

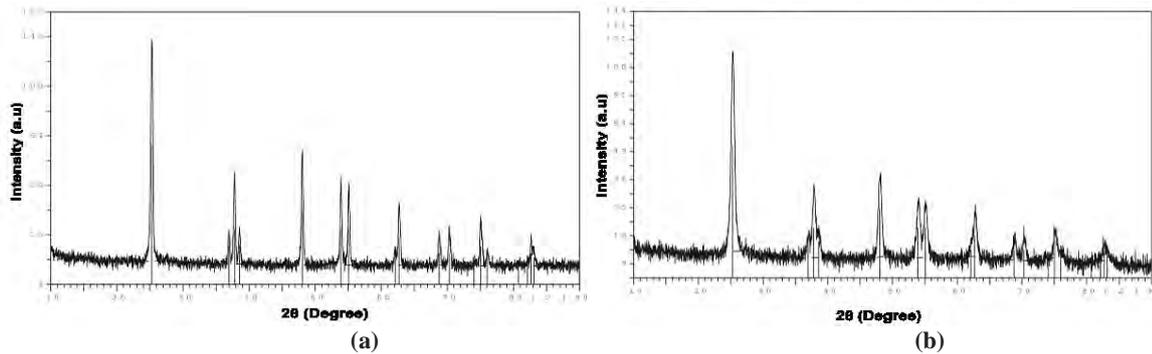

Figure 2: XRD patterns of (a) bulk-TiO<sub>2</sub> (b) nano-TiO<sub>2</sub> powder as-prepared

Figure 2 displays the X-ray diffraction pattern of bulk and nano-TiO<sub>2</sub> particles. It exhibits good crystallinity and all characteristic lines are attributed to the anatase phase in an excellent agreement with a reference pattern[28]. The average crystallite size of bulk and nano TiO<sub>2</sub> sample calculated from XRD line broadening using Scherrer equation is and 51 nm and 37 nm, respectively.

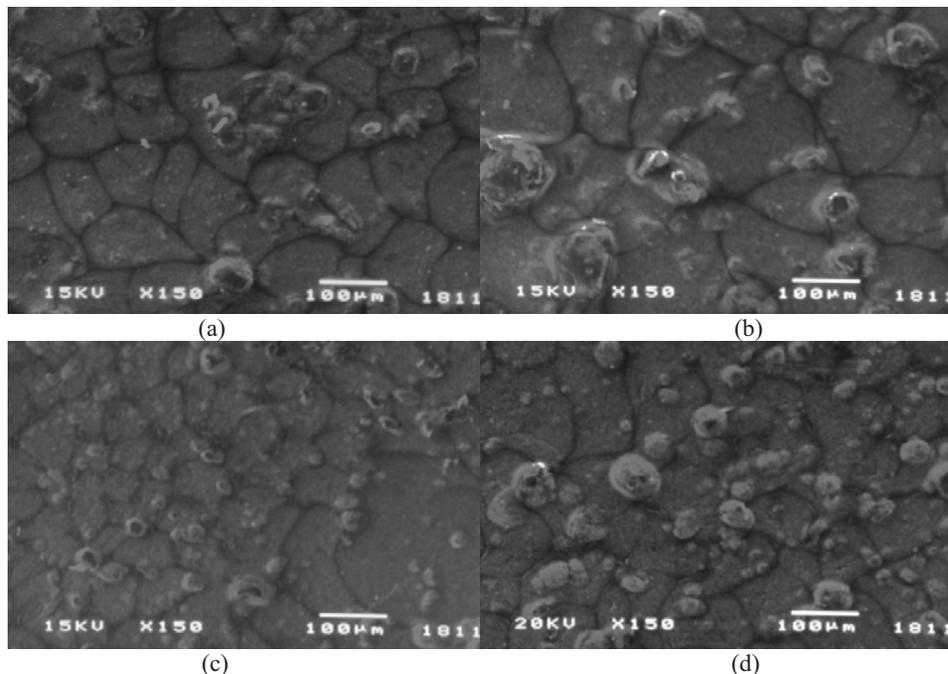

Figure 3. SEM images of TiO<sub>2</sub> anatase powder-coated PET plastic by using the concentration of (a) 0.05 g/ml, (b) 0.1 g/ml, (c) 0.2 g/ml, and (d) 0.4 g/ml

Photocatalysis process was studied by using the coated anatase powder and anatase nano-powder  $\text{TiO}_2$  catalyst on the PET plastic. Concentration of the catalyst used was varied 0, 0.05, 0.1, 0.2, and 0.4 g/ml. By increasing the catalyst concentration, more aggregates of  $\text{TiO}_2$  particles were observed in the SEM image as shown in Fig. 3 (a)-(d).

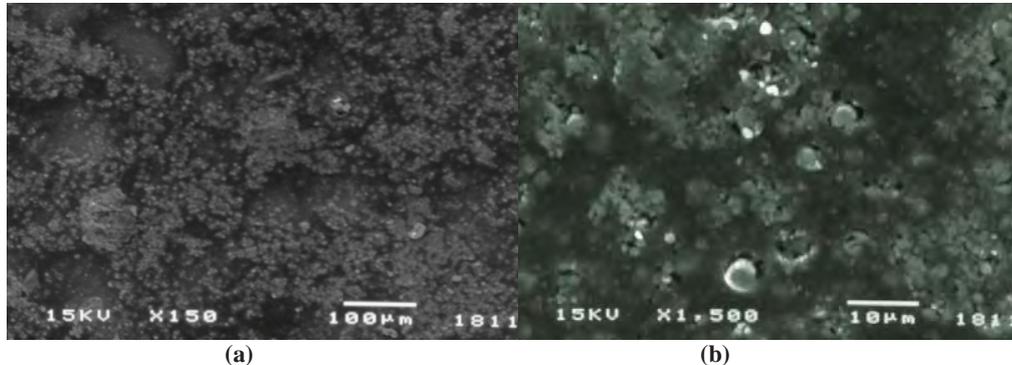

Figure 4. SEM images of  $\text{TiO}_2$  anatase nano-powder-coated PET plastic by using the concentration of 0.4 gr/ml (a) 150 times and (b) 1500 times of magnitude

It is obvious that when use the same concentration of  $\text{TiO}_2$  but with different  $\text{TiO}_2$  crystallite size, the different surface morphology observed as demonstrated in Fig. 3 (d) and Fig.4 (a). By means of the same magnitude of 150 times, the application of anatase nano powder shows more fine aggregate and homogeneity of particles formed than the application of anatase powder.

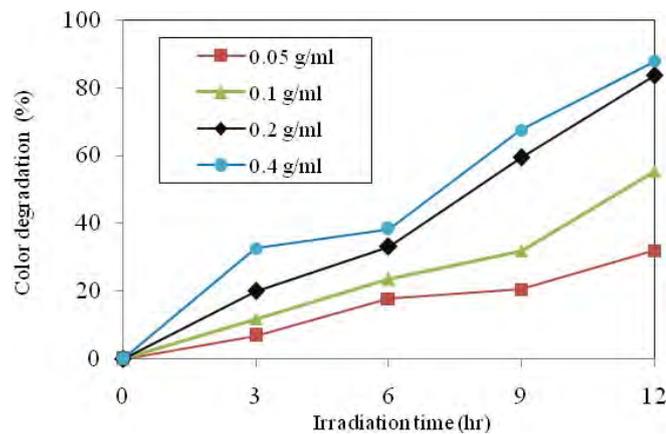

Figure 5. Effect of anatase powder  $\text{TiO}_2$  concentration on the color degradation percentage

The effect of catalyst concentration on the color degradation of RR2 can be illustrated in Fig. 5. In the experiment without using catalyst, there was no color degradation detected. The color degradation percentage increases with increasing catalyst concentration and irradiation time. The highest color degradation of 88% was achieved when use 0.4 g/ml of anatase powder  $\text{TiO}_2$ , as can be seen in the figure. The dosage of  $\text{TiO}_2$ -catalyst plays an important role in the photocatalytic decolorization of dyes [29]. Because the more the amount of catalyst the more of catalyst surface available to the photodegradation reaction take place.

By using the same catalyst concentration of 0.4 g/ml, the higher color degradation percentage was reached when apply the anatase-nano powder  $\text{TiO}_2$ . Almost complete of color degradation was monitored as presented in Fig. 6. Clearly the anatase-nano powder  $\text{TiO}_2$  has the higher effectiveness than anatase-powder  $\text{TiO}_2$ . It can be explained as the nano-structure of catalyst possesses the larger surface area so provide the more active surface to the reaction.

The photocatalytic activity of nano- $\text{TiO}_2$  was accounted to be higher than micron  $\text{TiO}_2$  (Degussa P25) in the degradation of active brilliant red X-3B [30]. Similar findings have been reported in the solar nanophotocatalytic decolorisation of Procion Reactive Red (H-E7B) and Procion Reactive Yellow (H-E6G), that the photocatalytic activity of nano- $\text{TiO}_2$  was found to be almost two times higher than that of micron- $\text{TiO}_2$  [31].

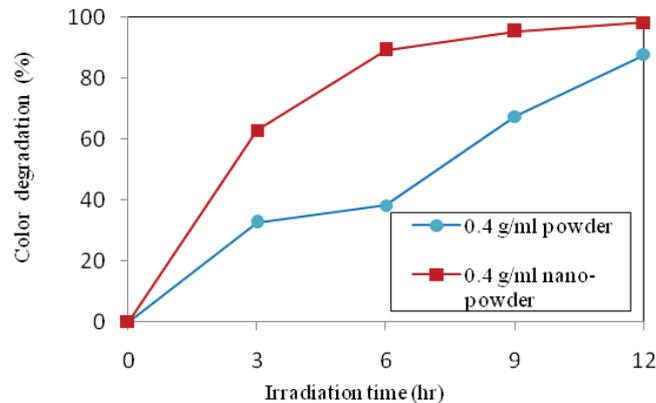

Figure 6. Color degradation of anatase powder and anatase nano-powder of TiO<sub>2</sub>

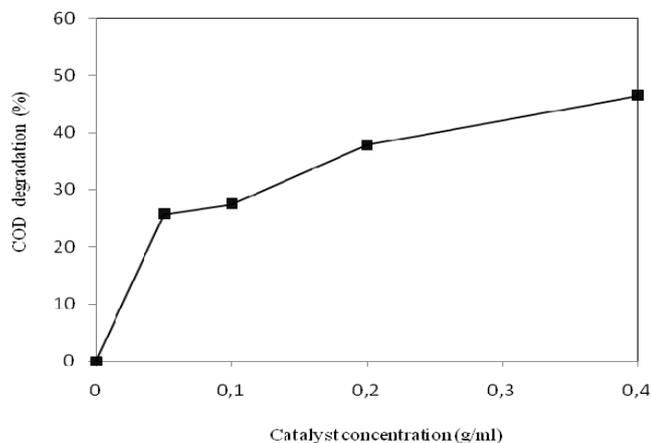

Figure 7. Effect of anatase powder TiO<sub>2</sub> catalyst concentration on COD degradation percentage

The pollutant degradation in the term of COD degradation percentage in the photocatalysis process under the sunlight by using the TiO<sub>2</sub>-coated PET plastic can be reported as exhibited in Fig.7. There was no COD degradation identified without the use of any catalyst. The COD degradation percentage increases with increasing the catalyst concentration. This result is in agreement with Neppolian et al. who conducted the study on solar/UV induced photocatalytic degradation of commercial textile dyes[31]. For the Reactive Yellow 17 (RY 17) dye, they found the percentage degradation of COD increases with the increase in the amount of TiO<sub>2</sub>. But further increase in the amount of TiO<sub>2</sub> from 500 to 600 mg in RY17, the percentage degradation decreases. Although the availability of active sites increases with the suspension of catalyst loading, but not the light penetration, hence the photo activation blocked.

The COD degradation of 46 % was achieved when using 0.4 g/ml of anatase powder TiO<sub>2</sub>. Furthermore, the COD degradation of 56 % was reached when using 0.4 g/ml of anatase nano-powder TiO<sub>2</sub>. The treatment of RR2 dye by photocatalysis process using nano-TiO<sub>2</sub> coated on PET plastic has been fulfilled the requirements of environmental quality standard of industrial wastewater effluent in Indonesia particularly in color and COD parameter. It reduced the color from 1750 to 30 pt-Co and the COD from 191 to 94 mg/l.

## CONCLUSION

The study of RR2 degradation under solar irradiation assisted by the TiO<sub>2</sub> catalyst-coated PET plastic was examined. It is found, by using 0.4 g/ml of bulk TiO<sub>2</sub>, the color degradation of 88% and COD removal of 46% was achieved. Furthermore, by using 0.4 g/ml of nano-size TiO<sub>2</sub>, the enhancement of color degradation and COD removal was observed, that is 98% and 56%, respectively. The results suggest that the use of solar irradiation could be a feasible technique for degradation of reactive dye sample.

## ACKNOWLEDGMENT

The authors would like to express gratitude the Directorate General of Higher Education Ministry of Culture and Education Republic of Indonesia for financial support through HIBAH BERSAING 2012.

## ABSTRACT

Hard water is water which contains high amount of Ca<sup>2+</sup> and HCO<sub>3</sub><sup>-</sup> ions and also many forms in nature. Hard water can cause the formation of crusts deposit in piping system and also can increase the detergent consumption in the washing process. The decrease of hardness can be done by pushing Ca<sup>2+</sup> and HCO<sub>3</sub><sup>-</sup> ions in hard water to precipitate into CaCO<sub>3</sub> by following the mixing process. The model of hard water used is solution of NaHCO<sub>3</sub> and CaCl<sub>2</sub> mixed by using mixer and equipped with rotary speed control. Variable measured are pH and solution conductivity by using pH meter and conductance meter in several mixer rotary speeds. The formation of CaCO<sub>3</sub> is measured by using EDTA complexometric titration. From this research, there is an increase of pH in NaHCO<sub>3</sub> solution by the increase of mixer rotary speed. The increase of NaHCO<sub>3</sub> solution's pH shows that there is migration of HCO<sub>3</sub><sup>-</sup> ions to be CO<sub>3</sub><sup>2-</sup> ions which can precipitate faster to form CaCO<sub>3</sub>. The mixing process can increase the NaHCO<sub>3</sub> and CaCl<sub>2</sub> solution conductivity which shows the decrease of hydrate ion's strength and may trigger the formation of CaCO<sub>3</sub>. The precipitation test result shows the increase of CaCO<sub>3</sub> formation because of the mixing process of NaHCO<sub>3</sub> and CaCl<sub>2</sub> solution. This result proves that the mixing of NaHCO<sub>3</sub> and CaCl<sub>2</sub> solution can increase the pH and conductance of solution, as well as the formation of CaCO<sub>3</sub>.

## Keywords

Mixing, CaCO<sub>3</sub> precipitation, Hydrate ion, Hard water

## 1. INTRODUCTION

Water contains a lot of Ca<sup>2+</sup> and HCO<sub>3</sub><sup>-</sup> ions are known as hard water. Calcium and Carbonate compounds are difficult to dissolve in water so that will separate from solution and form CaCO<sub>3</sub> particles which then produce crusts. Crusts in hard water can resist the flow of water in pipe and also can resist heat transfer process in heat exchanger equipment. The high of hardness can also cause the increase of detergent consumption, and also the formation of film layer in household equipment. CaCO<sub>3</sub> formation in hard water as CaCO<sub>3</sub> precipitation process is an equilibrium and slowing process. Increase of pH due to CO<sub>2</sub> release in solution will push precipitation of CaCO<sub>3</sub> as follow (equation 1) :

Saksono [1] found that mechanical agitation process on the CaCO<sub>3</sub> solution fastens the solute CO<sub>2</sub> to the gas phase so the pH solution will increase. The increasing of pH causes HCO<sub>3</sub><sup>-</sup> ion to be converted into CO<sub>3</sub><sup>2-</sup> ion and quickly create CaCO<sub>3</sub> as shown bellow (equation 2 and 3):

Ca<sup>2+</sup>, HCO<sub>3</sub><sup>-</sup>, and CO<sub>3</sub><sup>2-</sup> ions in hard water will be hydrated by polar water molecules as shown in Fig 1. The strength of ionic bonding with hydrate will influence the precipitation process.

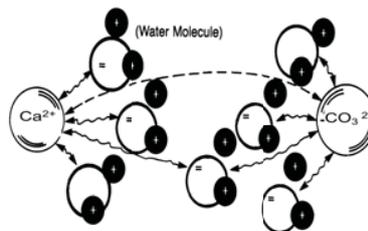

Figure 1: Ca<sup>2+</sup> dan CO<sub>3</sub><sup>2-</sup> ions and their hydrates

The hydrate ions bonding is low in strength and can be influenced by mechanical agitation process [2]. The decrease in hardness by pushing the  $\text{Ca}^{2+}$  and  $\text{HCO}_3^-$  ions to precipitate into  $\text{CaCO}_3$  can be done by mechanical agitation process. The mixing method is a method used in hard water which is cheap, simple, and also safe for human consumption compared to other method such as ion exchange resin or by the addition of  $\text{NaOH}$ . The process conceptual scheme to decrease the  $\text{Ca}^{2+}$  and  $\text{HCO}_3^-$  ions in hard water by using mixing and settling method has already proposed by Saksono [3] as shown in Figure 2 below.

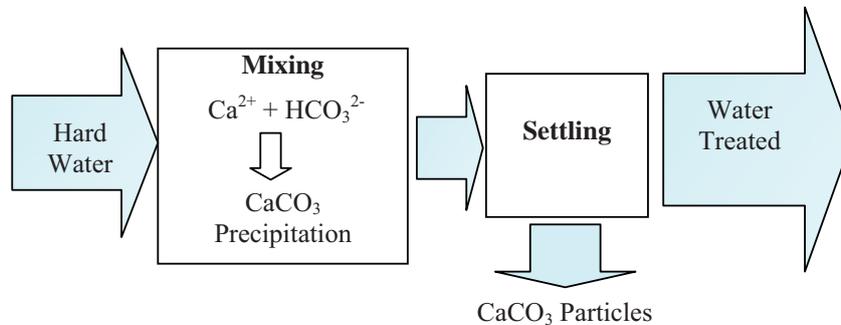

Figure 2: Schematic of mixing and settling process in hardwater treatment [3]

Hard water with high amount of  $\text{Ca}^{2+}$  and  $\text{HCO}_3^-$  ions is mixed in mixer until it precipitates to form  $\text{CaCO}_3$  particles. Hard water which has already mixed is then entered to agitation medium to be separated between water and  $\text{CaCO}_3$  particles. Answering how selective the mixing process can push the formation (precipitation) of  $\text{CaCO}_3$ , will be needed a preliminary study about the effect of mixing to the behavior of  $\text{Ca}^{2+}$  and  $\text{HCO}_3^-$  ions and also to the  $\text{CaCO}_3$  precipitation.

## 2. RESEARCH METHOD

This research used  $\text{CaCl}_2$  and  $\text{NaHCO}_3$  solution to observe the behavior of  $\text{Ca}^{2+}$  and  $\text{HCO}_3^-$  ions as hard water model by analyzing the change in pH and also solution conductivity.

The effect of mixing to pH and conductivity of each solution is observed separately in several rotation speed variations. Then,  $\text{CaCl}_2$  and  $\text{NaHCO}_3$  solution are mixed in a cylinder and the precipitation process is observed. Here are the explanations of this research.

**Hard water solution.** Electrolytes  $\text{CaCl}_2$  and  $\text{NaHCO}_3$  of reagent-grade and deionized water of the resistivity  $\approx 18 \text{ M}\Omega$ , which was obtained from Milli-Q water system were utilized as hardwater model.  $\text{CaCl}_2$  and  $\text{NaHCO}_3$  solutions were prepared by dissolving each electrolyte into the deionized water, and then kept in air-tight bottles in room temperature.

### Mixing process on each solutions.

250 ml of 0.01M  $\text{CaCl}_2$  and  $\text{NaHCO}_3$  are mixed separately in mixing medium (Ika Labortechnik RW 20) which has four 5-cm-blades and also equipped by rotary speed control (rpm). The mixing process is conducted for 30 minutes in plastic-cylinder-medium made from polypropylene with 10 cm inner diameter and 15 cm high and also fulfilled by 3 baffles.

The temperature of the solution in agitation and settling process equal to the ambient temperature of the surroundings (*i.e.*, room temperature, 28 – 29 °C). The pH and  $\text{CaCl}_2$  conductivity measurement is conducted before and after the mixing process by using Orion 250 A+ pH meter and Orion 105 A+ conductance meter. Fig 3 simplified schematic of mixing process in the presented work.

**Precipitation test.** 10 ml each of mixed  $\text{CaCl}_2$  and  $\text{NaHCO}_3$  solution is added together into reaction tube to measure the  $\text{CaCO}_3$  precipitation in a certain range of time by using EDTA complexometry method (accuracy 0.05 mg as  $\text{CaCO}_3$ ), and also the amount of ions  $\text{Ca}^{2+}$  consumed in solution as a measurement of  $\text{CaCO}_3$  precipitation. The flow diagram of this research is shown in Fig 4.

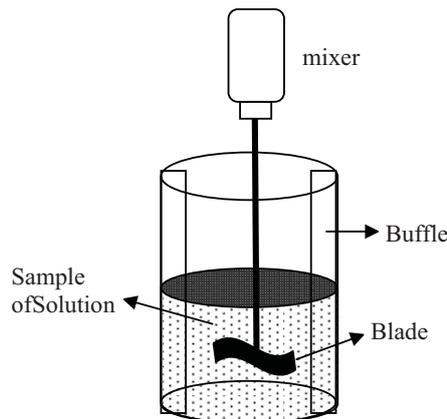

Figure 3: schematic of mixing process

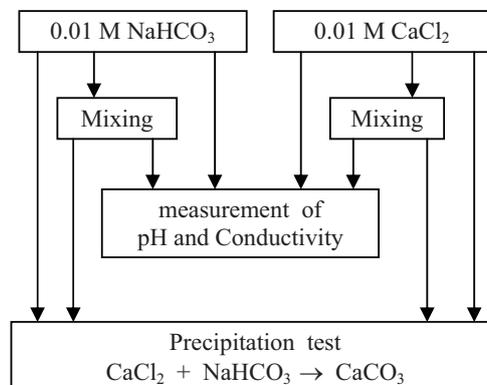

Figure 4: Research Flow Diagram

### 3. RESULTS AND DISCUSSION

The observation result of the effect of mixing to CaCl<sub>2</sub> solution is given in table 1. It can be seen the increase of NaHCO<sub>3</sub> pH after the mixing process which shows that there is releasing of CO<sub>2</sub> dissolved into gas phase and also the shifting of HCO<sub>3</sub><sup>-</sup> ions into CO<sub>3</sub><sup>2-</sup> ions in solution. The increase of rotary speed increases the solution pH of NaHCO<sub>3</sub>. There is no significant change of pH in the mixing process of CaCl<sub>2</sub> solution because of Ca<sup>2+</sup> and Cl<sup>-</sup> ions that is stable in the condition. Solution pH of NaHCO<sub>3</sub> is increase from 8.82 to 9.73 in 1500 rpm (Table 1). Hence, there are shifting of ion fractions of HCO<sub>3</sub><sup>-</sup> from 80% to 72% and increase of ion fractions of CO<sub>3</sub><sup>2-</sup> from 20% to 28% based on balance curve of carbonate solution (Fig 5).

Table 1: Effect of Mixing to 0.01 M NaHCO<sub>3</sub> and CaCl<sub>2</sub> Solution's pH and Conductivity at 30 Minutes Mixing Period

Round Velocity (rpm)	pH		Conductivity (mS.cm <sup>-1</sup> )		Increasing Conductivity (%)	
	NaHCO <sub>3</sub>	CaCl <sub>2</sub>	NaHCO <sub>3</sub>	CaCl <sub>2</sub>	NaHCO <sub>3</sub>	CaCl <sub>2</sub>
Non mixing	8.82	5.71	0.776	2.123	0	0
500	8.94	5.73	0.790	2.131	1.80	0.38
1000	9.52	5.72	0.825	2.163	6.31	1.88
1500	9.73	5.74	0.857	2.194	10.44	3.34

Cl <sup>-</sup>	1.81	0.43	340

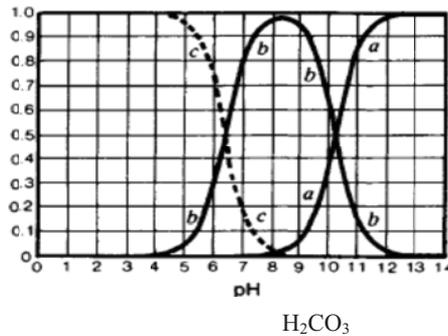

Figure 5: Carbonate and Bicarbonate ion fraction in solution vs pH Solution.[5]

The conductivity of electrolyte solution is able to show the mobility of the existing hydrates ions inside of the solution. The escalating of the conductivity of electrolyte on constant concentration, pressure, and temperature shows that there is a decreasing of hydrate ion diameter which comes with an decreasing of hydrate bond strength [6]. With other words, as the escalating of the conductivity increases, the strength of the hydrate ion bond will decrease and precipitation of ions is easier.

Ions, like Ca<sup>2+</sup> and CO<sub>3</sub><sup>2-</sup>, were covered by H<sub>2</sub>O molecules forming hydrated ion (Fig 1). The increasing of the conductivity of CaCl<sub>2</sub> and NaHCO<sub>3</sub> solution after the mixing process on Table 1 shows that there was a decreasing of the hydrate ion strength. The increase of NaHCO<sub>3</sub> conductivity is higher than CaCl<sub>2</sub>. It can be explained from data of ion's characteristic in Table 2. The thicker the hydrate ions ( $\Delta r$ ) will lead to the stronger the hydrate ions. The hydrate ions strength can be seen from the amount of the Hydration Gibbs Energy ( $\Delta G_{\text{Hydration}}$ ). Table 2 shows Ca<sup>2+</sup> have highest hydrate thickness and Hydration Gibbs Energy-nya. It shows that the strength of HCO<sub>3</sub><sup>-</sup> and CO<sub>3</sub><sup>2-</sup> hydrate ions was lower than CaCl<sub>2</sub>'s so it was easier to be effected by mixing process. This argument becomes the explanation why The increase of NaHCO<sub>3</sub> conductivity was much bigger than the increase of CaCl<sub>2</sub>'s conductivity.

Fig 5 shows the precipitation of CaCO<sub>3</sub> taken from higher mixed NaHCO<sub>3</sub> solution than mixed CaCl<sub>2</sub>. This result strengthens the previous explanation which states that the effect of mixing in NaHCO<sub>3</sub> solution is stronger in the weakening of its hydrate ions than the mixing of CaCl<sub>2</sub> solution. The mixing of un-mixed NaHCO<sub>3</sub> and un-mixed CaCl<sub>2</sub> solution shows the smallest CaCO<sub>3</sub> precipitation result. It happens because there is no increase of solution conductivity and also pH (Table 2), so the formation of CO<sub>3</sub><sup>2-</sup> is low and the strength of hydrate ions is relatively bigger/more stable compared to the mixed solution. Fig 6 shows that the rate of CaCO<sub>3</sub> precipitation from mixing sample in the first 30 minutes (nucleation zone) is higher than the un-mixed sample.

The preliminary step of CaCO<sub>3</sub> precipitation is the formation of CaCO<sub>3</sub> nuclei which is called as homogenous precipitation. Then, the nuclei will grow bigger to form CaCO<sub>3</sub> crystal which is called as heterogeneous precipitation. Fathi [7] got the super-saturation value needed to let the CaCO<sub>3</sub> homogenous precipitation is 40 times higher than its critical super-saturation, while for the heterogeneous precipitation is only 20 times higher than its critical super-saturation. It shows that the crystal growth of CaCO<sub>3</sub> (heterogeneous precipitation) is much easier to conduct than the nuclei formation of CaCO<sub>3</sub> (homogenous precipitation). The increasing pH shows that the amount of CO<sub>3</sub><sup>2-</sup> ions formed is higher, while the decreasing solution conductivity shows the weakening of hydrate in CO<sub>3</sub><sup>2-</sup> and Ca<sup>2+</sup> so that it will push the rate of CaCO<sub>3</sub> homogenous precipitation. Fig 6 shows the precipitation in the first 30 minutes (nucleation zone) that is about 8.1% for mixed NaHCO<sub>3</sub> sample which is much higher than the mixed sample of CaCl<sub>2</sub> that is only 2.7%, while the un-mixed sample is not yet precipitated.

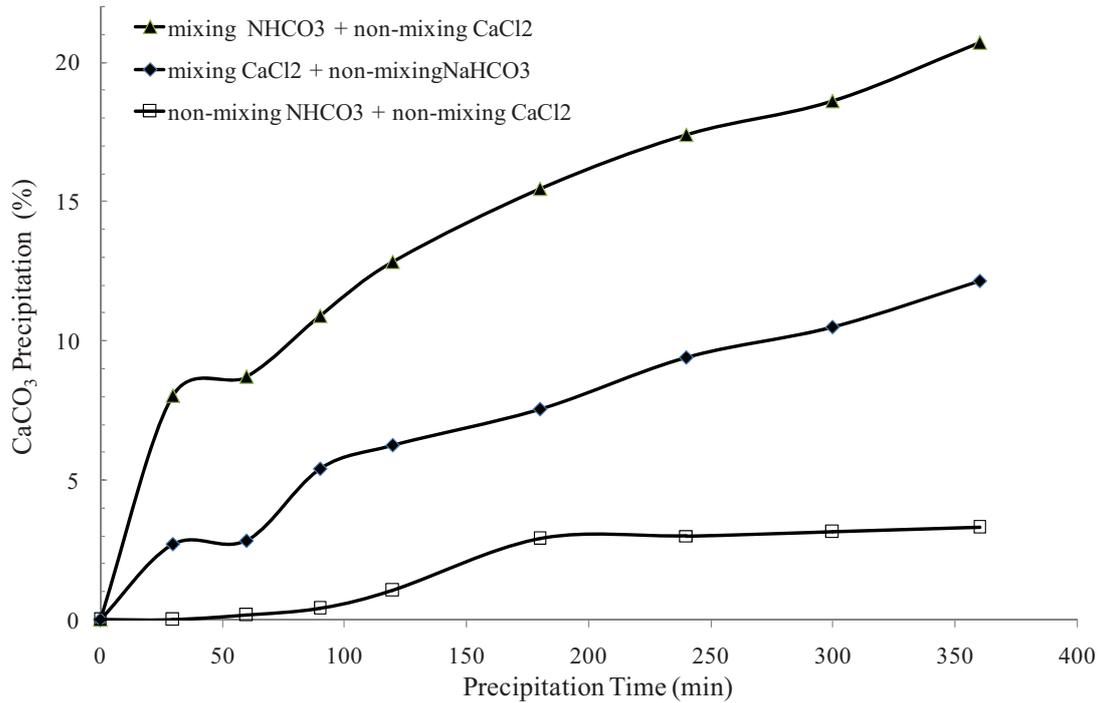

Figure 6: CaCO<sub>3</sub> Precipitation from 0.01 M NaHCO<sub>3</sub> and CaCl<sub>2</sub> by 30 Minutes Mixing at 1000 RPM.

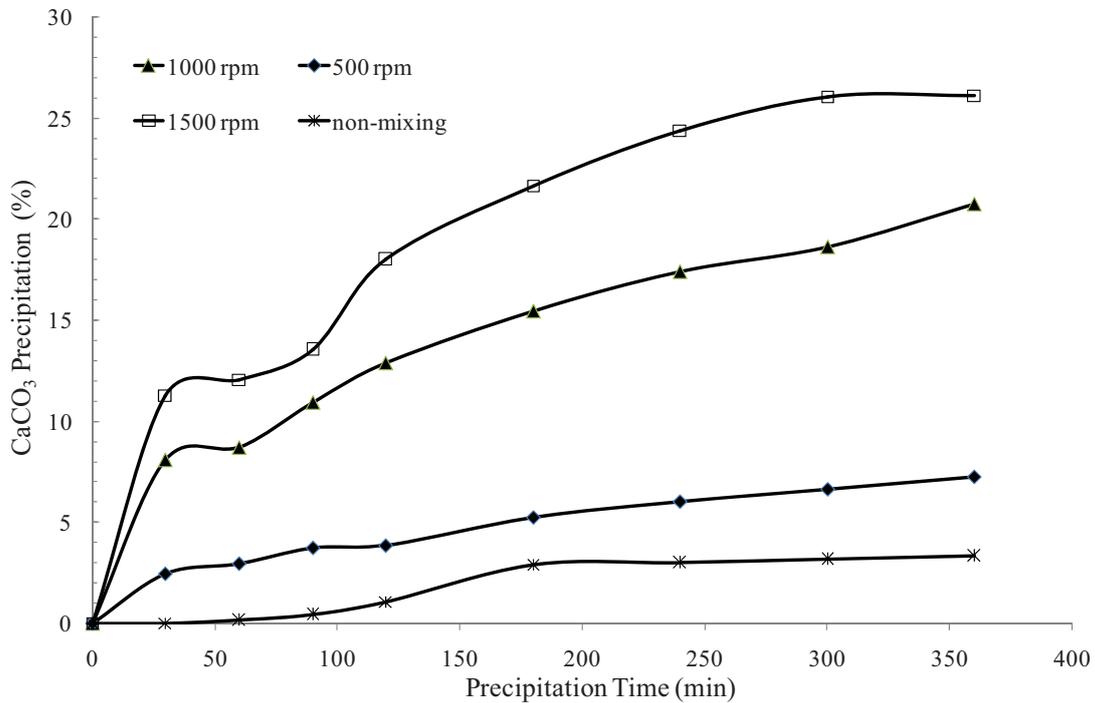

Figure 7: Presipitasi CaCO<sub>3</sub> Precipitation from 0,01 M NaHCO<sub>3</sub> mixing and dan CaCl<sub>2</sub> non mixing

Fig 7 shows that in the first 30 minutes zone of precipitation (nucleation zone), the precipitation of CaCO<sub>3</sub> flow rate increases significantly by increasing rotary speed (RPM). For process without mixing (un-mixed sample), it can't be seen that there is precipitation until the first 60 minutes, while in the 1500 rpm reaches 12% of precipitation. It shows that the mixing process is

effective to increase the precipitation of  $\text{CaCO}_3$  and rotary speed of mixer is the most influencing process variable to the rate of  $\text{CaCO}_3$  precipitation.

Table 2 shows that the increase of rotary speed of mixer in the solution of  $\text{NaHCO}_3$  causes the increase of solution pH and conductivity. It will affect to the increase of  $\text{CaCO}_3$  precipitation as shown in Figure 7. The higher the rotary speed of mixer can cause the increase of  $\text{CO}_2$  gas changed into gas phase and push the increase of  $\text{NaHCO}_3$  solution's pH. The increase of  $\text{NaHCO}_3$  solution conductivity by increasing of rotary speed of mixer shows that the strength of  $\text{HCO}_3^-$  hydrates ions is easy to be influenced by the mixing process (Table 1).  $\text{HCO}_3^-$  ionic bonding by its hydrates which is less strength by increasing the rotary speed of mixer causes the  $\text{HCO}_3^-$  ions is easier to interact by  $\text{Ca}^{2+}$  ions to form  $\text{CaCO}_3$ .

Other aspects which happened is the increase the rotary speed can increase the releasing of  $\text{CO}_2$  dissolved into gas phase from  $\text{NaHCO}_3$  solution, so the conversion from  $\text{HCO}_3^-$  ions into  $\text{CO}_3^{2-}$  ions happened (Equation 2). Furthermore, it will force the precipitation of  $\text{CaCO}_3$  (Equation 3).

#### 4. CONCLUSION

This research has already answered the hypothesis that mechanical agitation (mixing) in  $\text{NaHCO}_3$  and  $\text{CaCl}_2$  solution can cause the weakening of hydrates ions showed by the increase of solution conductivity and also the increase of  $\text{CaCO}_3$  precipitation. The mixing in  $\text{NaHCO}_3$  is also proved to increase the  $\text{HCO}_3^-$  ions conversion to form  $\text{CO}_3^{2-}$  which shows by the increase of solution pH.

The increase of rotary speed mixer causes the increase of solution conductivity, pH, and also  $\text{CaCO}_3$  precipitation.

The mixing conducted in this research is before the precipitation of  $\text{CaCO}_3$ . The next step needed to be observed is the mixing effect when the  $\text{CaCO}_3$  precipitation happened.

## ABSTRACT

Study of heating effect on coconut shell with a variety of holding time (10-50 hours) has been conducted at 350°C. After the heat treatment, samples were characterized using XRD and analyzed by employing “Match” software. A qualitative XRD analysis showed that the longer holding time has led to the phase formation of KCl, besides the amorphous carbon. The highest content of KCl phase, and the consequently lowest amorphous carbon, was achieved by the sample heated for 50 hours at 350°C. According the EDX analysis, the corresponding sample was dominated by the first five elements of C, O, K, Cl and Mg, signifying the presence of crystalline KCl, minor MgO and amorphous carbon.

## Keywords

Coconut shell, Heat treatment, KCl phase.

## 1. INTRODUCTION

Data of Asian Pacific Coconut Community (AAPC) provide information that Indonesia is a widest country with a growing area of coconut (*Cocos nucifera*): 3.86 million hectare with a production of 15.20 million items, equivalent to 3.03 million tonnes of copra per year. From copra production figures, there is a product in the form of coconut shell charcoal that can be used as fuel [1]. However, until now the coconut shell only used as fuel in a traditional manner, so it is necessary to produce coconut shell that has a higher value. The chemical composition of coconut shell includes lignin 29.4%, pentosans 27.7%, cellulose 26.6%, moisture 8%, 4.2% solvent extractives, uronic anhydrides 3.5% and ash 0.6% [2]. The coconut shell mainly contains water with Fe (0.01 mg/100mg), Mg (30mg/100g), P (37mg/100g), K (312mg/100g), Na (105mg/100g), Cu (0.04 mg/100mg), Cl (183mg/100g), and S (24mg/100g) [3].

The chemical compound of potassium chloride (KCl) is a metal halide salt composed of potassium and chlorine. In a pure state, KCl is odorless and has a white or colorless crystalline form of vitreous, the shaped of crystal structure is face centered cubic. Potassium chloride is widely used in scientific applications, one of them for making multilayer organic light-emitting diode (OLED) [4]. Previous studies provide information that the heat treatment process on a coconut shell resulted in KCl, but this compound was disappeared by heating at temperatures above 770°C [5-7]. To further study the presence of KCl, a research was conducted with young coconut shell heated at 350°C with variation of holding time from 10 to 50 hours. Characterization using X-ray diffraction (XRD) and energy dispersive X-ray microanalysis (EDX) were performed to study the phase formation during the heat treatment of coconut shell.

## 2. METHODS

The waste of coconut shell was dried naturally under of the sunshine and then thoroughly ground to be the 200 mesh powder using a mortar and pestle. After testing with DSC-TGA, the sample was placed on a crucible and heated at 350°C with a holding time for 10, 20, 30, 40 and 50 hours in an oxygen atmosphere. Samples were then characterized using XRD and analyzed by a Match software to search and match the phase content. To study the elemental composition, a characterization by EDX was carried out.

## 3. DISCUSSION

Coconut shell must be tested with DSC-TGA to know the mass changes toward temperature. The test results are shown in Figure 1. It shows that at temperatures above 350°C, the mass changes then persists up to temperature of 1200°C. At the temperature range of 100-120°C the water is evaporated, and at the temperature of 270°C the cellulose decomposition occurs. Acetic acid is formed at a temperature of 200-270°C. At the temperature of 270-310°C exothermic reaction takes has occurred. This phase, cellulose decomposition occurs intensively of into solution piroligant, wood gas and tar. Acid is an organic acid

with a low boiling point such as acetic acid and methanol were wood gas consists of CO and CO<sub>2</sub>. The temperature of 310-500°C occurs lignin decomposition, generated more tar while pirolignat solution decreases, CO<sub>2</sub> gas decreases while CO and CH<sub>4</sub> and H<sub>2</sub> increased. At the temperature of 500-1000°C is the phase of purification charcoal or carbon content [8]. DSC-TGA results can be determined that the heating to the heat treatment process was 350°C and this study used a variety of holding time: 10, 20, 30, 40, and 50 hours. After the coconut shell through the process of heat treatment with specified of temperature and holding time, carried out X-ray diffraction testing.

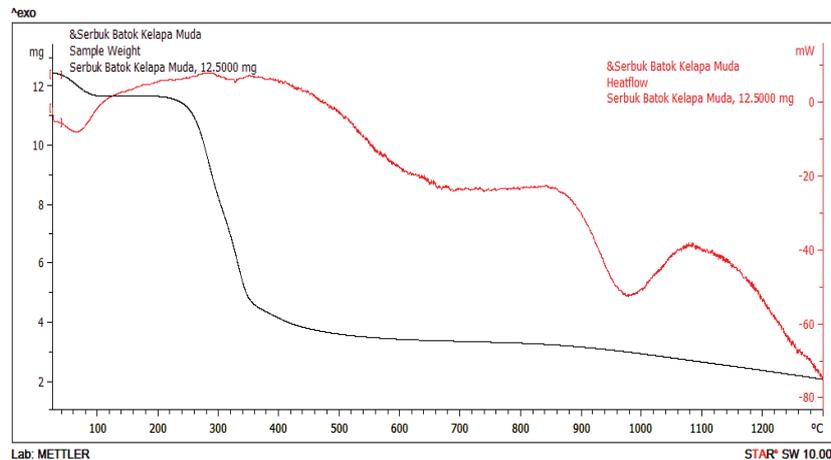

Figure 1: Result of DSC-TGA testing on young coconut shell.

From the results of the qualitative analysis of the diffraction data heating to 350°C and holding time during 10 hours obtained diffraction pattern is dominated by the phase "amorphous". Two diffraction peaks at 28°2θ and 41°2θ are KCl phase. Coconut shell with holding time during 20 hours, "amorphous" phase decreased but the KCl be more crystalline. Phase forming at holding time for 30, 40 and 50 hours identified the "amorphous" phase decreasing and increasing of potassium chloride (KCl) phase, as seen in Figure 2 with mark "x" as the crystalline phase of KCl. The longer of holding time, the sample showed KCl crystalline phases is higher and phase "amorphous" is more decrease. Holding time during 50 hours indicates the highest KCl crystalline phases and the formation of another phase with \* mark as MgO phase, then EDX testing required on samples upon heating with holding time in 50 hours.

Based on known results of EDX testing is the dominant element of carbon and oxides, with the percentage of atoms at the C and O elements in a row is 50.53% and 40.95%. There are impurities elements such as Na, Mg, Al, Si, P, S, Cl and K, which has the atomic percentage of 0.18%, 1.21%, 0.12%, 0.43%, 0.73%, 0.25%, 0.88 and 4.72%. The amorphous phase present in the sample identified an element of C, O, Na, Mg, Al, Si, P, and S. The most dominating element is the amorphous carbon phase. Increasing KCl phase was influenced by oxygen as atmospheric gas when using furnaces. The presence of elements of C in the sample can bind to the atmospheric then transformed become CO<sub>2</sub> bonding and other hydrocarbons bond released in the air. When the holding time is enhanced so the pyrolysis reaction is more perfect that of carbon decreases but liquids and gases (impurities) increase. Heat treatment time is optimal for purifying carbon coconut shell is 3 hours and the optimal temperature for heat treatment of coconut shell is 600°C [9]. So that the crystalline phase of KCl obtained when the holding time more than 3 hours. The highest of KCl crystalline phases obtained holding time during 50 hours.

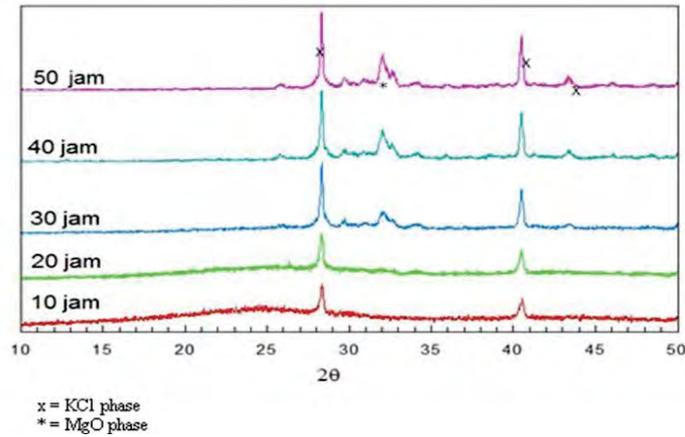

Figure 2: X-Ray Diffraction pattern on coconut shell at 350°C with holding time: 10, 20, 30, 40 and 50 hours.

Table 1: Result of EDX testing

Elements	Mass ratio (%)	Atomic ratio (%)
C	38.97	50.53
O	42.06	40.95
Na	0.26	0.18
Mg	1.89	1.21
Al	0.21	0.12
Si	0.77	0.43
P	1.45	0.73
S	0.52	0.25
Cl	2.00	0.88
K	11.86	4.72

For future research, heat treatment is needed at the optimal temperature (no more than 770°C) and holding time for obtain KCl in a higher percentage. There must be a method needed to separate the pure KCl from coconut shell, because there are some application of KCl for scientific applications, medicine, and food processing. Fortunately, this can be obtained from inexpensive materials such as coconut shells.

#### 4. CONCLUSION

Mass changes toward temperature in a young coconut shell can be determined by using DSC-TGA testing. Obtained at 350°C there is a change in the mass of the material. When a young coconut shell was heated at 350°C with a holding time for 10 hours, 20 hours, 30 hours, 40 hours and 50 hours obtained qualitative analysis results diffraction data is dominated by the phase "amorphous" and crystalline phases of KCl. Higher holding time, crystal growth occurs so that KCl phases increased. So holding time for 50 hours, there is the highest KCl crystalline phase. With EDX testing, unknown elements contained in the sample with 50 hour holding time are C, O, Na, Mg, Al, Si, P, S, Cl, and K. Elements of the most dominating and indicates the formation of an amorphous phase is the element of C. There is crystalline phase of KCl and C elements that identify the phases is amorf.

### ABSTRACT

Experiments were performed in a piping system to examine the effects of flow rate and  $\text{Cu}^{2+}$ , a common metal ion in wastewater, on kinetics of gypsum ( $\text{CaSO}_4 \cdot 2\text{H}_2\text{O}$ ) scale formation. The scaling was monitored by measuring the decrease in  $\text{Ca}^{2+}$  concentrations,  $[\text{Ca}^{2+}]$ , of the scaling solution. AAS analysis shows that  $[\text{Ca}^{2+}]$  reduces progressively after a certain induction time, during which time the concentration remains steady. Thus, the gypsum scale in pipes does not form spontaneously. Higher impurity concentrations (0.00 to 10.00 ppm  $\text{Cu}^{2+}$ ) result in longer induction time (26 to 42 min), which indicate that  $\text{Cu}^{2+}$  prohibit the scale formation. Moreover, the higher the impurity concentrations the less the scale mass produced. Reduction in scale mass was as high as 61% depending on impurity concentrations and flow rates. Data of  $[\text{Ca}^{2+}]$  versus time were used to calculate the reaction rate of the scale formation. It was found that the reaction follows a first order with rate constants between 5.83 and 7.63 per hour.

### Keywords

CO<sub>2</sub>, three-pass flow NTP reactor, DBD, CO, synthesis gas.

### INTRODUCTION

The increase of CO<sub>2</sub> emission is believed to cause climate change. One of the efforts to reduce the CO<sub>2</sub> emission is to decompose it into CO and O<sub>2</sub>, where CO can further be used as feedstock in the production of various useful chemicals. CO, along with H<sub>2</sub> gas known as synthesis gas (syngas) is a main component of industry gas, which has a significant role in producing various chemicals, such as urea, methanol, inorganic and organic carbonate, polyurethane and polycarbonate. DBD Non-thermal plasma has tremendous capability to decompose CO<sub>2</sub> gas at low pressures and low temperatures. The aim of this research is to observe the decomposition of CO<sub>2</sub> into CO and O<sub>2</sub> using three-pass flow configuration of DBD Non-thermal Plasma (NTP) reactor.

### METHOD

This experiment used three-pass flow DBD NTP reactors, that has the advantage could simultaneously cool the High Voltage Electrode (HVE) and preheat the gas feed flow before entering the plasma zone. The existence of this cooling process made this reactor did not require a separate cooling device in its operation.

The research parameters were feed flow rates and plasma reactor electric voltage. The experiment was carried out at reaction time of 2.1, 4.2, 6.3 and 8.4 minutes in R1, R2 and R3. The feed flow rates was 500, 1000 and 1500 cm<sup>3</sup> / min and the electric voltage was 5.44 to 9.5 kV.

### RESULTS AND DISCUSSION

Figure 1 indicated that the CO<sub>2</sub> conversion reached the peak at 2.1 minute and then decreased again after that. The decrease might be taken place due to the reverse reaction, that caused by the very high temperature inside the plasma reactor.

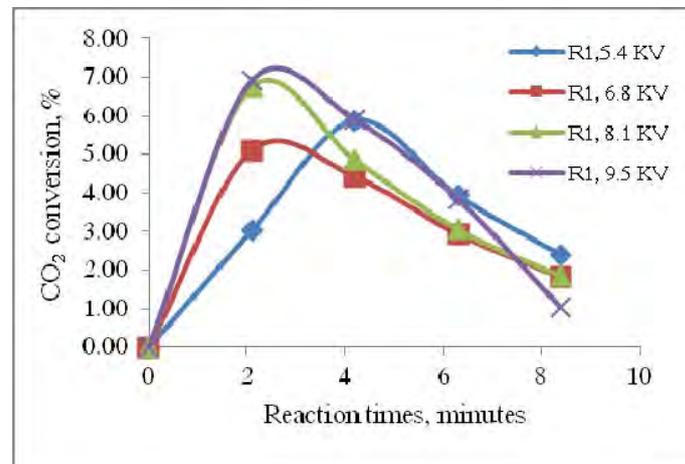

Figure 1: CO<sub>2</sub> conversion in R1 for various electric voltages and reaction times.

The highest conversion was reached for residence time of 5.01 minutes in the lowest feed flow rates.

The Specific Energy (SE) was about 270 kJ/mole, which is lower than previous experiments as well as its energy bonding.

## CONCLUSION

The decomposition of CO<sub>2</sub> in three-pass flow DBD NTP reactor were reached the peak of conversion at the reaction time 2.1 minute, and then declined again after that. This was caused by the reverse reaction due to the high temperature of plasma reaction. The CO<sub>2</sub> conversion increased with the increasing of electric voltage and residence time as well as decreasing the feed flow rate. The SE was 270 kJ/mole, being lower than previous experiment and its energy bonding as well.

### ABSTRACT

Since the energy crisis in 1973, the problem of energy into the world topic. Developed countries began to contest the new breakthrough in generating alternative energy which is much cheaper than oil and gas. Beside, sooner or later will run out of fossil fuels. One example of alternative energy is that hydrogen gas content of substance very much in nature. Hydrogen gas obtained by the process of electrolysis of water.

The water in the electrolysis into oxygen and hydrogen. Hydrogen gas that had levels above 4% and below 75% will explode more terrible than 3 kg LPG cylinder blast in the absence of fire when mixed with oxygen. Hydrogen gas as an alternative energy used to fuel the 135 cc motorcycle engine. Intended use Hydrogen gas is to conserve fuel. From the results of research on the use of hydrogen gas to be mixed with fuel obtained 135 cc motorcycle engine that the engine can blow sparks with the same power as before hydrogen gas mixed with the use of less fuel. Noted that the use of a mixture of hydrogen gas and gasoline fuel in the combustion chamber of gasoline can save fuel up to 50-60%.

### Keywords

*Electrolysis, hydrogen gas, mixed hydrogen with fuel*

### 1. INTRODUCTION

In the era of globalization, technology was evolves so rapidly, especially in the mining sector (gas and oil) and chemicals, the most important thing is the thermal efficiency of the engine and fuel used. Currently, the depletion of fuel the world has started to trigger upheaval in society. The government's decision to raise the price of fuel (BBM) certainly adds to the burden of the community in an already difficult economic condition. While there were no bright spots developing alternative energy fuel. The best solution in dealing with the problem is trying to find a good step toward an energy crisis that is expected to appear later when we are still dependent on fossil fuel use or fuel oil (BBM). Some researchers have been researching and developing materials dung and human waste which is processed an aerobically to produce methane gas called biogas. But alternative energy is widely used as a household fuel, and have not been developed in the automobile industry. Alternative energy is quite widely used in motor vehicles today is hydrogen gas.

Hydrogen can serve as energy for all uses as appropriate petroleum and natural gas, other than that it was only found in nature in the form of compounds. Hydrogen is available in water and organic compounds in the form of hydrocarbons, such as natural gas, coal, and biomass. Therefore, hydrogen must be produced through the use of energy before the hydrogen itself is available as an energy source. Decomposition of the chemical bonds in water will produce hydrogen that can be used as fuel. Hydrogen can be produced by several processes, including the process of electrolysis, photo electro chemical cells, photochemical, steam reforming, and the photo biology.

In the testing to be performed, use of hydrogen gas as a fuel blended with gasoline as a fuel can save, the 135 cc motorcycle engine up to 40%. How to produce hydrogen is by the process of electrolysis to separate water  $O_2$  and  $H_2$ . Hydrogen is obtained mixed with the fuel used so getting a new octane rating higher.

## 2. BASIC THEORY

### 2.1 Sections and Subsections

The fuel is a material that can be used to generate energy and produce mechanical work in a way that can be controlled. [5] In other words, the fuel is a substance that produces heat energy is mainly used. Most of the fuel produces energy when burned in air. The process used to convert fuel into energy include chemical reactions, such as combustion, and nuclear reaction (nuclear fission or nuclear fusion). Fuel is also used in the cells of organisms in a process known as metabolism. Hydrocarbon fuel source is most commonly used today, but many other substances can be used as well.

Comparison of gasoline and air mixture must be determined in such a way in order to obtain efficient and complete combustion. On the right ratio mix of gasoline and air are ideal (stoichiometric ratio) for the combustion process in the engine is 1: 14.7. [4] However, in practice, the optimum mixture ratio can not be applied continuously at every operational situation, for example: round when idle (slow) and a full load of vehicles consume fuel air mixture that fat, whereas in other circumstances the use of air petrol mixture can approach the ideal. It says mixed thin / poor, when in a mixture of gasoline and air there are more than 14.7 percentage of the air, whereas if it is less than that number is called a rich mixture / fat.

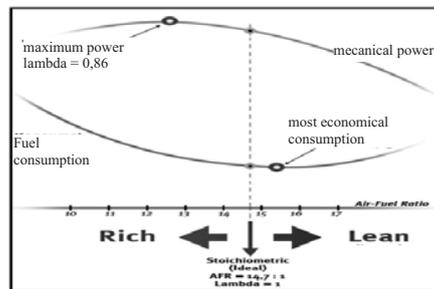

Figure1: Effect of water - fuel ratio on consumption and engine power

Each fuel combustion characteristics and values are different. Characteristics that determine the properties of the combustion process, which is less favorable properties can be perfected by way of adding chemicals to the fuel, with the hope of influencing the anti-knocking letup of power or fuel, and in this case pointed to what is called the octane number. The process of burning fuel in a gasoline motor or internal combustion engine greatly influenced by a number, whereas in Diesel motors greatly influenced by the cetane number.

The purpose of combustion of fuel to obtain energy is called the thermal energy (heat energy). Burning fuel results in the form of thermal energy can be in the form of energy into another, such as: energy for lighting, mechanical energy, and so on. Thus each of the burning fuel would be in getting some other form of energy that can be adjusted as needed. The remains of the burning of the fuel need to be noticed. Therefore the rest of the imperfect combustion products will be negatively affect the environment. This residue will contain toxic gases, which are mainly in the motor caused by the combustion of gasoline. While the results of that caused by the burning of diesel motors can lead to gas, dark smoke that will pollute the environment. But in fact, the pollution caused by the combustion in Diesel motors are not harmful to the environment, when compared with the residual gas combustion in motor gasoline.

### 2.2 Liquid Fuels

#### 2.2.1 Gasoline (petrol) - a standard 87 RON

Petrol is a liquid mixture derived from petroleum and is mostly composed of hydrocarbons and used as a fuel in internal combustion engines. The term gasoline is widely used in the oil industry, even in the company is not America. Sometimes the term gasoline motor is used to distinguish it from avgas, gasoline used by light aircraft. Fuel Type Gasoline is a common name for several types of fuel intended for combustion engines with ignition. In Indonesia there are several types of fuel type petrol which has a different quality of combustion. Quality value type of gasoline is calculated based on the value of RON (Octane Random Number). By RON gasoline is then divided into 3 types:

- 1) Premium (RON 88): Premium is a kind of distillate fuel oil yellowish clear. The yellow color is due to the additional dye (dye). The use of premium is generally to fuel gasoline-powered vehicles, such as cars, motorcycles, outboard motors and others. Fuel is often also called motor gasoline or petrol.

- 2) Pertamax (RON 92): intended for vehicles that require the use of high-octane fuel and unleaded (unleaded). Pertamax also recommended for vehicles produced over the year 1990 primarily been using similar technology with electronic fuel injection and catalytic converters.
- 3) Pertamax Plus (RON 95): This type of fuel is in compliance with the performance standards of the International World Wide Fuel Charter (WWFC). Intended for advanced technology vehicles that require the use of high-octane fuel and environmentally friendly. Pertamax Plus is highly recommended for vehicles with a compression ratio > 10.5 and also the use of technology Electronic Fuel Injection (EFI), Intelligent Variable Valve Timing (VVTi), (VTI), Turbochargers and catalytic converters.

### 2.2.2 Solar (high speed diesel)

Diesel, in Indonesia, better known as solar, is an end product which is used as a fuel in a diesel engine invented by Rudolf Diesel. Diesel is similar to heating oil, which is used in central heating. Diesel is used in diesel engines (cars, boats, motorcycles, etc.), a type of internal combustion engine. Rudolf Diesel originally designed the diesel engine to use coal as a fuel, but it is more effective oil. Diesel car trips completed on January 6<sup>th</sup>, 1930. The trip starts from Indianapolis to New York City - distance (1300 km). This proves the usefulness of the internal combustion engine.

## 2.3 ELECTROLYSIS OF WATER

The Separating hydrogen and oxygen using electricity. Water molecules can be broken down into the elements of the source by flowing electric current. This process is called electrolysis of water. At the cathode, two water molecules react with the capture of two electrons, reduced to H<sub>2</sub> gas and hydroxide ions (OH<sup>-</sup>). Meanwhile at the anode, two other water molecules break down into oxygen gas (O<sub>2</sub>), release 4 H<sup>+</sup> ions and electrons flow to the cathode. Ions H<sup>+</sup> and OH<sup>-</sup> experienced neutralization forming back some water molecules. Equal overall reaction of electrolysis of water can be written as follows.

Hydrogen and oxygen  $2H_2O(l) \rightarrow 2H_2(g) + O_2(g)$  gas produced from this reaction to form bubbles on the electrodes and can be collected. This principle is then used to produce hydrogen and hydrogen peroxide (H<sub>2</sub>O<sub>2</sub>), which can be used as fuel for hydrogen vehicles.

## 2.4 FUEL CONSUMPTION

*Fuel consumption* (FC) is a parameter which is used in the system to describe the combustion engine fuel consumption. Fuel consumption is defined as the amount of the resulting fuel consumption per unit time (cc / min). A low value indicates FC, economical fuel consumption. Therefore, a low FC values is very desirable to achieve fuel efficiency. Fuel consumption (FC) can be calculated using the following formula:

$$FC = \frac{V}{t} \quad (1)$$

where:

FC	: Fuel Consumption	[cc / min]
V	: Volume of the combustion chamber	[cc]
t	: time	[minutes]

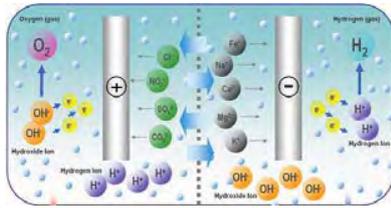

The things that affect the amount of fuel consumption as follows:

improper vehicle use, fuel system defective (leaking gasoline, gasoline dikarburator surface is too high, the air filter is dirty and low speed setting is not good), faulty ignition system (ignition time is not right, popping plugs incorrectly, damaged circuit breaker contact point) , low engine compression pressure.

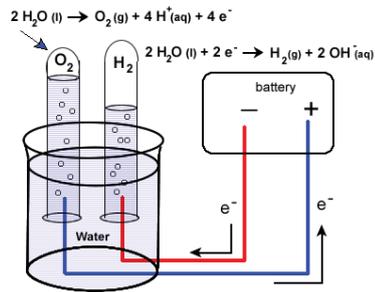

## 3. MAKING AND TRIAL

### 3.1 Tools and Materials

In manufacturing, the use of water electrolysis process using DC electric current to split water (H<sub>2</sub>O) into HHO gas is then used for combustion gases in the combustion chamber. The tools and materials that will be used to conduct research ways to produce hydrogen consist of two main parts:

(a)

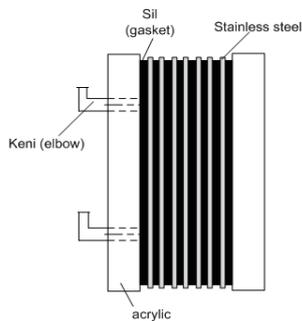

(b)

Figure 2: (a) Electrolysis I, (b) Electrolysis II

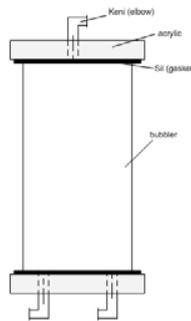

### 3.1.1 Generator Hidrogen

The components of the hydrogen generator are:

- |   |   |
|---|---|
| <p>1. Mica Plate (<i>acrylic</i>)<br/>         Quantity: 2 pieces<br/>         Size: 155 x 125 mm<br/>         Thickness: 10 mm</p> | <p>2. Plat Stainless steel<br/>         Total: 7 plate<br/>         Dimensions: 150 x 75 mm<br/>         Thickness: 1 mm, type: 316 L</p> |
| <p>3. Seals (gaskets)<br/>         Quantity: 8 pieces<br/>         Size: 150 x 75 mm<br/>         Thickness: 5 mm</p>               | <p>4. Elbow<br/>         Amount: 2 pieces<br/>         Size Do: 6 mm</p>  |
| <p>5. Nuts and Bolts<br/>         Quantity: 6 pieces<br/>         Size: M12<br/>         Length: 95 mm</p>                          |   |

(a)

(b)

Figure 3: (a) 6 cell hydrogen generator scheme is made, (b) scheme bubbler made

### 3.1.2 Bubbler

The components of the bubbler is (see figure 3 (b)):

- |   |  |
|---|--|
| 1. Bubbler<br>Quantity: 1 piece<br>Size: 175 mm diameter x 58 mm<br>Type: PVC   | 2. Acrylic<br>Quantity: 2 pieces<br>Size: 85 x 80 mm<br>Thickness: 10 mm |
| 3. Seals (gaskets)<br>Quantity: 2 pieces<br>Size: 65 x 65 mm<br>Thickness: 5 mm | 4. Nuts and Bolts<br>Quantity: 4 pieces<br>Size: M10<br>Length: 220 mm   |
| 5. Elbow<br>Total: 3 pieces<br>Do Size: 6 mm                                    |  |

### 3.1.3 The Other

- Hose are , diameter size: 6 mm, length: 2 m
- Distilled water
- KOH

The Explanation tool: This tool uses the media distilled water that has been mixed with KOH and then put in a bubbler to almost fill half the bubbler. Water that has been incorporated in part will lead to a hydrogen generator through one hose. Stainless steel that serves as conductor of the current deal.

### 3.2 Preparation tool

As for how to make hydrogen generator tool are:

- Give 3 holes on all stainless steel plates each with 2 holes are aligned on top and 1 bottom hole.
- Give a very large hole in the middle on all the seals (gaskets) size 150 x 75 mm.
- Provide 6 holes grooves on both the acrylic plate with 3 holes on the left side and 3 holes on the right side parallel to the size M12 bolt size. Then give the plot holes in the middle of two pieces the size elbow size 3/8 inch on one plate of mica.
- Align 7 pieces stainless steel plate in between the 8 seals (gaskets) size 150 x 75 mm and then sandwiched between two pieces of mica plate size 155 x 125 mm.
- Then between 2 mica mounted M12 bolts and nuts firmly to prevent leakage.
- For 2 holes in the mica plate, put 2 pieces of elbow 3/8 inch.

(a)

(b)

Figure 4: (a) Hydrogen Generator, (b) Bubbler

- Give one big hole on both seals (gaskets) size 65 x 65 mm.
- Give the plot holes 4 pieces at 2 mica plate size 85 x 80 mm the size of the nuts and bolts of M10 and 1 piece of plot holes in the middle of the plate-sized elbow 3/8 inch.

9. Give two pieces of hole groove on one mica plate size 85 x 80 mm the size of elbow 3/8 inch and 1 plot holes in other mica plate size 85 x 80 mm size Keni 3/8 inch.
10. Replace the seals at the top and bottom of the bubbler and the wedge using 2 pieces of mica plate size 85 x 80 mm and bolted using M10 bolts and nuts firmly to prevent leakage.
11. Then attach the two pieces of mica plate perforated elbow in 2 and 1 piece elbow in perforated acrylic plate 1.

#### 4. TRIAL AND ANALYSIS

After testing the device fabrication, testing consists of two phases, namely:

1. Testing to test out whether or not the HHO gas.
2. Tests on the vehicle to test the fuel savings.

##### 4.1. Testing to test out whether or not the HHO gas.

In this test experiment performed as in Figure 5 (a), and the resulting table 1 as follows:

Table 1: The test results came out much HHO gas

Current (Amperes)	Testing I (Litres / Minutes)	Testing II (Liters / Minutes)	Testing III (Litres / Minutes)	Average (Litres / Minutes)
5	0,13	0,14	0,13	0,133
7	0,2	0,21	0,22	0,21
8	0,25	0,26	0,24	0,25

##### 4.2. Tests on the vehicle to test the fuel savings.

The series of tests can be seen in Figure 5 (b), while the trial is divided into two parts, namely:

1. The test on the motor before replacing a hydrogen generator, while the attached test results in Table 2 below:

Table 2: The test results mileage on the motor vehicle without a gas mixture of hydrogen

Examination	Fuel Consumption (ml)	Mileage (km)	The Average Speed (km / h)
I	170	6,25	30-40
II	170	6,1	30-40
III	170	6,65	30-40
Average		6,33	30-40

2. Testing the motor after a hydrogen generator installed, while tests are carried out on the motorcycle brand "type Yamaha Jupiter MX 135 cc", after a hydrogen generator fitted with a speed of 30-40 km / h, would result in Table 3 as follows:

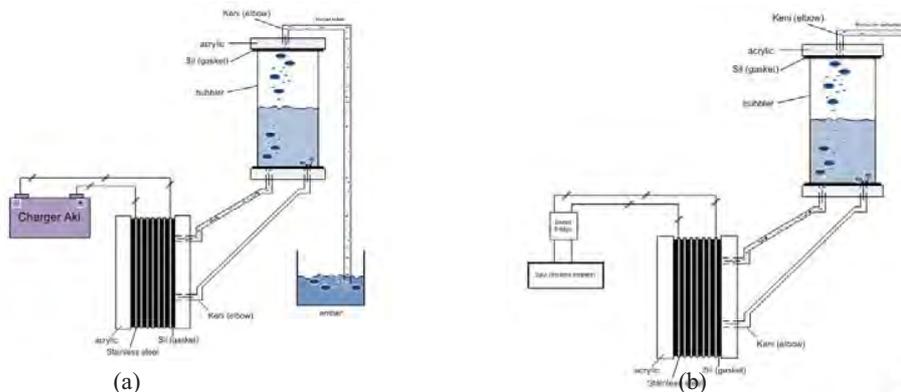

Figure 5: (a) hydrogen testing testing scheme, (b) testing scheme expenditure has hydrogen gas flowmeter and ampere meters

Table 3. The test results mileage on the motor vehicle with a gas mixture of hydrogen

Examination	Fuel Consumption (ml)	Mileage (km)	The Average Speed (km / h)
I	170	10,25	30-40
II	170	9,7	30-40
III	170	10,3	30-40
Average		10,08	30-40

### 3. Advanced testing mileage on the motor away

Do the test again in the motor at a sufficient distance away with using 3 liters of gasoline with and without HHO gas mixture with each test performed 3 times, we got the result as shown in Table 4 as follows:

Table 4 The comparison of mileage with and without the use of HHO gas mixture with 3 liters of gasoline consumption

Examination	Fuel consumption (litres)	Mileage without using gas mixtures HOH (km)	Mileage by using a gas mixture of BB + HOH (km)	The average speed (km / h)
I	3	105,65	165,85	40-60
II	3	107,20	163,25	40-60
III	3	108,25	166,70	40-60
Average		107,033	165,266	40-60

Figure 6: (a) When testing to determine the amount of HHO gas that comes out, (b) Installation of hydrogen in the motor generator tool

## 5. CONCLUSION

- From the manufacture of tools derived hydrogen generator turns out that water can produce hydrogen gas by electrolysis using electricity DC current which connect the electrodes in the form of stainless steel in a hydrogen generator. Equal overall reaction of electrolysis of water can be written as follows.

Hydrogen and oxygen gas produced from this reaction to form bubbles on the electrodes and can be collected.

- After testing the motor fuel without using a gas mixture of hydrogen and hydrogen gas mixture can be seen the difference. Without a gas mixture of hydrogen in the fuel can only be a distance of 37.2 km with one liter of gasoline. With a mixture of hydrogen in the fuel gas with only 1 liter of gasoline to a distance of 59.29 km. Efficiency means that not wasteful in fuel consumption has been fulfilled.

### ABSTRACT

Anatase TiO<sub>2</sub> enrichment from Bangka ilmenite (FeTiO<sub>3</sub>) has been conducted. First, ilmenite was mechanically activated using a planetary ballmill to obtain sub-micron sized particle followed by magnetic separation. Chemical treatment, dissolution of iron using hydrochloric solution, was performed to obtain titania rich residue. EDX data shows that the iron content was reduced in the titania residue. Ammonium hydroxide (NH<sub>4</sub>OH) solution was added to the washed precipitate, before adding H<sub>2</sub>O<sub>2</sub> solution (10%) that acted as a coordination agent to leach titanium from the residue in the form of ammonium peroxy titanate solution. The peroxy titanate powder was obtained by evaporating the ammonium peroxy titanate solution. XRD data show that TiO<sub>2</sub> anatase was formed after peroxy titanate powder was calcined at the temperature of 600°C. EDX data also shows that the obtained anatase TiO<sub>2</sub> still has impurities, such as silicon (0.98%) and iron (2.75%). Its photocatalytic activity was studied on photodegradation of Congo Red and compared with the photocatalytic activity of commercial TiO<sub>2</sub>, Degussa P-25. The photoreactivity test on degradation of Congo Red solution with the as-prepared Anatase gave 20% degradation which is still inferior compared to the results given by Degussa P25 (92%). This indicates that the impurities in as-prepared Anatase may cover the titania surface hindering the contact between Congo Red as well as UV-light and the active titania species.

*Ilmenite, HCl leaching, ammonium peroxy titanate, anatase TiO<sub>2</sub>, photoreactivity*

### 1. INTRODUCTION

The use of titanium products has been increasing from year to year. Rutile TiO<sub>2</sub> is one of titanium structure which is oftenly used as a white pigment in paint, food industry and cosmetics industries[1]. Rutile TiO<sub>2</sub> as pigment has non-corrosive properties, inert and resistant to UV rays. Besides rutile, TiO<sub>2</sub> has another structure, anatase, usually is applied as photocatalyst in various oxidation process and degradation of pollutant organic in water and air.

Until now, Indonesia imports various products of titanium although Indonesia has tons of ilmenite (FeTiO<sub>3</sub> mineral) with reserves about 40 million tons deposits which are naturally the main source of titanium. Ilmenite was formed as a primary mineral in maficigneous rocks, concentrated in a layer and found as waste from mining tin or zirconium sand. In Indonesia, Ilmenite is usually found as side product in tin mining [2]. Many works have been carried out to remove the iron from ilmenite in order to upgrade titanium in the compound which usually results in an increased quantity of rutile TiO<sub>2</sub>.

Recent developments show that a lot of research concerned in improving the extraction of TiO<sub>2</sub> from ilmenite as well lower energy consumption [3]. Nowadays about 60% of the world's TiO<sub>2</sub> pigments are manufactured by the chlorination route, in which natural, synthetic rutile and titanium-rich slag are used as feedstocks. In industry, chlorination process includes elevated temperature and use of chlorine gas, which require high energy and relatively dangerous condition. Hydrochloric acid treatment (also named as hydrochloric leaching) in the present of hydrogen peroxide was an alternative route that recently reported [4].

Two preliminary treatments on ilmenite, such as oxidation and mechanical activation were mostly conducted in order to increase the amount of iron to be removed from the ilmenite structure [5]. Mechanical activation was reported to assist the elimination of iron from ilmenite becomes more effective [5]. Its effectiveness was influenced by the physical and chemical properties, compositions and textures of ilmenite itself.

In this work, an attempt to obtain anatase type of  $\text{TiO}_2$  from Bangka ilmenite was reported, which is different to the target usually aimed in ilmenite extraction, rutile type of  $\text{TiO}_2$ . Extensive characterization on Anatase  $\text{TiO}_2$  properties as well as photocatalytic test in degradation of Congo Red in water environment were reported. The results in Anatase  $\text{TiO}_2$  enrichment process as well as photocatalytic test are discussed.

## 2. MATERIALS

Ilmenite ( $\text{FeTiO}_3$ , with Fe:Ti ratio of 12.10/22.5) was supplied from Bangka island as a side product at PT Timah Indonesia. HCl,  $\text{H}_2\text{O}_2$  30%,  $\text{NH}_4\text{OH}$ , and Congo Red dye were p.a. grade from Merck.  $\text{TiO}_2$  Degussa P-25 was supplied from Department of Chemical Engineering, Universitas Indonesia.

## 3. EXPERIMENT

Certain amount of raw Ilmenite was placed into planetary ball mill at 400 rpm for 3h followed by treatment with magnetic separator prior to iron separation. The sub-micron sized ilmenite powder then was reacted with HCl 20% solution and heated at 105 °C in the three-neck flask equipped with a condenser under stirring condition for 2 days. Variations were conducted by oxidizing Ilmenite and adding NaCl. Then  $\text{NH}_4\text{OH}$  12.5% was added until the solution reached pH 9, followed by addition of  $\text{H}_2\text{O}_2$  10% under continuous stirring. The pH must be maintained at pH 9. This mixture was stirred for 40 min at 40°C and the filtrate was separated from the residue and heated at 100°C to precipitate titanate peroxo. The precipitate then was dried at 80°C for 1 h followed by calcination at 400 dan 600°C to give anatase  $\text{TiO}_2$ . Finally photocatalytic test was carried out in degradation of Congo Red dye using the as-prepared Anatase, and commercially available  $\text{TiO}_2$  Degussa P-25, as photocatalysts.

## 4. ANALYSIS

XRD analysis characterized the structure of the residue and precipitation by referring to JCPDS (Joint Committee of Powder Diffraction Standards) files for related mineral, while analysis of the elemental compositions was performed both on solids (using EDX) and the filtrate (using AAS). The image of precipitation was observed by SEM. Bandgap energy of the titania was measured using UV-vis DRS. Concentration of Congo Red during photocatalytic study was determined using UV-vis spectrophotometer.

## 5. RESULT AND DISCUSSION

### Mechanical Activation

Bangka Ilmenite has a composition as shown in Table 1. It appears that it has a high content of titanium with impurities such as aluminium, calcium and silicon. It can be seen that after ilmenite was treated using magnetic separator (MS), the non-magnetic content (such as C, Al, Ca, Si and S) were decreased even not detected using EDX.

Table 1: Ilmenite composition determined with EDX

% wt	C	O	Al	Ca	Si	S	Ti	Fe
Raw Ilmenite	3.35	52.40	3.66	1.07	1.35	0.42	25.22	12.10
After treated with Magnetic-Separator	2.06	58.02	2.70	-	0.92	-	26.87	12.18

The XRD patterns of Bangka Ilmenite are shown in Fig. 1. Mechanical activation was carried out in order to breakdown the Ilmenite into finer particulate (up to submicron after planetary ball mill treatment) and physically separate nonmagnetic impurities from Ilmenite using magnetic separator. It is reported that the ball mill treatment increased the effectiveness of the ilmenite leaching reaction due to the increase in surface area and reactivity on surface after treatment that may be caused by a change in the crystal structure [6]. It can be seen in Fig. 1 that the intensity of some peaks increased and some new peaks

appeared which indicating that the crystallinity of ilmenite structure was enhanced after mechanically activated through ballmill treatment.

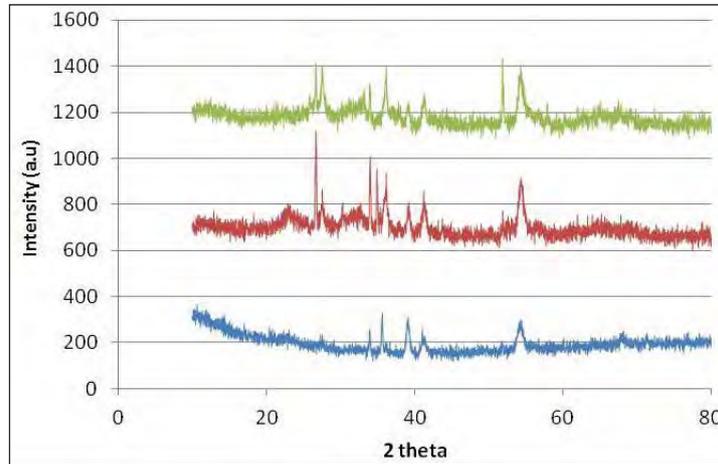

Figure 1: XRD pattern of Ilmenite: raw, mechanically activated, oxidized (top to bottom), referring to JCPDS file No. 29-0733 for Ilmenite, syn, Iron Titanium Oxide FeTiO<sub>3</sub>

### Oxidation

Oxidation of ilmenite is expected to change the Ilmenite surface because modification of surface due to diffusional processes occurs at high temperatures. In this case, the iron species is moving faster than titanium and tend to migrates toward area with oxygen high content. Thus, Fe cations in Ilmenite will migrate to the surface in hematite structure forming eggshell, so Fe will be leaching easily [7]. However, in this work, as shown by the XRD pattern in Fig. 1, no phase of hematite (Fe<sub>2</sub>O<sub>3</sub>) was identified, referring to JCPDS file No. 33-0664. This may due to only small amount of hematite was formed.

### HCl Leaching

Leaching process was carried out in order to dissolve iron from ilmenite (FeTiO<sub>3</sub>) and leave Rutile type of TiO<sub>2</sub> as solid part. In this process, hydrochloric acid was used because it has capability to dissolve impurities, e.g. iron as ferric chloride, and the acid solution can undergo regeneration. Plausible mechanism reactions that occur are listed below.

In this work, 6 variation of HCl leaching processed were conducted. The details of the experiments and results are listed in Table 2. The iron content in the filtrate was analyzed and the results were summarized in Fig. 2.

Table 2: Variation of HCl Leaching Process on Ilmenite

Process No.	Experiment
1	HCl leaching (8 h)
2	Oxidation & HCl leaching (8 h)
3	HCl leaching (48 h)
4	Oxidation & HCl leaching (48 h)
5	HCl leaching (48 h)+ NaCl
6	oxidation & HCl leaching (48 h)+ NaCl

It can be seen in Fig. 2 that oxidation process prior HCl leaching (Process 2 and 4) caused small increase in iron content in the filtrate, compared to their direct HCl leaching counterpart (Process 1 and 3, respectively). This results is in agreement with work reported by Janssen and Putnis [8]. Furthermore, the addition of NaCl to fresh HCl solution was not the best way to provide Cl<sup>-</sup> ions to attract iron that intact to ilmenite structure. Successful extraction of iron is a key factor in obtaining TiO<sub>2</sub> enriched ilmenite, because the more soluble Fe indicates that the more TiO<sub>2</sub>·xH<sub>2</sub>O or TiO<sub>2</sub> rutile (*synthetic* rutile) formed. The

ratio of Important elements (Ti, Fe and O) contained by the residue from leaching process are displayed in Fig. 3. Residue 4 is a result from the 48-h HCl leaching of oxidized ilmenite provided the highest Ti/Fe ratio. This is supported by the AAS data from Filtrate 4, in which it has the highest leached-Fe content. Therefore, Residue 4 was selected for further extraction to get the perokso titanate compound.

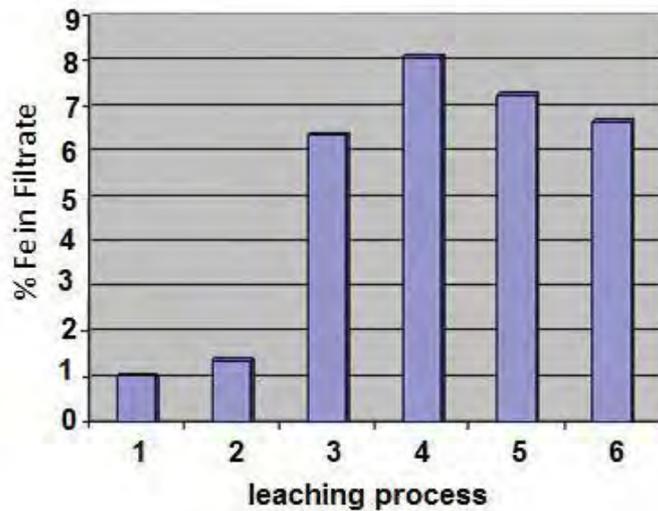

Figure 2: Fe content in the filtrate from HCl leaching process (determined from AAS analysis)

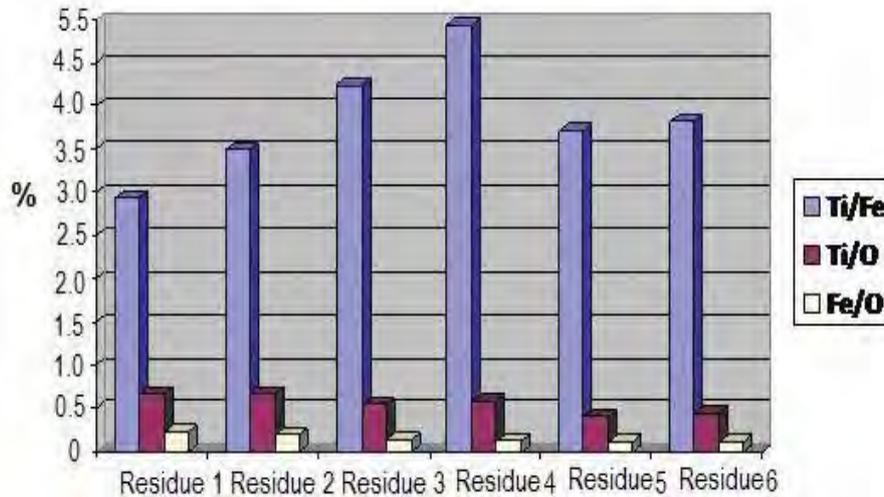

Fig. 3: Elemental composition in the Residue obtained after various HCl leaching process.

**Peroxo Titanate Solid**

EDX data shows the composition of peroxo titanate solid such as Table 3. It can be seen that the solid is Ti-rich with Fe and Si remain as impurities. In this solid, the titanium is still amorphous so that calcinations is necessary to obtain crystalline TiO<sub>2</sub>.

Table : Elemental composition of ammonium peroxo titanate powder (EDX measurement)

Element	Ti	O	Cl	Fe	Si
% wt	53.55	41.14	1.58	2.75	0.98

Fig. 4 shows the XRD patterns of TiO<sub>2</sub> after calcined at 400°C and 600°C. After calcination at 400°C, the typical peaks of TiO<sub>2</sub> anatase appeared weakly, indicating that at this temperature TiO<sub>2</sub> anatase crystal was not yet formed. Whereas the calcination at 600°C the peaks of TiO<sub>2</sub> anatase crystal have appeared clearly. Based on the SEM (Fig. 5) The Crystal was growing unevenly and hasn't a uniform size of particle. Generally, The size crystal is about 9-12 μm and has a rhombus shape or square

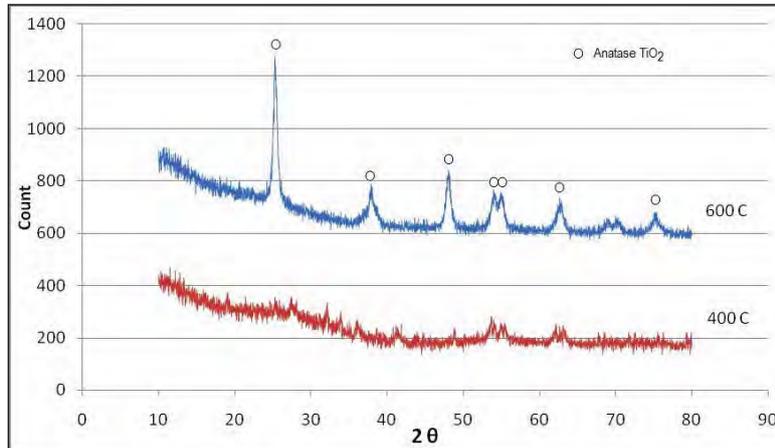

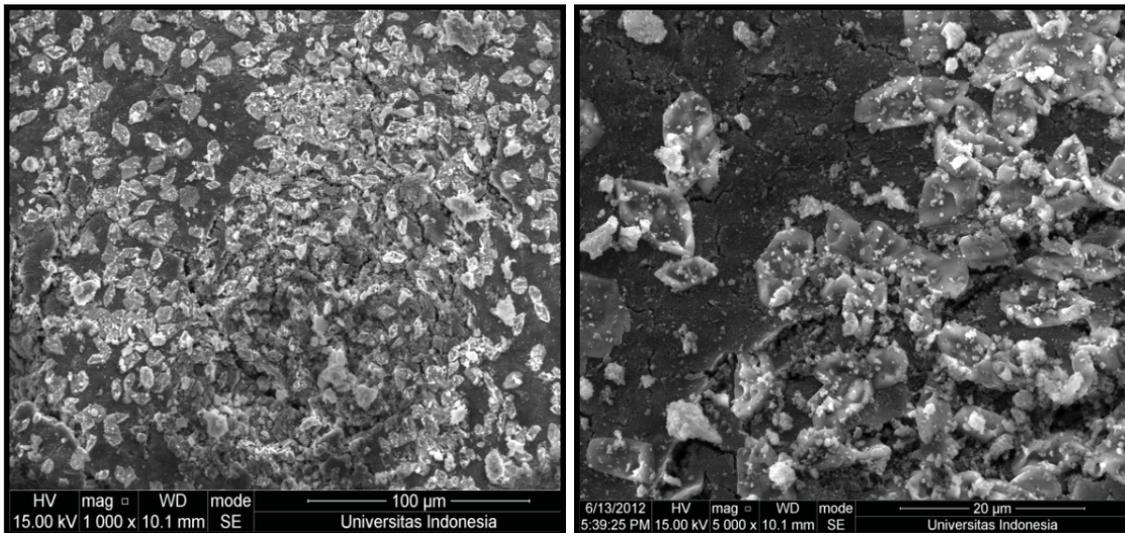

Figure 4: XRD patterns of TiO<sub>2</sub> prepared from calcinations of ammonium peroxy titanate salt, referring to JCPDS file for TiO<sub>2</sub> anatase, No. 04-0477.

Figutr 5: SEM TiO<sub>2</sub> Anatase (Calcination at 600°C)

From UV-DRS data (KM factor vs Energy (eV)) the value of band gap energy was determined, and it is found that the as-prepared TiO<sub>2</sub> has bandgap energy (3,08 eV) lower than that of *degussa P25* (3,34 eV). This could be due to the impurities intact to the structure as explained earlier.

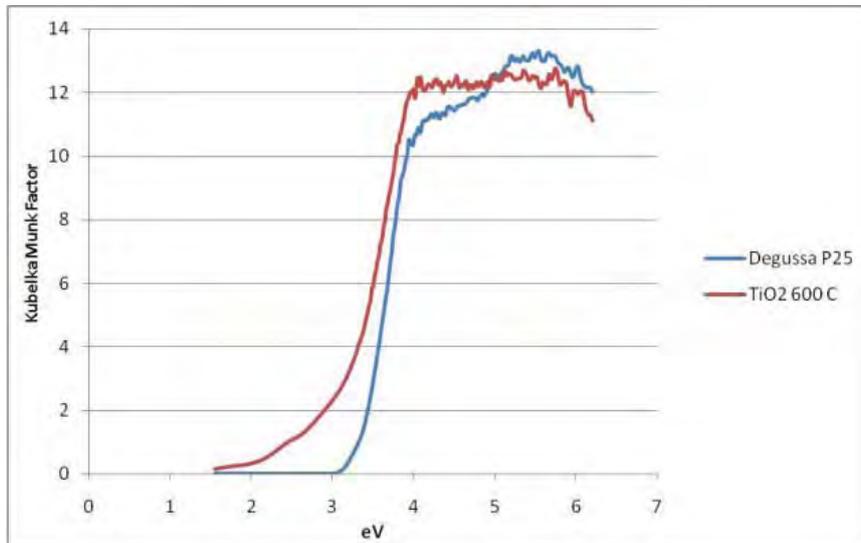

Figure 6: Plot of Kubelka Munk factor vs energy (eV) from TiO<sub>2</sub> dan Degussa P25

### Photocatalyst Test

Photocatalyst Test of TiO<sub>2</sub> anatase (calcination at 600°C) was carried out in photodegradation of congo red dye, and Degussa P25 was also employed for comparison. Fig. 8 shows that photocatalytic activity of Degussa P25 is still superior compared to that of the as-prepared anatase TiO<sub>2</sub>. After 3h, the as-prepared TiO<sub>2</sub> was only able to degrade 20% from the entire dye solution, whereas more than 80% of Congo Red concentration was degraded using P25 photocatalyst. This poor performance, again, may due to the presence of impurities such as silicon and iron extracted from ilmenite and covering the surface of TiO<sub>2</sub>. Thus, it is difficult for UV-light penetrate to TiO<sub>2</sub> surface and excite the electrons in Ti-d orbital.

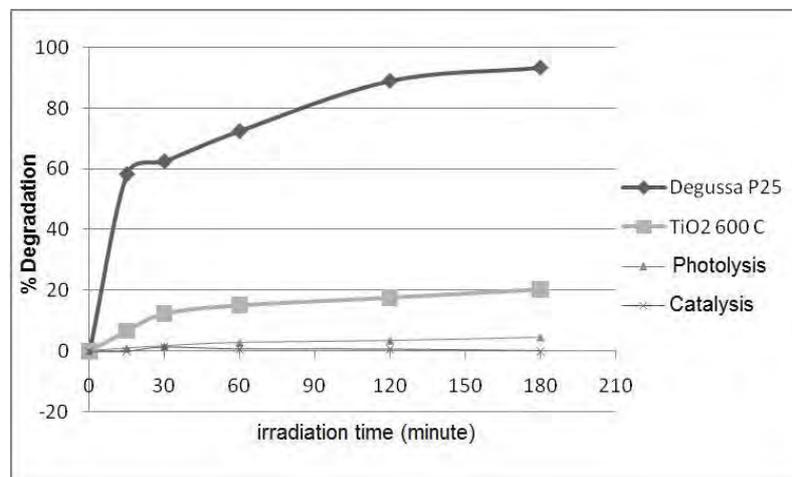

Figure 7: Degradation of CongoRed Solution under various catalytic condition

### 6. CONCLUSION

Anatase TiO<sub>2</sub> has been extracted from ilmenite Bangka after subjected to mechanical activation, HCl leaching and formation of intermediate ammonium titanate peroxo compound; although it still has impurities such as silicon and iron. Anatase TiO<sub>2</sub> from ilmenite Bangka has an inferior photocatalytic activity in photodegradation of CongoRed dyes compared with Degussa P25. Further investigation should be conducted in order to obtain higher quality of Anatase TiO<sub>2</sub>. Nevertheless, this result shows that Bangka Ilmenite is promising to be used as natural resource to obtain anatase TiO<sub>2</sub> photocatalyst.

## ACKNOWLEDGMENT

This research was partially funded by HPTP (Postgraduate Research Grant from Higher Directorate of Education, RI) year 2012.

### ABSTRACT

Iron sand contains magnetite, hematite, ilmenite, alumina, silica, and other minerals. The presence of titania in ilmenite gives value-addedness to iron sand. This research is intended to see the effect of Na<sup>+</sup> cation in the destruction process of ilmenite crystal in Titania extraction.

In this research, magnetically separated iron sand was mixed with NaCl or NaOH, and burned with temperature variation: 400, 600, and 800°C. After that, characterization with XRD of sample before and after roasting and with SEM of sample after magnetic separation were conducted. The results of XRD measurement of roasted iron sand-NaCl mixture showed no destruction of ilmenite crystal structure. It can be observed that peak was resulted from Fe<sub>3</sub>O<sub>4</sub>, Fe<sub>2</sub>O<sub>3</sub>, TiO<sub>2</sub>, and NaCl compound. While result of SEM mapping on concentrate and tailing showed that area Fe and Ti atoms were closely arranged. The results of XRD measurement on roasted iron sand-NaOH mixture showed the destruction of the iron sand ilmenite crystals, as seen by the formation of new compounds. New peaks from NaFeO<sub>2</sub>, NaTiO<sub>2</sub>, Na<sub>0.75</sub>Fe<sub>0.75</sub>Ti<sub>0.25</sub>O<sub>2</sub>, and TiO<sub>2</sub> compounds were seen obviously. Also, result of SEM mapping showed that Na<sup>+</sup> cations could penetrate into ilmenite's crystal. One of the proposed mechanisms was that, NaOH has an ability to damage ilmenite crystals due to the fact that NaOH has lower melting point compared to that of NaCl, thus making NaOH much more reactive. Also, it can be deduced that the mobility of ion is larger than mobility of solid. When iron sand is roasted in high temperature, NaOH was melted and Na<sup>+</sup> cationic could penetrate easily.

### Keywords

Iron sand, ilmenite, titania, NaCl, NaOH

### 1. INTRODUCTION

Indonesia is a rich country in natural resources. One of the abundant natural resources in Indonesia is iron sand. Iron sand with total more than 2 billion tons (Kemenperin, 2007) spread along the southern coast of Java, Sumatera, West Nusa Tenggara, etc. Iron sands contain magnetite (Fe<sub>3</sub>O<sub>4</sub>), hematite (Fe<sub>2</sub>O<sub>3</sub>), ilmenite (FeTiO<sub>3</sub>), alumina (Al<sub>2</sub>O<sub>3</sub>), silica (SiO<sub>2</sub>) and small amounts of other mineral, with variation content in different location.

Various methods have been made in the making of titania's concentrate from ilmenite such as magnetic separation, roasting, milling, etc. However, the method still has disadvantage because strong bond between Fe-O-Ti in ilmenite crystals ( $\text{FeO} \cdot \text{TiO}_2$ ). Thus, titania as ilmenite is tough separated with iron.

One method in concentrate titania making is adding chemical compounds. The addition of chemical is expected to assist in the destruction of the crystal structure, E. Foley and Kathryn P. Mackinnon (1970), using  $\text{Na}_2\text{CO}_3$  and  $\text{K}_2\text{CO}_3$  in ilmenite. TA Lasheen (2008) using soda caustic ( $\text{Na}_2\text{CO}_3$ ) on titania slag from rosetta ilmenite and roasted at  $850^\circ\text{C}$ .

In this research, a  $\text{Na}^+$  cationic effect towards iron sand's ilmenite crystal destruction is investigated.  $\text{NaOH}$  and  $\text{NaCl}$  is used in this research as source of  $\text{Na}^+$ .

## 2. EXPERIMENTAL

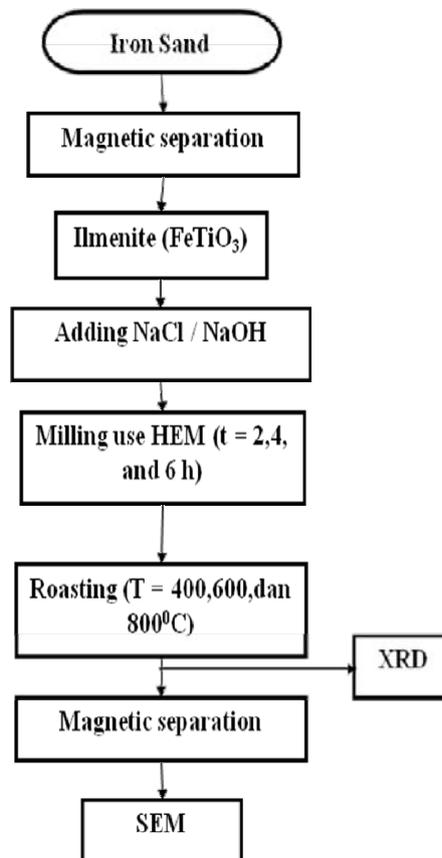

Figure 1. Experimental scheme

In this research, iron sand come from Sukabumi, Jawa Barat. Iron sand is separated by washing with water to remove impurities such as dust, gravel. Iron sand that has been washed, is separated using magnetic separator to remove silica and other nonmagnetic impurities. Titania concentrate in ilmenite is added  $\text{NaCl}$  or  $\text{NaOH}$  with a mole ratio ilmenite: $\text{NaCl}/\text{NaOH}$  at 1:2. A mixture of 10 grams, is milled using High Energy Milling E3D (HEM E3D) for 2 hours, 4 hours, and 6 hours. After the mixture was milled, is roasted at temperature  $400^\circ\text{C}$ ,  $600^\circ\text{C}$ , and  $800^\circ\text{C}$ . before and after combustion, sample was characterized using XRD to see changes in the crystal structure and the effect of chemical reagent on ilmenite. The result of magnetic separation is characterized by Scanning Electron Microscope (SEM).

## 3. DISCUSSION

Figure 1 shows a roasted mixture ilmenite- $\text{NaCl}$  and ilmenite- $\text{NaOH}$ . Figure shows that the colour of the sample after roasted changes from black into red.

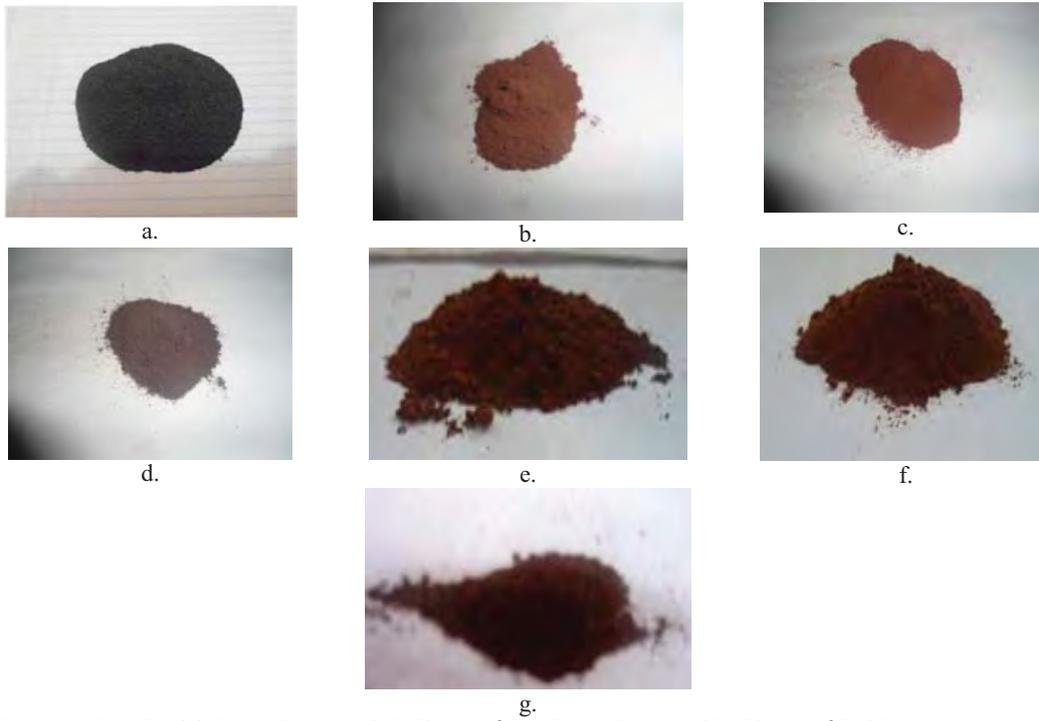

Figure 1: a. Iron Sand, b. Roasted iron sand-NaCl at 400 °C, c. Roasted iron sand-NaCl at 600 °C, d. Roasted iron sand-NaCl at 800 °C, e. Roasted iron sand-NaOH at 400 °C, f. Roasted iron sand-NaOH at 600 °C, g. Roasted iron sand-NaOH at 800 °C.

The red colour on roasted iron sand-NaCl, indicate that contain iron oxide  $Fe_2O_3$ , result of oxidation from iron sand because of effect of heating.  $Fe_2O_3$  intensity increases with increase of roasted temperature. It can be caused due to the oxidation reaction on Fe as follows:

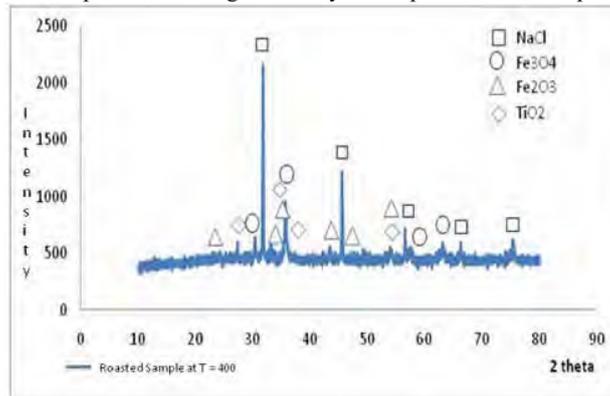

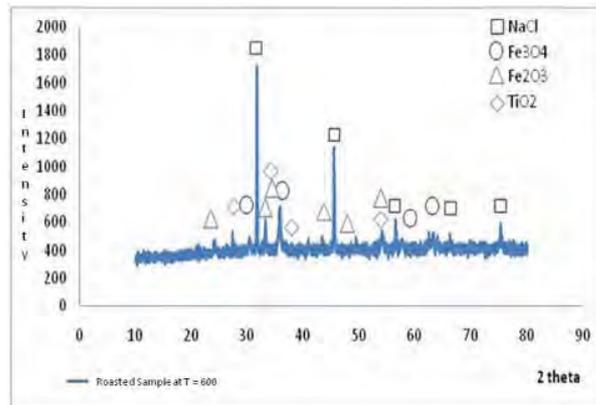

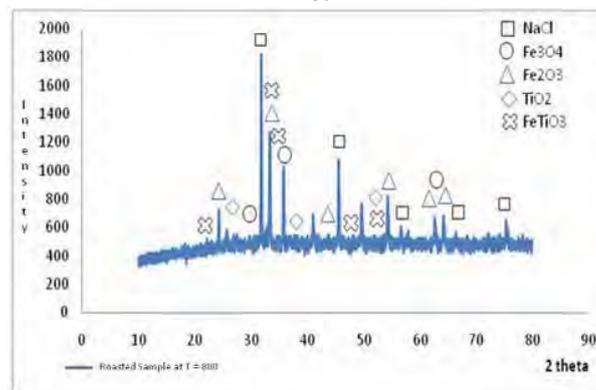

Figure 2 shows XRD characterization of roasted iron sand-NaCl where there are four main compound in the sample, i.e NaCl,  $Fe_2O_3$ ,  $Fe_3O_4$ , and  $TiO_2$ .  $TiO_2$  intensity has increased in temperature 600°C but decreased at 800°C. Magnetite ( $Fe_3O_4$ ) intensity decreased along with increasing temperature due to oxidation to  $Fe_2O_3$ . The existence of peaks from NaCl, showed that not all NaCl can react with iron sand. It can be proved with high intensity of the peak of each temperature.

a.

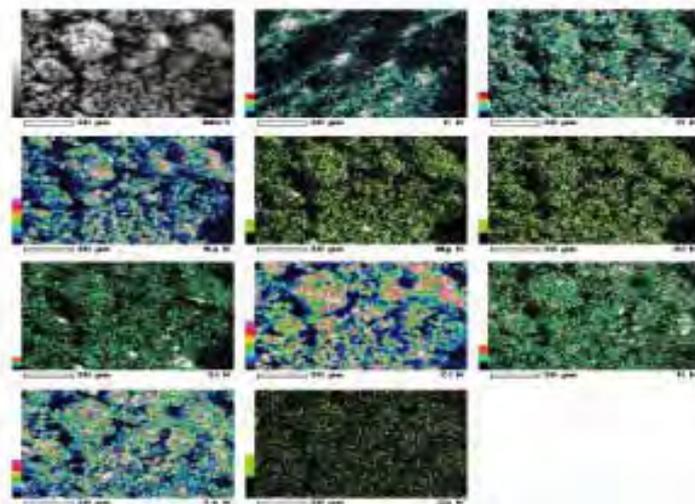

b.

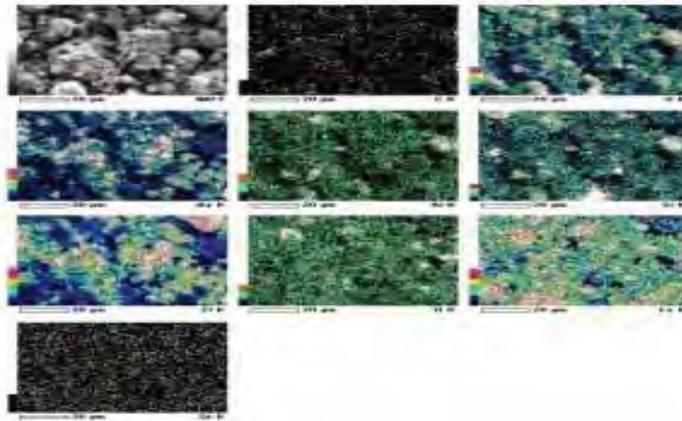

c.

Figure 2: XRD measurement of roasted iron sand-NaCl at a. 400°C, b. 600°C, and c. 800°C.

The result of mapping the concentrate and tailings on iron sand-NaCl after magnetic separation is showed in figure 3. Seen in the results of mapping, distribution Fe and Ti atoms adjacent and occupy the same area so it can be expected the bonds between atoms of Fe-Ti-O can't be separated by NaCl.

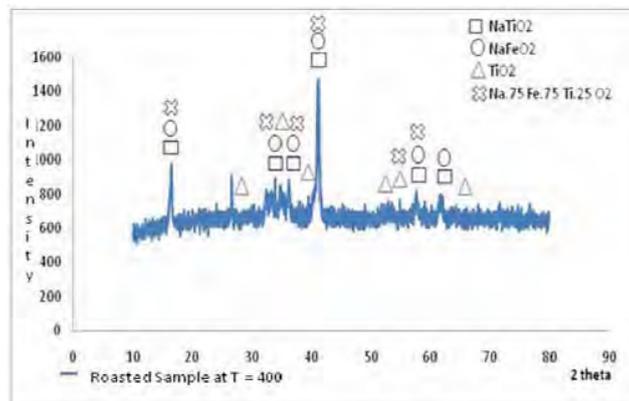

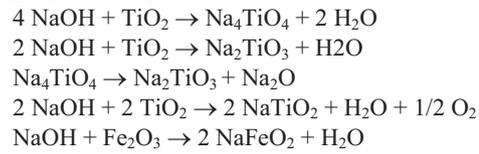

a.

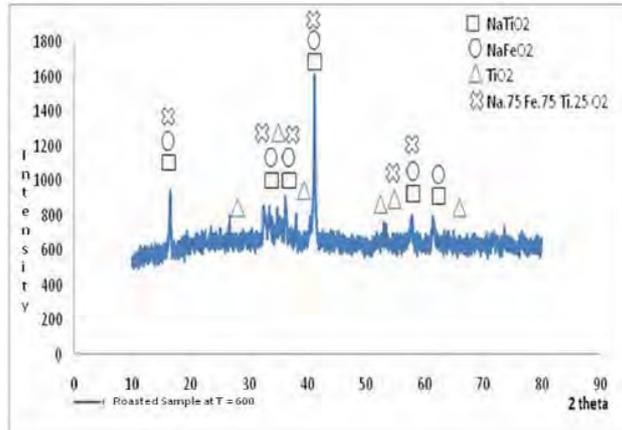

b.

Figure 3: Mapping of roasted iron sand-NaCl at a. concentrate, b. tailings.

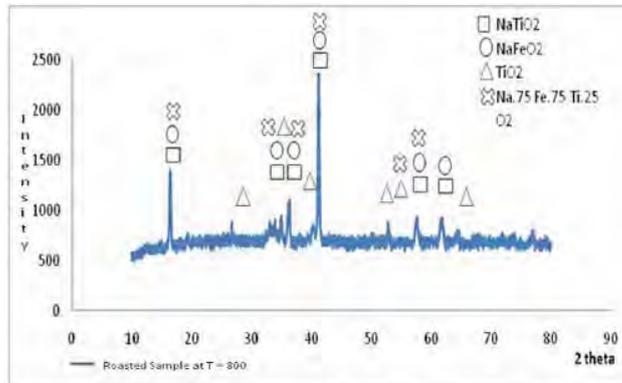

In figure 4 shows XRD results on roasted iron sand-NaOH. The reaction between iron sand with NaOH form novel compound i.e NaFeO<sub>2</sub>, NaTiO<sub>2</sub>, Na<sub>0.75</sub>Fe<sub>0.75</sub>Ti<sub>0.25</sub>O<sub>2</sub>, and TiO<sub>2</sub> as follows:

a.

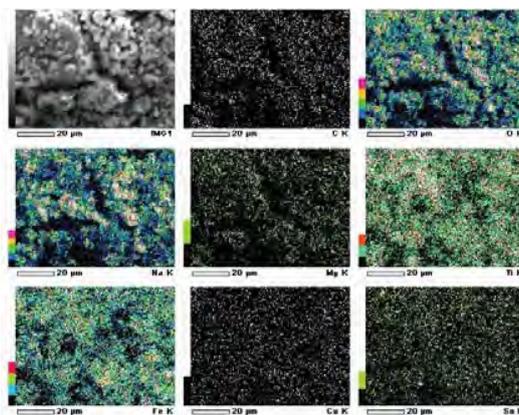

b.

c.

Figure 4: XRD results of roasted iron sand-NaOH at a. 400°C, b. 600°C, and c. 800°C.

Intensity of the three compound are  $\text{NaFeO}_2$ ,  $\text{NaTiO}_2$ , and  $\text{Na}_{0.75}\text{Fe}_{0.75}\text{Ti}_{0.25}\text{O}_2$  increase along with increasing temperature.  $\text{Na}^+$  cationic can destruct ilmenite crystal because it can penetrate between crystal and bind to Fe and Ti to form  $\text{NaFeO}_2$ ,  $\text{NaTiO}_2$ , and  $\text{Na}_{0.75}\text{Fe}_{0.75}\text{Ti}_{0.25}\text{O}_2$  (Figure 5). The possibility why NaOH is able to provide a better reaction than NaCl due to NaOH has a melting point at  $318^\circ\text{C}$ , resulting in temperature above  $400^\circ\text{C}$  will be more readily reacts with iron sand than NaCl that has a melting point of  $801^\circ\text{C}$ .

a.

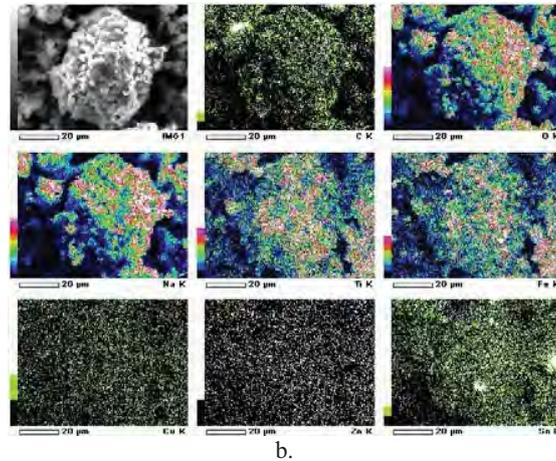

Figure 5. Mapping of roasted iron sand-NaOH at a. concentrate, b. Tailings

#### 4. CONCLUSION

NaOH has an ability to damage ilmenite crystals due to the fact that NaOH has lower melting point compared to that of NaCl, thus making NaOH much more reactive. Also, it can be deduced that the mobility of ion is larger than mobility of solid. When iron sand is roasted in high temperature, NaOH was melted and  $\text{Na}^+$  cationic could penetrate easily.

## ABSTRACT

The study was conducted to determine the performance of activated carbon adsorbent and influence of TiO<sub>2</sub> on the insertion of activated carbon in adsorbing gas combustion CO and smoke cleared. Activated carbon is made with raw coconut shell charcoal is chemically activated by the activating agent ZnCl<sub>2</sub> 65% with a mass ratio of ZnCl<sub>2</sub>/charcoal 4:1. Activation process is performed to a temperature of 700<sup>o</sup>. The incorporation of activated carbon with TiO<sub>2</sub> through the insertion method. Including the process undertaken by impregnation with stirring and sonication followed by calcinations at a temperature of 400<sup>o</sup>C. Smoke to be tested is the result of burning a mixture of sawdust, paper, cables, and charcoal. Varied the size of activated carbon are 74 μm, 125 μm and 420 μm. While the varied mass are 1 gram, 3 grams and 5 grams. The fastest time in clearing of smoke is up to the value of opacity is 10% achieved by the activated carbon adsorbent is inserted as much as 3 grams of TiO<sub>2</sub> is for 28 minutes. Activated carbon is inserted TiO<sub>2</sub> can increase the clearing of smoke performance by an average of 12.50% and the adsorption of CO gas of 12.12%. Highest adsorption capacity is achieved by AC-TiO<sub>2</sub> adsorbent as much as 1 gram is equal to 29.568 mg /mg adsorbent.

## 1. INTRODUCTION

Fire is an event that can not be avoided. Statistics in Jakarta noted that there are hundreds of cases of fires every year. In addition to causing losses of hundreds of billions of dollars, fires can also cause casualties. According to data from 1998 to 2007, an average of 30% of the fire victim's life can not be saved [8]. In the case of fire, smoke poisoning death rate is much greater than the deaths due to burns injury. In the world, 85% of deaths in cases of fires are caused by heavy smoke and toxic gases [1].

Cases smoke from fires contains many compounds that are harmful to health. Some of the content of the smoke produced, among others, carbon dioxide (CO<sub>2</sub>), carbon monoxide (CO), water vapor, particulates, and some toxic compounds such as NO<sub>x</sub> and SO<sub>x</sub>. Although not described quantitatively, CO including many gas produced during a fire. Carbon monoxide does not irritate but very dangerous (toxic) gas CO dubbed the "silent killer" (the silent killer). The presence of CO gas can be very dangerous if inhaled by humans because it would replace the gas of oxygen associated with hemoglobin in the blood. CO gas will flow to the heart, brain, and vital organs. Bonding between CO and hemoglobin to form carboxyl hemoglobin is 200 times much stronger than the bond between oxygen and hemoglobin. The result is fatal. First, the oxygen will not compete with current CO binds to the hemoglobin molecule. This means that oxygen levels in the blood will be reduced. Second, the CO gas will inhibit oxidation of cytochrome complex. This cause intracellular respiration becomes less effective. Finally, the CO can bind directly to the heart muscle, and bone cells. The most serious effect is poisoning occurs directly on the cells, also cause disturbances in the nervous system [2]. Limit carbon monoxide exposure allowed by OSHA (Occupational Safety and Health Administration) is 35 ppm for 8 hours/working days. Exposure to 1000 ppm CO gas for a few minutes can cause death. Hence the fact that some people have described about the dangers of CO gas, smoke from fires should be reduced or clarified. Several researchers have conducted research related to the clearing of smoke on the content of CO gas. A study is ever to evaluate the potential of nanoparticles in clearing of smoke in an enclosed space with multiple uses nanoparticles and ordinary powder [3]. Previous research has also been carried out clearing of smoke and fire extinguishing using MgO which has been patented by Mulukutla et al, 2007 [4]. However, the results of these studies can not be said to be effective with CO gas adsorbed percentage which is still low.

One way to reduce the levels of CO gas is in the process of adsorption by the adsorbent, where the absorption of CO gas that

accumulates on the surface of adsorbent. In the adsorption process, the adsorbent surface area is a major parameter in considering the adsorbent to be used. Activated carbon adsorbent is one potential use as an adsorbent because it has large surface area. One of the potential natural materials for its manufacture is coconut shell. Coconut shell charcoal has a large surface and hollow with a layered structure. Another plus is not toxic, easily available, economical, and effective.

In this study, activated carbon from coconut shell charcoal impregnated with  $\text{TiO}_2$  for use as adsorbent in adsorbing CO gas and fire fumes clear. Merging is done to increase the performance of adsorption of CO and smoke clearing. Coconut shell charcoal media inserted  $\text{TiO}_2$  affect the adsorption of CO and  $\text{NO}_2$  gas, and more optimal in reducing the concentration of CO and  $\text{NO}_2$  gas, compared to coconut shell charcoal medium without insertion of  $\text{TiO}_2$  [5]. The presence of  $\text{TiO}_2$  is abundance in Indonesia, especially in the province of Bangka Belitung.

In its usefulness as a purifying fire smoke and gases absorb CO, is expected to activated carbon from coconut shell charcoal combined with  $\text{TiO}_2$  this will be a technique that is more effective and efficient than other adsorbents that have been used previously.

## 2. EXPERIMENT

There are several stages in this study, including preparation of activated carbon, CO gas adsorption test of fire smoke, and data processing. Preparation of activated carbon -  $\text{TiO}_2$  done with two main activities, namely the stage of making activated carbon from coconut shell later stage pasting  $\text{TiO}_2$  on activated carbon.

### 2.1 Production of Activated Carbon

Coconut shell as the manufacture of activated carbon first through carbonization conducted in a furnace at a temperature of  $400^\circ\text{C}$  for 2 hours. After that, coconut shell charcoal which has been turned into a crushed and sieved to the size variation of  $74\mu\text{m}$ ,  $125\mu\text{m}$  and  $420\mu\text{m}$ . Furthermore, each with various sizes of charcoal enters the activation stage. Activation is done by activating the chemical activation agent in the form of  $\text{ZnCl}_2$ . Charcoal obtained from carbonization process  $\text{ZnCl}_2$  solution are mixed with 65% by comparison activating agent / charcoal at 4:1. The mixture is then stirred (stirrer) on a hot plate with a temperature of  $200^\circ\text{C}$  to form a slurry and harden.

Furthermore carbon follows the pyrolysis process at a temperature of  $700^\circ\text{C}$  for 1 hour activation (after the activation temperature is reached). Activation process on activated carbon was carried out without the presence of free oxygen with  $\text{N}_2$  gas flow during the activation process with a flow rate of  $100\text{ cm}^3/\text{min}$ . In the absence of air or free oxygen is not expected to damage the pore structure of the raw material which will result in losses occurred (loss of material) on the final results of activated carbon.

Subsequently the sample was washed with 0.1 N HCl solution to remove alkali compounds on carbon. Washing is done at a temperature of  $85^\circ\text{C}$  for 30 minutes. When finished washing with HCl and then do the washing or rinsing with distilled water until neutral pH, and then dried at  $110^\circ\text{C}$  for 24 hours.

### 2.2 Insertion of $\text{TiO}_2$ on Activated Carbon

Preparation of  $\text{TiO}_2$  on activated carbon insertion begins by dissolving the amount of  $\text{TiO}_2$  Degussa P-25 to 100 ml of demin water and stirred for 10 min sonication. Furthermore activated carbon is added to a solution of  $\text{TiO}_2$  (Active Carbon comparison with  $\text{TiO}_2$  Degussa P-25 was 75:25) and followed by sonication for 20 minutes. After that, the mixture was heated on a hot plate with a temperature of  $110^\circ\text{C}$  to dry mixture. Coconut shell charcoal layer structure formed after the insertion of  $\text{TiO}_2$  molecule is still fragile, so it is necessary to further warming or calcined at  $400^\circ\text{C}$  for 1 hour to stabilize the layer structure of coconut shell charcoal.

### 2.3 Characterization

To measure the surface area of the adsorbent, BET testing was conducted. Tests used the BET brand Autosorb 6B Quantochrome in Chemical Reaction Engineering and Natural Gas Convention Laboratory, Department of Chemical Engineering, FTUI, Depok. Afterwards, FE-SEM testing was done to see patterns and pores on the surface of adsorbent. Furthermore, EDX analysis was carried out for the chemical composition of surface elements on adsorbent. FESEM-EDX test performed in SEM Laboratory Department of Metallurgical and Materials Engineering Faculty of Engineering University of Indonesia. EDX test equipment system works as an integrated feature of the FE-SEM and can not operate alone.

### 2.4 Adsorption Test and Smoke Saturation

Smoke and CO gas adsorption test were performed in a testing chamber made of acrylic material with a size of 40 cm x 40 cm x 120 cm. Testing chamber scheme can be seen in Figure 1. Adsorption smoke test performed at three different points in the testing chamber. Point 1 is the point of testing within 105 cm from the bottom of the testing chamber. Point 2 is the midpoint of the testing chamber, which is at a height of 60 cm from the bottom of the testing chamber. Point 3 is the lowest point of testing, 15 cm from the bottom of the testing chamber. Furthermore, the location of the sensor CO<sub>2</sub> is around the point of opacity testing, it is attached to the wall within 60 cm from the bottom.

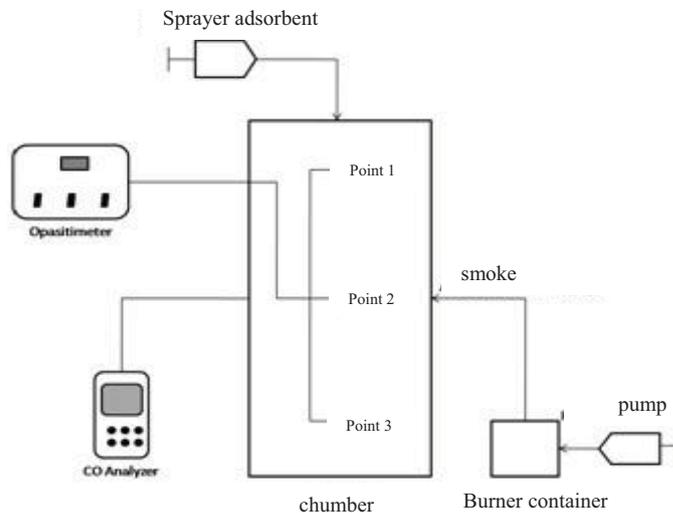

Figure 1: Testing chamber scheme

Adsorption of CO gas and fire fumes clearing was performed by activated carbon and activated carbon with inserted TiO<sub>2</sub> adsorbent. Activated carbon size was varied for 74 μm, 125 μm, and 420 μm. Each size is then varied for 1 gram, 3 gram and 5 gram of mass. Nevertheless, AC-TiO<sub>2</sub> varied for 1 gram and 3 grams of mass.

At first the test chamber was cleaned and leak checking conducted. Burned material is paper, wires, plastic, sawdust and charcoal. So that combustion takes place uniformly, kerosene was added into material tested. Burning is done in a container inside the combustion fumes pumped into the testing room until the smoke reaches the percentage saturation > 90% and levels of CO gas in the smoke chamber stable. After that, to test the ability of the adsorbent in CO gas adsorption, adsorbent was sprayed through a hole located at the top of the testing chamber. Then, observation is done to see changes in the value or level of clarity smoke opacity and changing levels of CO gas in the test chamber. Observation of the changes made to the value of opacity value reaches the value of 0.1 or 10%, where the darkness of smoke reaching 10%. Otherwise, the observation of CO gas levels change every minute for 30 minutes.

### 3. RESULTS AND DISCUSSION

#### 3.1 Adsorbent Characterization

Some characterization performed on the adsorbent surface structures include analysis using FE-SEM testing, analysis of the chemical composition of the adsorbent sample using EDX testing, analysis of the adsorbent surface area using BET analysis methods.

##### 3.1.1 Surface Structure (FE-SEM Test)

FE-SEM testing was done to see a pattern or surface structure of the adsorbent, especially pore formed. Surface structure of the test results with FE-SEM can be seen the basic structure of the surface of carbon materials that have been activated as in Figure 2.

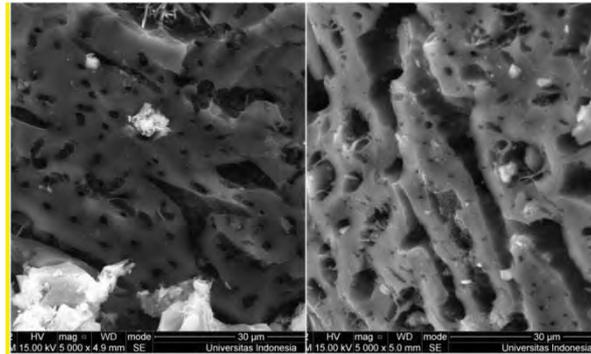

Figure 2: FE-SEM results of activated carbon with a magnification of 5000 times

From Figure 2 can be seen the carbon formed after activation or pore space, with pore diameters varying the micro pores, meso pores and macro pores. These pores are formed during the process in which carbon reacts with activating agent ( $\text{ZnCl}_2$ ). Ability to activate  $\text{ZnCl}_2$  (pore forming) carbon is based on functions of dehydration. During the activation process,  $\text{ZnCl}_2$  eliminate hydrogen and oxygen atoms from the carbon material as water rather than as an organic component of oxygen, so it is good for porosity generation and increasing carbon content. Additionally,  $\text{ZnCl}_2$  is an activating agent that can alter the behavior of the pyrolysis of carbon precursors.  $\text{ZnCl}_2$  will be interspersed into the carbon matrix by impregnation. When pyrolysis causes dehydration of  $\text{ZnCl}_2$  impregnation of carbon precursors leads to authoring and aromatization along with the creation of pores. During the activation process, molten  $\text{ZnCl}_2$  formed above the boiling point of  $\text{ZnCl}_2$ . Activation temperature increases further, the interaction between the carbon atoms and Zn occur resulting in a significant widening of carbon interlayers and creates pores in the carbon matrix. During the interaction with carbon,  $\text{ZnCl}_2$  helps removal of water from the structure by cutting carbon hydrogen and oxygen from carbon precursors. Result of  $\text{ZnCl}_2$  activation is the formation of micro pores.

Further tests of FE-SEM was conducted back on activated carbon that has been inserted  $\text{TiO}_2$ . FE-SEM test results can be seen in Figure 3.

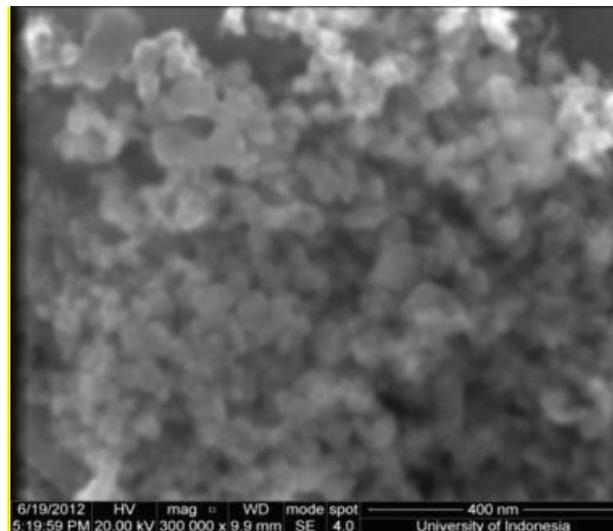

Figure 3: FE-SEM results of activated carbon-  $\text{TiO}_2$  with a magnification of 300000 times

Figure 3 shows the change of the activated carbon material performed after the insertion process. These changes can be observed clearly by comparing the surface structure is formed. Image with 300000 times magnification is more focused on  $\text{TiO}_2$  that has been inserted in the activated carbon.

### 3.1.2 Composition (EDX Test)

EDX analysis was conducted to identify the elemental composition of specimens (samples tested). In this case, EDX is used to compare the elemental composition of the activated carbon pre-activated, after activated and activated carbon that has been inserted  $\text{TiO}_2$ . EDX test results on the adsorbent shown in Figure 4.

On activated carbon, it is detected that there is Cl and a few of Zn element. Cl element existed comes from the rest of activating agent of  $ZnCl_2$  which is not vaporized when pyrolysis process and residual leaching with HCl occur. Zn contained in the carbon after activation is less than 1%. This indicates that almost all of  $ZnCl_2$  entrained and lost during washing. Visible element of Ti and O is contained in many of the most active carbon inserted by  $TiO_2$ . This indicates that  $TiO_2$  has been successfully inserted on the surface of activated carbon. The elements Fe and Al in the activated carbon that has been inserted  $TiO_2$  are impurities produced at the time of preparation.

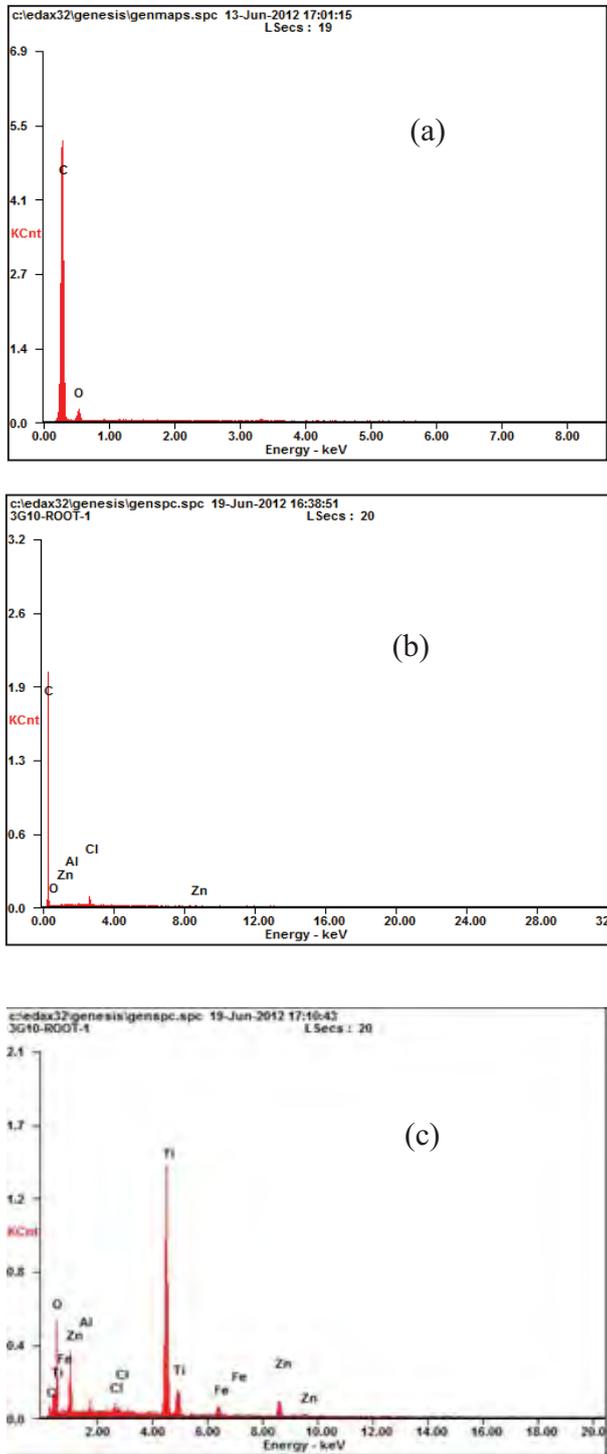

Figure 4: EDX Result of element composition in carbon  
 (a) Before activation (b) After activation (c) After activation with  $TiO_2$  insertion

### 3.1.3 Surface Area (BET Test)

To find the surface area of the adsorbent, BET analysis methods were conducted. BET test is done to look for changes in the surface area of the activated carbon and activated carbon were inserted TiO<sub>2</sub>. From the BET test results in Figure 5, an increase in the surface area of activated carbon after insertion of TiO<sub>2</sub>. This is because the insertion of TiO<sub>2</sub> molecule will increase the volume of the space between the layers of coconut shell charcoal coconut shell so that the surface area increases.

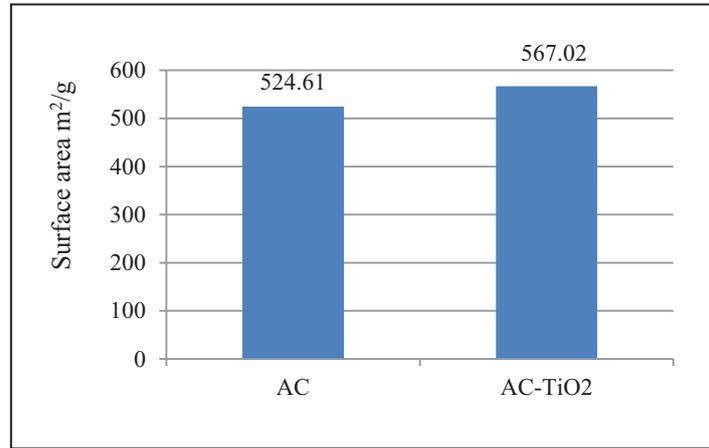

Figure 5: BET test result

## 3.2 Adsorption Test Result

### 3.2.1 Clearing of Smoke

$t_{10}$  value of each point for each adsorbent with variations in the size and mass are summarized in the chart in Table 1.  $t_{10}$  value indicates the time needed to reach the 10% level of clarity.

Table 1: Mass and size of activated carbon effect to  $t_{10}$  value

	$t_{10}$ (minutes)								
	Point 1			Point 2			Point 3		
	1 g	3 g	5 g	1 g	3 g	5 g	1 g	3 g	5 g
AC 420 $\mu\text{m}$	35	38	42	38	40	44	40	43	46
AC 125 $\mu\text{m}$	33	34	36	34	35	37	36	37	40
AC 74 $\mu\text{m}$	31	32	35	32	33	36	33	35	38
AC -TiO <sub>2</sub>		28	33		30	34		32	36

Based on Table 1, it can be concluded that point 1 for each adsorbent has a value of  $t_{10}$  is smaller than point 2 and point 3.  $t_{10}$  values are small, suggests that the time required to achieve opacity value of 10 is shorter. This is because the smoke inside the test chamber will fill the entire room moving then collided and caused sprayed adsorbent will absorb the smoke that drops down. From the results of Table 1, when compared with the variation of the mass of activated carbon and particle size, the best adsorbent in clarifying the smoke is activated carbon with the largest mass is 5 grams and the smallest particle size is 74 $\mu\text{m}$ . This indicates that the size of the adsorbent affects the time to achieve a certain level of clarity ( $t_{10}$ ). The smaller the particle size of the adsorbent and the adsorbent mass, the better the smoke cleared. This is due to the smaller size of the adsorbent surface area will become larger. Contact with the smoke particles are also becoming more widely, so that more smoke particles are absorbed, resulting in a faster clear smoke. While more and more mass is sprayed, would make the number of particles in contact with the smoke more and more.

When compared with activated carbon that has been inserted TiO<sub>2</sub>, it can be seen that the AC-TiO<sub>2</sub> adsorbent is better than activated carbon to clear smoke without TiO<sub>2</sub>. This is consistent with the results of surface area AC-TiO<sub>2</sub> greater than activated carbon without TiO<sub>2</sub>. The greater the surface area of the adsorbent, the greater the adsorption performance. Results achieved AC-TiO<sub>2</sub> as much as 3 grams to achieve opacity value at point 1 is 10 for 28 minutes while the AC-sized TiO<sub>2</sub> reached 74  $\mu\text{m}$

without opacity value of 10 in 32 minutes. From these results, it can be concluded insertion of  $\text{TiO}_2$  can increase job performance of activated carbon in the smoke cleared at 12.50%. The difference is not very significant, is consistent with the results of extensive tests on AC- $\text{TiO}_2$  surface that is not much different than the surface area of activated carbon without  $\text{TiO}_2$ .

### 3.2.2 CO Gas Adsorption

CO gas reduction results in 30 minutes can be seen in Table 2. CO gas can be adsorbed because it has a smaller particle size of the adsorbent pore size. CO particle diameter is 0.376 nm, whereas it is known that the activated carbon has a pore size of an average diameter of 117.2 Å and activated carbon (AC) were inserted  $\text{TiO}_2$  has the size of an average pore diameter of 86.17 Å or equal to 8.62 nm.

Table 2: The Effect of mass and size particle of activated carbon to CO gas adsorption

	5 grams Adsorbent		3 grams Adsorbent		1 grams Adsorbent	
	Lowering Level of CO for 30 minutes					
	%	ppm	%	ppm	%	ppm
AC 420 $\mu\text{m}$	9.21	88	8.49	74	5.62	50
AC 125 $\mu\text{m}$	11.73	141	9.31	98	7.22	76
AC 74 $\mu\text{m}$	11.92	187	11.01	165	8.95	129
AC - $\text{TiO}_2$			14.83	185	10.67	154

From Table 2 it can be seen that the mass of adsorbent and adsorbent particle size affects the results of the adsorption of CO gas. The best activated carbon on lowering CO levels is them with the largest in mass and smallest in particle size, which is 5 grams and 74  $\mu\text{m}$ . The smaller the particle size of the adsorbent and the adsorbent mass, the better the CO gas adsorbed. This is due to the smaller size of the adsorbent, surface area will become larger. Contact with CO gas particles are also becoming more widely, so that more particles are absorbed CO gas. While more and more mass is sprayed, would make the number of particles in contact with CO gas is more so the adsorbed CO particles is more to. Table 2 also shows that the insertion of  $\text{TiO}_2$  on activated carbon adsorption have an influence in the performance. AC- $\text{TiO}_2$  as much as 1 gram can lower the CO level is better, for about 154 ppm, compared with AC 74  $\mu\text{m}$  as much as 1 gram of which is only able to reduce levels of CO for about 129 ppm. From these results it can be said that the insertion of  $\text{TiO}_2$  on activated carbon adsorption can increase the performance of CO gas that is equal to 19.38%. The difference is not very significant, is consistent with the results of extensive tests on AC- $\text{TiO}_2$  surface that is not much different than the surface area of activated carbon without  $\text{TiO}_2$ .

To view the ability of the adsorbent to adsorbate binding molecules can be seen from the adsorption capacity. Adsorption capacity is obtained by calculating the mass of adsorbed CO gas (mg) per unit mass of adsorbent (mg). Adsorbent adsorption capacity by any of the test results is shown in Table 3. From the results of the adsorption capacity in Table 3 shows that the adsorption capacity of the adsorbent is best achieved by the smallest particle size but with the smallest mass. The smaller the particle size, the better adsorbent adsorption capacity, according to the results of the influence of particle size on adsorption performance has been discussed in the previous section. CO gas adsorption capacity of the largest obtained AC- $\text{TiO}_2$  1 g, amounting to 29.57.

Table 3: Adsorption capacity for each adsorbent

	5 grams Adsorbent	3 grams Adsorbent	1 grams Adsorbent
	Adsorption Capacity (mg adsorbat/mg adsorbent)		
AC 420 $\mu\text{m}$	3.3792	4.736	9.6
AC 125 $\mu\text{m}$	5.4144	6.272	14.592
AC 74 $\mu\text{m}$	7.1808	10.56	24.768
AC- $\text{TiO}_2$		12.224	29.57

#### 4. CONCLUSION

From the discussion above, it can be concluded as follow:

1. Activated carbon can be used as adsorbent of CO gas and smoke purification medium.
2. The decrease level of CO is increase as the mass of activated carbon increase and the size of activated carbon particles decrease.
3. The insertion of TiO<sub>2</sub> can wider the surface area of activated carbon from 524,612 m<sup>2</sup>/g to 567,02 m<sup>2</sup>/g.
4. The insertion of TiO<sub>2</sub> in activated carbon for 1 gram adsorbent mass can increase the smoke purification for about 12.50%.
5. The insertion of TiO<sub>2</sub> in activated carbon for 1 gram adsorbent mass can increase CO gas adsorption for about 19.38%.
6. The highest adsorption capacity can be reached by 1 gram AC-TiO<sub>2</sub> adsorption for about 29.57 mg/mg adsorbent.

### ABSTRACT

This research utilized polyvinylchloride (PVC) hollow fiber membrane to remove dissolved oxygen from water. This process is very important in producing ultra pure water that is widely used in industries such as semiconductor, pharmaceutical, food and steam power plant. In steam power industry for example, dissolved oxygen in water has to be reduced to the level below 0.5 ppm in order to prevent corrosion in the piping system in the boiler. Meanwhile, in the steam power plant dissolved oxygen in water has to be reduced to the level below 10 ppb in order to prevent wafer oxidation. This research aims to evaluate the performance of PVF hollow fiber membrane contactor to remove dissolved oxygen from water via vacuum degassing process. The fiber used in the experiments has pore size of 0.025  $\mu\text{m}$ . Number of fibers in the contactor and water flow rates is varied in the dissolved oxygen removal process through membrane contactor via vacuum degassing process. Meanwhile, there were two feed flow system for water in the membrane contactor namely shell side flow and tube side flow. Experimental results show that mass transfer in the liquid phase controls the overall mass transfer coefficients. The overall mass transfer coefficients as well as oxygen fluxes increase with increasing water flow rate and decreasing number of fibers in the membrane contactor. Friction factor of the fluids in the shell side and tube side flows are higher than predicted by theoretical value indicating that the fiber did not behave as smooth pipe. Overall mass transfer coefficients in the tube side were higher than in the shell side due to channeling effect.

### ABSTRACT

In this study carried out the reduction of NO<sub>2</sub> gas from motor vehicles. The increase number of motor vehicle produce high level of air poluting gas, particularly nitrogen dioxide (NO<sub>2</sub>). Instalation of adsorbent at the exhaust line can overcome this problem. This study use natural zeolite modified with TiO<sub>2</sub> as adsorbent. Zeolite was activated with HF 1%, HCl 6M, and NH<sub>4</sub>Cl 0,1M solution. Next, it was calcinated and modified with TiO<sub>2</sub> using sol-gel method. In this study, some phenomenons related with NO<sub>2</sub> adsorption is explained, such as influence of initial gas concentration, duration of contact, loading of TiO<sub>2</sub>, and application at motor vehicle. For pure NO<sub>2</sub> gas, the adsorption test shows the increase of adsorbed NO<sub>2</sub> by zeolite which is modified by TiO<sub>2</sub>. Zeolite with 10%, 20%, and 30% of TiO<sub>2</sub> loading has better adsorption capacity than zeolite which is unmodified by TiO<sub>2</sub>. The increase of TiO<sub>2</sub> loading up to 20 wt% in natural zeolite will increase the adsorption capacity of natural zeolite. However, the decrease of adsorption capacity is occurred between natural zeolite/TiO<sub>2</sub>-30% and natural zeolite/TiO<sub>2</sub>-20%. The adsorption test of modified natural zeolite to NO<sub>2</sub> gas from vehicles emission results information that natural zeolite/TiO<sub>2</sub>-20% can adsorb NO<sub>2</sub> gas up to 45–49% from its initial concentration. Natural Zeolite/TiO<sub>2</sub> 20% can adsorb pure NO<sub>2</sub> gas until 70% from its initial concentration.

### Key words

*Natural zeolite, TiO<sub>2</sub> adsorption, NO<sub>2</sub>, Vehicles Emission*

### 1. INTRODUCTION

Air quality, especially in big cities like Jakarta, is now highly contaminated by pollutants and has reached the threshold which is very harmful to human health. 70% of air pollutants in major cities contributed by the transportation sector. Pollution seems to have an inescapable result of continued swelling number of vehicles each year. In Jakarta, it is amounted to 6.5 million units with a growth rate of 10% per year [4]. The high consumption of fossil fuels (hydrocarbons) as a vehicle fuel and the lack of alternative energy sources is the cause. Combustion is a complex chemical reaction between a fuel and an oxidant accompanied by the production of heat which is sometimes accompanied in the form of fluorescent light or fire. If burning is done by using air as the oxygen source, the nitrogen was also added to the equation though it does not react to show the composition of the exhaust gases, is presented in Equation 1.

However, in reality the combustion of hydrocarbons produces other products, such as CO and NO<sub>x</sub>. Formation of NO and NO<sub>2</sub> occurs in internal combustion engines, where the reaction between nitrogen and oxygen in the air at high temperatures to form NO, then further reaction between NO with more oxygen to form NO<sub>2</sub>, as shown in the folowing equations:

In some major cities are known NO<sub>x</sub> levels in the air are as follows: 0.063 ppm in Bandung, 0.017 ppm in Surabaya, 0.054 ppm in Yogyakarta, and 0.067 ppm in Medan, with a threshold value of ambient air quality standard for NO<sub>x</sub> are: 0.05 ppm corresponding Kep. 02/MENKLH/1998 [1]. Air containing NO gas can cause interference with nerves system that causes seizures. If this continues to poisoning can cause paralysis. Meanwhile, toxicity (toxicity) of NO<sub>2</sub> gas is four times more powerful than the toxicity of NO gas. The most sensitive organs to NO<sub>2</sub> gas pollution is the lungs. Lung contaminated by NO<sub>2</sub> would swell so people breathing difficulty that can lead to death. Air pollution by NO<sub>2</sub> gas can also cause the formation of

Acetil Peroxy Nitrates which are abbreviated as APN. APN is irritating to the eyes so that the eyes sting and watery. To overcome the dangers of environmental degradation caused by motor vehicle exhaust, control of pollutant gases can be done by adding a catalyst in motor vehicle exhaust. This catalyst is a media decoder of CO and NOX result of combustion and converted into CO<sub>2</sub> and N<sub>2</sub>. One of the materials that can be used is the natural zeolite (NZ) modified with TiO<sub>2</sub>. Results of previous studies showed that natural zeolite can reduce NO<sub>2</sub> gas significantly [1]. Other research suggests that the insertion of TiO<sub>2</sub> into the activated carbon can increase the power of activated carbon adsorption of the NO<sub>2</sub> gas than without the insertion of TiO<sub>2</sub> [3].

This study aims to determine the optimal conditions on a combination of natural zeolite modified with TiO<sub>2</sub>, which is used to reduce NO<sub>2</sub> from motor vehicle exhaust. This study used natural zeolite as adsorption media. Zeolite is a natural mineral or rocks which chemically belonged to the mineral silica and alumina expressed as hydrated silica, finely shaped, and the result of secondary products that are stable at surface conditions as derived from the process of sedimentation, weathering or hydrothermal activity. Zeolite is a compound of alumina silica (Si/Al) having pores and a relatively large surface area, so it has a high adsorption properties. Before being used as an adsorbent, zeolite must be activated in order the number of the pores are more opened so that the pore surface area increases. Zeolite which is suitable for adsorbent is the one when it is enabled, it will give Si/Al high ratio (10-100). Zeolite with the high ratio of Si/Al is hydrophobic [6]. So that the adsorption capacity of zeolite did not undergo reduction, water molecules must be removed from the cavity of zeolite, namely by heating to a temperature 150°C. Adsorption can occur due to the interaction between the forces on the surface of a solid adsorbent with adsorbate molecules. From the results of previous studies it is known that the mineral of zeolite can absorb the gases CO<sub>2</sub>, H<sub>2</sub>S, and H<sub>2</sub>O as much as 25% [6]. Therefore, zeolites are used as adsorbents because of porous crystal structure, have a large surface area, high thermal stability, non-toxic, and effective. The catalyst used is TiO<sub>2</sub>. TiO<sub>2</sub> is one kind of metal oxide semiconductor catalysts in the photocatalytic process. TiO<sub>2</sub> plays a leading role in the photocatalytic processes due to the various advantages of physical and chemical properties such as high photo catalytic activity, stable, and non-toxic. Commercially, TiO<sub>2</sub> is also readily available and widely produced.

## 2. EXPERIMENTAL

There are several steps that are conducted to prepare natural zeolite adsorbent- TiO<sub>2</sub> (NZ/TiO<sub>2</sub>) and also the testing procedure of NZ/TiO<sub>2</sub> to reduce NO<sub>2</sub> gas.

### 2.1 NZ/TiO<sub>2</sub> Preparation

NZ is firstly crushed and filtered to get ± 420 μm in size. NZ is then soaked in 2% HF solution for 10 minutes, and stirred frequently. Furthermore, NZ is immersed in a 6 M HCl solution at 90 °C for 30 minutes. After that, NZ soaked in a solution of 0.1 M NH<sub>4</sub>Cl for 5 days, with stirring for 3 hours / day at a temperature of 90°C. Lastly, NZ calcined at 500 °C for 5 hours. TiO<sub>2</sub> sol was prepared by sol-gel method using TiO<sub>2</sub> Degussa P-25. TiO<sub>2</sub> is sonicated in water for 20 minutes. Furthermore, NZ is soaked in a solution of TiO<sub>2</sub> for 10 minutes. Then mix of NZ/TiO<sub>2</sub> are evaporated, and then followed by calcination at a temperature of 400 °C for 2 hours.

### 2.2 Adsorption Test of NZ/TiO<sub>2</sub>

Experimental of adsorption is done by using the following equipment configuration:

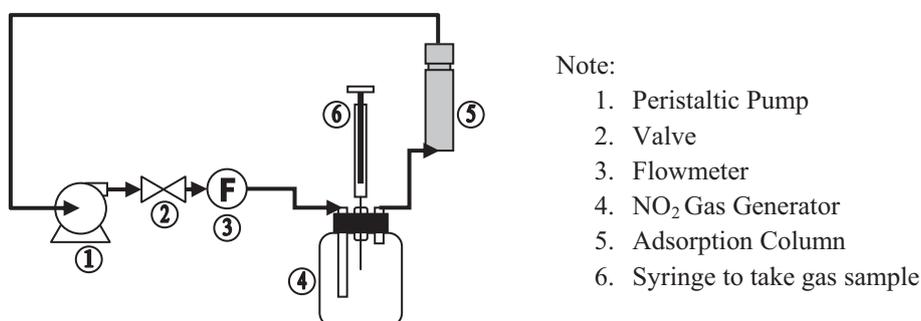

Figure 1: Equipment scheme for pure NO<sub>2</sub> gas adsorption

NO<sub>2</sub> gas analysis was performed by the method of Griess-Saltzman. NO<sub>2</sub> gas was generated from a standard solution of NaNO<sub>2</sub> and was treated with 6 M HCl, while the adsorbent was placed on the adsorption column. Gas flow formed NO<sub>2</sub> for 1 hour with a flow rate of 0.1 L/min. NO<sub>2</sub> gas samples were taken before and after doing the experiment and passed into a solution of

Griess-Saltzman. Qualitative method was adapted from ASTM procedure D1607. A number of the absorbed  $\text{NO}_2$  oxidized and dissolved in the Griess-Saltzman reagent containing N-(1-naphthyl) ethylenediamine dihydrochloride. Griess-Saltzman test solution will change color to red-purple when there is  $\text{NO}_2$  in the sample gas. Then the test solution was analyzed using UV-Vis spectrophotometer at a wavelength of 550 nm. The experiments were conducted for each of the NZ with  $\text{TiO}_2$  loading variations at different initial concentrations. Adsorbent with the best reduction capability is then used to test the adsorption on motor vehicles. Equipment scheme for  $\text{NO}_2$  gas adsorption from vehicle emissions is shown in Figure 2.

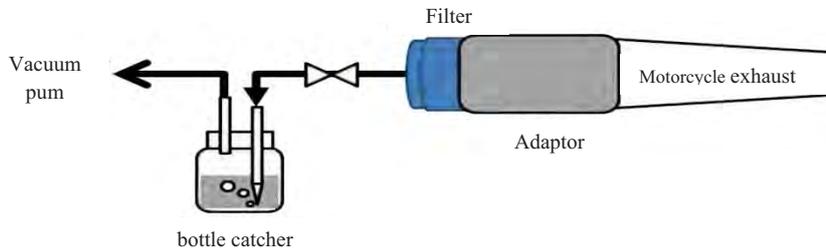

Figure 2: Equipment scheme for  $\text{NO}_2$  gas adsorption from vehicle emissions

### 3. RESULTS AND DISCUSSION

The experimental results are discussed include NZ characterization, and testing of the  $\text{NO}_2$  gas adsorption NZ/ $\text{TiO}_2$  artificial or from motor vehicles.

#### 3.1. Natural Zeolite Characterization

NZ who have and have not been through the stages of preparation and modified with  $\text{TiO}_2$  were characterized by EDAX and BET. Characterization results are presented in Table 1 and Table 2.

Table 1: The Si/Al ratio

Adsorbent	$\text{SiO}_2$ (wt%)	$\text{AlO}_2$ (wt%)	$\text{TiO}_2$ (wt%)	Si/Al
NZ	37,85	4,39	-	8,62
Activated NZ	54,20	2,26	-	23,98
NZ/ $\text{TiO}_2$ -20%	50,08	2,72	21,63	18,41

Table 2: Surface area

Adsorbent	Surface area ( $\text{m}^2/\text{g}$ )
NZ	23,35
Activated NZ	44,29

Characterization of the results shows that an increase in the ratio of Si/Al in NZ activated from 8.62 to 23.98. This is consistent with the expected results because zeolites are both used as adsorbent is a zeolite with Si / Al ratio ranged between 10-100, and the lower the zeolite Si/Al, the better the zeolite adsorption to  $\text{NO}_2$  gas [1]. On the other hand, on NZ/ $\text{TiO}_2$ -20% can be seen that there is  $\text{TiO}_2$  on zeolite surface of 21.63 wt%. The formation of  $\text{TiO}_2$  on the surface of the zeolite showed that the synthesis process NZ/ $\text{TiO}_2$  relatively successful.

It can be seen also that an increase in the surface area of 23,35  $\text{m}^2/\text{g}$  to 44.29  $\text{m}^2/\text{g}$ . This increase occurs because the NZ immersion in a solution of 2% HF, HCl 6 M, and 0.1 M  $\text{NH}_4\text{Cl}$  oxide impurities contained in NZ has been dissolved to form an empty space in the zeolite crystals.

#### 3.2. Adsorption Test of NZ/ $\text{TiO}_2$

The test is conducted to see the ability of zeolite on adsorbing  $\text{NO}_2$ . The adsorption test result can be seen in Figure 3. Based on Figure 3, it can be seen that there is an increase in the amount of  $\text{NO}_2$  adsorbed by zeolite modified with  $\text{TiO}_2$ .  $\text{TiO}_2$  zeolite loading of 10%, 20% and 30% by weight have a better adsorption power than the unmodified zeolite with  $\text{TiO}_2$ . This shows the increasing loading up to 20 wt% of  $\text{TiO}_2$  on zeolite, the adsorption of the zeolite increased to. However, there is a decrease in the adsorption power NZ/ $\text{TiO}_2$ -30% compared with NZ/ $\text{TiO}_2$ -20%.

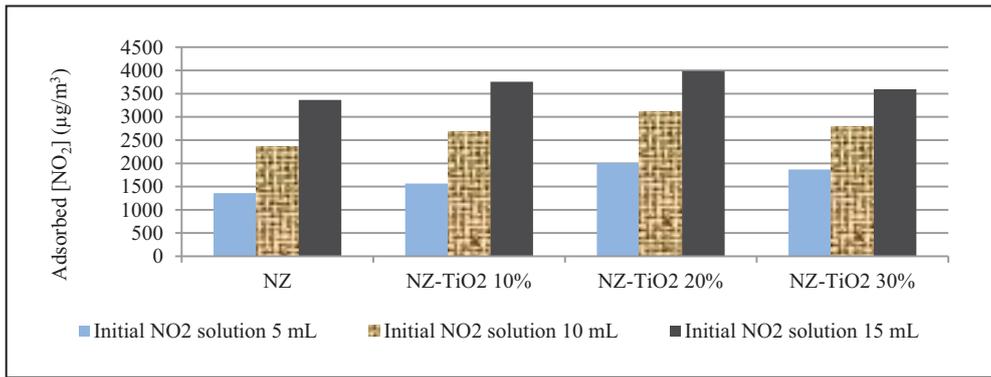

Figure 3: Loading effect of TiO<sub>2</sub> for 0%, 10%, 20% and 30% to NO<sub>2</sub> adsorption

### 3.3 Isotherm Pattern of NO<sub>2</sub> Gas Adsorption by NZ/TiO<sub>2</sub>

Isotherm patterns used in this study are Freundlich isotherm. The pattern of adsorption isotherms and the maximum adsorption of zeolite to NO<sub>2</sub> gas can be determined by the equation:

$$(x/m) = kc^{1/n} \quad (4)$$

where (x/m) is the amount of NO<sub>2</sub> adsorbed per unit mass of adsorbent (mg /g), c is the initial concentration of NO<sub>2</sub> (µg/m<sup>3</sup>), k and 1/n is the Freundlich isotherm equation constants. Figures 4-7 show the effect of initial concentration on the amount of gas adsorbed NO<sub>2</sub> and Freundlich equation.

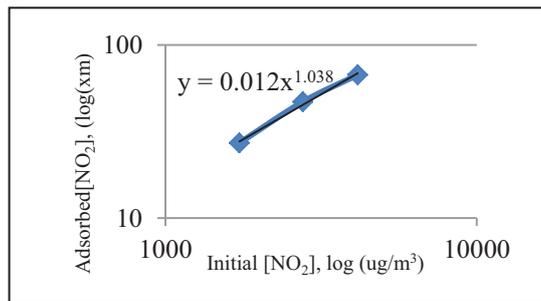

Figure 4: Effect of initial concentration of the amount of NO<sub>2</sub> adsorbed on zeolite without modification

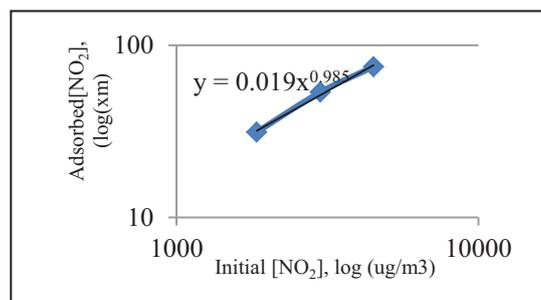

Figure 5: Effect of initial concentration of the amount of NO<sub>2</sub> adsorbed on NZ/TiO<sub>2</sub>-10%

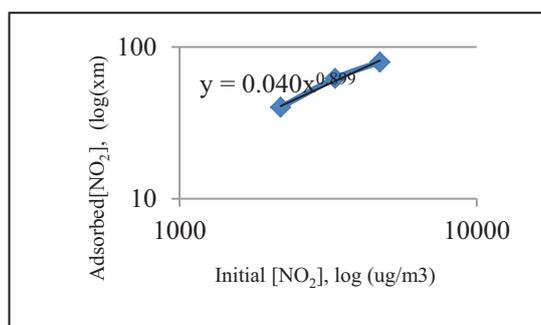

Figure 6: Effect of initial concentration of the amount of NO<sub>2</sub> adsorbed on NZ/TiO<sub>2</sub>-20%

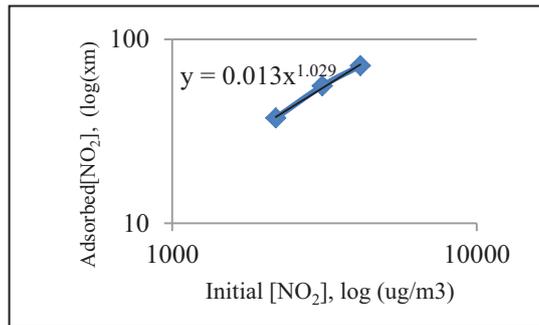

Figure 7: Effect of initial concentration of the amount of NO<sub>2</sub> adsorbed on NZ/TiO<sub>2</sub>-30%

Obtained from the equation for each graph, it is known the Freundlich isotherm adsorption constants  $k$  and  $1/n$  for each adsorbent, as shown in Table 3 below.

Table 3: The constant value of  $k$  and  $1/n$  for each adsorbent

Adsorbent	1/n	K
NZ	1,0380	0,0120
NZ/TiO <sub>2</sub> -10%	0,9850	0,0190
NZ/TiO <sub>2</sub> -20%	0,8990	0,0400
NZ/TiO <sub>2</sub> -30%	1,0290	0,0013

Based on the value of  $k$  and  $n$  are obtained, it is seen that the power NZ/TiO<sub>2</sub>-20% have the best for NO<sub>2</sub> gas with low initial concentrations, followed NZ/TiO<sub>2</sub>-10%, and NZ/TiO<sub>2</sub>-30%. While the natural zeolite without modification has the lowest adsorption capacity for NO<sub>2</sub> gas with low concentrations. This shows the influence of TiO<sub>2</sub> to NO<sub>2</sub> gas in the reduction process. It can be seen that, with the increasing number of TiO<sub>2</sub> on zeolites, the ability of zeolite to reduce NO<sub>2</sub> gas is increasing. TiO<sub>2</sub> zeolite loading of 20%, has a better capability than the reduction NZ/TiO<sub>2</sub>-10% and zeolite without modification. However, a decrease in the adsorption when loading TiO<sub>2</sub> on zeolite reached 30%. It is caused by too much content of TiO<sub>2</sub> on zeolite surface, can lead to seal the pores of adsorbent.

Experiment to create a model of the Langmuir isotherm can not see a match between the data obtained with the Langmuir isotherm models, as indicated by the low value of  $R$  obtained Langmuir isotherm equation ( $R < 95\%$ ). This suggests that the Langmuir isotherm models do not apply to the NO<sub>2</sub> gas adsorption process is done. It also means that the process of adsorption of NO<sub>2</sub> was not able to meet the assumptions used to develop the Langmuir isotherm equation. Langmuir isotherm is applicable if the adsorbent has a particle size and shape are uniform, while the adsorbent used still has a particle size distribution that is wide enough (35-40 mesh). Another assumption must apply the ideal gas. This assumption can be approximated by using the gas at low concentrations. However, as the ambient gas used to dilute sorbate gas in this experiment is a gas mixture that contains water (water vapor). The use of air as a diluent gas intended for NO<sub>2</sub> were tested in the air close to the real situation as one pollutant.

### 3.4 Adsorption Test of NO<sub>2</sub> Vehicle Emission

Adsorption ability of the adsorbent was applied to the motor vehicle as a motor vehicle exhaust emissions is one of the biggest sources of NO<sub>2</sub> gas. Adsorbents used in this experiment the adsorbent with the best adsorption capability in the earlier experiment, ie NZ/TiO<sub>2</sub>-20%. The experiments were performed several times with repetition three times. Results of experiments are presented as follows.

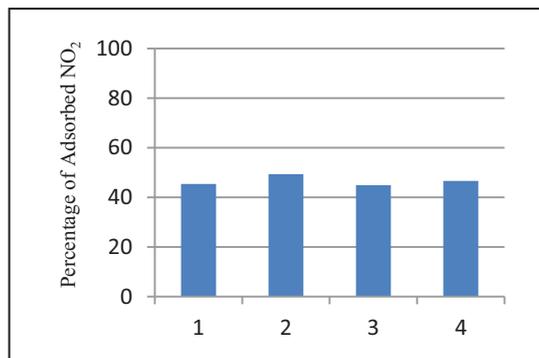

Figure 8: Percentage of NO<sub>2</sub> gas adsorbed from vehicle emission by NZ/TiO<sub>2</sub>-20%

From the above data it can be seen that NZ/TiO<sub>2</sub>-20% NO<sub>2</sub> gas can adsorb up to 45-49% of the initial concentration. These results are still far below the adsorption ability NZ/TiO<sub>2</sub>-20% of the NO<sub>2</sub> gas at the time of testing in the laboratory. NZ/TiO<sub>2</sub>-20% at the time of testing NO<sub>2</sub> gas adsorption is able to adsorb up to 70% of the initial concentration. The decrease is due to interference by carbon dioxide and water vapor gas emissions are high on the vehicle [1]. The mixture will be more dominant on the surface of zeolite fill sites are used, thus reducing the portion that can be occupied by molecules NO<sub>2</sub>. Hal It happens because of the nature of zeolite that has a high affinity for water, so it is very easy to adsorbed water (Suraputra, 2011). This causes problems not optimal zeolite used as an adsorbent for application on vehicles. Therefore, more research needs to be done in order to be more hydrophobic zeolite so as to reduce interference on the zeolite due to high moisture content.

#### 4. CONCLUSION

From the research that has been done, some conclusions can be drawn as follows:

1. The higher the initial concentration of the gas, the higher the amount of NO<sub>2</sub> are adsorbed by natural zeolite.
2. This is due to the increase of the BET surface area of 23.35 m<sup>2</sup> natural zeolite/g to 44.29 m<sup>2</sup>/g and Si/Al ratio of zeolite from 8.62 to 23.98.
3. Natural zeolite with the maximum adsorption to adsorb NO<sub>2</sub> gas is natural zeolite with 20% TiO<sub>2</sub> loading.
4. Natural zeolite with 20% TiO<sub>2</sub> loading can reduce motor vehicle emissions of NO<sub>2</sub> gas up to 45-49% initial concentration.

### ABSTRACT

Apoptin is a small protein encoded by chicken anemia virus (CAV). It has ability to induce apoptosis of human tumor cells selectively. This protein was expressed as a recombinant protein by employing *Bacillus subtilis* as hosts for expression in soluble fashion. To improve cell penetrating ability of the Apoptin, the C-terminal of the protein was fused with octaarginine. MTT assay were used to identify antitumor effect of Octaarginin-Apoptin. The viability of cell was analyzed when the cell incubated in the concentration protein of 0.1, 1 and 10 µg/mL for 72 h. The results of the MTT assay indicated that Octaarginin-Apoptin was able to induce apoptosis of HeLa cell lines in a dose-dependent manner. The recombinant apoptin without fusing with octaarginine, have no ability to induce apoptosis of HeLa cell lines. This octaarginine-apoptin may in the future allow the development of a therapeutic protein that is able to specifically kill tumor cells.

### Keywords

Apoptin, octaarginine, MTT assay, Cervix cancer.

### ABSTRACT

Hydroxyapatite/chitosan (HApC) composite has been prepared by precipitation method and used for removal of heavy metals ( $\text{Cr}^{6+}$ ,  $\text{Zn}^{2+}$  and  $\text{Cd}^{2+}$ ) from aqueous solution. The HAp and 3H7C composite with HAp:chitosan ratio of 3:7 (wt%) were characterized by Fourier transform infrared spectroscopy, X-ray diffraction and scanning electron microscopy-energy dispersive X-ray spectroscopy. The SEM results showed that HAp is spherical-shaped and crystalline, while chitosan has a flat structure. SEM micrograph of 3H7C composite reveals crystalline of HAp uniformly spread over the surface of chitosan. The crystal structure of HAp is maintained in 3H7C composite. Chitosan affects the adsorption capacity of HAp for heavy metal ions; it binds the metal ions as well as HAp. The kinetic data was best described by the pseudo-second order. Surface adsorption and intraparticle diffusion take place in the mechanism of adsorption process. The binding of HAp powder with chitosan made the capability of composite to removal of  $\text{Cr}^{6+}$ ,  $\text{Zn}^{2+}$  and  $\text{Cd}^{2+}$  from aqueous solution effective. The order of removal efficiency ( $\text{Cr}^{6+} > \text{Cd}^{2+} > \text{Zn}^{2+}$ ) was observed.

E-mail: muharam@che.ui.ac.id*

### **ABSTRACT**

The government is setting up a program of city gas utilization for household sector. People are not convinced of the safety of city gas. One of the accidents people worry about is gas leakage in a city gas utilization system, such as kitchen. Leaking gas is not dangerous when fire can be prevented. Therefore, the information on potential fire caused by leaking gas and ways to prevent are needed. This research was intended to obtain the information on fire prevention caused by leaking gas in a kitchen through simulation. The system modelled in the research is a rectangular room of 3 m x 2 m x 3 m. The models consider mass and momentum balances, and were solved using COMSOL Multiphysics. The simulation results show that when leaking gas detected, the leakage hole must be closed. Even if there is an exhaust system, the safe limit is not reached.

## ABSTRACT

*This research was conducted to determine the impact of reaction time on the quality of carbon nanotubes (CNTs), CNT's yield and also methane conversion. CNTs were grown on alumina balls coated Fe/Mo/MgO catalyst prepared by sol-gel method. The decomposition reaction carried out in CVD reactor at 850°C with methane as carbon source. The reaction time of 15, 30, 45 and 60 min. were used to evaluate its impact. FE-SEM method was used to characterize CNT. The FE-SEM images show that CNT has been successfully grown on alumina balls with diameter approximately 50 until 130 nm. but it didn't form aligned CNT. The less evenly catalyst coating and less homogenous of catalyst composition are the causes of this result. The reaction performance shows that CNT's yield is increases when the reaction time increases, while the methane conversion decreases due to the catalyst deactivation.*

## Keywords

*Aligned CNT, methane decomposition, Fe/Mo/MgO, alumina ball*

## 1. INTRODUCTION

Carbon Nanotube (CNT) is a material that has a lot of advantages over other materials. The advantages are as follows: chemical reactivity, electrical conductivity, optical properties and also young's modulus [1]. Because of its advantages, CNT becomes one of the most applicative materials for devices, fuel cell, composites, etc. Bundles of CNT that oriented into certain direction is called aligned CNT. Aligned CNT can be use on some application such as the self-cleaning application, DNA biosensor, glucose sensor, pH, NO<sub>2</sub>, etc [9]. Therefore, the research on aligned CNT is very important to develop.

Various studies about CNT have been carried out in Chemical Engineering Department University of Indonesia, but haven't been able to generate aligned CNT. It is caused by the number of parameters that need to be considered such as substrate shape and type, catalyst, and also some reaction condition such as reaction time. In this research, reaction time is becoming our major concern. On the other hand, there are many other researches that has successfully generate aligned CNT by using some substrate, catalyst and method. Aligned CNT can be grown on porous silica substrate [5]. However, among the aligned CNT produced, there are several CNT that is not vertically aligned. This caused by the form of the pore in the substrate is not uniform [5]. On the other side, aligned CNT that growth on glass substrate without pores has better CNT quality [8] and the usage of spherical substrate make the reaction occured continuously [12]. Therefore alumina ball become the substrate of this research to grow aligned CNT.

Meanwhile, in the selection of the catalyst, Fe/Mo/MgO catalyst that has Fe active site was choosen. It is based on a variety studies that has been done such as ferrocene [3,12] and Fe catalyst [2,4]. Meanwhile, methane is the carbon source and CVD is the method used in this research.

This research was conducted to find out the influence of reaction time on the orientation of CNT, CNT's yield and also methane conversion, as there is a possibility that the orientation of the CNT is affected by the length of time reaction.

## 2. RESEARCH METHODS

The CNT were grown by chemical vapour deposition method on alumina ball with 2-4 mm of diameter, methane as the carbon source and hydrogen gas to reducing the catalyst. The Fe/Mo/MgO catalyst with 1/0.1/13 molar ratio and catalyst was prepared

using sol-gel method by mixing  $\text{Fe}(\text{NO}_3)_3 \cdot 9\text{H}_2\text{O}$ ,  $(\text{NH}_4)_6\text{Mo}_7\text{O}_{24} \cdot 4\text{H}_2\text{O}$ ,  $\text{Mg}(\text{NO}_3)_2 \cdot \text{H}_2\text{O}$ , and citric acid, into deionized water. Two stages of calcination at  $550^\circ\text{C}$  and  $850^\circ\text{C}$  was conducted to the sol-gel, to get the catalyst powder. The CVD reactor made by quartz with 4.5 cm of inner diameter and 50 cm of length. The arrangement of reactor system can be seen in Fig. 1.

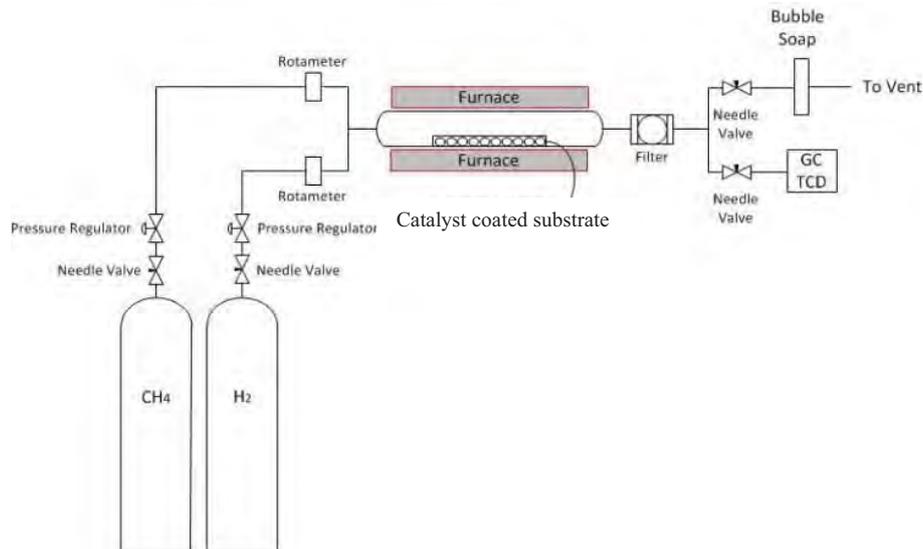

Figure 1: Equipment layout

At the beginning, the furnace was set at  $850^\circ\text{C}$ . Hydrogen was supplied into the reactor at a flow rate of 20 mL/min for 30 minutes to reducing the catalyst, and followed by methane gas at a flow rate of 80 mL/min. The 60, 45, 30 and 15 minutes of time reaction was used in this research. The output gas composition was analyzed using Shimadzu 8-APT Gas Chromatography (GC) with active carbon column & C-R6A TCD Detector, every 5 minutes during the reaction.

The catalyst properties were characterized by X-Ray Diffraction (XRD) and Scanning Electron Microscopy – Energy Dispersive X-ray (SEM-EDX) methods. The XRD characterization is done using a Shimadzu 7000 ( $\text{CuK}\alpha = 0,1541 \text{ nm}$ ), and the SEM-EDX characterization was performed by using Carl Zeiss Bruker MA-EVO10. The morphology of the catalyst coating and the growth of CNT were characterized by FE-SEM method using Inspect F50 by FEI.

### 3. RESULTS AND DISCUSSION

#### 3.1 Catalyst Characteristics

$\text{Fe}_3\text{O}_4$  and  $\text{MgO}$  are the desired crystal structure catalyst, which both of them are proved their existence through the result of XRD characterization before hydrogen reduction as shown in Fig. 2(a). The presence of  $\text{MgO}$  crystal in the catalyst helps the dispersion of Fe active site and prevent the sintering of Fe catalyst. Meanwhile, the presence of  $\text{Fe}_3\text{O}_4$  is the source of Fe active site [10].

The reduction of Fe/Mo/MgO catalyst is performed to produce Fe and Mo catalyst active site [10]. Fig. 2(b) shows the existence of  $\text{MgO}$ , but there are no Fe or Mo peak through the XRD result. This is happen due to its very small composition of Mo in the catalyst. In the other hand, Fig. 3 shows there are Fe, Mo, Mg and O in Fe/Mo/MgO catalyst.

FE-SEM images of alumina coated catalyst [Fig. 4] shows the less evenly catalyst coating, especially at 80.000 and 300.000 times of magnification [Fig 4.(c) and (d)]. This was caused by the spray coating method which is difficult to produce an uniform coating and may lead to irregular position of Fe particles.

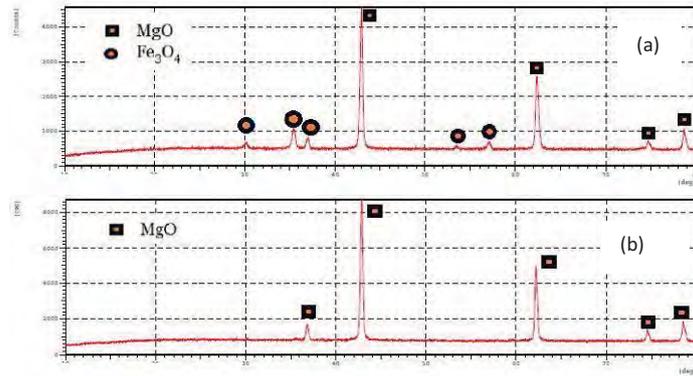

Figure 2 : XRD characterization result of Fe/Mo/MgO catalyst. before (a) and after (b) reduction

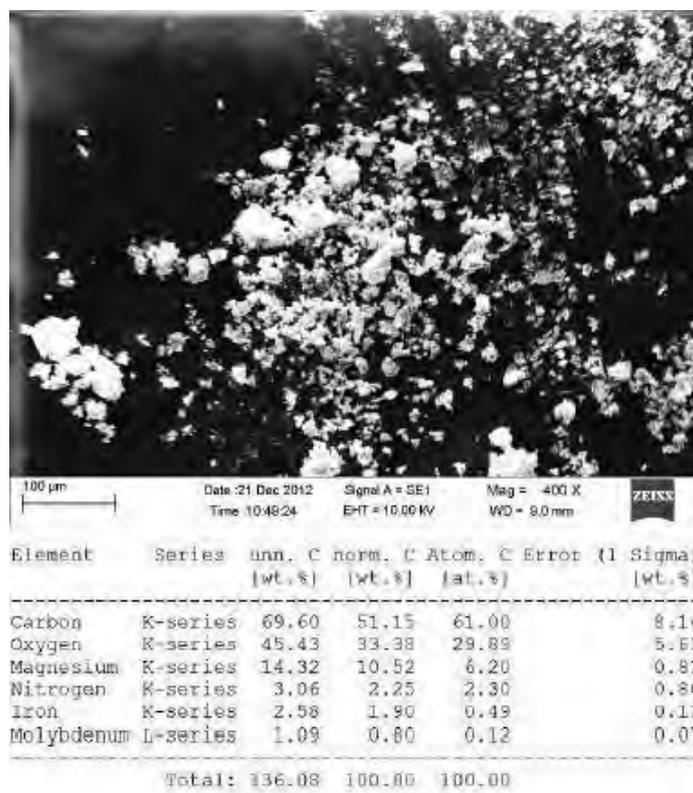

Figure 3 : SEM-EDX result of Fe/Mo/MgO reduced catalyst

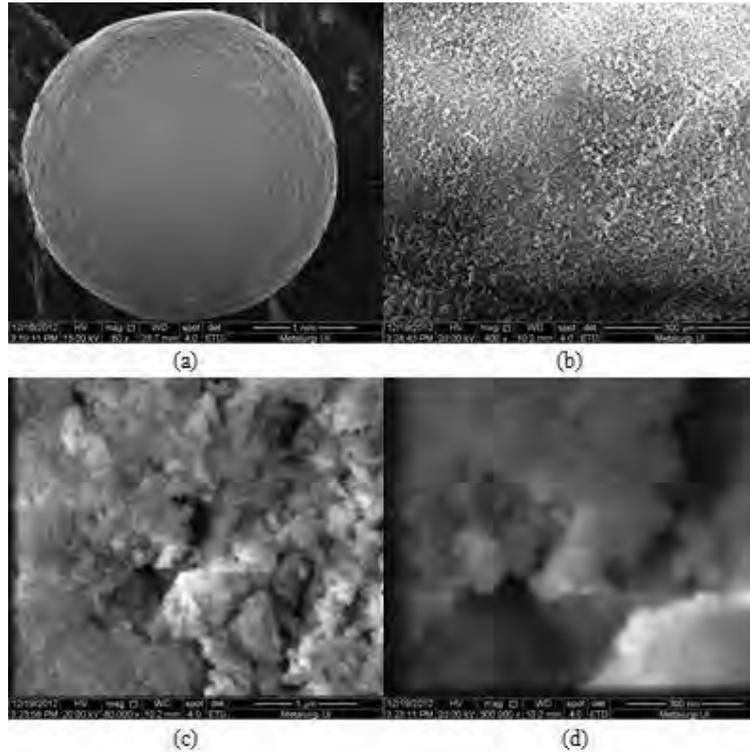

Figure 4 : FE-SEM images of alumina coated catalyst at : 80x (a), 400x (b), 80.000x (c) and 300.000x (d) magnification

### 3.2 CNT Characteristics

CNT has been successfully growth on alumina ball at all reaction time variation. FE-SEM images of alumina overgrown CNT [Fig. 5 and 6] shows that the decrease in reaction time produce a more tidy CNT bundles. The decrease in reaction time also impact the diameter of CNT:  $\pm 130$ ,  $\pm 100$ ,  $\pm 75$  and  $\pm 50$  nm in 60, 45, 30 and 15 minutes of reaction time respectively, which is caused by the growth. Unfortunately, there is no aligned CNT produced. It was caused by the less evenly catalyst coating and less homogenous of catalyst composition.

The less evenly catalyst coating caused the Fe catalyst can be placed in all sections so the CNT is grow unpredictable. Meanwhile, reference [14] shows that the difficulty of making a homogenous composition of the catalyst cause the existence of catalyst particle that rich in Fe composition and catalyst particle that rich in Mo composition. Based on volcano curve, we know that Fe particle has better reactivity than Mo particle. The difference in particle reactivity cause CNT will go higher on Fe particle than Mo particle and loss its orientation [14].

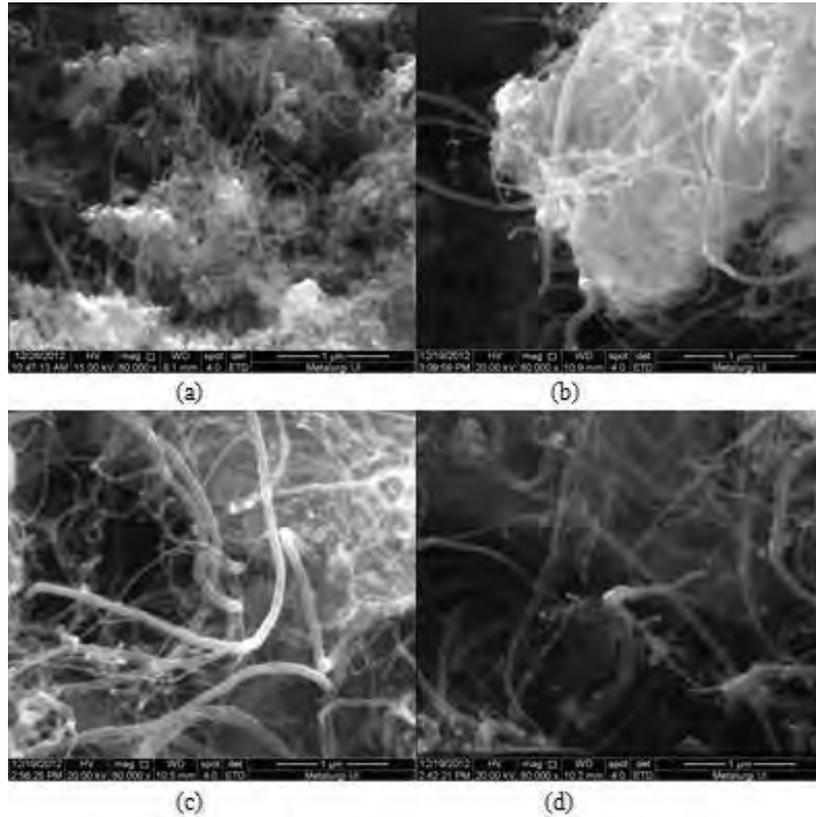

Figure 5 : FE-SEM images of alumina overgrown CNT on 80.000x magnification at : 15 (a), 30 (b), 45 (c) and 60 (d) minutes of variation times

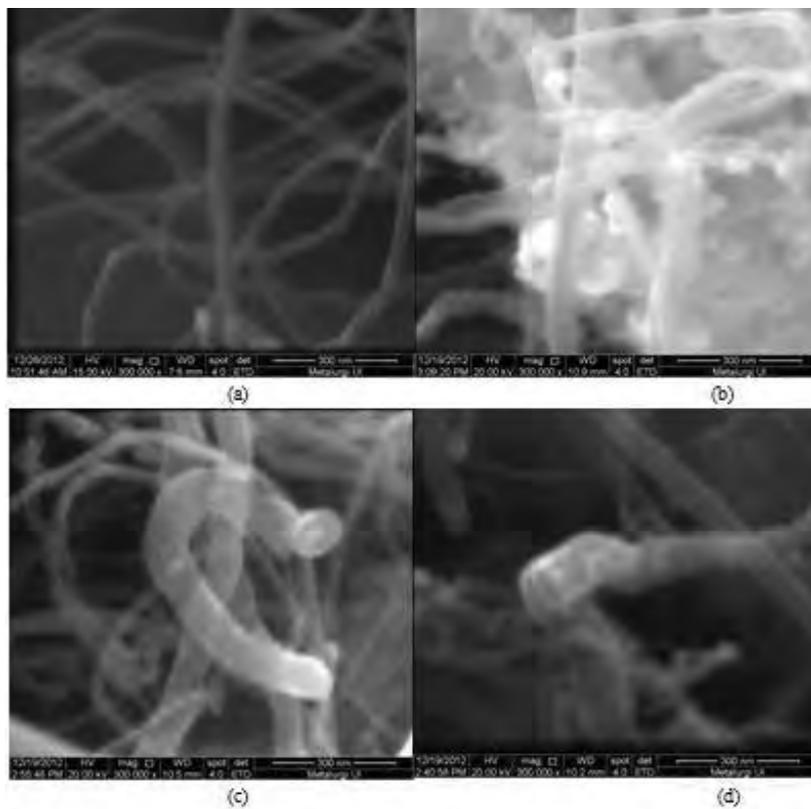

Figure 6 : FE-SEM images of alumina overgrown CNT on 300.000x magnification at : 15 (a), 30 (b), 45 (c) and 60 (d) minutes of variation times

### 3.3 Reaction Performance

Carbon loss was calculated by using the initial carbon mass balance and the modified carbon mass balance by identification of carbon loss. The initial carbon mass balance was calculated by using the raw data that we got during the research such as the feed rate that measured by flow meter and product rate that measured by a bubblesoap. In the other side, the modified carbon mass balance was calculated by using feed and product rate that have been corrected.

Table 1 shows that there are some carbon loss happend in this research. Carbon loss happend because of some error, such as decrease in methane flow rate due to the growth of CNTs, product flow sampling error, methane gas converted into another higher gases, some CNTs was carried away from the reactor by the gas flow, unstability of feed flow rate due to the unstable flowmeter [13]. Growth of CNT reduce the empty space in the reactor that makes a pressure drop and the resulting decline of methane flow rate [13]. By calculation, there is a bit decrease in carbon loss [Table 1]. The unidentified carbon loss caused by the other error as mentioned above. The TCD type of gas chromatography can not detect the presence of other gases such as  $C_2H_4$ ,  $C_2H_6$ ,  $C_2H_2$  and  $C_4H_{10}$  [13]. Therefore, we need FID type of gas chromatography to detect those gases. This error causes the calculated carbon mass balance si not accurate and causes huge amount of carbon loss.

Table 1: Carbon loss calculation

Time Variation (minutes)	Theoretical Carbon (g)	CNT Mass (g)	Carbon Loss	Carbon Loss (corrected)	
15	0.23	0.15	34.41%	33.33%	± 1.59%
30	0.65	0.30	53.79%	52.49%	± 1.72%
45	0.82	0.31	62.14%	60.35%	± 1.72%
60	0.95	0.43	54.96%	52.06%	± 1.71%

Methane conversion is decending when the reaction time increase [Fig. 7]. It is happened because the occurrence of catalyst deactivation [11] and CNT has grown on the catalyst [13]. Its cause the surface area of the catalyst that can be used to perform the reaction is getting smaller and results in decending methane conversion.

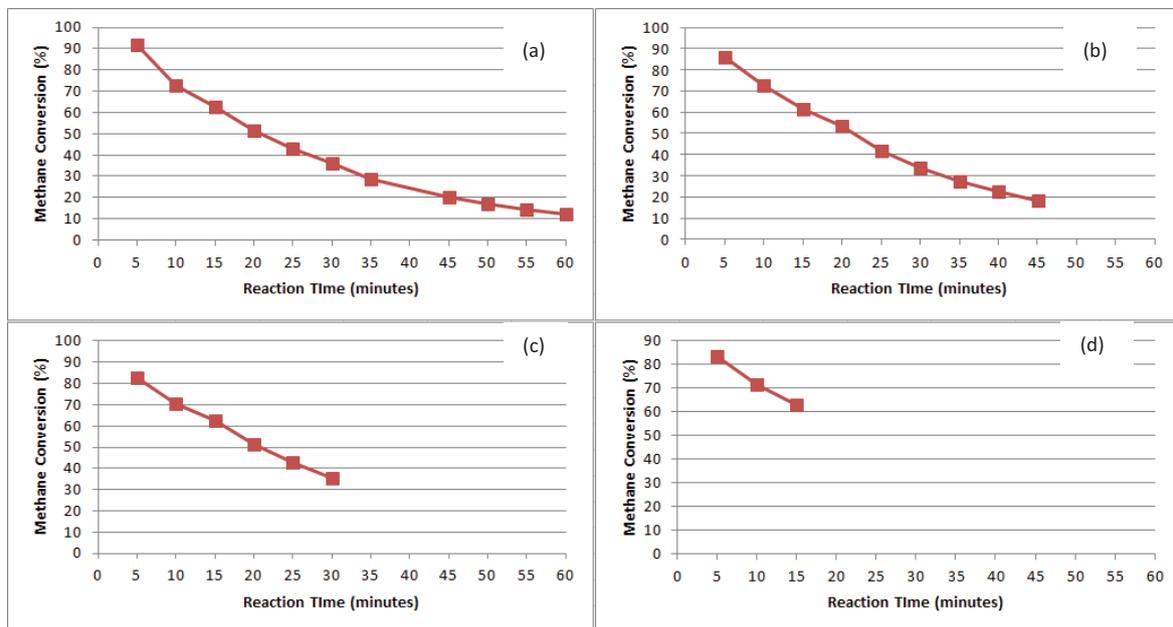

Figure 7 : Methane conversion : 60 (a), 45 (b), 30 (c) and 15 (d) minutes of reaction time

Yield is describe as the amount of CNT produced compared with the amount of catalyst used. The reaction time variation impact the CNT's yield as the CNT's yield was increasing when the reaction time increase. Fig. 8 shows the produced CNT's yield for 15, 30, 45 and 60 minutes of reaction time is 0.41, 0.52, 0.54 and 0.75 gCNT/gCat, respectively. This result indicates that CNT is still growing until the carbon source is no longer exist.

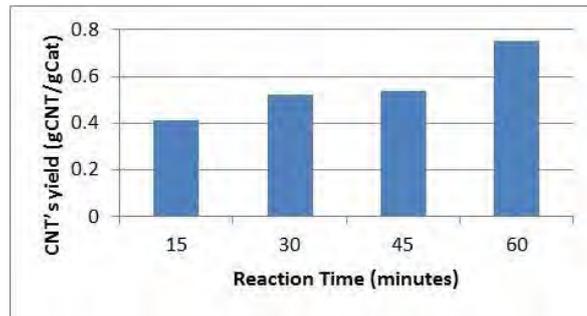

Figure 8 : CNT's yield at some reaction time variation

#### 4. CONCLUSION

Carbon nanotubes have grown on spherical substrate coated Fe/Mo/MgO catalyst and methane by CVD method. The variations in reaction time performed have shown that CNTs grown more tidy in a shorter reaction time. Unfortunately, there are no indication that aligned CNT have grown by using this combination of catalyst, substrate, carbon source and method. It is happened because of the less evenly catalyst coating and less homogenous of catalyst composition. The variation of reaction time impact the CNT's yield, where CNT's yield is increasing when the reaction time increase. It indicates that CNT is still grow until the carbon source is no longer exist. The methane conversion has decreased along the reaction time because the occurrence of catalyst deactivation.

### ABSTRACT

Annonaceous acetogenins are bioactive compounds present in the leaves of *Annona muricata* (soursop) with significant anti-cancer activities. In this study, acetogenin-rich ethanol fraction extracted from soursop leaves was further separated and isolated using a simple open column chromatography technique with silica gel as the stationary phase. The separation procedure consists of three steps, each step employing sequential elution with organic solvents having different polarity as the eluent. Eluted fractions rich in acetogenin compounds were identified using the Kedde reagent which formed a distinctive dark green complex with the unsaturated  $\gamma$ -lactone group present in all of the annonaceous acetogenin compounds. HPLC analysis showed that the initial methanol fraction, as well as isolates from the second and the third isolation steps, contain bullatacin, squamostatin-A, and squamostatin-D. Bullatacin produced from this study can be used further as a standard compound for quantitative analysis of other acetogenin compounds contained in soursop leaves extract.

## ABSTRACT

One of the aspect quality of the product refinery for the requirement of atoumotive is the hydrocarbon products with high octane number ( $> 88$ ) in order to be accepted well as primary quality fuel. In the conventional industrial refinery processing, the producing of the high octane number hydrocarbons usually employs the reactions of : catalytic reforming, hydrocracking, alkylation or catalytic cracking. This research is intended to give an overview of alternative route for recovery the high quality hydrocarbons from ethanol. Ethanol is one of the biomass derivative compound, could be generated renewably from fermentation process. The reaction of the ethanol conversion to hydrocarbons could be performed using the mixture catalyst of the  $\gamma$ -alumina and H-ZSM-5 with weight composition (5, 10, 15 %wt). The catalytic reaction test was carried out by fixed bed reactor at atmospheric pressure during 3 hours raction, with each of catalyst composition examined and reaction temperatures. The results showed that the reaction of ethanol to the containing hydrocarbons product such as aromatic, isoparaffin, olefin was obtained significantly. The calculation result of the high octane number up to 109.5 was achieved using catalyst composition 15% HZSM-5-75 %  $\text{Al}_2\text{O}_3$  at 450 °C. This such high octane number is due to isoalkane and aromatic hydrocarbons produced as the main comprising component in the product.

*Ethanol, hydrocarbons, mixture of H-ZSM-5 and Alumina, octane number, reaction catalytic conversion*

## 1. INTRODUCTION

Crude oil is one of the unrenewable source of energy. It is because of how the crude oil formed in the earth. Crude oil existed because of decomposition of a long dead organism which is buried in the earth for a very long time. The time it took for it to become crude oil could be a hundred's or even thousand years. This minimum quantity of crude oil means that an export and import to satisfy the demand must be done. In this case, Indonesia have to import the crude oil to satisfy the demands. Crude oil production in Indonesia until the end of 2009 was 900,000 barrel per day and 50 percent of that production was exported outside the nation. At that time, crude oil needs in indonesia was 1.4 million barrel per day, therefore Indonesia still have to imported 950,000 barrel per day of crude oil to satisfy that much demand [1]. To solve this problem, a new source of crude oil well need to be discovered and built, but even so, the demands would not be fulfilled until 2015 [2]. Because of those problems, the needs of alternative energy beside the crude oil is increasing to solve the problems of this limitation.

In the study of ethanol catalytic transformation over zeolite HZSM-5 catalyst showed that the mechanism of reaction is similar with those in MTG (methanol to gasoline) reaction [3]. Moreover, the range of product made from this reaction is also similar [4]. This showed us that the process in MTG reaction generally could also be used in ETG reaction. The study of hydrocarbon production with hybrid catalyst (physical mixed catalyst or bifunctional catalyst) have also been done before which used  $\text{B}_2\text{O}_3$ /Zeolit as the catalyst and the feed on that research use the mixture of palm oil and methanol with catalytic reaction [5].

One of the quality indicator of fuel like gasoline that really familiar with us all is octane number (RON). For example, a commercial gasoline produce by PT. Pertamina have an octane number of 88 for premium, and 92 for pertamax. The difference between that two kind of gasoline in octane number is very little. But, this little difference have a greater impact on the machine performance and the price of these gasoline. Basically, octane number of chemical compound is related to what kind of hydrocarbon compound involved. Generally, hydrocarbon compound that have an ability and capability to boost an octane number is for example an aromatic compound, cycloparaffins (naphta), and an iso-paraffins compound. Because of that, a hydrocarbon mixture which contain those kind of hydrocarbons will have a higher octane number than those whose not. Generally, those hydrocarbons were made from the processing of crude oil. In this research, those hydrocarbon compounds

will be synthesized from ethanol which is not the product of crude oil, thus made it renewable because ethanol can be obtain from renewable source like fermentation.

The purpose of this research is to get an optimum variable on this catalytic reaction of ethanol into high octane hydrocarbons with RON above 88. The variable consist of reaction temperature and ratio of mixture between  $\text{Al}_2\text{O}_3$ -ZSM-5 catalyst.

## 2. METHOLOGY

The first step on this research is the mixing of the catalyst to create a desired catalyst composition ratio. An  $\text{Al}_2\text{O}_3$ /HZSM-5 catalyst mixture is a combination of catalyst where the catalyst is supporting each other in the reaction. HZSM-5 composition in this research will be vary from 5%, 10%, 15%, and 20%.

Next step in this research is reaction test. This is the main step in this research. Ethanol will be used as the feed for conversion reaction. Ethanol will be fed into the fixed bed reactor containing the already prepared and mixed  $\text{Al}_2\text{O}_3$ /HZSM-5 catalyst. So that the ethanol will become a smaller molecule compound through the catalytic reaction. The general procedure to put this reaction into practical means is first, fed the ethanol into the reactor, then the output product of reactor which is in gas phase will be cooled in the condensation system to get the liquid phase product, while the remaining gas phase product will be flowed into the gaseous bag. At the end of the flow of liquid product, n-heptane will be putted on to do the bubbling of the uncondensed gas product so that the liquid product in this research will be greater.

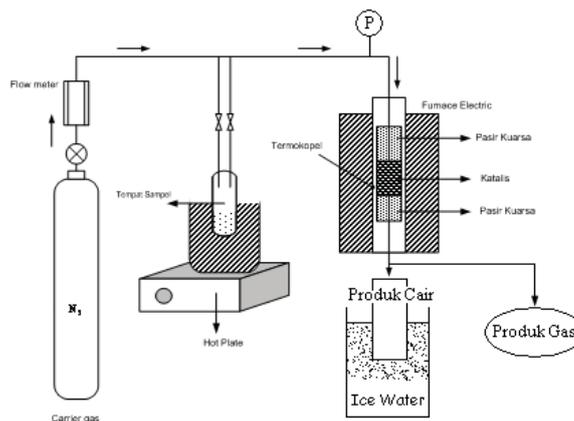

Figure 1: Schematic diagram of experimental set-up for ethanol catalytic reaction in a atmospheric fixed bed reactor

The last step is analyzing the liquid product from the experiment. On this step, the liquid product of catalytic reaction from the synthesis of hydrocarbon compound from ethanol reaction will be analyzed. The liquid product will be analyzed using GC/MS. From this analysis, all of the compound produce from the reaction in liquid product will be clear, and we also could quantify and identify this compound. This is very vital in order to calculate the octane number of the product later.

## 3. RESULT AND DISCUSSION

To identify the product from reaction, Gas chromatography-Mass Spectrometer (GC/MS) analysis will be used. The data from GC/MS instrumentation will be processed using the software which is connected with the computer and the instrumentation. The resulting data from GC/MS analysis will be on the form of peak spectrum (chromatogram) and the hydrocarbon product identification for each peak appeared based on  $m/z$ . From this peak, the characteristic of each compound could be analyzed qualitatively and quantitative based on the peak area or peak height, because each peak have a different peak characteristic. This peak characteristic will be analyzed based on the similarity with the peak that already in the library of the software and will be sort between the match quality to identify what is the compound of those peak based on match quality. Moreover, with GC/MS, the retention time of each compound could be identified along with the percent area of each compound which is the main point to get the quantification or composition of each compound in the analyzed product. Here are some typical chromatogram of the GC-MS for the sample resulted from the reaction using HZSM-5 with 5% at various temperature 350 °C, 400 °C, 450 °C depicted at figure 2, figure 3, figure 4, and figure 5 for 15 % HZSM-5 at 350 °C, irrespectively.

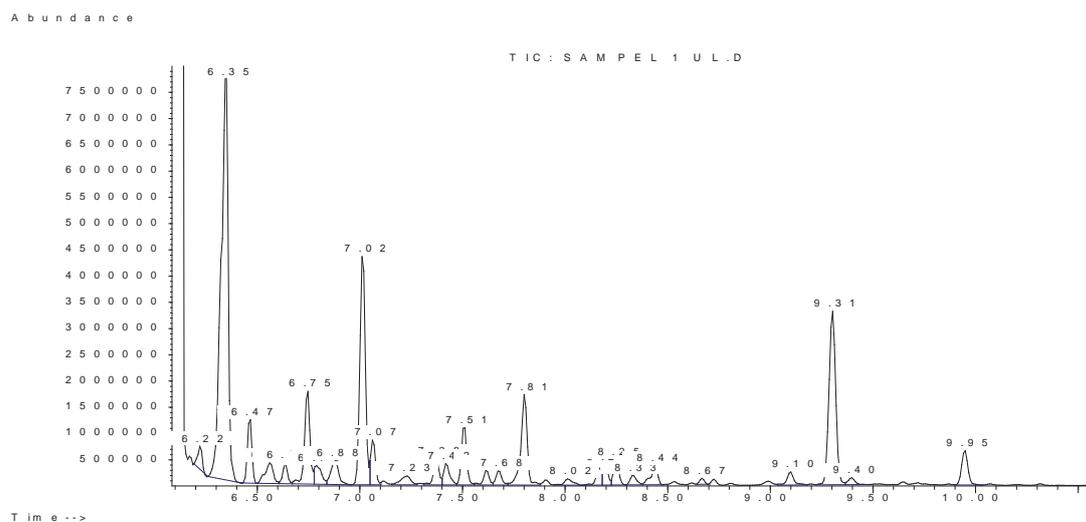

Figure 2: The chromatogram for the sample resulted from the acetone reaction using 5% HZSM-5-Al<sub>2</sub>O<sub>3</sub> at 350 °C

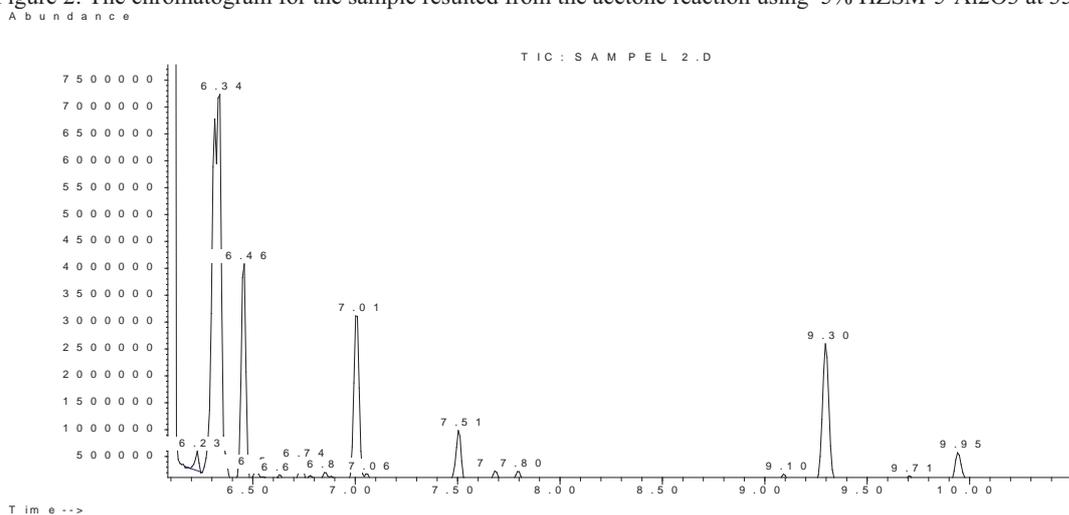

Figure 3: The chromatogram for the sample resulted from the acetone reaction using 5% HZSM-5-Al<sub>2</sub>O<sub>3</sub> at 400 °C

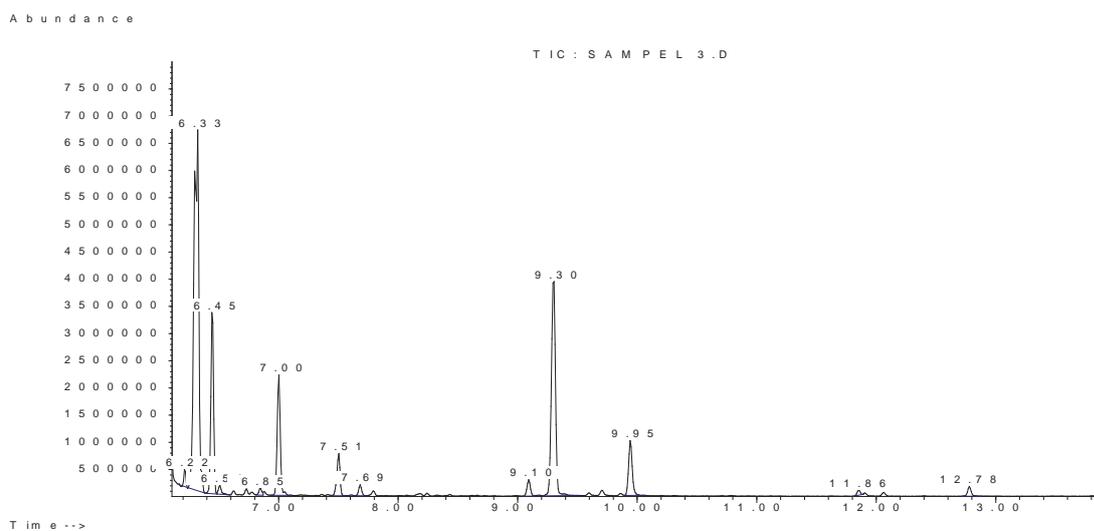

Figure 4: The chromatogram for the sample resulted from the acetone reaction using 5% HZSM-5-Al<sub>2</sub>O<sub>3</sub> at 450 °C

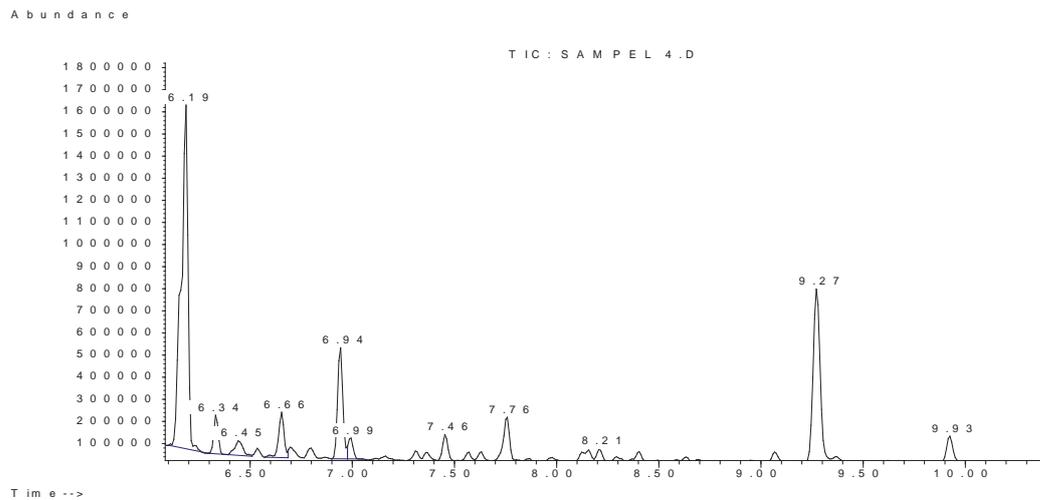

Figure 5 : The chromatogram for the sample resulted from the acetone reaction using 15% HZSM-5-Al2O3 at 350 °C

Table 1 : The Classified Hydrocarbon compositions from Catalytic Reaction of Ethanol

Catalyst mixture (%w) (H-ZSM-5-Al2O3)	5%	5%	5%	15%	15%	15%	20%	20%	20%
Temperature (°C)	350 °C	400 °C	450 °C	350 °C	400 °C	450 °C	350 °C	400 °C	450 °C
Hydrocarbon Compound (%w)									
Olefin	1.36	1.11	1.03	15.12	51.96	1.34	1.93	0	0
Cycloparafin	83.32	50.12	29.09	49.67	12.2	28.52	45.39	77.74	53.96
Aromatic	2.2	43.26	67.59	35.21	35.84	51.6	48.47	22.1	45.34
Isoparafin	0	0	2.29	0	0	17.21	0.61	0	0
n-parafin	0	0	0	0	0	0.53	0	0	0
The Others (Unknown)	13.12	5.51	0	0	0	0.8	3.6	0.16	0.7
	100	100	100	100	100	100	100	100	100

The product analyzed with GC/MS then will be calculated using the equation to calculate each octane number of the sample hydrocarbon product. Because of that, the quantification of composition from the analyzed product using GC/MS was very essential on this research. To calculate the octane number, first each of the compound have to be categorized based on each hydrocarbons chain structure i.e. Olefin, cycloparafin, aromatic, isoparafin and n-parafin hydrocarbon. Based on the amount of hydrocarbons in each category, will be calculated using the equation to get the product octane number as you can see below [6].

$$\begin{aligned}
 \text{RON} = & 69.0306 - 1.0729Y_{NP} + 0.7875Y_{IP1} + 0.0976Y_{IP2} \\
 & + 0.3395Y_{CP} + 0.4049Y_{AR} \dots\dots\dots (1)
 \end{aligned}$$

where:

- Y = Fraction of each category
- NP = N-Paraffin (without C5)
- IP1 = Iso paraffin from C5 to C7
- IP2 = Iso paraffin other than C5 to C7
- CP = Cycloparaffin
- AR = Aromatic

The octane number of liquid product from the calculation can be seen on figure 6.

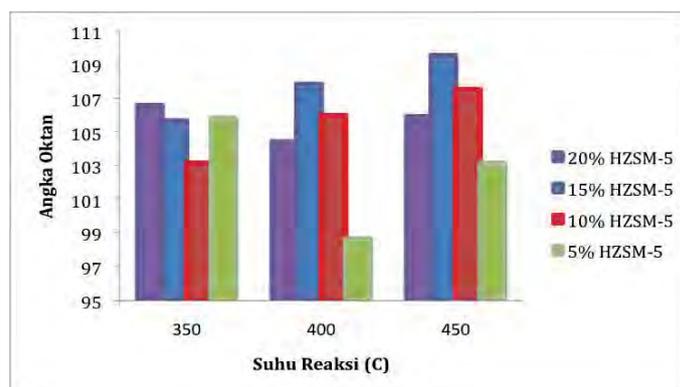

Figure 6: The Calculation results of the Octane Number for each hydrocarbon product

From figure 6 we may see the product octane number with various parameter, from catalyst  $Al_2O_3/HZSM-5$  ratio composition (5% to 20% HZSM-5) to reaction temperature (350 °C, 400 °C, and 450 °C). From this figure above, we can see that the optimum condition to get the highest possible octane number in this research is 15% HZSM-5 catalyst composition at reaction temperature of 450 °C. The resulting octane number of the product at this condition is 109.6. At this condition, the aromatic content of the product maybe not as high as the condition at 10% HZSM-5 but higher than at the lower temperature. We knew that aromatic hydrocarbon have a very high octane number. But, why did at 10% HZSM-5 at the same temperature the octane number is lower even though the aromatic content is higher.

This shows us that aromatic content which have a generally very high octane number isn't the only compound that affecting greatly on octane number. We can see that on 15% HZSM-5 at 450 °C reaction temperature, another compound that could

Table 2 : The composition of liquid hydrocarbon product using 15% HZSM-5 At 450 °C

no	name	RT	%w
1	Cyclopentane, methyl-	2.553	0.27
2	Benzene	3.008	2.14
3	Pentane, 2,3-dimethyl-	3.083	2.41
4	Hexane, 3-methyl-	3.224	9.09
5	Pentane, 2,3,4-trimethyl-	3.433	5.35
6	Cyclohexane, methyl	5.743	25.13
7	Cyclopentane, ethyl-	5.835	3.48
8	Cyclohexene, 4-methyl-	5.933	0.27
9	3,5-Dimethylcyclopentene	6.13	0.53
10	Cyclopentene, 3-ethyl-	6.208	0.27
11	Toluene	6.517	22.99
12	Cyclohexene, 1-methyl-	6.577	0.27
13	Ethyl ester of 1-Methyl-2-methylene	7.703	0.27
14	Cyclohexane, 1-methyl-4-methylene	8.414	0.27
15	3-Heptyne, 5-methyl-	8.603	0.27
16	Benzene, ethyl-	9.508	0.80
17	o-Xylene	9.898	21.93
18	p-Xylene	10.585	3.48
19	2,3-Dimethyl-3-phenylbutan-2-ol	12.809	0.00
20	Benzene, 1,2,3-trimethyl-	13.833	0.27
21	Hexadecane	23.918	0.00
22	Pentadecane	26.441	0.27
23	Hexadecane	28.232	0.27

affect the octane number even greater than aromatic compound also present. This compound is isoparaffin, which is present at 17% weight of the product. The presence of this isoparaffin considerably boost the octane number. And because of that, the octane number at this variable was higher than any other variable. But, the presence of isoparaffin compound throughout this

research was very minimum. And this is resulting in the majority of octane number was very dependant on aromatic and cycloparaffin content. Therefore, the trend of octane number rising along with the temperature rising is the effect of the aromatic content improvement. The identification of each compound present on the product with 15% HZSM-5 at 450 °C can be seen at the table below (table 2). And the product distribution using 15% HZSM-5-Al<sub>2</sub>O<sub>3</sub> catalyst at various reaction temperature can be seen at figure 7 below.

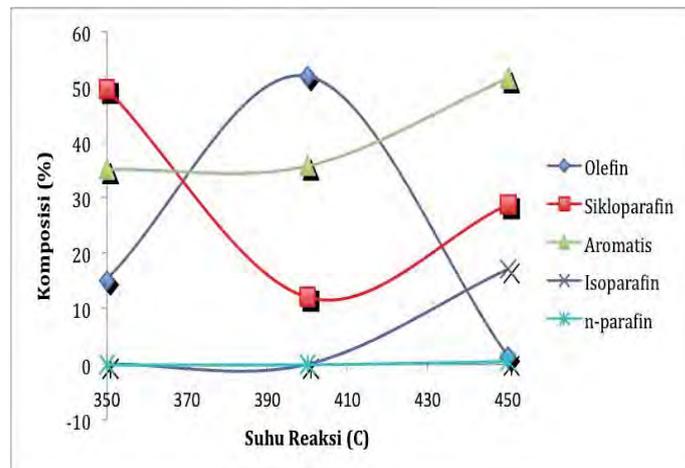

Figure 7 : Product distribution of hydrocarbon compound using 15% HZSM-5 Catalyst at various reaction temperature

From figure 7 we can see that at temperature 400 °C there is a change of product selectivity distribution from cycloparaffin into olefin. This is could happen because of the reaction chain on this ethanol reaction to hydrocarbons. Based on the previous research of ethanol to gasoline (ETG) reaction, the reaction starts from ethilen and end with aromatic or paraffin. The first reaction is the forming of ethylene from dehydration of ethanol, then the oligomers formation. From there, the reaction chain split into two possible route, either directly into a cyclic compound, or becoming an olefin first than into cyclic compound (might become a paraffin compound too). And the last part is from cyclic to aromatic compound [7].

This significant change on product distribution might be caused by the conversion of oligomer compound to olefin was greater than the one directly change into cyclic compound, and because of that the cycloparaffin conversion was dropped resulting the rise of the olefin compound, including the cyclo olefin compound.

#### 4. CONCLUSION

The synthesis of high quality hydrocarbon for possible fuel from ethanol over HZSM-5 - Al<sub>2</sub>O<sub>3</sub> catalyst has been successfully investigated with resulting a high octane number above 88. The containing hydrocarbons product such as aromatic, isoparafin, olefin was confirmly established and hence, the calculation result for the high octane number attained 109.5. This high octane number was achieved using catalyst composition 15% HZSM-5-Al<sub>2</sub>O<sub>3</sub> at 450 °C. And this is due to isoalkane and aromatic hydrocarbons produced as the main comprising component in the product.

### ABSTRACT

Several biodegradable polymers have been explored to develop biodegradable edible films in order to reduce the use of conventional plastics. In this study, edible biocomposite film is made from gelatin filled with Bacterial Cellulose Microcrystal (BCMC). BCMC is produced from nata de coco paste, which is hydrolyzed with cellulase enzyme. In making biocomposite, gelatin matrix is first dissolved in distilled water and then mixed with BCMC filler solution in ultrasonic bath. The solution resulted is then casted and dried in room temperature. The addition of BCMC is proven to improve physical properties, mechanical, and thermal properties of the resulting material. BCMC distribution of SEM showed increasing the tensile strength test results, DSC, and WVTR. When the BCMC concentration was varied from 1-4 wt% of the gelatin mass, tensile strength and glass transition temperature (T<sub>g</sub>) increased from 37.07 MPa to 74.04 MPa and 27.520°C to 39.60°C, respectively. Water Vapour Transmission Rate (WVTR) decreased from 37.77 gr.m<sup>-2</sup>.h<sup>-1</sup> to 19.73 gr.m<sup>-2</sup>.h<sup>-1</sup>. Tensile test and DSC results also increased when varying the sonication time from 3-6 minutes, from 48.57 MPa to 57.23 MPa and 25.890°C to 37.290°C. WVTR decreased from 36.09 gr.m<sup>-2</sup>.h<sup>-1</sup> to 20.54 gr.m<sup>-2</sup>.h<sup>-1</sup>.

## Process Making of a Calcium Sulfonate Complex Biogrease and Its Antiwear Performance

Sukirno\*), Rizky Aulia Prasasti Dewi

Departemen Teknik Kimia, Fakultas Teknik Universitas Indonesia

\*)E-mail : [sukirno@che.ui.ac.id](mailto:sukirno@che.ui.ac.id)

### ABSTRACT

Sulfonate grease is most newly type of grease among many types of lubricating greases, nevertheless this type of grease has already get popularity due to its antiwear superiority. In this research, calcium sulfonate complex biogreases have been produced using base oil of epoxidized palm oil. The thickening agent is an overbased detergent, a mixture of calcium sulfonate and calcium carbonate as the main thickening agent, and calcium hydroxy stearate and calcium acetate as the complexing agent. The biogrease is manufactured via saponification process in a closed batch reactor, follow by cooling step and homogenization step. Product quality test conducted for the biogrease are, penetration test and dropping point test to measure the stability of the matrix of the thickening agent, and four ball wear test to measure antiwear performance of the product. The best quality of the calcium sulfonate komplek biogrease has composition 56.03% thickening agent which consist of calcium sulfonate, calcium carbonate, calcium hydroxystearate, and calcium acetate. This biogrease has a dropping point 301 °C at NLGI 2. The calcium sulfonate complex biogrease show an excellent antiwear performance and outperform that of calcium stearate-acetate complex biogrease. The calcium sulfonate complex biogrease produced the amount of wear 0.02 mg, while the calcium stearate-acetate complex biogrease produced the amount of wear 0.4 mg, from four ball wear test at the same test condition. The antiwear superiority of this biogrease is considered as the contribution boundary layer of calcite crystal which is formed by series process adsorbing, packing and crystallization of CaCO<sub>3</sub> amorf on friction surface.

This paper introduces a holistic view to intelligent transport systems (ITS) by providing four different perspectives to it: the technological, economic, system performance and market views. These perspectives are essential in understanding the full picture of ITS, which is much more than just advanced transportation engineering. ITS requires management tools coming from systems engineering. These tools are ITS architectures. ITS has unique features related to transport economics and it differs from the traditional transport engineering solutions. ITS can improve transport system performance in numerous ways, but it is furthermore an important business segment for many technology companies and it has become an industry by its own right. Each of these perspectives call for different types of expertise and management of ITS, which as a meta-system is almost as demanding management object as the entire transport system.

### **ABSTRACT**

Maintaining color consistency throughout the cartridge or printer life is an important engineering challenge for color laser printer manufacturers. Since color reproduction is susceptible to variations in operating, performing calibrations at specific intervals to compensate for operating conditions is a common approach to ensure consistent tone reproduction. This research focused on utilizing operating information to improve the sensor mapping which predicts colorimetric tone reproduction (CTR) values on printing media obtained from densitometer readings measured on substitute media in calibration. Time-series sensor data and color measurements have been collected from off-the-shelf color printers under a variety of operating conditions. The data analysis shows that the sensor mapping has distinctive behaviors under different levels of relative humidity and cartridge toner consumption. In addition, the sensor mapping has been found to be sensitive to tone level and the variation of cartridges. A new sensor mapping model including a cartridge classification module was proposed to not only compensate for environmental and consumable conditions, but also to consider cartridge variation. The experimental results show that the accuracy of the sensor mapping can be improved by the compensations of environmental and consumable conditions. The data-driven study also shows that the cartridge classification by selected operating parameters is feasible, and the accuracy of cartridge classification is acceptable. The overall accuracy of the sensor mapping can be improved by ~ 40% on average after considering the operating information.

# Analysis on Consumer Adoption Process in Marketing Strategy Implementation using A System Dynamics Model (Study Case of Fast-Moving Consumer Goods Product)

Akhmad Hidayatno, Rama Raditya, Edelina Melisa

## ABSTRACT

Marketing strategies have different implications on diffusion factors in the consumer adoption process. A system dynamics model could give a better understanding between the interaction of variables in the diffusion factors and its influence in the consumer adoption process. The basis for the model is Bass Diffusion Mode. In addition, the model tested three different scenarios, namely business as usual, word of mouth marketing, and social media marketing in order to understand how different parameters of diffusion factors affect the adoption process. This research will produce behavior over time analysis of customer number, potential customer, and adoption rate on each scenario. Based on analysis, promotion is the important factor for increasing awareness of product, while word of mouth marketing is important for product adoption.

## Keywords

*Bass diffusion model, system dynamics, consumer adoption, marketing strategy, word of mouth, marketing modeling*

## 1. INTRODUCTION

With Indonesia's economic growth, there has been a substantial increase in the purchasing power of consumers. This power has been influencing the marketplace by expanding market potential and creating higher and more competitiveness pressure. Therefore, in order to maintain its position in the marketplace, a business must select and execute the right marketing strategy. Marketing strategies discuss about advertisement, customer satisfaction, customer needs identification, high quality product development, distribution, and promotion [1]. All of which will affect the consumer adoption process.

The example of the consumer adoption process is consumer response toward a product may vary when a product is launched on the market. Some consumers, who will immediately adopt the product without interference from trends and social systems, are categorized as innovators. While the rest, who will adopt as a result of the pressure of the social system and trends, are categorized as imitators. Variables that influence the adoption process are the diffusion factors [2].

Word of mouth is one of the most influential diffusion factors in the consumer adoption process. A research study in Jordan found that negative word of mouth has a bigger role in consumer adoption decision than the positive word of mouth. The source of word of mouth also plays an important role in the decision-making process [3]. There is evidence that word of mouth can enhance and increase the promotion effectiveness and has a great effect in the product sales.

This research developed a system dynamic model in order to understand how various diffusion factors can affect the adoption process, based on the Bass diffusion model. The Bass diffusion model is a model framework that represents a product adoption process. System dynamics has the advantage of showing the dynamic complexity of a system, such as the interaction of variables influencing the consumer adoption process, and captures how a change in a variable can affect the other variables. The model could help strategy planners and policy makers in marketing organizations to make a better marketing strategy decision.

## 2. METHODOLOGY

### 2.1 Model Conceptualization

This research uses a system dynamic approach for modeling, consisting of four major steps: model conceptualization, development, validation and usage through scenarios. Model conceptualization is represented in the building of a system diagram. A system diagram represents the interaction and feedback from the variables. It provides a comprehensive understanding about the model. **Error! Reference source not found.** shows the system diagram for the consumer adoption process developed in this research. External variables are variables used as the input for the process in an endogenous model structure, however their values do not

influenced by the variables' interaction and feedback. Promotion strategy scenarios are variables determined by the user of model for understanding the effect of each scenario. The goal indicator is shown as the output of the model.

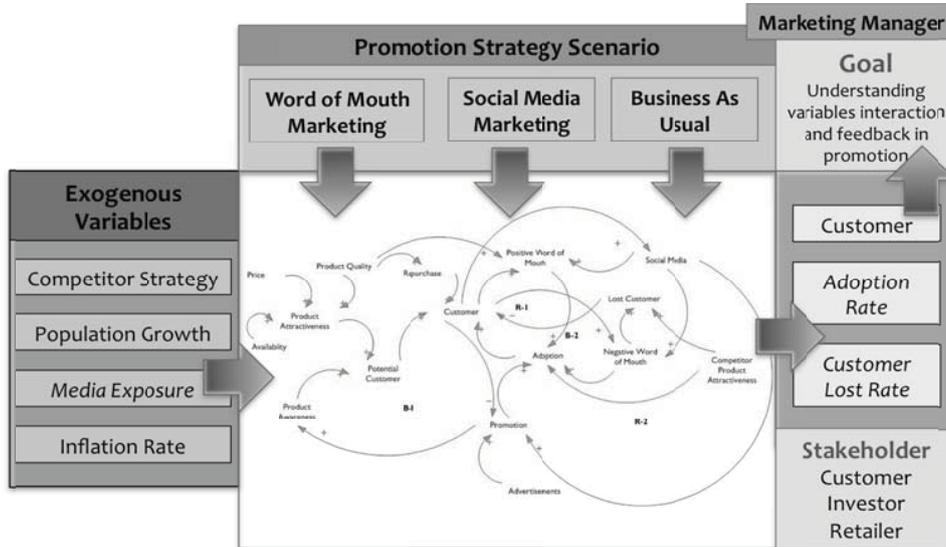

Figure 1: System Diagram

## 2.2 Model Development

Using bass diffusion model as the base, the developed model showed the basic process of transformation from potential customer into customer, that were expanded by inserting the variables that affect industry market potential and variables that affect customer change into lost customer (Figure 2). There are two groups of diffusion factors: promotion and word of mouth.

The model incorporated primary data from Focus Group Discussion (FGD) and market research secondary data from a well-known FMCG company. In FGD, there were 16 participants from age group of market target of the consumer goods. The discussion were focused on the relationship and weight the effect of various promotion methods, factors which influence world of mouth and buying, how the effect of WOM is, etc. The secondary data consist of as target market, population growth target, etc.

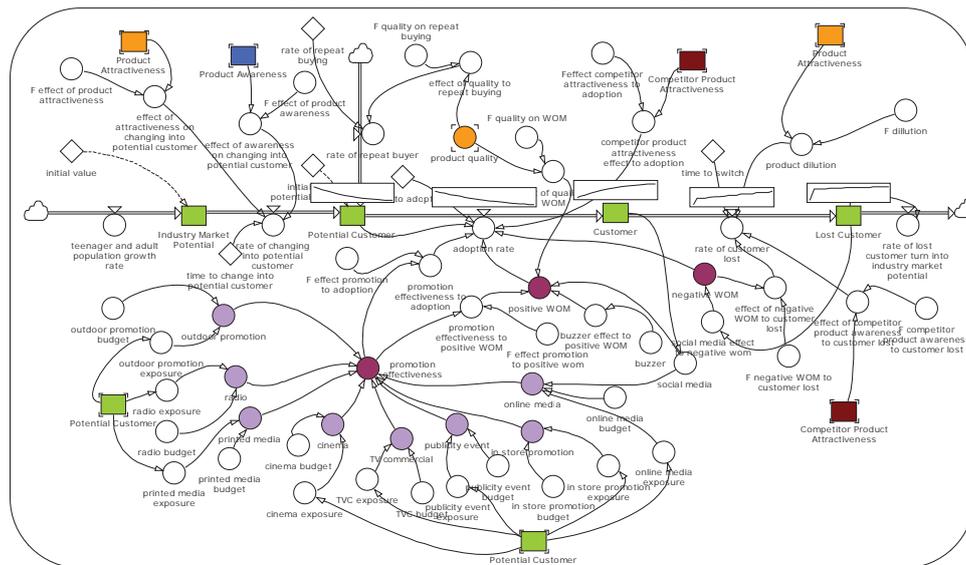

Figure 2: Model Stock and Flow Diagram

### 2.3 Model Validation

Reference mode is graphical representation of behavior over time (BOT) from system acquired from expert judgment or literature study. Behavior-reproduction-test validation test uses reference mode in order to check the validity of model by comparing BOT of model with BOT of reference mode. A valid model has marginal different between BOTs. This research use BOT from customer-adoption-rate, number of customer, and number of potential customer for validation.

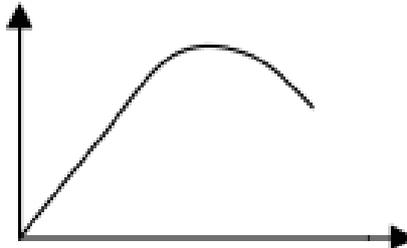

Figure 3: Reference Modes for Adoption from Word of Mouth

The horizon line shows the time and the vertical line indicates the number of people who adopt a product influenced the effect of word of mouth. The starting rate of the product adoption is low and expected to increase gradually until one point and then it decreases. [6]

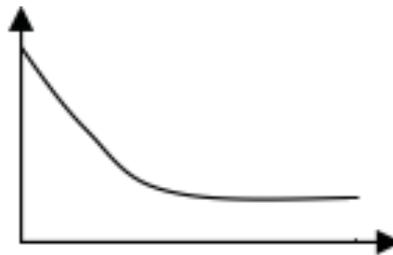

Figure 4: Reference Mode for Adoption from Advertisement

The adoption of the products is high at the time that the product enters the market, then people gradually purchase the goods because of word of mouth instead of company's advertisements, therefore it will decrease over time [6]. The horizon line shows the time and the vertical line indicates the number of people who adopt a product because of the advertisements.

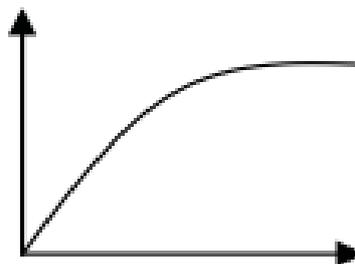

Figure 5: Reference Mode for Customer

Bass states that the number of customers increases at first at the time of launching the new product to the market, after that it reaches to a constant rate [6]. The horizon line shows the time and the vertical line indicates the number of people who adopts the product.

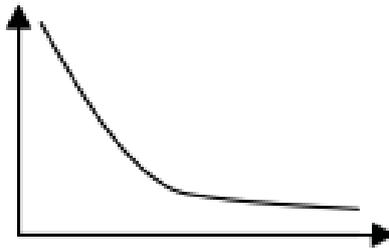

Figure 6: Reference Mode for Potential Customer

The number of potential customer is high at the first time the product enter the market, and it will decreases gradually over time [6]. The horizontal line shows the time and the vertical line indicates the number of potential customer.

We run developed model in order to see the output of model created through interaction between endogenous and exogenous variables inside structure of model. Developed model runs for five years according to common long term planning of company. The output of the model (Figure 7 and Figure 8) indicated that the model have similar Behavior Over Time (BOT) output graph with reference model on Figure 4 for Adoption Rate, Figure 5 for Customer, and Figure 6 for Potential Customer.

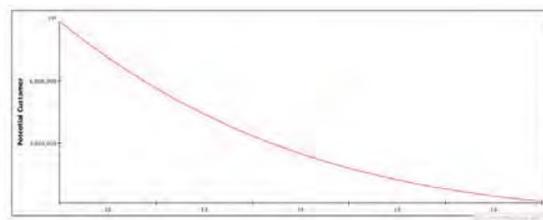

Figure 7: Behavior Over Time Potential Customer

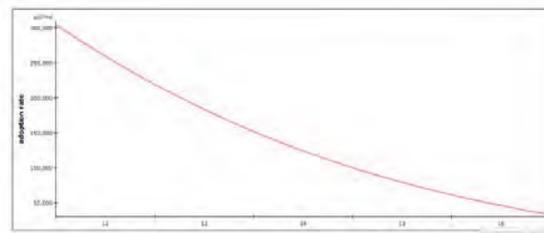

Figure 8: Behavior Over Time Adoption Rate

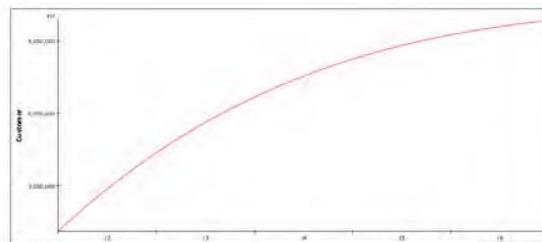

Figure 9: Behavior Over Time Customer

### 3. RESULTS AND DISCUSSION

There are three scenarios implemented: business as usual, word of mouth marketing, and social media marketing. The business-as-usual scenario results are the one that used to validate the model.

Table 1: Scenario Effect on Variables

	Business as Usual	Word of Mouth Marketing	Social Media Marketing
--	-------------------	-------------------------	------------------------

<b>Product Quality</b>	90 quality	200 quality	90 quality
<b>Budget for Online Media</b>	Min: Rp 2.200.000.000 Max: Rp 2.899.924.585	Min: Rp4.400.000.000 Max:Rp 5.799.849.170	Min: Rp 4.400.000.000 Max: Rp 5.799.849.170
<b>Buzzer</b>	10 people	50 people	10 people
<b>Promotion</b>	Linked to “adoption process” variable	Unlinked to “adoption process” variable	Linked to “adoption process” variable
<b>Multiplier of Social Media on WoM</b>	0.68	0.68	1
<b>Budget for Publicity Event</b>	Min: Rp 1.225.000.000 Max: 1.614.730.734	Min: 1.225.000.000 Max: 1.614.730.734	Min: 2.450.000.000 Max: 3.229.461.469

The second scenario is word of mouth marketing (WOM). In this scenario, we would like to see the effect of word of mouth marketing strategy and disregard the promotion effect in the adoption process. The model cut the promotion feedback to adoption rate hence promotion only influences product awareness. The variables intervened are the ones that directly influence the word of mouth, they are product quality, online media, and buzzer (Table 1).

The last scenario is social media marketing (SMM). It focuses on customer engagement through various kinds of promotional effort. Variables intervened in this scenario are social media, online media, and publicity event (Table 1).

The results of the three scenarios are Figure 10 for the Business as Usual Scenario, Figure 11 for Word of Mouth Marketing Scenario and Figure 12 for Social Media Marketing Scenario.

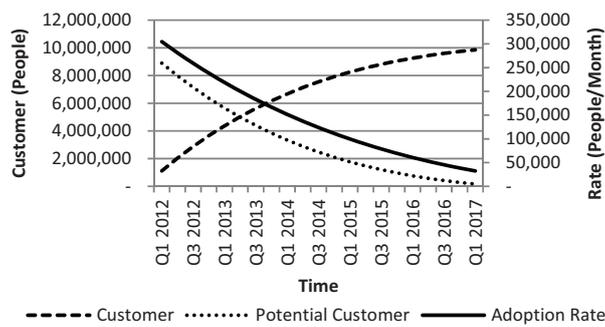

Figure 10: Behavior Over Time for Business as Usual Scenario

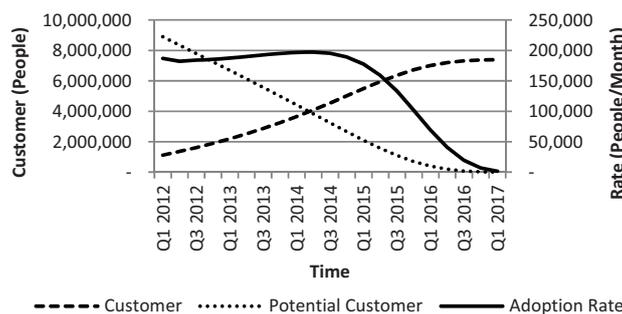

Figure 11: Behavior Over Time for Word of Mouth Marketing Scenario

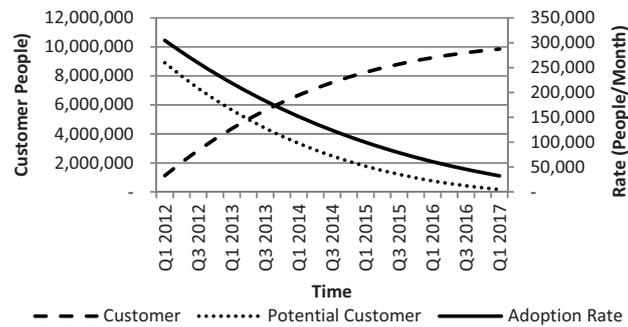

Figure 12: Behavior Over Time for Social Media Marketing Scenario

The result of adoption rate variable in word of mouth marketing scenario shows a significant difference from the other scenarios, because it only captures the behavior of adoption from word of mouth, which is not very high at the beginning and then increases up to eighteen percent and then declines (Figure 11). While the other two scenarios capture the behavior of adoption from advertisements, which is high at the beginning then decreases over time. The balancing structure of promotion, word of mouth, and competitor's attractiveness influences the adoption rate.

Customer variable shows an exponential growth curve behavior, as the result of business as usual and social media marketing scenarios, meaning that the growth rate is higher at the beginning and then slowing down at the end of the simulation period. Meanwhile, the word of mouth scenario indicates rather an S-shaped growth curve behavior, which means that the growth rate is almost the same during the time simulation period. The customer variable is the result of balancing structure of lost customer, potential customer, and repeats buying variables.

The third variable observed in this research is potential customer. All of the scenarios implemented show similar result for potential customer variable, which is an exponential decline curve behavior. It means that the number of potential customer is high at the beginning and then it decreases as higher numbers of potential customer already turn into customer. This variable is also a result of balancing structure of promotion, product awareness, product attractiveness, and customer.

From all scenarios, we acquire the expected behavior result for adoption rate from the word of mouth marketing strategy. Because it shows an increase for half of the time period then starting to decline rather than the other two scenario which only decline without any increase at all during the simulation period. For the customer and potential customer variable, though all scenario show similar behavior over time result, the business as usual and social media marketing have a higher number of people compared to word of mouth marketing scenario.

#### 4. CONCLUSION

Managing and using word of mouth as part of promotion strategy have significant difference in consumer adoption process. Promotion itself is most suitable for raising product awareness and attractiveness, however when it comes to adoption or buying decision, word of mouth has the bigger impact. The combination of each diffusion factor matched with the stages of the product introduction is the most effective and efficient promotion strategy.

## ABSTRACT

Fashion can be categorized as a perishable product which has the high uncertainty. Thus, many retailers usually conduct the strategy to provide the discount price to prevent the perishable characteristic and to minimize the inventory. This study developed the dynamic pricing in revenue management which is more parsimony, simpler, and more applicative in Indonesia considering on the consumer strategy. The model was developed under two conditions, namely monopoly and duopoly. In the duopoly model, two-person game is used where the customer valuation is considered as competitor. In addition, the development model stages were divided into four scenarios that are the deterministic and stochastic of demand model, the revenue model, and the pricing model developed from the best reaction of function. Based on the case study among four scenarios of model development, two-person game with considering the stochastic of demand model is strongly representing the actual system. This model can be generated to the products observed, easy to use and disregard the composition of myopic and consumer strategy in system.

## Keywords

*Perishable, fashion retailer, revenue management, game theory, consumer strategy*

## 1. INTRODUCTION

Fashion can be categorized as a perishable product which has the high uncertainty [1]. The perishable and uncertainty of product is commonly caused by the changing of customer value towards the product during the particular period, such as the different customer value between selling season and discount season. Furthermore, fashion also has the short product life cycle in which has the long of distribution time and waiting time. For instance, most of the fashion product produced in the US and Europe, must distribute their product to retailer in other countries. Thus, the retailer must consider the distribution time, reorder point, and demand forecast in order to maximize profit and handle the uncertainty of the fashion product. One method developed to manage the problem of such a fashion product is known as Revenue Management (RM).

Actually, RM has been used for managing several businesses, such as restaurant, aviation industry, hotel management, car rental, retailing and so forth. There are unique characteristics in business implementing RM. Firstly, the product must have the exact and limit capacity. Therefore, the first characteristic can affect the perishable of product in which the product cannot be sold in another selling season. For instance, the fashion product must be sold in the end of selling season. Hence, to eliminate the perishable characteristics, retailer usually provides the discount season. Secondly, the product has the high fixed cost yet the low variable cost. Thirdly, the product also has the different demand in each period yet it can predict the pattern of demand itself. Ultimately, the product can provide the different customer segment with the different value in the same product [2].

Customer segment in fashion retailing is commonly divided into two types, namely myopic customer and strategic customer [2]. Myopic customer is the type of customer who will buy directly when the price provided is less or equal with their own value to the product. Meanwhile, strategic customer is the type of customer who will optimize their buying behavior as the response towards the price strategy provided by the company. Hence, second type of customer will seek and wait to buy the product until the end of selling season to get the product with the cheapest price.

Regarding to the strategic customer who always maximizes their value, the competition between fashion retailer and customer itself is occurred. It is caused by the rationality between the players in which the strategic customers want to optimize their value of product while the companies want to maximize the profit obtained. The condition of the competition between strategic customer and company is sufficient to be depicted by the game theory. The game theory is usually used for two or more player

which has the interdependent relationship among the others [3]. On the other hand, game theory also had been used for several companies, such as to simulate and increase the ability of decision maker with providing valuable insight of player interaction who has the different needs [4].

Basically, there are many methods and studies explaining the competition of player in game theory, such as the study of [5] and [6]. However, the study of [5] and [6] is strongly complex to be adopted in Indonesia. Whereas, the complexity of system needs the uniformity of data and the adequate of data, in which in Indonesia the data are difficult and confidential to be obtained.

The other approaches to simulate the strategic customers had been conducted by [1]. Nevertheless, this model only considered the arrival demand from myopic customer. Therefore this study extends the study of [1] by developing mathematical model which considers the strategic customer behavior. On the other hand, this study also utilizes the price as the main consideration in the decision variable in RM that is combined with game theory in order to find the equilibrium point of price. Briefly, this model is not only used for deciding the optimal selling value in monopoly market without considering strategic customer but it also enables to decide the optimal selling value in the competitive market with considering strategic customer behavior. In addition, it also measures the revenue model developed in order to represent the real phenomena occurred in fashion retailer industry.

## 2. METHOD

This study is started by the collecting of data. The data is obtained from two inputs, namely the revenue of retailer in selling women dress and the quantity of product which is sold during the particular selling season. The data is collected from the fashion retailer in the biggest shopping centre in Yogyakarta. Nevertheless, in term of collecting data, many data is difficult and sensitive to obtain, such as the revenue of the retailer. Therefore, in this study, the revenue of the retailer can be assumed as the multiplication between the quantity of product sold and the selling price in the particular period, in which the quantity of product sold, is collected from the quantity of demand from myopic and strategic customer.

Having collected data, the model can be started to develop by using spreadsheets. In this stage, all data must be assessed and reduced which are sorted by the significance of the product towards the revenue and demand. Subsequently, the significant products selected are utilized by the game theory in terms of revenue management. Furthermore, they are modeled in demand and revenue by using monopoly and two-person game. In order to develop model, this study refers to model from [1] and [7]. Different with the previous model from [1] and [7], this model considers strategic and find the equilibrium point between two types of customer.

For demand modeling, the data collected are divided into two types, namely deterministic and stochastic demands. The deterministic demand is modeled by linear regression analysis in order to find intercept and coefficient value in each variable. Subsequently, the developed model is tested by using statistical test. On the other hand, the stochastic demand is utilized by distribution fitting whether the distribution is appropriate or not. If the distribution is appropriate, the CDF value can be found. Meanwhile, if the distribution is inappropriate, thus the CDF value can be found by empirical approach in order to obtain coefficient value. Subsequently, both the deterministic and stochastic demands are validated by using statistical test using SPSS 16.0. By using statistical test, the result of the model can be assessed whether it is significantly different or not compared to the actual data. Therefore, if the data have not significantly different with the actual data, the model can be stated as valid and sufficient to predict the expected value which can be accomplished of the retailer in the equilibrium point.

## 3. RESULT AND DISCUSSION

This study collects the data from the biggest shopping centre in Yogyakarta. However, the shopping centre consists of 40 different products of women formal attire obtained from January 2010 to April 2012. Therefore, the variability of product is high in which several products have the routine demand in each month yet the others do not have the demand in each month. This phenomena can affect the bias whether all products is considered to count in the model. Hence, to reduce bias, the product must be assessed and reduced sorted by the significance of the product towards the revenue and demand. By using the plotting data and pareto analysis, the product can contribute significantly towards the revenue and demand only four, namely long sleeve shirt, long blouse, short blouse and trouser. Hence, for developing model, only four products will be used both on monopoly and two-person game.

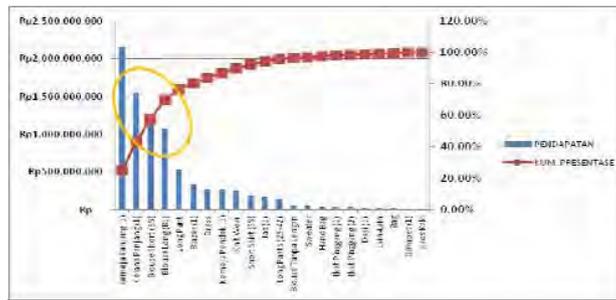

Figure 1: Pareto Diagram of Retailer's Revenue

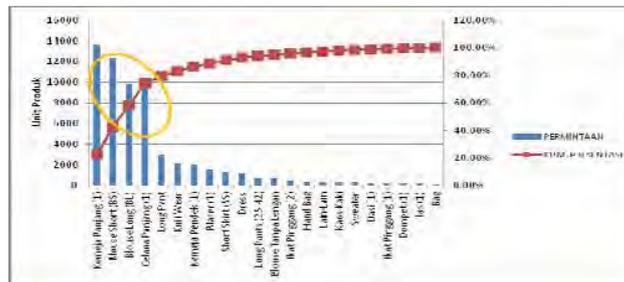

Figure 2: Pareto Diagram of Demand

### 3.1. Monopoly Model

Actually, there are two criteria in monopoly model, namely deterministic and stochastic model. In the deterministic model, the demand is assumed as certain and comes from the myopic customer. Therefore, the retailer can be stated as monopoly because they can control in terms of deciding the price to their customer completely.

The first step to build the deterministic monopoly model is by deciding the demand model for each product. The demand deterministic is built with assumptions the linear function from price [1].

$$d_{mono, det}(p) = a - bp$$

$$d_{mono, det}(p) \geq 0 \quad (1)$$

With  $d_{mono, det}$  = demand in deterministic monopoly

- $a$  = intercept
- $b$  = coefficient of price
- $p$  = price in each product

From this linear equation, the deterministic demand model can be achieved for four types of product depicted in Table 1. Having the deterministic demand model for each product, the revenue model of retailer must be built in order to obtain the best reaction function, in which  $\pi_{mono, det}$  depicted revenue of retailer obtained by multiplying between the price value and demand.

Table 1: The Deterministic Monopoly of Demand Model

Product Type	The Demand Model
Trouser	$d_{CP, mono, det}(p) = 1028,747 - 0,004 p$ (2)
Long Sleeve Shirt	$d_{KP, mono, det}(p) = 1669,486 - 0,007 p$ (3)
Long Blouse	$d_{BL, mono, det}(p) = 1073,876 - 0,006 p$ (4)
Short Blouse	$d_{BS, mono, det}(p) = 1515,714 - 0,009 p$ (5)

$$\pi_{mono, det}(p) = p[d_{mono, det}(p)] \quad (6)$$

Almost similar with deterministic model, in stochastic model, the customer is categorized as myopic customer without considering strategic customer. However, in this model, demand is considered as uncertain and probabilistic. Therefore,

customer demand always follows the particular distribution by conducting fitting distribution. In this model, the stochastic demand model conducted follows the model proposed by [1] in which  $d_{mono,sto}$  is demand in stochastic monopoly,  $N$  is market size of retailer assumed as random and probabilistic and  $F(p)$  is cumulative distribution function from price. On the other hand, in order to get CDF, finding the sufficient distribution with the data is required by using Stat::Fit.

$$d_{mono,sto}(p) = N(1 - F(p)) \tag{10}$$

The sufficient distribution of fashion product is Weibull because the fashion product can be categorized as perishable and the value of product is related towards time. CDF value from Weibull distribution can be obtained as following in which  $p$  is price,  $\alpha$  is form parameter,  $\beta$  is scale parameter and  $e$  refers to exponential. After CDF value is stated as appropriate, the demand model in stochastic monopoly can be developed which is depicted in equation 12.

$$F_w(p|\alpha,\beta) = 1 - e^{-\left(\frac{p}{\beta}\right)^\alpha} \tag{11}$$

Tabel 2: The Parameter Value of Product

Jenis Produk	Paramater Skala $\alpha$	Parameter Bentuk $\beta$
Trouser	4.395	195661
Long sleeve	5.160	195834
Long blouse	4.349	141268
Short Blouse	4.287	128187

$$\begin{aligned} \pi_{mono,sto}(p) &= p[d_{mono,sto}(p)] \\ &= pN(1 - F_w(p|\alpha,\beta)) \\ &= pN\left(1 - e^{-\left(\frac{p}{\beta}\right)^\alpha}\right) \end{aligned} \tag{12}$$

### 3.2. Two-Person Game Model

This model is divided into two types, namely deterministic two-person game model and stochastic two-person game model. The competition of two-person game in this study is competition between retailer and strategic customer in one-shot game. Strategic customer will maximize surplus from valuation affecting competition for retailer. The customer valuation is assumed to follow uniform distribution [8].

On the other hand, in the two-person game model, retailer is assumed as myopic customer and the strategic customer act as opponent who must be competed. Therefore, this model adopts model in [7] by using multiple linear regression in order to predict demand in myopic and strategic customer.

Different with monopoly model, the number of deterministic demand achieved by retailer in two-person game has the particular composition which is portion between the number of myopic and strategic customer in the system. However, in this study, information about composition of myopic and strategic customer is unavailable. Hence, building several scenarios of demand model is required. Scenario conducted in order to build deterministic two-person game uses myopic customer composition as much as 50%, 60%, 70%,80% and 90% from total of demand. Afterwards, demand model will be used for building general revenue model in myopic customer depicted in equation 13.

$$\begin{aligned} \pi_{1,sto} &= p_{1r}[d_{1,sto}(p_{1r},p_{2r})] \\ &= p_{1r}(h_{1r} + g_{1r}p_{1r} + h_{1r}p_{2r}) \\ &= p_{1r}h_{1r} + g_{1r}p_{1r}^2 + h_{1r}p_{1r}p_{2r} \end{aligned} \tag{13}$$

Almost similar with deterministic two person game, stochastic two-person game also considers behavior of strategic customer. Nevertheless, the number of demand from each customer will provide the different valuation price with probabilistic factor. In line with deterministic model, stochastic model also adopts model developed by [7] which is added strategic customer.

$$d_{1,sto}(p_{1r},p_{2r}) = N[1 - F(p_{1r}) + 1 - F(p_{2r})] \tag{14}$$

$F(p_M)$  is CDF value from price provided by retailer when only myopic customer is appeared in the system, while  $F(p_s)$  is CDF value from valuation price provided by strategic customer. Therefore, for achieving CDF value from sufficient theoretical distribution, fitting distribution must be conducted by using Stat::Fit. By conducting fitting distribution, three products, namely long sleeve, long blouse and short blouse fulfill assumption of Beta distribution. Meanwhile, trouser does not fulfill any distribution hence the approach conducted for this product is by using empirical distribution. Nevertheless, even though Beta distribution is continue distribution which is closest to three products, yet CDF in Beta distribution is difficult to define due to the characteristic of no closed form [9]. Consequently, for finding CDF  $F(p_M)$  and  $F(p_s)$  from four products, empirical distribution is required. The general CDF value from retailer price is depicted in equation 15, while strategic customer is showed in equation 16 in which i, j, k, and m are constant.

$$F(p_M) = i + j/p_M \tag{15}$$

$$F(p_s) = k + mp_s \tag{16}$$

Table 3: The Comparison between CDF Value of Retailer Price and Strategic Customer

Product Type	CDF Value $F(p_M)$ of Retailer Price	CDF Value $F(p_M)$ of Strategic Customer
Trouser	$F_{TP}(p_M) = -0,688 + 0,66 \times 10^{-6} p_{Mf}$ (17)	$F_{TP}(p_s) = -1,882 + 1,72 \times 10^{-4} p_s$ (21)
Long sleeve	$F_{LSP}(p_M) = -0,884 + 7,42 \times 10^{-6} p_{Mf}$ (18)	$F_{LSP}(p_s) = -1,475 + 1,91 \times 10^{-4} p_s$ (22)
Long blouse	$F_{LBP}(p_M) = -0,610 + 8,66 \times 10^{-6} p_{Mf}$ (19)	$F_{LBP}(p_s) = -2,733 + 8,48 \times 10^{-4} p_s$ (23)
Short blouse	$F_{SBP}(p_M) = -0,587 + 9,86 \times 10^{-6} p_{Mf}$ (20)	$F_{SBP}(p_s) = -2,472 + 8,54 \times 10^{-4} p_s$ (24)

After CDF value is obtained for each product, the demand model of two-persons game stochastic can be conducted by substituting equation 15 and 16 to general equation two-person game stochastic demand in equation 25.

$$d_{M,sto}(p_M, p_s) = N[1 - F(p_M) + 1 - F(p_s)]$$

$$= N[1 - (i + j/p_M) + 1 - (k + mp_s)]$$

$$= N(2 - i - j/p_M - k - mp_s) \tag{25}$$

#### 4. VALIDATION

Model validation is required in order to confirm whether model represents the actual system or not. Validation is conducted by using statistical test for comparing the difference between mean in output and actual system. Output model compared are output demand model from deterministic monopoly, stochastic monopoly, deterministic two-person game, and stochastic two-person game.

Nevertheless, before conducting statistical test, normality test must be conducted to define the model can be assessed by using parametric or non parametric method. From normality test, Ho cannot be rejected thus the data are distributed normally. In other words, the parametric test, t-test can be used for assessing this model.

The result of t-test with significant level 95% provides information that the demand for each product can be modeled both deterministic and stochastic. On the other hand, significant p-value provides the result, as following:

1. The sufficient model applied in trouser is deterministic two-person game with composition myopic customer as much as 60%
2. The sufficient model applied in long sleeve is deterministic two person game with composition myopic customer as much as 80%
3. The sufficient model applied in long blouse is deterministic two person game with composition myopic customer as much as 50%

4. The sufficient model applied in short blouse is deterministic monopoly.

Even though deterministic two-person game is sufficient model applied for three products, yet this model has limitation because it is strongly related to the number of myopic customer composition in the system. Hence, alternative model, stochastic two-person game must be conducted which has the best significant value for three products. In order to find the significant differences between revenue output stochastic and deterministic two-person game, t-test is conducted.

According to Table 4, there are no significant differences between output in deterministic and stochastic two-person game. Therefore, revenue prediction can be conducted by using stochastic two-person game without considering the number of particular customer in the system. On the other hand, even though sufficient model applied in short blouse is deterministic monopoly, yet there are no significant differences when using stochastic two-person game.

Table 4: The Result of t-test in Two-Person Game Model

Model	Trouser		Long Sleeve		Long Blouse		Short Blouse	
	Sig.	Decision	Sig.	Decision	Sig.	Decision	Sig.	Decision
Deterministic Two-persons Game	0,469	do not reject	0,884	do not reject	0,479	do not reject	0,381 do not reject	
Stochastic Two-persons Game								
Deterministic Monopoly								

## 5. CONCLUSION

According to result explained in the previous chapter, there are two points that can be summarized. Firstly, the best mathematical model applied for all fashion products is stochastic two-person game. This model not only can be generalized for all products, but it is also easier to be used without considering myopic and strategic customer composition in the system. In addition, by selecting stochastic two-person game as the representative model, it depicts that behavior of strategic customer is required in revenue management.

Secondly, modeling process considering valuation from strategic customer in Indonesian fashion retailer can be conducted. Ultimately, stochastic and deterministic results are comparably no different.

## ABSTRACT

This research is aimed at accelerating and expanding economic development to strengthen national and global competitiveness and realizing good governance in coal mining. A target outcome to be achieved is an academic paper as the basis for the preparation of local legal products on managing the special port of coal. The object of research is community around coal mining operations in East Kalimantan. The research sample is five regencies and analyzed by the SWOT method. The result shows that the Mahakam River has a high economic potency as a means of transportation to distribute coal from the stockpile to the ship through the construction of special port. The regional government need to issue regional regulation on special port construction. The strategy developed to achieve the acceleration and expansion of economic development is by utilizing the support of local governments and taking advantage of river transport facilities.

## Keywords

*Regulation, river transport, coal special port*

## 1. INTRODUCTION

Coal mining as the main sector replacing the timber, evidenced by the 913 mining business license permission issued by local government are scattered throughout the regencies and cities in East Kalimantan, from those numbers 560 companies are exploration and 353 companies are exploitation. (Department of Mine and Energy East Kalimantan, 2012). The data is beyond mining business license permission issued by the central government. Various problems caused by coal mining activities concerning some aspects such as environmental, socio-cultural, economic, health, infrastructure. All happened because of weak governance system in mining activities from the planning, implementation, outputs and outcomes are not integrated and sustained planned in accordance with sustainable environmental concepts.

The emerging problem is the destruction of many public roads crossed by vehicles transporting coal to the stockpile or port. Transporting coal passing the public road contributes 15 times accelerating of road destruction before the times. Most companies holds the local license do not have a special road to transport coal. The local government responded by forbidding coal transport vehicle on a public road starting in September 2013. The government plan is successful to encourage mining companies to build a special road transport mine or transfer using transport modes Mahakam River. Utilization of river transport is preferred by coal mining entrepreneurs evidenced by the emergence conveyor belt located along the Mahakam river by 29 locations, majority in Kutai Kartanegara Regency and in the last three years there are 92 locations of special ports listed on the Department of Transportation East Kalimantan.

Furthermore, to maintain the security the development and management of special facilities and infrastructure of coal mining is necessary to be regulated in the form of regional regulations. Because until now East Kalimantan province has not had legislation that regulates the hauling road, special port and the environmental impact of coal mining. The benefit by issuing special port regulations is expected to provide multiplier effect on the acceleration and expansion of the economy. The results of this study in the form of an academic paper to be used as the input of public policy decisions of local government in the coal mining sector.

Optimizing the benefits of coal mining operations is expected to drive the acceleration and expansion of the national economy when creating a good governance of coal mined either by regulating the management of facilities and infrastructure to be owned and its impact by the coal companies. Regulations can be made by the Government in accordance with their responsibility to provide guidance, supervision and control under the local regulations and its derivatives laws products on transport infrastructure of coal mining and environmental impact management.

## 2. METHODS

Population are society around coal mining companies operating in East Kalimantan . Samples taken from 5 regencies /cities that has been widely exploited their coal they are Samarinda, Kutai Kartanegara, Paser, East Kutai and Berau. Data collection method is by distributing of questionnaires, conducting focus group discussion (FGD), as well as literature study. A questionnaire was compiled based on research that is directed to the object of the public, companies, and local governments. Questionnaires were prepared using a range of categories linkers scale values: 5=Strongly Agree (SST), 4=Agree (ST), 3=Undecided (RG), 2=Disagree (D), 1=Strongly Disagree (STS). The number of instruments in question to the community around coal mine as many as 24 items, the instrument for the company is 30 items. FGD was conducted to the communities around the mining area which actually obtain a direct impact on mining operations. Interview is emphasized as a method to obtain information related to mine operations to the stakeholders at the local level such as regional development agency, department of transportation, the department of mines, environment agency and the regional council. Other secondary data obtained through the study of literature. The data collected were analysis with SWOT matrix method.

## 3. RESULT

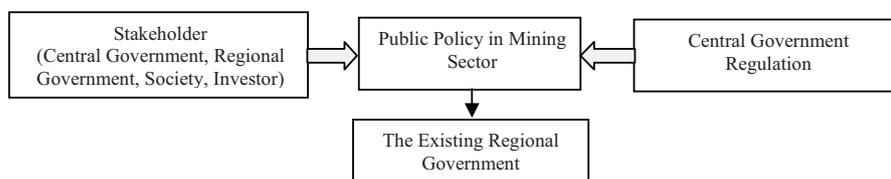

FGD is conducted at 4 (four) locations in Kutai Kertanegara, Berau, Pasir Regency and Samarinda City. The participants are societies around the coal mining area consisting of local community and company employees. Each FGD followed by 10-15 members of the public. The information obtained directly from the public related to mining activity in the positive sides are: raising the price of land surrounding the mining area, employing the local skill or unskilled people, opening of business opportunities, the implementation of community development program. Whereas the negative sides are: air pollution, mud flood, public health problems, the decline in soil fertility, the death of a plant that grows in the garden, the damage of ex-mine environment, the damage to public roads, noise pollution, the degradation of local wisdom, the erosion of cultural values, the shifting of agricultural land and residential area into land mine, communities conflicts.

From the data collected indicate an imbalance between mining companies operating in East Kalimantan as many as 913 companies but only 21 (twenty-one) firms reporting reclamation guarantees. This means that only a few companies executed post-mining reclamation (The Department of Mining and Energy East Kalimantan, 2012). It is also found that there is only a few special ports in East Kalimantan. The length of road in the southern part of East Kalimantan which extends from Paser District to the border of South Kalimantan reach to 240 km, and 225 km is damage. Road improvements have only done to the suffered severe damage road. In general, road damage in East Kalimantan, including in the Southern District caused by a mismatch between load tonnages passing vehicles. Load roads in East Kalimantan only class III B the maximum of 8 tons, while passing vehicles with a payload to 16 tons. The vehicles are owned by coal mining companies palm plantation companies and heavy equipment transport vehicles (Department of Highways East Kalimantan, 2012).

The perception of the people and employee who live around the area of the coal mining operations of 4 (four) regencies/cities averagely found that they very much agree with the average percentage of 85.6% (public) and 86.4% (employee) which means the majority absolutely agree method that: the construction of special port regulated by local regulation, every coal mining company must obey the regulation and should be met with the government requirement in administrative, feasibility study, and environmental impact studies, special port in the river is absolutely supporting the coal mining business and the right choice for the transportation of coal, development of special ports or terminals should pay attention to the social-economic, increase employment absorption, improving and expanding economy, expanding the business opportunities for the surrounding communities of the port, and eventually increase regional revenue.

## 4. DISCUSSION

From the result of the SWOT analysis, the strategies that should be develop by the regional government in coal mine management is strength-opportunity strategy. The strength are the potential of the Mahakam River to transport coal, the mining location close to river, the availability of Mahakam River bank as the location of special port, The huge deposit of coal. Whereas the opportunities are catching the coal business opportunities, Fulfilling domestic coal demand, increasing regional revenue, expanding the public access to get opportunities for employment. In optimizing the strengths to catch the opportunities, the regional government needs to issue regulation on the management of special port. Therefore, the model of the public policy is as follow figure 1.

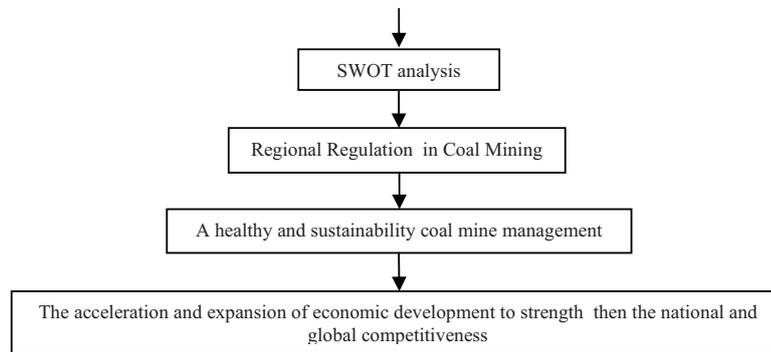

Figure 1: Public Policy Model in Mine Coal Management

The potential for coal resources in Indonesia come from East Kalimantan, and the potential is already excavated by mining investors, but its management is still not optimal. The number of companies operating in the mining activities that have not made clear and clean indicates that the problem of mining relating with the regulation does not function properly. A large number of licenses issued by the government of district/City so far indicate that issuance of permit of coal mining is uncontrolled. Besides, it also shows how easy people go into the coal mining business. How difficult to obtain data on how much production of coal in East Kalimantan indicates that monitoring does not work optimally

Coal mining activities conducted by many companies concession or license of central or local government with an obscure or unclear mining license must take the consequences of environmental capacity issues. If mining operations are not managed properly, the benefits can not be enjoyed by people rather unfortunate consequences. Therefore it is necessary to create healthy, transparent, accountable and sustainable as well as environmentally sustainable operational governance of coal mine.

In the issue of local license exploration and exploitation checking the documents must be done and field checking and cross-sector coordination should be done, the results of verification of all the parties is then used to submit to the regent /mayor to set permissions. At the time of permit issued, there is already a commitment to run the company's corporate social responsibility program with primary emphasis is empowering community. Checking the environmental impact analysis document should be done regularly before starting mining activities will vary with the condition after exploitation activities carried out. Checking on the waste management such as solid waste, liquid and air waste also needs to be done regularly.

Referring to the data processing both primary and secondary research analysis reinforces that any well-run business in the mining sector should have sustainable development. Wishes and desires of the community at large public companies that coal mining operations carried out in an orderly manner according to the rules in force, and performed in a sustainable manner by considering environmental sustainability. Society also expects that the exploitation of coal carried out in an environmentally friendly and provide maximum benefit for the community, local government, and the state.

The existence of a coal mine in East Kalimantan has not been able to keep a balance between the interests of corporate interests - local government - the public. Strategies and policies coal companies should refer to the triple bottom line that are economy, social and planet. Means there should not be harmed by operating coal mines, if the company is able to run consistently rules issued by the central government and local governments related to mining, environmental protection and other relevant laws and regulations derivatives. There was also a commitment of local government to carry out development and supervision of mining operations.

Establishment of good governance is indicated with a number of conditions including: 1) there is the efficiency and effectiveness of the company's coal mining operations, 2) there is transparency related to the status of the mine permitting, land concessions, reclamation guarantees, treatment and disposal of waste products, the implementation of reclamation , the amount of production, corporate social responsibility, land rent, non-tax state revenue, 3) there is a public accountability associated

with the production, which in reclamation deposit insurance, implementation of reclamation, and budget as well as the implementation of corporate social responsibility programs, payment of taxes.

Patterns of public policy in the field of regional economic development through the optimization of the management of coal mining as a stimulus to the acceleration and expansion of economic growth that can provide a multiplier effect on various other related fields. Multiplier effect on public policy will involve opening up opportunities for employment and business potency community, growing and opening new areas of economic growth, rising incomes, minimize traffic accidents due to road hauling.

## 5. CONCLUSION

Based on the analysis and discussion, it can be concluded that:

- a. The coal industry in East Kalimantan has positive and negative impact, the negative impact is greater than the positive one.
- b. The utilization of the river in East Kalimantan as a means of coal transportation is effective
- c. The regional government has an authority to regulate and supervise the special port construction along river in East Kalimantan.

## 6. ADVICE

In order to realize a good, clean, healthy, efficient, effective, accountable and environmentally sustainable governance of coal mine, then:

- a. Need to be issued legal products on special port and other related regulation ..
- b. The coal mining company need to be audited.
- c. Need public participation in supervising coal mining operation.
- d. Need cross-sector coordination to implement the local or central legal product ( regulation ).

## ABSTRACT

With high economic growth, the Indonesia's Fast-Moving Consumer Goods (FMCG) companies also experiencing a rapid market growth that has attracted more new players in the market. For both new and established FMCG companies, success in building and sustaining a brand is the key driving factor in winning the competition. A major concern in brand equity, as measurement of the intrinsic value of the brand competitiveness, is how to understand the behavior of brand equity overtime in relationship to the brand management strategy the major concern. This is especially true for an established mature brand to stay ahead. Therefore, this research develops a system dynamic model simulating the impact of brand strategy implementation to brand equity as a medium for understanding these relationships. Brand equity consists of brand-loyalty, brand-awareness, brand association and perceived product quality. Brand strategy consists of 6P factors: product, price, place, promotion, proposition and pack. The research investigates three plausible scenarios: aggressive competitor, business-as-usual, and passive competitor. The model shows how mature brand would have a different behavior than new brand that requires a different 6P branding strategy than a new or growing brand.

## Keywords

*Simulation, System Dynamics, Brand Strategy, Brand Equity, Brand Awareness, Brand Loyalty*

## 1. INTRODUCTION

With the increased market-size of Fast-Moving Consumer Goods (FMCG), due to Indonesia's high economic growth, has lured new companies to enter the market or old companies to expand its current product portfolio. Any mature product must be able to defend itself with the wave of new or rebranding old product. Which means brand strategy represents a key important aspect in marketing for FMCG companies. However, the process of building and sustaining a brand is highly complex and unstructured. Many dynamic variables, which are mostly tacit knowledge, affects this process and makes it difficult for brand managers to predict how branding strategy implementations could affect the brand as a whole.

This research developed a model that would help brand managers, who are responsible for a brand specifically in FMCG companies. The purpose of the model is to produce a brand equity model as a learning tool for brand managers to simulate interactions amongst indicators of brand equity in the system in order to evaluate the implementation of 6Ps branding strategies. It is suggested that the development of a system dynamic model will enhance the decision making process of brand managers.

## 2. LITERATURE REVIEW

Competition among brands is one of the most important key that determines business competitiveness to win the market. Companies with strong brands portfolio will have better options to compete rather than competing in price and specification alone [1]. Brand is a set of attributes that sticks to certain product or service, such as character, value, association, and quality that consumers have in mind and could interfere with consumers buying process [2]. Brand management roles are very crucial in managing brands to grab market potential through the application of branding strategy. According to Martins (2000) and Sampaio (2002), branding is an effort that aims to generate and develop brand value. Branding is also perceived as brand management process to generate brand equity and in turn will make the brand become more valuable and maximize its effect among the competitions [3]. The concepts that endorse brand equity are the most popular common practices in modern businesses since it considered as key business performance in maximizing its profit.

Brand equity is an example of a complex system that is affected by dynamic interaction among factors, both among elements that structure it and the interactions among those elements to the application of branding strategy. Aaker (1991) defines brand equity as a set of added values that is given by a brand to a product or service [4]. Brand equity give an added-value in increasing marketing efficiency and affectivity, build brand-loyalty, increase profit margin, and increase bargaining position toward seller [5]. Brand concept that aligns with brand equity will enable companies to evaluate their brand more effectively therefore will be able to develop a better branding [6].

For the model, brand equity consists of four elements: brand-awareness, brand-loyalty, perceived-quality, and desire-to-buy brand [7]. Oliver (1997) describe brand-loyalty as consumer commitment to repeat purchase of a product, although it is rather situational and very much affected by marketing effort to change this tendency [6]. Brand awareness is the ability of potential consumers to recall or remember a brand and link it to its product or service. Perceived-quality is defined as consumer's perspective toward overall quality of a product or service. It is rather subjective and cumulative over time [6]. Otto & Bois (2001), defined desire-to-buy brand as consumer's aspiration to buy certain brand [7].

There is a need of a learning medium, in a form of a model, to solve this brand complexity to highlight the interactions among brand equity elements and with branding strategy. With a more understanding of these interactions, brand managers will be able to evaluate their branding strategy to survive and grow as competition is getting crowded. It should be able to accommodate the concept of brand equity as the accumulation of relevant consumers and their expectations [8]. System dynamics methodology could accommodate understanding these complexities understanding through behavior changes over time when there is a change in the structure [9]. System dynamics is also accommodates scenario implementation test needed in this research. It could also show how it affects toward the whole system behavior [10].

### 3. RESEARCH METHODS

The research methodology follows the four steps of systems dynamics modeling methodology of conceptualization, development, validation, and model usage and analysis.

#### 3.1. Model Conceptualization

Interaction amongst variables and feedback from each variable are the focus in system dynamics modeling. System diagram is a perfect tool to represent interaction and feedback from variables. Figure 1 shows the system diagram for Brand Equity Model. The primary users are brand managers, which have to manage the brand to achieve desired key outputs from the system: brand-awareness, desire-to-buy brand, brand-loyalty and product perceived-quality. Other stakeholders of the system would also influence the output definition from the system. Brand managers would like to exercise certain branding scenarios to the interaction in the model and see how the results changes. The model must also account input from exogenous variables such as price, availability media exposure, shown on the left side of the diagram.

Based on the systems diagram, the construction of the model was starting by examining Otto's Brand Equity Model (Figure 2). In this linear model, desire-to-buy brand approached to be the effect pool from three other brand equity indicators. Considering the definition of brand equity as value added generated by the brand, desire-to-buy brand becomes the closest indicator for assessing Brand Equity success in adopting consumers. Otto also stated that desire-to-buy brand indicator is able to summarize the effects produced by other elements such as brand-awareness, brand-loyalty, and perceived-quality [7].

However, Otto's model does not explain about how each variable affecting the adoption process of a product. Therefore, a new concept, shown in Figure 3, was developed on explaining how each stage in the adoption process influence bay the variables Otto's model.

Figure 4 illustrates the translation of the Otto's model into CLD. It shows how product attractiveness and customer satisfaction can build perceived-quality. Increased in perceived-quality is the result of the interaction amongst four factors: product, price, packaging, and availability, and balanced by the brand negative image. Perceived-quality is considered as 'moment of truth' to consumers, whether the product is good or not. If consumer perceived it acceptable and preferable, consumers will tend to buy more and increase brand-loyalty. In turn, brand-loyalty will affect customer satisfaction.

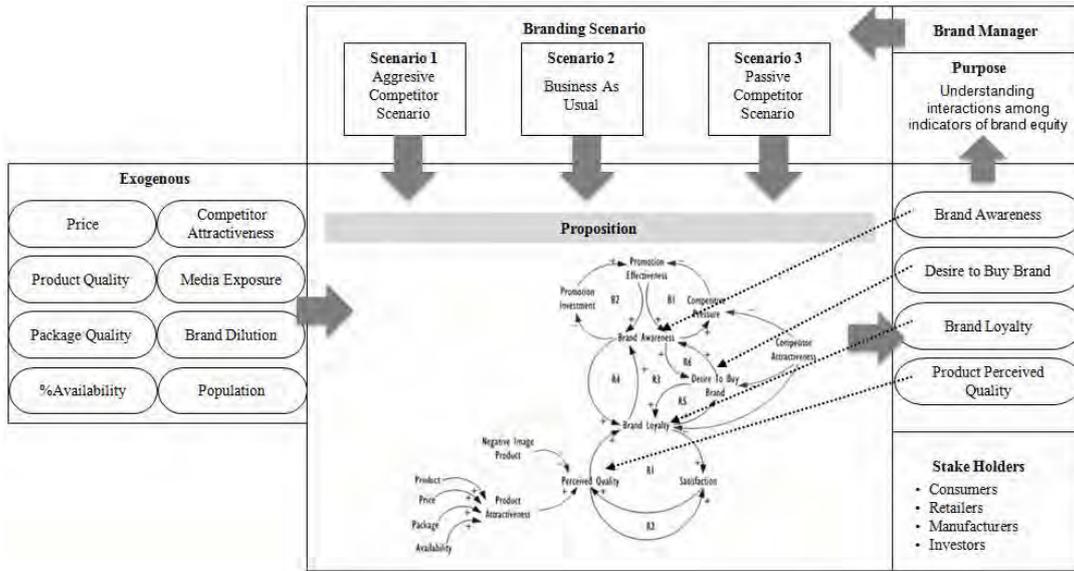

Figure 1: Model Conceptualization of Brand Equity Model as a System Diagram

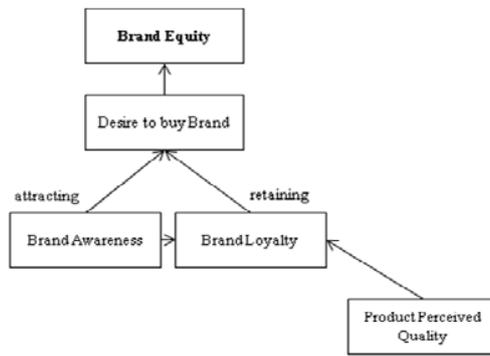

Figure 2: Model Assumptions based on Otto's Brand Equity Model

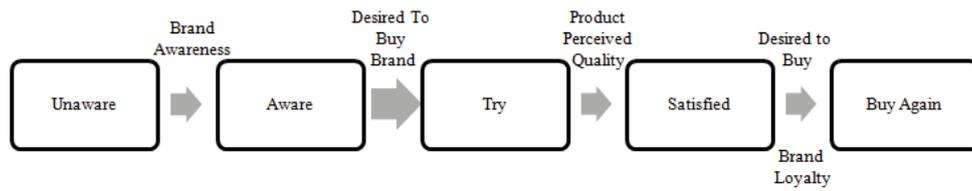

Figure 3: How Each Brand Variables affecting the Adoption Process

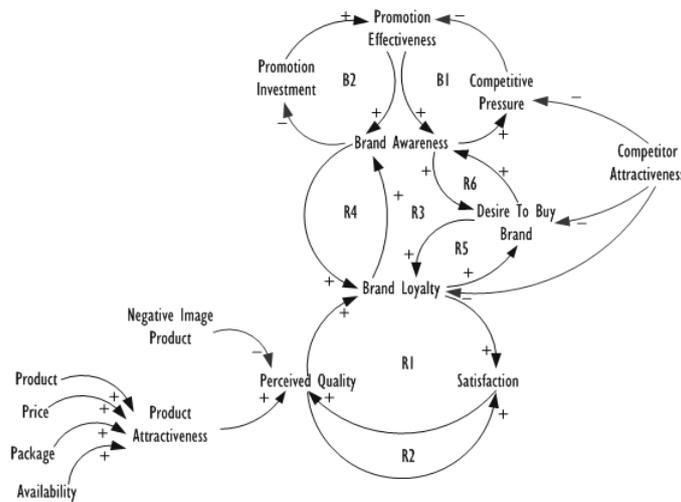

Figure 4: Causal Loop Diagram of Brand Equity Model

In brand-awareness, promotion effectiveness will affect brand-awareness but can be distracted by the distortion of competitor attractiveness. Promotion investment is likely to improve the effectiveness of promotional campaigns and the effectiveness of this campaign will ultimately increase brand-awareness. The more consumers know the brand; it will increase brand-loyalty. Likewise, the more loyal consumers know the brand better. Desire-to-buy brand can influence brand-awareness and brand-loyalty. In turn, they can also affect the desire-to-buy brand. Besides distorting promotion effectiveness, attractiveness competitors will also distract the desire-to-buy brand and brand-loyalty.

### 3.2. Model Development (SFD)

In order to complement the secondary data obtained through company reports, a Focus Group Discussion (FGD) was conducted to gain insight on the relationships of the model. The model was shown and discussed in the FGD, and the complete model is illustrated in Figure 5

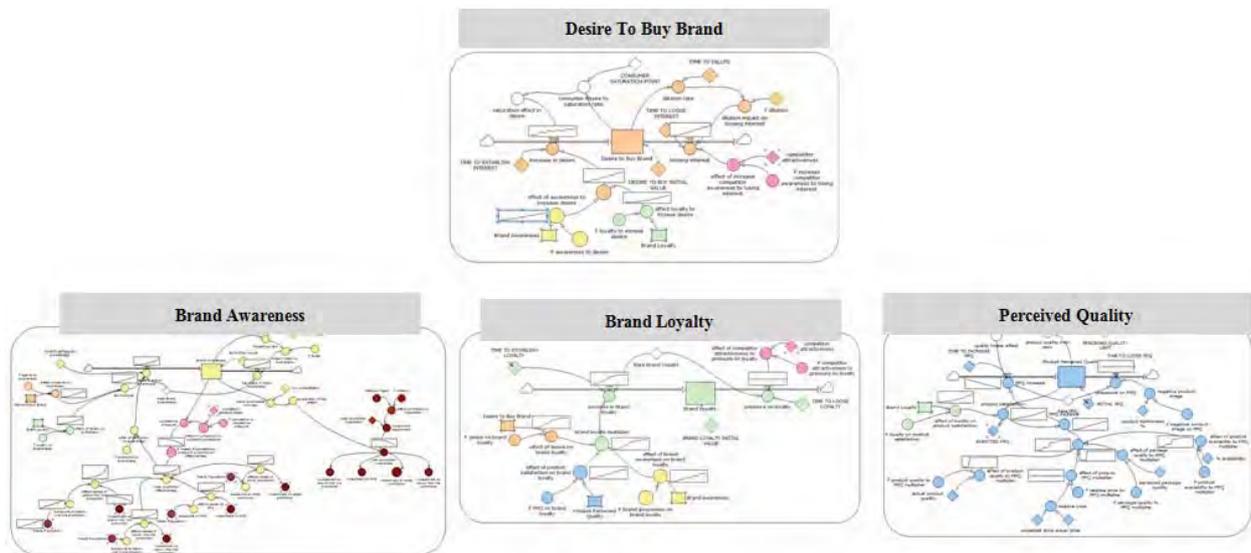

Figure 5: Brand Equity Model Birds-Eye View

### 3.3. Model Validation

The model underwent four validation methods in SD: dimensional consistency test, structure assessment test, behavior validation test, and sensitivity analysis test. For the behavior validation test, output from our model validate the reference mode from Otto's desire-to-buy brand variable (Figure 6) [7].

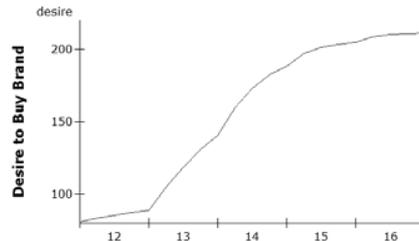

Figure 6: Desire-to-buy Brand Indicator Model Simulation Validation

Sensitivity analysis validation aims to determine how sensitive a variable affect other variables and sees whether the response of the model is appropriate with the response in real behavior condition. The model used two exogenous variables: brand-loyalty and competitor attractiveness.

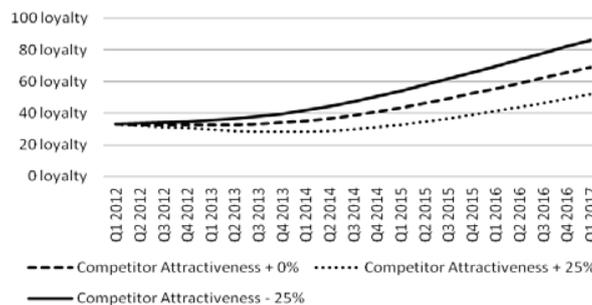

Figure 7: Brand-loyalty toward Competitor Attractiveness Change

Based on Figure 7, we can see that level of competitor attractiveness is strongly influence the brand-loyalty. Competitor Attractiveness will give pressure to brand-loyalty. A higher increase of Competitor Attractiveness will result a higher pressure on brand-loyalty that may caused decline in brand-loyalty value. These behaviors correspond with the real live perceptions.

### 3.4. Scenario Development

From the results of simulation scenarios, conducted summary on each indicator of each scenarios to get an idea of how the effect of these scenarios running on each indicator. Since brand strategy links with competitor brand strategy, the scenarios were developed based on the brand manager's plausible responds to any changes in the competitor brand strategy. Any competitor strategy would affect their products attractiveness. Business-as-usual scenario illustrates the currently implemented 6Ps branding strategy. Aggressive-competitor scenario is when the brand manager responds if competitor aggressively increases its product competitiveness. Passive-competitor scenario is when the competitor actually loosens the product brand positioning. The model runs for five years, a long term planning perspectives for a FMCG company.

## 4. RESULTS AND DISCUSSION

### 4.1.1 Desire-to-buy Brand

Figure 9 shows the behavior over time of desire-to-buy brand which rose slowly at first, but then accelerated and slowed down again at the end of the period because of the balancing effect of the variable representing the dilution effect of consumer boredom.

On passive-competitor-scenario, desire-to-buy brand experienced faster movement behavior over time curve resulting greater value than business-as-usual scenario as much as 3% by the end of the simulation period. Meanwhile, on aggressive-competitor-scenario, desire-to-buy Brand experience slower movement behavior over time curve resulting decline value than on business-as-usual scenario as much as 3% by the end of the simulation period.

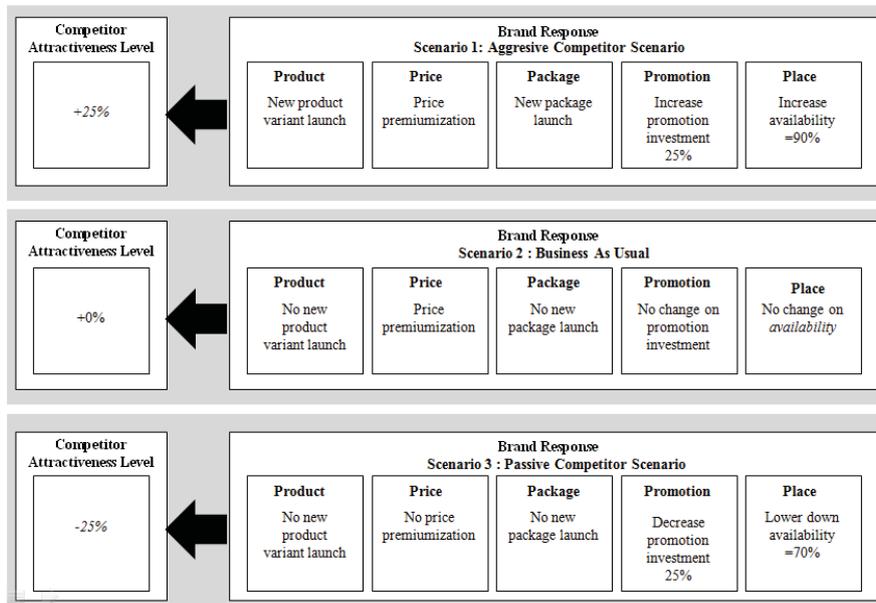

Figure 8: Scenarios for 6P Branding Strategies

#### 4.1.2 Brand Awareness

Figure 10 shows how brand-awareness creates an exponential curve behavior over time, as the effect of the interaction between promotion investment and promotion exposure. Two balancing-loop structures on the CLD between brand-awareness, investment promotion and brand-awareness, and with the competitive pressure on promotion effectiveness is not significantly influence the brand-awareness to create a limit to growth behavior. Both loops just reduce the growth level of the brand-awareness. These behaviors show loyalty in mature brand is very strong comparing to any attack from competitors promotion.

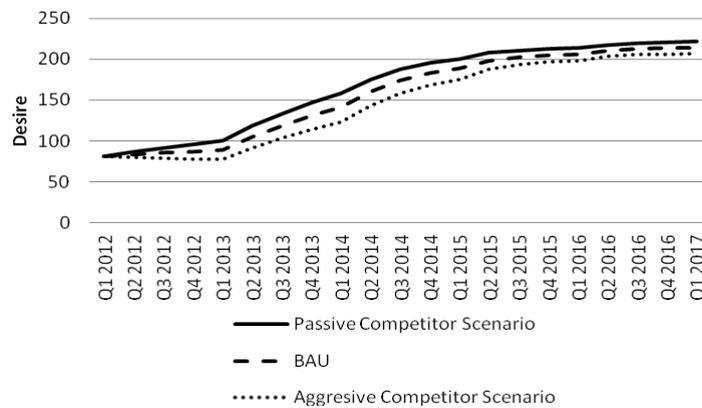

Figure 9: Desire-to-buy Brand Behavior Over Time in Each Scenarios

Between the scenarios, on aggressive-competitor-scenario, brand-awareness indicator performance decreased compare to its simulation result on business-as-usual scenario implementation. Promotion effectiveness is one of the most influencing variable to brand-awareness, which itself is influenced by the promotion investment, promotion exposure, as well as competitive pressure caused by competitors attractiveness.

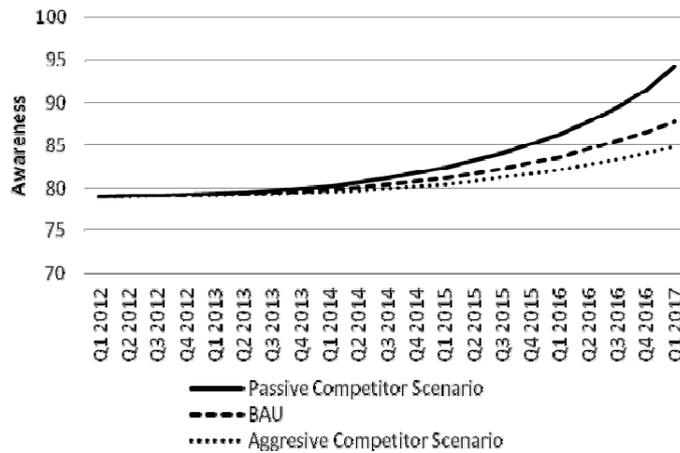

Figure 10: Brand-awareness Behavior Over Time in Each Scenarios

In the case of a mature brand, the distortion from competitor attractiveness plays a bigger dominating effect to promotion effectiveness. Therefore, when it reaches to a saturation point, increase in consumer awareness level is slowing down. Consumers are uninterested with the same marketing messages. This would affect on the brand-awareness performance. It shows in the aggressive-competitor-scenario by experiencing slower movement on behavior over time curve and declining brand-awareness value as much as 3% by the end of the simulation period.

From the model, brand-awareness indicator performance on passive-competitor-scenario increased by 7% compared to the scenario. This happens due to a decline in attractiveness competitors that has an effect of investment promotion become even stronger in promotion effectiveness, although the investment amount is reduced.

#### 4.1.3 Brand Loyalty

Brand-loyalty also increased exponentially due to the reinforcing loop structure between brand-awareness, brand-loyalty, desire-to-buy brand, and perceived-quality (Figure 11).

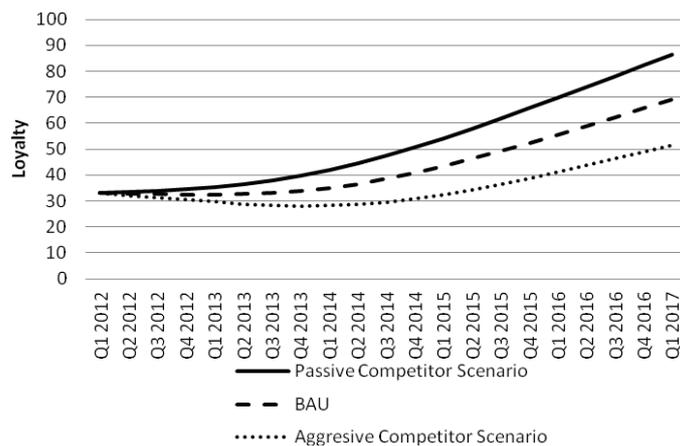

Figure 11: Brand-loyalty Behavior Over Time in Each Scenarios

Brand-loyalty on aggressive-competitor-scenario shows lower performance than business-as-usual, as the competitor awareness increased. Since competitor awareness influenced brand-loyalty in reverse, brand-loyalty went down by 25% as competitor awareness increased. On the contrary, brand-loyalty indicator on passive-competitor-scenario experience faster movement on behavior over time curve than business-as-usual scenario much as 25% at the end of the simulation period

#### 4.1.4 Perceived Quality

Figure 12 shows that perceived-quality is remained constant due to the fact that the brand has reached a mature stage in its brand life cycle. The launch of new products, new packaging, premium price, and improved distribution availability do not show significant effect on perceived-quality.

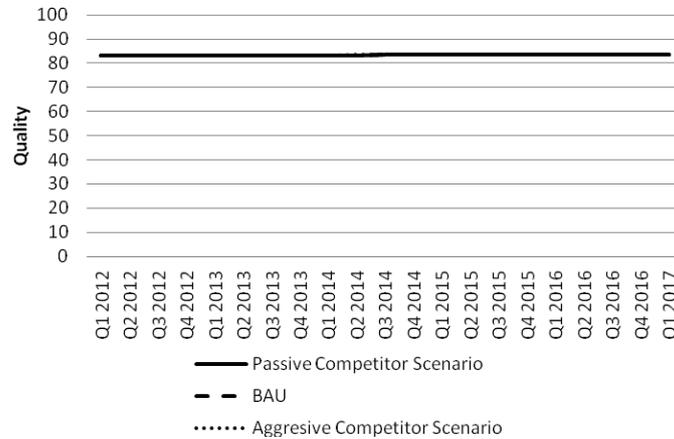

Figure 12: Brand-awareness Behavior Over Time in Each Scenarios

The lack of significant change in the perceived-quality also leads to lack of changes in satisfaction level, which in turn resulted to lack of change in the perceived-quality in total.

Perceived-quality on passive-competitor-scenario changes in two variables of the 6Ps branding strategy: distribution availability level (reduced to 70%) and price premium level. The simulation results of perceived-quality on passive-competitor-scenario showed similar results with the business-as-usual scenario; whereas on aggressive-competitor-scenario, a launch of new products and packaging and increases availability has caused slightly better result than business-as-usual scenario.

## 5. CONCLUSION

Based on the model, mature brands performance depend on competitor attractiveness. In a passive-competitor environment, when the competitor attractiveness declined, performance of all brand equity indicators moves up even when all branding strategy elements declined. On the contrary, when the competitor attractiveness increased and all the company branding strategy elements rose, the performance of all brand equity indicators declines. Therefore, mature brand should be very careful on maintaining its competitiveness against competitors, because it would need higher effort just to reach back its prior position on all indicators once the brand lost its prime position.

## ABSTRACT

Entertainment event ticket is characterized as perishable product with fixed capacity as it cannot be saved as inventory for other events in the future. Moreover, ratio of fixed and variable cost is too high so remaining ticket indicates that event organizer lose revenue. To anticipate it, nowadays, event organizers tend to sell ticket in different price rates: the longer time from the D-day of the event the cheaper the price is. They offer part of capacity with discount fare and the rest with full fare. Based on that condition, there are two basic decisions for managing entertainment ticketing to gain optimal profit: capacity allocation and price rate. This research proposes to develop capacity allocation and optimal pricing model for each class of customers using revenue management approach. In this paper, capacity allocation model is developed into two model types. Firstly, using Littlewood model, two-class booking limit shows how to allocate capacity to two customer types. Secondly, heuristic EMSR-b (Expected Marginal Seat Revenue Version B) approach is used to develop n-class booking limit offering more than two price rates. Capacity allocation and optimal pricing models are then investigated by simulating models and evaluating the decision due to revenue performance in deterministic and stochastic condition. Based on case studies used, stochastic condition is more representative to actual system than the deterministic one. Optimal price rate and booking limit for both two class and n-class in stochastic condition are further recommended.

## Keywords

*Entertainment event ticketing, revenue management, booking limit, Littlewood two class model, n-class model*

## 1. INTRODUCTION

Nowadays, entertainment ticketing strategy has been varying developed. Due to business objective, to gain profit as much as possible, the most widely used is pre-sale method. The method, like airline ticketing, allows event organizer sells the same product (ticket) in different price rates, but airline ticketing offers wider level fare with more fluctuate changes in price based on time-frame. For entertainment event, event organizer which applies pre-sale method determines some classes, the higher the price rates, the closer the payment to the D-day of entertainment event. Certainly, event organizers have their own way to maintain capacity for each given class.

Actually, in several cases, pre-sale methods can increase revenues. For instance, Northwest Ballet Organizer, in Palm Beach Opera Sandiego, increased price about 5 dollars when sold tickets reached 80% of capacity, and 10 dollars each ticket when sold tickets reached 90% of capacity. Applied method increased successfully revenue about 1.5-2%<sup>[1]</sup>. The method can increase revenue smoothly in the end of the event<sup>[1]</sup> and give significant impact in business performance. If event organizer provides less lower class, the remaining capacity/ticket possibly cannot be sold, namely deadwood. The other way, if the event organizer provides more lower class, revenue will be not optimal. Deadwood loss its value when the event ends. That condition indicates that entertainment ticketing is similar to perishable product. Therefore, revenue management (RM) can be applied for entertainment ticketing. Thus, in this research, simulation using revenue management approach in entertainment ticketing is developed. The model includes capacity allocation and pricing model that can be simple decision support for practitioners.

## 2. LITERATURE REVIEW

Originally, revenue management has been examined since 1972 by Littlewood and it focused on airline ticketing. Nowadays revenue management is widely used in the other domains, like hotel, retailer, electric power supply, car rental, etc. Revenue management can model these domains properly because the domains have same basic property which is perishable product. Other characteristics of perishable product are the limited sale period, having price sensitivity, and having stochastic demand [2].

Theoretically, revenue management is defined as how to deliver product to the right consumer with the right price in the right time [2]. To achieve that condition, there are two perspectives in revenue management, pricing-based revenue management and quantity-based revenue management [3]. Pricing-based RM explores which level of price rate appropriate for each class of consumer is. On the other hand, quantity-based RM determines capacity allocation for each class. Therefore, perishable product can be delivered exactly to the right customer in the right time.

Revenue management is ever applied for pricing modeling of tour site in China [4] where previously, government increased the price based on cost-oriented method before RM was finally applied. The model is used to predict when the management should increase the price based on the remaining capacity namely backward induction. Revenue management is also applied for S&E (Sport and Entertainment) ticketing [5] to predict the best switching time of price changes to get optimal profit.

This research applies revenue management for S&E ticketing with live concert/entertainment concert as case study. Not only capacity allocation model with backward induction to predict optimal booking limit but also pricing model to decide the best offered price for each type of costumers are successfully developed. Hopefully, it can improve previous research done by Dake [5] which is only focused on capacity allocation. Booking limit model is then developed into two kinds: two class according to Talurri model and n-class using EMSR-b (*Expected Marginal Seat Revenue Version B*) and pricing model is also developed in both deterministic and stochastic conditions.

## 3. BOOKING LIMIT MODELS

Ticketing business with pre-sale/discount fare and normal fare are confined to limited capacity. Discount fare happen priory and then remaining tickets are sold with the normal fare with value greater than discount price. In practice, capacity allocation is decided by intuitive approach. Theoretically, it can be evaluated by revenue management approach. The following subchapter explains two models of booking limit. These models are represented the existing model and can be used to evaluate optimal capacity allocation.

### 3.1. Two-class booking limit

Littlewood two-class booking limit is applied to model capacity allocation for two levels of prices, high fare and low fare. In this model, demand of discount fare is assumed that happen previously and then followed by demand of high fare. Thus, there are rooms which are offered for discount fare called booking limit and the remaining room is protected for high fare called protection level. Booking limit is symbolized as  $b$  while protection level is symbolized as  $y$ .

This model shows optimal booking limit ( $b^*$ ) and optimal protection level ( $y^*$ ). Both parameters have relation as shown in equation (1) below where  $C$  is the capacity.

$$b_2^* = C - y_1^* \quad (1)$$

Protection level is defined as the function of cumulative distribution function of arrival customer which is one of the continuous distribution types as shown in equation (2). This model can explain demand uncertainty.

$$y_1^* = F_1^{-1} \left( 1 - \frac{P_2}{P_1} \right) \quad (2)$$

Which  $P_2$  is the high fare and  $P_1$  is the low fare.

Based on equation (1) and (2), optimal booking limit and protection level can be calculated manually and simulated for each ratio of price ( $P_1$  and  $P_2$ ). Calculation result of booking limit and protection can be easily determined. The result of the

simulation is then formed as linear regression. Equation (3) shows that the higher the ratio of price is, the more the room protected and vice versa. It is logically explain real condition in the system. Ratio itself is symbolized as  $r$ .

$$b = m + nr \quad (3)$$

Which  $m$  and  $n$  are parameter or intercept.

### 3.2. N-class booking limit

Littlewood booking limit is one alternative to determine capacity allocation. In this section, more advance method to find optimal decision for allocating all resources (capacity) is explored. This method called  $n$ -class booking limit is applied for several classes of costumers. The method is currently and widely used in the context of revenue management because it is easily notated, directly used, and close to real optimal solution.

Two of most familiar heuristic method is EMSR-a (Expected marginal seat revenue-version a) and EMSR-b (expected marginal seat revenue version b) [7]. Index and notation used in this model are same as the model of two-class booking limit. It also assumes that the model fit with certain continuous distribution.

Actually, EMSR-a is indicated resulting the higher protection level than the real optimal protection level because it does not use average statistic model to aggregate demand, so it causes pooling effect resulting higher protection level. Due to that reason, EMSR-b is preferably applied in this research. The basic idea is aggregation of demand for the previous class so  $n$ -class is changed into two-class form. For instance, forth class will be evaluated instead of three previous classes. First, second, and third classes are considered as only one class. Revenues of those classes are next accumulated and average revenue is used as divisor.

For  $(n+1)^{th}$  class, protection level will be determined as  $y_n$ . Cumulated demand for  $n^{th}$ ,  $(n-1)^{th}$ , 1st class is defined by the following equation (4). The weighted revenue for 1<sup>st</sup>,  $(n)^{th}$  is obtained by calculating  $\bar{p}_n$  as shown in the equation (5).

$$S_n = \sum_{k=1}^n d_k \quad (4)$$

$$\bar{p}_n = \frac{\sum_{k=1}^n p_k E[d_k]}{\sum_{k=1}^n E[d_k]} \quad (5)$$

EMSR-b equation is assumed that it is distributed normally. Equation (6) explains how  $y_n$  can be calculated.

$$y_j = \mu + z_\alpha \sigma \quad (6)$$

Which  $\mu = \sum_{k=1}^n \mu_k$  is mean and  $\sigma^2 = \sum_{k=1}^n \sigma_k^2$  is variance of the aggregation of demand from  $(n+1)^{th}$  stage where  $z_\alpha = \Phi^{-1}\left(1 - \frac{p_{n+1}}{p_n}\right)$  and  $\Phi^{-1}$  reflects the inverse of cumulative function of normal distribution.

## 4. REVENUE MODEL

To evaluate booking limit model, revenue becomes indicator whether booking limit model optimizes business performance itself. Firstly, demand model is developed in two conditions: deterministic demand model and stochastic demand model. Deterministic model provides simple form but it has limitation because it only can be applied in certain range. If the point exceeds the range, the calculated demand results zero or negative value. Therefore, stochastic model is also evaluated in this case and may represent the system better. Secondly, revenue model which consists of demand model and booking limit model is created by accommodating both pricing-based and quantity-based perspectives.

Revenue management assumed that the only factor affecting demand is price. Based on that statement, demand model is developed as function of price. Price itself consists of several stages depending on level of customers. Here, equation (7) is

deterministic demand model and equation (8) is the stochastic demand model. The equations show that if the price declines, then the demand increases and vice versa. So, the demand and price are negatively correlated.

If demand model is successfully modeled and checked by statistic tool that there is no significant different between model and real system, it can be used for further analysis. Revenue model with both demand and booking limit model is next logically developed into three conditions: when the demand exceeds the capacity, when the demand ranges from booking limit to capacity, and when the demand is less than booking limit. It is mathematically explained by equation (9) – equation (11). The model as shown in equation (9) counts single class revenue up into accumulated revenue.

$$d_{det(p)} = a - bp \quad (7)$$

$$d_{stoc}(p_n) = N(f(p_n)) \text{ Which } f(p_n) = e^{-p_n \lambda} \quad (8)$$

$$R_{acc} = \sum_{i=1}^n R_n \quad (9)$$

$$R_n = \begin{cases} p_n d_n & \text{if } d_n < b < C \\ p_n b_n & \text{if } C > d_n \geq b \\ p_n C & \text{if } d_n \geq C \end{cases} \quad (10)$$

$$R_n = \begin{cases} p_n(a - bp_n) & \text{if } d_{det_n} < b < C \\ p_n(C - \gamma_{n-1}) & \text{if } C > d_{det_n} \geq b \\ p_n C & \text{if } d_{det_n} \geq C \end{cases} \quad (11)$$

## 5. SIMULATION AND ALTERNATIVE SOLUTIONS

In this section, simulation using study case is needed to prove developed model: booking limit model, pricing model, and revenue model as shown in equation (1)-(11). The case is an entertainment event in Yogyakarta in 2011. This entertainment event is an annual event so result in this study can be considered in future time. It offered two price rates, high price (Rp150.000) and low price (Rp100.000) with fixed capacity (700 seats). The event organizer initially allocated 30% for high price and 70% for low price without logical consideration. By doing that strategy, they obtained Rp72.250.000. They got actually 210 seats sold out with high price and 420 seats sold out with low price. It means that there were remaining seats or they allocated too many rooms for high price. By applying the developed model above, we can evaluate whether their decision had been optimal or not yet. Three scenarios for two conditions (deterministic and stochastic) have been developed to evaluate and to find the best strategy.

1. One-class pricing strategy in deterministic and stochastic condition
2. Two-class pricing strategy in deterministic and stochastic condition
3. n-class pricing strategy in deterministic and stochastic condition

Before running simulation, basic parameter should be determined to classify better or worse business which is revenue model containing both quantity-based RM and pricing-based RM. As shown in equation (8)-(11), equation (12) is deterministic demand model and equation (13) is stochastic demand model. Both model can be substituted as the input for revenue model as mentioned by equation (11).

$$d_{det(p)} = 1857,813 - (0,012p) \quad (12)$$

$$d_{stoc} = N(e^{-p_n \lambda}) = N(e^{-8581 \times 10^{-6} p_n}) \quad (13)$$

The simulation uses random prices in range of Rp100.000-Rp250.000 based on historical data of entertainment events in Yogyakarta.

### 5.1. One-class pricing strategy

Two class or n-class model have a risk because of the fluctuate prices. It can influences costumer and organizers may loss their demand. So, in this case, one-class model is also evaluated. If the output of one-class model results higher revenue, it can be used as recommendation.

In range of Rp100.000-Rp250.000, by applying Rp120.000 for both deterministic and stochastic condition, we got the greatest revenue (Rp70.128.912). It can be explored detail in Figure 1. Unfortunately, the result of this model cannot be recommended because the expected revenue is less than actual revenue. It may be concluded that one-class model cannot offer better result in this case.

### 5.2. Two class model

Firstly, booking limit model is basically developed by arrival costumer rate so it can adapt or adjust uncertain demand. Figure 2 shows the correlation between protection level and ratio of high and low prices called discount rate. Based on figure 2, the greater the discount rate offered to the customer, the more the capacity protected for high price. It can be logically explained that if number of rooms with discount rate offered to costumer is more, the revenue should decreases. Therefore, the more rooms should be offered in high price. The correlation between booking limit and discount rate can be explained mathematically by equation (14).

$$h = 78,063 + 620,7 \frac{P_2}{P_1} \tag{14}$$

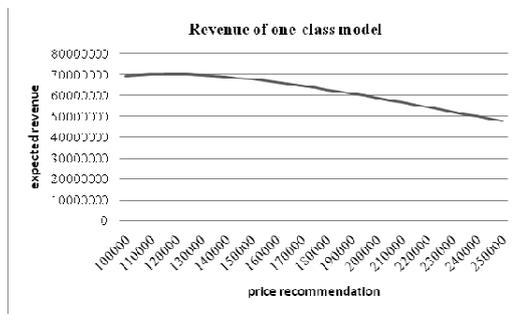

Figure 1: Revenue Output for One-Class Model

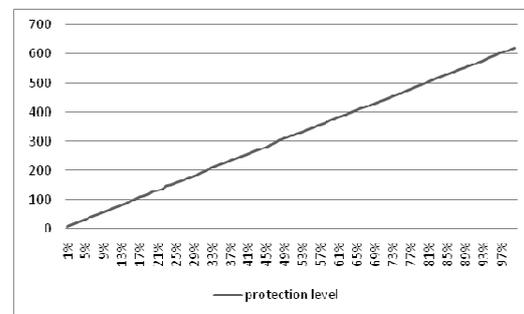

Figure 2: Protection Level for each discount rate

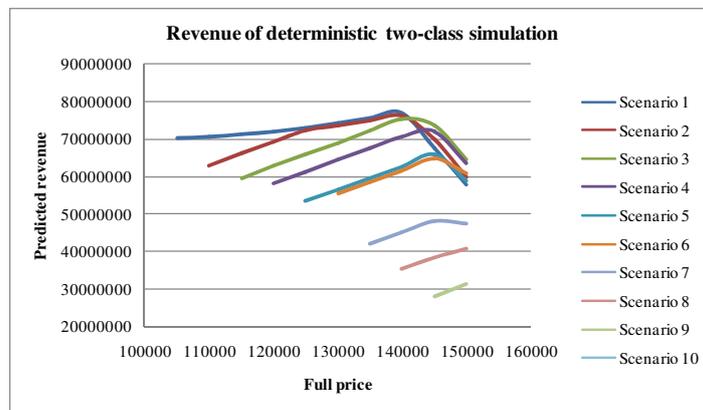

Figure 3: The result of two-class deterministic simulation

The two-class model simulation uses price in range of Rp100.000-Rp250.000 based on the historical data of entertainment event in Jogjakarta for both discount and full prices in deterministic and stochastic condition. However, because of restrictiveness of deterministic model, the simulation uses only price in range of Rp100.000-Rp150.000 because the price excess Rp150.000 values negative result. Meanwhile, stochastic simulation applies price in range of Rp100.000-Rp250.000.

In the simulation, full price is varied in the range of price with a given discount price on each scenarios. For example, in the 1<sup>st</sup> scenario, discount price is fixed which is Rp100.000 and full price is varied from Rp105.000-Rp150.000. Thus, local optimal revenue can be defined for each scenario by applying the model of equation (7)-equation (11). The results for both deterministic and stochastic conditions are depicted in the figure 3 and 4. The following table, Table 1 and Table 2, explains optimal combination of discount and full fare in each scenario.

According to Figure 3 and Table 1, best pricing strategy for deterministic simulation is Rp100.000 as discount price and Rp140.000 as full price with predicted revenue greater than actual revenue (Rp77.035.834) which rises about 6% from the actual revenue. Stochastic simulation as shown in Figure 4 and Table 2 predicts the best pricing for both discount and full price which are Rp145.000 and Rp230.000 respectively.

Table 1: Simulation result of two-class deterministic model

No	Discount price	Full price	Expected revenue	No	Discount price	Full price	Expected revenue
1	Rp100.000,00	Rp140.000,00	Rp77.035.834,00	6	Rp125.000,00	Rp145.000,00	Rp64.819.990,00
2	Rp105.000,00	Rp140.000,00	Rp76.256.480,00	7	Rp130.000,00	Rp145.000,00	Rp48.205.555,00
3	Rp110.000,00	Rp140.000,00	Rp75.264.545,00	8	Rp135.000,00	Rp150.000,00	Rp40.776.705,00
4	Rp115.000,00	Rp145.000,00	Rp72.031.380,00	9	Rp140.000,00	Rp150.000,00	Rp31.286.370,00

### 5.2.2. N-class model

In this case, it is assumed that there are three classes of customer. Optimal pricing in first and second class are set which are Rp100.000 and Rp125.000 respectively. Thus, n-class model searches optimal price for the third class. As explained before in subchapter 2.1, class is in order and notated as  $p_{n-1} > p_n$ . Customer arrival of the  $n^{\text{th}}$  class happens previously than the  $(n-1)^{\text{th}}$  class. Thus, arrival demand of discount price happens previously and followed by the arrival demand of higher price.

Figure 5-Figure 6 shows the simulation result which is calculated from some alternative  $n^{\text{th}}$  price and Table 3-Table 4 shows specific results and predicted revenues for both deterministic and stochastic conditions. The best pricing strategies are Rp150.000 for deterministic condition and Rp205.000 for stochastic condition.

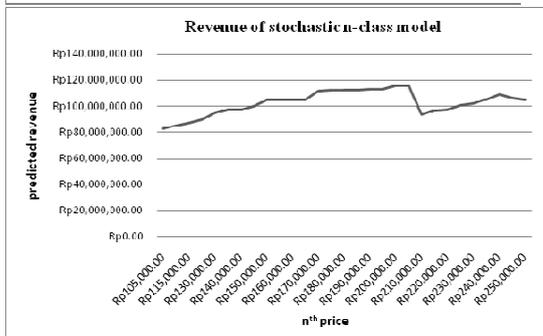

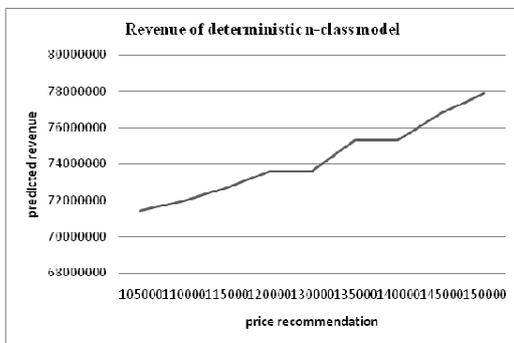

Figure 5. The result of deterministic n-class simulation

Figure 6. The result of stochastic n-class simulation

Table 3.  $n^{\text{th}}$  price recommendation for deterministic simulation

No	Alternative price	Expected revenue	No	Alternative price	Expected revenue

14	Rp175.000,00	Rp111.935.793,41	29	Rp250.000,00	Rp105.292.590,37
15	Rp180.000,00	Rp112.145.493,41			

## 7. CONCLUSION

According to the research objective, booking limit model is successfully developed with three conditions: one-class, two-class, and n-class specifically for three-class in the case. It is generated into revenue model which combines both pricing-based RM and booking limit itself as quantity-based RM. Revenue model is developed in two conditions: stochastic demand and deterministic demand. From both conditions, stochastic is more representative because it can apply wider price range while deterministic has price range limitation. Based on case study, the simulation recommends two-class with optimal discount fare and high fare which are Rp145.000 and Rp230.000 respectively. For further research, developing customer valuation and switching time as consideration for revenue management model is suggested.

## ABSTRACT

Case study is conducted in one of the leading retailers in Jakarta to determine its customer favorable green bag with aim to increase its usage through fitted distribution system for sustainability of Go Green program. Questionnaire with a sample of 357 is conducted in five Carrefour stores within Jakarta regions to uncover the favorable type of green bag by the retailer customers. Cloth bag (39%) is found to be favorable and customers are fully aware of its eco-friendly property (42%). A follow-up questionnaire and face to face interview with 350 customers is carried out in the stores located in North and East Jakarta. 95.43% of the respondents claim to support the replacement of plastic to cloth bag and 55.14% of the respondents prefer big cloth bag made from spun-bond nonwoven (51.71%) with a tote type (59.43%) and standout design (66.86%). Cloth bag distribution system is later designed based on customers' preference of having one free cloth bag for a minimum amount spent (58%).

## Keywords

Cloth bag, retailer, distribution system

## 1. INTRODUCTION

### 1.1. Go Green Program

Awareness on the environment issues arises worldwide as can be seen with the various "go green" programs proposed by multinational companies such as General Electric, McDonalds, Starbucks, Body Shop, Wal-Mart, Whole Foods, Honda, Hewlett-Packard, and many more. At first, it appears that going green will cost more in the short-term; however these companies aware that going green will pay off in the long-term with reputation points and invaluable word of mouth endorsement by the customers. In its simplest form, going green means elimination of wastes which save money leading to sustainability. For example, Wal-Mart, the multinational consumer goods retail company, introduced innovative ways to reduce waste and forced thousands of Wal-Mart suppliers to embrace sustainability from reducing packaging size which save approximately \$3.4 billion a year to reduction in overall carbon emission rate by 16 percent from 2005 to 2008. Wal-Mart's green course is triggered by its awareness on their customer trend and behavior towards sustainability issues. Wal-Mart's 2010 progress report on sustainability shows sharp reduction in plastic bags usage and reduction of printouts of store reports which worth \$20 million saving [2].

### 1.2. Plastic Bags in Retail Industries

The use of plastic bags in retailing became widespread in supermarkets in developing countries such as Indonesia since 1990s with rate of 500 billion to 1 trillion plastic bags annually. The plastic shopping bags in corporate retailing or traditional market are increasingly seen as more of an environmental hazard instead of convenience. This triggered various regulatory policies to control the use of plastic bags and researches on the public costs of plastic bag usage. It takes hundreds of years for a plastic bag to degrade and their existences quickly fill up landfills [7]. In 2009, a research is conducted by Greeneration Indonesia in over five major cities in Indonesia and it showed that 700 plastic bags are used per person per year. In other words, over 41 billion plastic bags are used in 2010 [13] and Jakarta alone generates 13.25% plastic waste of 6000 ton of waste every day.

### 1.3. Green Bag Distribution Program

P.T. Carrefour Indonesia started “Go green” program over four years ago. Carrefour customers are able to purchase a green bag located near the cashier for IDR 2,000 or IDR 10,000. Shall the bag torn or unusable, customers may exchange it with a new one in any Carrefour store as long as it is still within the six-month warranty period. Unfortunately, the response from its customers is not as expected. Based on a brief random observation conducted in several Carrefour stores in Jakarta vicinity on March and April 2012, none of the Carrefour customers purchase nor use a green bag when they do shopping in Carrefour. This fact triggers the need to examine their customers’ awareness of its “go green” program and their preference on the attributes of green bags which later on can be used to plan a more effective and efficient green bag distribution system.

## 2. LITERATURE REVIEW

### 2.1. Questionnaire and Interview

The purpose of qualitative research is to find out a person’s perspective. Questions which are perceived as invasion of privacy or confrontation can be better obtained from qualitative methods through a formal, structured-survey. Self-administered questionnaire must reconcile to closed-end questions which allow the respondents to simply checking a box or circling the proper response [1].

The assignment of numbers is made according to rules that should correspond to the properties of the question items. Four types of measurement scales are nominal (dichotomous “yes” or “no” scale), ordinal or rank order (comparative), interval (Likert, Stapel, semantic-differential), and ratio (certain scales with special instructions). Attitude rating scales are generally classified as for single-item scales and multiple-item scales. Single-item scales only have one item to measure a construct and the itemized-category scale is the most widely used although in some situation comparative scales, rank-order scales, or constant-sum scales are used. Multiple-item scales are commonly used to measure attitude toward complex objects [1].

Individual interviews are conducted face to face with the respondents and have two basic types: nondirective and semistructured where the differences lie in the amount of guidance the interviewer provides [1]. The success of interview depends on the interviewer, respondent, guiding skill of the interviewer, and the ambiance of the interview session. Unfortunately, face-to-face interview method may generate high cost and there is a possibility that the responses are affected by how the interviewer phrases the questions but structured interview can overcome this problem. Observation methods are often not considered due to its limitation in providing information on current behavior. Yet, direct observation is frequently used to obtain insights into research behavior or related issues. Observational methods suffer similar limitation as the face-to-face interview.

### 2.2. Descriptive Statistics

In practice, underlying probability distribution mass function is commonly unknown. However, it can be estimated through taking a random sample as representative sample. Data observations can be either categorical or nominal data. Categorical data record several categories or types an observation takes while numerical data may be either integers or real numbers [8]. Once a data set has been collected, it can be summarized by simply recording the frequencies of occurrences which later can be used to find the underlying necessary information.

### 2.5. Green Bags

Degradable plastic bag is a type of green bags which within reasonable amount of time, can be biologically broken down into their base compounds [4]. The synthetic bag is polyethylene blended with a prodegradant additive to increase the speed of decaying process. The disadvantage of this bag is if it ends up in landfill, they will degrade faster than conventional polyethylene bags which could potentially increase the degradation of food waste and contribute to greenhouse gas generation when they degrade [5].

Paper bag [5] has higher degradation rate, over a 6-month period, compared to other materials. Moreover, it is highly recyclable. Unfortunately, if it is compared to degradable plastic bag, it has higher contribution to global warming. This is because the pulping and bleaching processes produce higher air emissions and waterborne waste compared to plastics manufacture. Moreover, there is environmental impact of timber growing and harvesting on land degradation and biodiversity. Although the cost of paper bag is approximately 4-5 times more than plastic bag, paper bag is claimed to be more prestigious and commonly used in upper class society [10].

Cloth or so called reusable bag delivers environmental gains over the full life cycle of the bag. Reference [5] explains that supermarket sector has estimated an increase of 5 seconds in every transaction for using reusable bags which could result in

additional costs to the customers as well as other costs such as administration, stolen goods and equipment, auditing, monitoring, and education. Despite the fact that cloth bag will increase the costs, it give major benefits in material reduction or resource savings and reduction in litter.

### 2.6. Cloth Bag Materials

Drab or calico is a not fully processed plain-woven textile made from unbleached and may contain unseparated husk parts. Drab bag can be used for approximately 1 year and is stronger than plastic bag. The drawback of drab is the raw material requires 10% pesticide and 25% insecticide [5]. Frings [6] states that producing cotton with 100% pesticide and insecticide free will increase the cost up to 30%. Canvas [15] is an extremely heavy-duty plain-woven fabric. The modern canvas is made of cotton or linen and it comes in two basic types: plain and duck (tighter threads). It can also be made from polyester, acrylic to replace wool, or nylon to replace silk [14].

Jute is a rain-fed crop with little need for fertilizer or pesticides and is 100% biodegradable. IGD predicts by 2014, biodegradable bag such as jute bag will replace polyethylene bag [9] although currently is not preferable by the shopper because of its rough surface, not waterproof, and cost more [12, 3]. Spun bond nonwoven is a fabric-like material made from long fibers bonded together by chemical, mechanical, heat, or solvent treatment [11]. Typically, it is lack of strength unless densified by a backing. Spun bond nonwoven can be recycled after use, given the proper treatment and facility which make this bag eco-friendly compared to the other types of green bags [4]. Its fabric provides functions such as liquid repellence, resilience, stretch, softness, washability, and cushioning [6]. These properties allow this type of material achieve good balance between produce use-life and cost.

## 3. FIRST QUESTIONNAIRE RESULT ANALYSIS

### 3.1. Overall Customers' Behavior

For population with infinite number, a minimum of 349 responses is needed in order to have error rate up to 5%. The first questionnaire is distributed to Carrefour customers in five different stores in which each store represents each county in Jakarta: Carrefour Puri Indah (West Jakarta), Carrefour Menteng Prada (Central Jakarta), Carrefour Mall of Indonesia (North Jakarta), Carrefour Ambassador (South Jakarta), and Carrefour Cempaka Putih (East Jakarta). Approximately 70 responses are collected from customers in each representative store. This questionnaire consists of 15 items which measure customers' awareness level of environmental issue, Carrefour "Go Green" program, and, their preferences among grocery bags (degradable plastic bag, cloth bag, and paper bag). A total of 357 responses were collected for the first questionnaire with results as follow. Variation of the items sold (39%) and its strategic location (38%) become the important aspects for the customers to do grocery in Carrefour whereas price (19%) is ranked afterward (See Figure 1: **Customer's Main Reason Selecting Carrefour**). This implies that shall a strategy is chosen which requires an increase in item cost(s), such increment may not give significant impact which triggers Carrefour's customers to shop in other retailers because Carrefour competitive advantages are in location and the variation of the items sold.

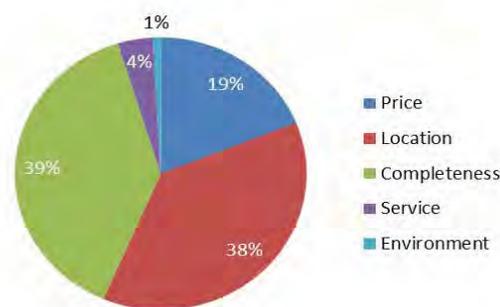

Figure 1: Customer's Main Reason Selecting Carrefour

95% of Carrefour customers are aware of the environmental issue can be supported through introducing green products to the society and 98% of the customers support Carrefour "Go Green" plan through the implementation of green bags. Among the three types of grocery bags, 50% of customers remain prefer degradable plastic bags compared to cloth bags (39%) and paper bags (11%) yet they believe that cloth bags (42%) and paper bags (36%) are environmental friendlier than degradable plastic bags. Apparently, as can be seen in *Table 1: Customers Reasons to Choose Selected Types of Bag*, the customers will choose degradable plastic bags mainly if it is environmental friendly (39%) and free of charge (32%). Similar observation was

conducted to the other two bags. Customer will choose cloth bag mainly if it is durable (31%) and paper bag will be chosen if it is environmental friendly (33%).

Table 1: Customers Reasons to Choose Selected Types of Bag

	Plastic bag (%)	Cloth bag (%)	Paper bag (%)
Free of charge	32	20	18
Durability/Reusability	18	31	19
Environment	39	19	33
Design	7	18	18
Others	5	11	11

By ranking the preference of the customers for each type of bag, it can be concluded that the main reasons for the customer choosing a particular bag is mostly due to its environmental friendliness, reusability or durability, and free of charge with weight quite indifferent among the three criteria (See Table 2: *Weighted Average on Customers' Preference of Each Type of* ).

Table 2: Weighted Average on Customers' Preference of Each Type of Bag

	Average	Plastic bag	Cloth bag	Paper bag
Free of charge	3.50	4	4	2.5
Durability/reusability	4.00	3	5	4
Environment support	4.33	5	3	5
Design	2.17	2	2	2.5
Others	1.00	1	1	1

The top three reasons are further evaluated except the environmental support factor. As for reusability factor, evaluation is conducted on the frequency of reusing the bag. A correlation is found between customer's preference on bags and its reusing frequency. As stated previously, the customers prefer degradable plastic bags (50%) compared to cloth bags (39%) and paper bags (11%). The frequency of reusing the bags is also reduced significantly from plastic bags to cloth bags and paper bags (see Table 3: *Frequency of Reusing Bags*) as their bag preference changes.

Table 3: Frequency of Reusing Bags

Reuse frequency	Plastic bag (%)	Cloth bag (%)	Paper bag (%)
Always	17	10	7
Usually	30	32	15
Sometimes	42	43	49
Never	11	15	28
Others	0	1	1

The last factor, free of charge, is then evaluated by obtaining input from the customers as for the price range for cloth bag. Degradable plastic bags are not evaluated because the cost of it by default is zero whereas the paper bags are evaluated yet not discussed considering paper bags are the least favorable grocery bags for Carrefour customers. 17.93% of the customers are willing to pay up to IDR 10,000, 17.37% of the customers prefer to have the bag for free, and 17.37% of them prefer to pay no more than IDR 5,000.

### 3.2. Gender Based Customers' Behavior

Clustering the responses based on gender (105 male and 251 female), in general there is no indifference as for the main reasons the customers shop in Carrefour, preference on grocery bags, frequency of reusing the bags, as well Carrefour's "Go Green" program. However, as for the awareness on environment friendly products, female respondents have different insight with the male respondents. 48% of the male respondents believe that paper bag is environmental friendlier than cloth bag (38%) whereas only 31% of the female respondents believe that paper bag is environmental friendlier than cloth bag (44%).

Moreover, the three main reasons female respondents will decide to use cloth bags are if the cloth bag is durable and reusable, has an attractive design, and free whereas the male respondents chose cloth bags if it is durable, reusable, supports environment, and free. As for paper bag, female respondents will choose such bag if it supports environment, durable, reusable, and has an attractive design, however, the males are focusing more onto its support towards environment, durable, reusable, and free of charge (see Table 4: *Customers Reasons to Choose Selected Types of Bag (Based on Gender)*).

Table 4: Customers Reasons to Choose Selected Types of Bag (Based on Gender)

	Plastic bag (%)		Cloth bag (%)		Paper bag (%)	
	M	F	M	F	M	F
Free of charge	32	31	24	18	18	18
Durability/reusability	18	18	30	32	20	19
Environment	39	39	27	16	36	32
Design	7	7	11	22	17	19
Others	4	5	9	12	9	12

By weighting customers' preference for each type of bag, as can be seen in *Table 5: Weighted Average on Customers' Preference on Grocery Bags (Based on Gender)*, both male and female respondents will choose a certain type of bag based on its support towards environment and reusability whilst free of charge and design becomes the third important aspect for male and female customers, respectively.

*Table 5: Weighted Average on Customers' Preference on Grocery Bags (Based on Gender)*

	Average	
	Male	Female
Free of charge	<b>3.33</b>	3.00
Durability /reusability	<b>4.00</b>	<b>3.83</b>
Environment	<b>4.67</b>	<b>4.00</b>
Design	2.00	<b>3.17</b>
Blank	1.00	1.00

Although in the overall, gender does not give significant effect on the behavior of the Carrefour customers, disparity between answers in certain factors are quite significant. For instance, while both degradable plastic bags and cloth bags are still favorable for both genders, the percentage disparity between these two bags is wider for male (19%) compared to female (7%). In addition, as for the necessity to "go green" issue, most of the female respondents chose "somewhat agree" whereas male customers show almost no difference between "agree" and "somewhat agree." This finding is confirmed further with the fact that 100% of the male respondents "somewhat agree" and "agree" that Carrefour shall "go green" whereas female respondents only 97%.

*Table 6: Cloth Bag Price (Based on Gender)*

	Male		Female	
	Max Price IDR 5,000	Max Price IDR 10,000	Highest	IDR 0
Max Price IDR 5,000	51.4	62.5	16	18
Max Price IDR 10,000	31.4	40.6	14	<b>19</b>
Highest IDR 0	16	18	<b>17</b>	18
IDR 5,000	14	<b>19</b>		
IDR 10,000	<b>17</b>	18		

From *Table 3: Frequency of Reusing Bags*, most of the male respondents are willing to pay up to IDR 10,000 per cloth bag and female respondents prefer to pay no more than IDR 5,000 per cloth bag. Carrefour female customers are more willing to spend compared to the male customers to obtain a cloth bag according to their preference.

### 3.3. Region Based Customers' Behavior

Region based clustering epics different information related to Carrefour customers' behavior. Customers in West, Central and North Jakarta believe that cloth bags are environment friendlier than the other type of grocery bags. However, South Jakarta customers believe the opposite and it is confirmed by 67% of them (highest response) supports the implementation of paper bags in Carrefour outlets.

East Jakarta customers equally believe that both cloth and paper bags are environment friendly. In fact, among the five regions, East Jakarta customers are the most supportive ones towards green bags (99%) as well as Carrefour "go green" program (100%). As for preference among bags, customers in all regions except North Jakarta prefer degradable plastic bags over cloth bags and paper bags. Whilst, customers in North Jakarta have equal preference amongst plastic and cloth bags and Central and East Jakarta considerably prefer plastic bags among the other bags (see *Table 7: Customers Preference on Grocery Bags (Based on Region)*).

*Table 7: Customers Preference on Grocery Bags (Based on Region)*

	West (%)	Central (%)	North (%)	South (%)	East (%)
Plastic bag	44	<b>54</b>	<b>46</b>	47	<b>55</b>
Cloth bag	37	34	<b>46</b>	41	37
Paper bag	17	11	7	11	8
Blank	1	0	0	1	0

For all regions, the top three customers' preference is indifferent for plastic bags: free of charge, durable, reusable, and support environment. As for cloth and paper bags, on the other hand, different region shows different preferences as can be seen in *Table 8: Customers Reasons to Choose Selected Types of Grocery Bags (Based on Region)*<sup>8</sup>. Design becomes an important factor for North and South Jakarta while free of charge, reusability, and support towards environment remain in the top three factors for the other regions.

Table 8: Customers Reasons to Choose Selected Types of Grocery Bags (Based on Region)

	Plastic bag (%)					Cloth bag (%)					Paper bag (%)				
	West (W)	Central (C)	North (N)	South (S)	East (E)	W	C	N	S	E	W	C	N	S	E
Free of charge	37	21	32	27	39	29	19	15	19	17	21	19	18	14	18
Reusability	15	11	30	20	14	31	39	34	30	24	23	19	20	26	10
Environment	33	57	27	43	35	12	23	30	20	11	28	41	35	39	23
Design	11	6	10	7	0	17	13	20	30	13	20	16	25	19	13
Blank	4	4	1	3	11	11	7	1	1	35	8	6	1	3	37

In overall, West, East, and Central Jakarta customers are indifferent. Their preference is on free-environment friendly-reusable bags, whereas South Jakarta emphasize not only on environment friendliness and reusability of the bag but also its attractive design. North Jakarta customers, on the other hand, prefer environment friendly and reusable grocery bags with equal importance level on free of charge and design.

Table 9: Weighted Average on Customers' Preference on Grocery Bags (Based on Region)

	West	Central	North	South	East
Free of charge	4.00	3.50	3.00	2.67	3.67
Durability /reusability	4.00	3.83	4.00	3.83	2.67
Environment	3.67	4.67	4.00	4.33	3.00
Design	2.33	2.00	3.00	3.17	1.67
Blank	1.00	1.00	1.00	1.00	4.00

As can be seen in Table 10: **Cloth Bag Price (Based on Region)**, Central and North Jakarta customers are willing to pay up to IDR 5,000 per cloth bag. West and East Jakarta customers are willing to spend up to IDR 10,000 per cloth bag whereas South Jakarta customers believe that they should get the cloth bag for free. It can also be seen from the table that Carrefour customers in West Jakarta is more willing to pay certain amount to obtain a cloth bag compared to the other regions.

Table 10: Cloth Bag Price (Based on Region)

		West (%)	Central (%)	North (%)	South (%)	East (%)
Cloth bag price	Percentage on each amount					
	IDR 0	15	10	17	24	21
	IDR 5,000	13	20	18	21	14
	IDR 10,000	23	17	15	10	24
Maximum amount will be spent for a cloth bag	IDR 5,000	65	57	61	54	58
	IDR 10,000	51	30	39	26	42

#### 4. SECOND QUESTIONNAIRE RESULT ANALYSIS

Based on the first questionnaire evaluation on region based responses, it can be concluded that 97% of North Jakarta customers, in fact, support Carrefour "go green" program and their preference between degradable plastic bags and cloth bags is indifferent. East Jakarta, on the contrary, is the most supportive towards Carrefour "go green" program (100%) despite the fact that degradable plastic bags (55%) become their preference.

Thus, second questionnaire and interview are completed for 350 respondents total in two Carrefour outlets (175 respondents on each outlet) to find the mean to distribute the cloth bag as well as their preference on the material used, size, design, and type of cloth bag. One outlet in each North Jakarta, Emporium Pluit, and East Jakarta, Tamini Square, are chosen as representatives of the best and worst possible success rate of cloth bag distribution system.

##### 4.1. Gender Based Cloth Bag Preference and Distribution System

Both female (269 respondents) and male (81 respondents) customers prefer to obtain one free cloth bag for every minimum amount spent instead of stamp collection program. Furthermore, to ensure sustainability of using the green bag, both genders agree on having point collection for every usage of green bag when they do their grocery in Carrefour which later can be exchanged to a gift or voucher as can be seen in Table 11: **Cloth Bag Distribution System**. Both male and female respondents prefer spun bond nonwoven tote cloth bag but male respondents prefer medium size cloth bag while female respondents choose large size cloth bag (see Table 12: **Cloth Bag Features**).

Table 11: Cloth Bag Distribution System (Based on Gender)

How to get the green bag?	M (%)	F (%)
Minimum amount spent	78	65
Stamp collection	21	35
Others	1	0

Reward on using the green bag in the next visit	M (%)	F (%)
Cash back	35	33
Point collection	<b>65</b>	<b>67</b>

Table 12: Cloth Bag Features (Based on Gender)

Material	Size		Carrying Style	
	M (%)	F (%)	M (%)	F (%)

Canvas	12	17	Handbag	20
Jute	12	17	Messenger bag	8
Spun bond nonwoven	<b>59</b>	<b>49</b>	Backpack	6

#### 4.2. Region Based Cloth Bag Preference and Distribution System

Irrespective the regions, as can be seen in the following Table 13: *Cloth Bag Distribution System (Based on Region)*, both North and East Jakarta customers prefer to obtain a cloth bag for every minimum amount spent and obtain point rewards every time they use the green bag instead of plastic bag for carrying the purchased items. Additionally, spun bond nonwoven large size tote green bag is preferable for both North and East Jakarta customers (see Table 14: *Cloth Bag Features (Based on Region)*).

Table 13: Cloth Bag Distribution System (Based on Region)

How to get the cloth bag?	North (%)	East (%)
Minimum amount spent	<b>65</b>	<b>71</b>
Stamp collection	34	29
Others	1	0

Reward on using bag the next visit	North (%)	East (%)
Cash back	34	32
Point collection	<b>66</b>	<b>68</b>

Table 14: Cloth Bag Features (Based on Region)

Material	Size		Carrying Style	
	North (%)	East (%)	North (%)	East (%)
Drab/Calico	20	14	Shoulder	<b>60</b>
Canvas	16	15	Hand	25
Jute	15	17	Messenger	7
Spun bond nonwoven	<b>49</b>	<b>54</b>	Backpack	9

#### 4. CONCLUSION

A descriptive research is conducted to find Carrefour customers awareness on Carrefour “go green” program and their preference on the attributes of the favorable green bags. Two questionnaires were distributed with 357 respondents for the first questionnaire and 350 respondents for the second one.

From the analysis of the first questionnaire, in the overall, the main reasons Carrefour customers choose a particular bag is mostly due to its environmental friendliness, reusability durability, and free of charge with weight quite indifferent among the three criteria. This is confirmed by performing further analysis which shows that customers’ preference among the green bags is positively correlated with the frequency of reusing the bags. As for pricewise, excluding degradable plastic bags, 17.93% of the customers is willing to pay up to IDR 10,000, 17.37% of the customers prefer to have the bag for free, and 17.37% of them prefer to pay no more than IDR 5,000. This explains why the current Carrefour “go green” program is quite unsuccessful.

Male and female respondents show indifferent focus on the attributes of preferable green bags: environment support and reusability. However, male customers prefer free of charge as the third important aspect from green bag distribution and they fully support Carrefour “go green” program. Design becomes the third important aspect for female customers and they prefer to pay no more than IDR 5,000 per cloth bag. Yet, they are more willing to spend compared to the male customers to obtain a cloth bag which comply with their preference.

North Jakarta customers somewhat is the least supportive on Carrefour “go green” program among the other regions and their preference between degradable plastic bags and cloth bags is indifferent. Shall they have to purchase a cloth bag with a maximum price of IDR 5,000 will trigger them to purchase the cloth bag as long as the design is according to their preference. South Jakarta also believes that attractive design is important, yet they prefer to get the cloth bag for free. East Jakarta is the most supportive towards Carrefour “go green” program despite the fact that degradable plastic bags become their preference

and they are willing to spend up to IDR 10,000 per cloth bag. West Jakarta customers are also willing to pay no more than IDR 10,000 per cloth bag.

Per the evaluation on the second questionnaire and interview, regardless the gender and best or worst possible regions, Carrefour customers prefer spun bond nonwoven tote green bag. The different is only for the size of the green bag whereas the male customers prefer the medium size whilst the female customers prefer the large size.

## 5. FURTHER RESEARCH

A standout design yet ergonomics green bag and minimum amount the customers are willing to spend shall be done as follow up on the results of this preliminary research to determine the most effective and efficient green bag distribution system. The transportation modes Carrefour customers use to go to the location shall also be taken into consideration in creating the most suitable grocery green bag.

In addition, considering the preference of green bags for most customers are remain in degradable plastic bags, whilst degradable plastic bag is somewhat the least environment friendly among the other type of green bags, further analysis shall be done to determine how much extra amount is the customers willing to pay for each plastic bag which will trigger them to switch to utilize cloth bag instead of plastic bags or decide to do their grocery in another retailer.

# Value Chain Upgrading Scheme of Thermoplastic Recycling Manufacturing Systems: A Product Quality Perspective

Djoko Sihono Gabriel

Faculty of Engineering, University of Indonesia, Depok 16424  
E-mail: dsihono@yahoo.com

## ABSTRACT

In this research, main problem of (thermo) plastic recycling system is focused in gaining more benefit through better quality of products. Therefore, how to measure product quality of recycled products and then to formulate appropriate quality improvement within its context in a value chain upgrading schemes are very important. Development of quality improvement and value chain upgrading scheme through its manufacturing system capability was carried out through literature survey as well as analyses based on its stages of operation.

A new set of capability indicators and indexes were proposed in this research, used in assessing a recycling system capability, both its strength and weakness, through a comprehensive comparison of recycled products characteristics to its virgin material. A focused direction within a comprehensive scheme of value chain upgrading in a perspective of product quality improvement also proposed based on manufacturing processes knowledge as reference in weakness elimination or reduction program within an individual firm.

This new constructed knowledge provides clear directions to (thermo) plastic recycling firms in improving product quality through their manufacturing capabilities enhancement which also important to policy makers, regulators as well as facilitators in supporting programs for plastic recycling industry development. Buyers of recycled plastic also can use it in evaluating quality of recycled (thermo) plastic according to raw material specification required by their end product.

## Keywords

*Plastic recycling, capability, value chain, product characteristics*

## 1. INTRODUCTION

Existence of post-consumer plastic cause a lot of environmental problems, but if managed properly, these material has some potential to be recycled. Previous research on plastic recycling performance according to Andradý [1], Dijkgraaf & Vollebergh [2], Grosse [3], Gunter & Kaulich [4], Manrich and Santos [5], Kaufman & Themelis [6], Simmons, Kaufman and Themelis [7], more focused on elimination of waste quantity and its negative impact to environmental quality. Recycling performance was also assessed in different perspective, financial benefits, like another business activities, as stated by Cokins [8], Vadgama [9], Gomes, Yasin and Lisboa [10], and Gomes, Yasin and Lisboa [11]. Ehrenfeld [12], the European Commission [13], Huisman and Stevels [14], Lal [15], Ouattara, Azzaro-Pantel, Pibouleau, Domenech, Baudet and Yao [16], and Prasad, Pagan, Kauter and Price [17] combined those two perspectives of assessment, known as eco-efficiency.

Assessment perspective of recycling systems that focused on value chain upgrading according to Kaplinsky and Morris concept [18] as well as its roadmap on value chain upgrading has not been a concern amongst current research. Manufacturing capability to produce recycled material based on the characteristics of virgin material become a strategic issue, so with a higher quality of product will strengthen financial and economic feasibility of the recycling business. More recycled plastic waste in better quality of product will be more financial and economic benefits as well as reduce more negative impacts and virgin material consumption in plastic goods industry.

### 1.1. Plastic

Polymers can be either rubber or elastomeric, and plastic. According to Barry, Baker and Mead [19] plastics can be classified further into thermoset and thermoplastic. Because of huge difficulties in recycling of thermoset, this research focused on one derivate of thermoplastic. Thermoplastic is in a solid state at room temperature, but transformed into viscous liquid when heated to a certain temperature, and so financially feasible to be produced in various forms of goods for many purposes. This type of plastic can be repeated cycles of heating-cooling without significant degradation that allow for recycling. Examples of thermoplastic are poly ethylene (PE), poly vinyl chloride (PVC), poly propylene (PP), poly styrene (PS) and nylon.

### 1.2. Plastic Consumption and Generating of Its Waste

According to the Coordinating Ministry for Economic Affairs [20], imports of plastic materials in Indonesia reached U.S. \$ 3,419 million and imports of processed plastic U.S. \$ 743 million, while its export values were respectively U.S. \$ 960 million and U.S. \$ 680 million in 2010. Production capacity of plastic polymer consisting of PE, PP, PVC and PS in Indonesia is 2,010 metric tons per year with a per capita consumption of 7.44 kg and generated 1.008 million metric tons waste as stated by Adibroto [21]. For all types of goods according Meidiana & Gamse [22], average waste generation was 1.12 kg/capita/year, of which 14% was in plastic waste, increased about 4 times from previous six years.

### 1.3. Problems and Opportunities

Recycled of thermoplastic is one of important alternatives of material or substitution of plastic virgin material. Recycled thermoplastic has more value if its properties meet a number of requirements in the manufacturing of plastic goods. Its value enhancements can be achieved through a value chain upgrading, which requires an effective strategic measurement of process capability.

Value enhancement of recycled thermoplastic will be achieved through availability of:

- (1) indicators and indexes that describe capability of a thermoplastic recycling, and
- (2) value chain upgrading schemes, developed based on those indicators and indexes, which also contribute a new knowledge within scope of this research.

## 2. MANUFACTURING SYSTEM OF THERMOPLASTIC RECYCLING

According to ASTM D5033-00 in Fisher [23], plastic, and also thermoplastic goods, can be recycled into raw materials with three different categories, with the fourth type of recycling called *quaternary recycling* does not produce material, but energy. *Primary recycling* produces material with characteristics similar to those of the original product or virgin material within this context. Product of *secondary recycling* has characteristics different from those virgin materials, and *tertiary recycling* produce basic chemicals or fuels from segregated plastic scrap or plastic material that is part of a municipal waste stream or other source. In a perspective of production by Manrich & Santos [5], primary and secondary recycling of (thermo) plastics called mechanical recycling with sequences: (1) identification, separation and classification of different types of Plastics; (2) grinding; (3) washing with or without addition of cleaning agents; (4) drying; (5) silos; (6) agglutination (films and products with fine thickness); (7) extrusion; and (8) granulation, can be viewed as a manufacturing system as shown in the figure below.

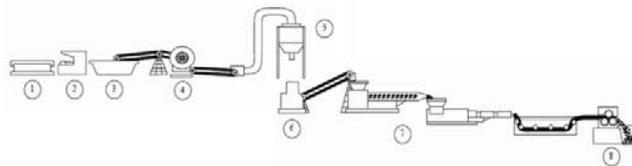

Figure 1.  
 Complete plastic recycling scheme of mechanical recycling (Manrich & Santos [5])

## 3. CHARACTERISTICS OF RECYCLED MATERIALS AS CAPABILITY INDICATOR

### 3.1. Purpose of Capability Indicator

According to Juntilla [24], quality of recycled (thermo) plastics are strongly influenced by operating capabilities of its manufacturing system and also related to its manufacturing performance. Operating capability is a performance integration of a complex tasks in producing output through implementation of technology and an efficient material flow, as stated by Hayes, Wheelwright, and Clark [25]. An appropriate indicator that able to recognize capabilities of a (thermo)plastic recycling system becomes an important tool in this context of research.

Indicators have numerous applications. They compress large amounts of information from different sources into a format easier to understand, compare and manipulate. Companies can use indicators to set targets and monitor consequent success. Interpretation becomes easier if targets can be set for the indicators themselves. These targets help the decision-maker visualize what actions will need to be emphasized in future. Gallopin [26] identifies the following major functions of indicators: (a) assessing conditions and trends in relation to goals and targets, (b) reflecting the status of a system, (c) providing early warning information, (d) anticipating future conditions and trends, (e) comparing across place and situations, and (f) highlighting what is happening in a large system.

More specific application, according to Azapagic and Perdan [27], indicators of sustainable production would enable identification of more sustainable options through: (a) comparison of similar products made by different companies, (b) comparison of different processes producing the same product, benchmarking of units within corporations, (c) rating of a company against other companies in the sector, and (d) assessing progress towards sustainable development of a sector. Krajnc

and Glavic [28] mentioned, to achieve sustainable production, a company should incorporate social and economic indicators as well. Most of the indicators included can be applied across industry. Capability indicators developed in this research will be used internally in measuring achievement of a (thermo) plastics recycling system. For this purpose it is necessary to evaluate quality indicators for optimizing its benefits. The four-phase criteria of indicator quality according to U.S. Environmental Protection Agency [29] are as follows: (a) conceptual relevance or soundness, (b) feasibility of implementation (current and future), (c) response variability, and (d) interpretation and utility.

### 3.2. Products and Materials

Plastic products are made of different types of polymer materials, so not all types of polymers tested in this research. Samples of virgin homo polymer pellet named Inflated Poly Propylene Film (IPP Film) and pellets of recycled products made from IPP Film produced by a factory in Solo and a factory in Bandung used as material in this research.

### 3.3. Measurement, Indicator and Index of Capability

In this research, quality of recycled (thermo) plastics pellets proposed as capability level of its recycling system. Characteristics of its virgin material (IPP Film), are used as important benchmark of capability measurement in assessing recycling system capability based on its quality of products. The required capability indicator is an indicator that able to identify discrepancy between quality of recycled (thermo) plastics pellets and quality of its virgin material pellets. Measurement of capability and its indicators are important in understanding capability of a manufacturing system. Recycling firms, policy makers and buyers of recycled products will take its advantages for their own interest.

Characteristics of plastic material by Shah [30] include mechanical, thermal, electrical, weather-related properties and optical properties and another hundreds of properties. Characteristics of material tested in this research were only properties that important for the products made from IPP Film homo polymers as its virgin material. Some mechanical, thermal and optical properties tested according to ASTM standards. Testing specimens prepared and tested by Polymer Technology Center - BPPT, Tangerang to test the melting point temperature and luminous transmittance level, and by Testing and Calibration Laboratory, Center for Chemical and Packaging, Jakarta to another tests.

In this research, a radar chart proposed in mapping of testing results of four types of specimens: virgin material of IPP Film homo polymer, brown recycled materials, green recycled materials and transparent recycled material. But information in this chart is very difficult to interpret directly, because of huge different between nominal testing results figures between characteristics of material. So, its nominal figures of testing result could be transformed in a more accurate manner. Purpose of radar chart will appear by using percentage of value, a comparison between testing result figures of recycled materials to its virgin material. Testing result of virgin material used as reference point with 100% score. Both higher and lower than figure of virgin material are assessed below than 100%.

In reviewing status of a recycling system capability, this research proposed a set of indicators which reflect discrepancies between characteristics of recycled materials and its virgin material. A recycled material is stated as perfect if it has characteristics similar to its virgin material. Discrepancies between characteristics of those materials reflect lower quality of recycled material compared to its virgin material. Higher discrepancies reflect lower quality of recycled material and proposed as lower capability of its recycling system.

Table 1: Specimen Characteristics Figures and Capabilities of Recycling Systems

Material characteristics	Measurement of specimen characteristic & capability indicator	Average Testing Results & Capability Indexes of Recycling System (%)			
		Virgin material	Brown recycled material	Green recycled material	Transparent recycled material
1 Density	Kilogram/liter	0.88	0.83	0.84	0.85
	Capability (%)	100%	94.3%	95.5%	96.6%
2 Tensile yield strength	Kilogram/cm <sup>2</sup>	374.08	364.54	356.95	367.36
	Capability (%)	100%	97.4%	95.4%	98.2%
3 Elongation yield strength	%	14.86	13.84	15.89	12.53
	Capability (%)	100%	93.1%	93.1%	84.3%

Source:

Testing result by Polymer Technology Center, BPPT, Tangerang and Testing and Calibration Laboratory, Center for Chemical and Packaging, Jakarta

Stages of indicators measurement of a recycled material are as follow:

1. Result of a virgin material characteristic testing, i.e. 165.64 °C for its melting point, scored with 100%
2. Result of brown recycled material characteristic testing for its melting point is 160.89 °C, scored with  $1 - ((165.64 - 160.89)/165.64) = 0.971$  or 97.1%.
3. Both higher and lower figures of recycled material characteristic testing result reduce its quality with its nominal discrepancy to virgin material figure.

Figures of this indicator measurement reflect capability of a recycling system in a perspective of its recycled material quality, for the above example, its melting point. If a set of material characteristics considered, tested and calculated, will can be identified an overall indicators of a recycling system in those scope of material characteristics. Brown recycled material, show overall capability of its manufacturing system with 80.0%. This figure illustrates the overall capability index of a factory in Solo after produced a batch of brown recycled thermoplastic. Representation of these figures in a radar chart shows a visual interpretation with variation of discrepancies between material characteristics.

Figure 2. Radar Chart of Producers Capability for Four Sample of Materials

This chart revealed significant differences of capabilities between three manufacturing systems of thermoplastic recycling factories compared to the virgin material manufacturing system capabilities. For three samples of recycled material, its mechanical and thermal characteristics are assessed as “good” sample condition by the Testing and Calibration Laboratory. These results of mechanical and thermal characteristics testing are better than its optical properties, especially in luminous transmittance level for recycled material in brown and green. Overall index of capability of individual manufacturing system are 80.0%, 73.9% and 89.6% for brown, green and transparent recycled material producers. Specific capability index for each category of material characteristics especially with low and lowest capabilities reflect manufacturing problems at each factories of brown and green recycled products. For example in luminous transmittance level – ultra violet, manufacturing capability of brown recycled products has very deep discrepancy compared to its virgin material.

In managing thermoplastic recycling processes, these indicators and radar charts proposed as information as well as tools in measuring capabilities in a recycling systems. System status reflected by indicator figures can be used to measure effectiveness of management in a recycling system, in line with indicators implemented for sustainable development measurement by Bossel [31]. A weak status of a manufacturing system needs to be resolved through a product quality improvement scheme in a context of thermoplastic recycling system. For a recycled material, the higher its quality index, expected the higher its selling price. Quality index of a recycled material also reflects its capability to reduce virgin material consumption.

#### 4. VALUE CHAIN UPGRADING SCHEME

Value chain was introduced by Michael E. Porter in 1985 in a context of competitive advantage related to firm's cost and its uniqueness of capabilities. Diagram of a generic value chain was introduced by Ankli [32] as showed by the following figure. A more detailed value chain in thermoplastic recycling are constructed in eight series of major operation stages in term of plastic recycling processes sequence by Manrich & Santos [5].

Figure 3. Generic Value Chain by Porter According to Ankli [29]

Recycled materials in Indonesia are generally classified as *buyer-driven commodity*, therefore, its value chain categorized as *buyer-driven commodity chains* by Kaplinsky and Morris [18]. This fact is a serious problem in value chain upgrading of thermoplastic recycling systems, because specifications of products are more directed by dominant retailers or marketers that order recycled thermoplastic. Development of these class of products are more focused on product acceptance by customers, therefore recyclers have less attention in improving quality of their products products in broader perspectives of quality. In this type of business environment, producers have less opportunity to gain their advantages by selling product with higher price. Stakeholders interaction within this environment affected in a product category as secondary recycling with lower quality than its virgin material, so it can not be categorized into primary recycling according to Andradý [1].

If this buyer oriented paradigm not be resolved in a long term, producers are unable to optimize their quality of products. They are also unable to produce recycled thermoplastic with higher selling price, so the whole value chain is not in an optimum status. In other words, thermoplastics recycler in general tends to meet a market-driven pattern, to supply recycled thermoplastic material according to buyer's specifications, less consider initiative of producers. A breakthrough for this kind of market trap is urgently required in promoting role of recycled material producers. Appropriate capability enhancement is the answer in term of how to produce materials that exceed quality as buyer wants. Kaplinsky and Morris [18] proposed a comprehensive scheme named as value chain upgrading include: process upgrading, product upgrading, functional upgrading, and chain upgrading. Product upgrading as sub-scheme in thermoplastic recycling context directs producers to produce higher quality with better selling price rather than previous scheme directed by traders.

Product upgrading sub-scheme needs accurate information about recent quality of products that in a more specific purpose, reflected by characteristics of recycled thermoplastic as well as characteristics of its virgin material. Discrepancies between recycled thermoplastic characteristics and its virgin material plotted in a radar chart with supporting table of testing result figures. This set of information reflected capability indicator and index than can be used as a directive tool for product quality improvement, through a target of product quality. Target of product quality improvement should be followed with action plans based on detailed stage of operations in producing recycled thermoplastic. These efforts are categorized as process upgrading according to Kaplinsky and Morris [18]. Detailed value chain with eight consecutive processes adopted from Manrich & Santos [5] described in the following figure.

Figure 4.

Value chain in thermoplastic recycling system

- (1) identification, separation and classification; (2) grinding; (3) washing; (4) drying; (5) silos; (6) agglutination; (7) extrusion; and (8) granulation.

Product upgrading sub-scheme of brown recycled material illustrated pattern of action plans in a context value chain upgrading of thermoplastic recycling. This recycled product indicates low capability index of its manufacturing system in the characteristics of luminous transmittance level - visible, with 48.8% index. If this index will be upgraded from 48.8% to 70% for example, it is necessary to identify appropriate factors that influence its luminous transmittance level - visible. The next step is to evaluate its recent operations capability at eight stages of operation, starting from material separation to granulation. A comprehensive review identified a set of factors, impacts of influence and scheme of product upgrading related to each operation capability. The following table describes a value chain upgrading in a context of product upgrading sub-scheme, especially in improving recycling system's capabilities in order to enhance luminous transmittance level indicator of brown recycled pellet.

Table 2: Value Chain Upgrading Scheme in a Context of Product Upgrading Based on Luminous Transmittance Level Characteristics

	Affecting Factors on	Influence on Product

## 5. CONCLUSION

Useful strategic knowledge for value chain upgrading of thermoplastic recycling systems were discovered by this research. Thermoplastic recycling systems as material producers need indicators and indexes of their capability as well as value chain upgrading schemes in improving their manufacturing capability. Producers are able to develop a more comprehensive value chain both of backward as well as forward value chain, therefore more innovative shared value will be created with more benefits for broader community according to Porter and Kramer [33].

On a broader scope of management policy makers, regulators and facilitators can also use these indicators as well as indexes in identifying capability of thermoplastic recycling systems in a region, which is useful in improving capabilities not only for a producer but also producers in a certain region. For public, especially users of recycled products can use these capability indicators and indexes in reviewing position of manufacturers in a context of their capabilities and product quality. They can choose recycled products which are appropriate for its specific uses in more optimum quality and cost, according to specifications required by the end product and its selling price.

## ABSTRACT

Industries are always searching for higher efficiency while maintaining a certain level of effectiveness of their product performances. However, these two objectives sometimes are progressing in opposite ways. This issue has become an important consideration in green or sustainable manufacturing. This paper is aimed at implementing the green manufacturing by using the design for Six Sigma method at a food industry. The material of non-conforming product has been analyzed and it is found that it can be reused partially and thus reducing waste. Accordingly, design for Six Sigma method is implemented, and it includes five stages, i.e. define, measure, analyze, design and verify. From the define stage, it was found seven critical to quality (CTQ) and it was measured that the process capability was very low. From the analyze stage it was found that the characteristic of dough (mixed of material including meal for reuse) had the highest priority for improvement. At the design stage, an experiment was done with dough hardness as a response and the experiment involved 3 factors, i.e. water, sugar, and meal (reuse material). The result showed that water and meal significantly influenced the dough hardness ( $p$ -value=0,000) and interaction of water and meal was significant at  $p$ -value=0,015. At the verify stage, the presence of meal as reused material met cookies thickness and diameter, but it caused instability of cookies weight.

## Keywords

*Green manufacturing, design for Six Sigma, Food product*

## 1. INTRODUCTION

The contribution of the primary industry, manufacturing sectors and service sectors in economies changed as per capita incomes increased. It has been studied by researchers in estimating development patterns of industries [1]. In case of Indonesia, after the economic crisis in 1998, contribution of industry to economic growth has been increasing. In 2011, the growth of industrial sector even is higher than national economic growth. By definition, industry converts and adds value of raw materials into products and services that are needed by customer. Industries are always searching for higher efficiency while maintaining a certain level of effectiveness of their product performances. However, these two objectives sometimes are progressing in opposite ways, and furthermore, industrial developments has been largely at the expense of the environment damage.

Environmental protection became an important issue following reports of disaster caused by industry [2]. This issue has become an important consideration in green sustainable manufacturing. It is important for industry to obtain significant benefit from its business using green or sustainable manufacturing strategy. Industrial competitiveness can be obtained through improved industry profitability, improvement in society and environmental sustainability. Pro-poor and pro-environment are inclusive in a comprehensive growth or profit manufacturing strategy, and it is known as the triple bottom line strategy. McCarty et al. [3] proposed Six Sigma method for industry to design and deploy environmental programs. Recent development makes green manufacturing a competing manufacturing strategy [4]. Recent development encourages researcher to study green or sustainable aspects in manufacturing systems (see e.g. [5], [6]).

Among industrial sectors, foods, drinks and tobacco has the highest contribution to industrial growth in Indonesia. However, food industry is still facing problem of producing a lot of waste from its production, including waste of raw material or rejected product. Tight standard and regulation is one factor of waste problem. Food industries are encouraged to improve their production processes. A company (abbreviated as KI) is one among food industries that implement continuous quality improvement of its production in order to reduce waste. KI has been successful in reducing waste, but still has problem of product inconsistency that at the end produce non-conforming product.

Research on non-conforming product resulted in an opportunity to reuse non-conforming product as an additional material in a limited amount. This paper deals with reuse of non-conforming product as an additional material at KI. Since it is new to KI, design for Six Sigma method is employed to set the level of the amount of non-conforming product as an additional material. This opportunity is also indicating the reduction of preparation process that may result in cost efficiency. The paper is

organized in chapters. After introduction, we will briefly discuss the benefit of Six Sigma method, and is followed by implementation of design for Six Sigma before concluding the paper.

## 2. SIX SIGMA

Six Sigma method uses a new approach for continuous quality improvement, which is adapted from Japanese Kaizen [7]. Six Sigma is aimed at reducing defects to near zero. It is fit with the Crosby's idea of quality performance known as zero defect. Crosby's idea uses the definition of quality as "conformance to requirement" where a non-conforming product can be considered as a defect product (see e.g. [8], [9]). Compared to Juran's "fitness for use" or Deming's "customer satisfaction", the "conformance to requirement" defines the lowest level of achievement of quality. However, "conformance to requirement" is a simple definition and well accepted especially by operator at the shop-floor level.

As a continuous quality improvement method, Six Sigma is a customer satisfaction oriented by producing zero defect [10]. The term "sigma" is used to mention unit of standard deviation in statistics and Six Sigma means that the specification limits is  $\pm 6$  standard deviation. Six Sigma primary concern is reducing defect to near zero level. Six Sigma views level of quality tougher compared with other statistical quality control approach that for decades used specification or tolerance limits  $\pm 3$  standard deviation that allows 2.7 defects per thousand opportunities. Six Sigma considers this 2.7 defects per thousand opportunities rate as 3 sigma level, and the target of Six Sigma is 6 sigma level. This target will result in a defect target rate at 3.4 defects per million while allowing bias up to 1.5 standard deviation. It means that if an industry is able to achieve 6 sigma level, then it is not necessary to control production process that may bias up to 1.5 standard deviation but still produces low defect rate. Accordingly, in case of no bias, the defect rate will be near zero per million opportunities.

Using this very low level of defect, not only at Motorola, some companies had experienced a lot of savings such as at GE and Allied Signal [11]. Following its initial fruitful results at Motorola and GE, many companies are also experiencing saving from Six Sigma implementations, including in Indonesian companies (see e.g. [12], [13]). Harry and Schroeder [7] stated that Six Sigma is a new strategy to improve business performance by increasing customer satisfaction level using various statistical tools. Moreover, Six Sigma is aimed at improving the bottom line by designing and monitoring daily business activities in order (i) to reduce waste and (ii) to increase customer satisfaction. The first objective is the basic consideration in lean manufacturing, which thus Six Sigma implementation is also known as Lean Six Sigma. Six Sigma for designing uses 5 steps of Define-Measure-Analyze-Design-Verify (DMADV), and for monitoring and improvement use 5 steps of Define-Measure-Analyze-Improve-Control (DMAIC). Description of these steps is given in Table 1.

Table 1: Steps in Six Sigma method.

Steps	Design	Improvement
1. Define	Define the project goals and customer needs	Define the defects and critical to quality
2. Measure	Measure customer needs and specification	Measure the level of defects and sigma
3. Analyze	Analyze the process options	Analyze the source of defects
4. Design/Improve	Detailed design the process	Perform improvement
5. Verify/Control	Verify the performance to meet customer needs	Control to eliminate defect

Critical to quality (CTQ) is a measurable characteristic of a product or process that has specification limits, in which the product or process is defined as conforming by the customer; otherwise it is defined as defect. A complex product or process can have more than one CTQs, which thus increase the number of opportunities of defect. Accordingly, Six Sigma implementation involves people with multidisciplinary backgrounds, and thus Six Sigma implementation is a group based quality improvement as in quality control circle (QCC) in Kaizen method. Moreover, authority in decision making makes Six Sigma implementation is performed in an integrated hierarchical arrangement called "people power" usually following organizational hierarchy, which is not common in Kaizen method. If necessary, external expert can be involved as "master black belt" with capability in practical and theoretical aspects of statistics.

## 3. IMPLEMENTATION AND DISCUSSION OF DESIGN FOR SIX SIGMA

KI produces cookies as "short dough" that is produced using mixed materials with low extensibility and elasticity. Short dough material usually consists more fat and sugar than water. The product is not only consumed for Indonesian market, but is also exported for 20 market in Asia and Pacific. Each market demand is specific, which thus lot of production for each market has its own specification. Today, KI is the biggest producer of cookies in Asia. In general, cookies production involves processes of material preparation, mixing, forming, baking and packaging. At material preparation process, all incoming raw materials are inspected and put into container in batch for mixing. The amount of ingredient for each batch is determined by R&D division to be suitable to specific customer needs.

At mixing process, bulk and solid ingredients are put into mixing container and are mixed using rotary mixer for 22 minutes using horizontal single arm peerless mixing machine. Afterwards, mixed ingredients are put into a container and sent to forming process. The weight of each batch of mixed ingredients is 1000 kg. Forming process is started with rolling process to form a layer with certain thickness. Rotary moulder is used to form cookies with certain dimension and texture. Formed cookies are then put on conveyor for baking process. The baking machine long is 100 m that is divided into 6 baking zones with different temperature. Subsequently, operator takes sample for each batch to observe visually the required texture and to measure cookies diameter and thickness. If ten samples are found as non-conforming, then all products in one batch are considered rejected. After baking process, cookies are transferred to sandwiching using long conveyor for cooling. The major production at KI is sandwich cookies with certain filler such as cream, chocolate, peanut butter or jam. Diameter and thickness are critical for packaging. KI uses fixed packaging in order to assure from damage in storing before it is opened by customer. This fixed packaged requires a certain precision of cookies dimension to be fitted to the package dimension. Table 2 exhibits some critical parameter of each process to assure the quality of the product.

Table 2: Critical parameter for each process.

Process	Critical parameter	Method of inspection
1. Mixing	Temperature	Thermometer at 3 location
2. Forming	Weight	Digital weigh scale for each sample
3. Baking	Water content	Water content analyzer
	pH	pH meter
	Weight	Digital weigh scale
	Dimension	Digital caliper for thickness and diameter
	Color and texture	Organoleptic and visual
4. Sandwiching	Weight	Digital weigh
5. Packaging	Leaking	Vacuum tester
	Weight	Digital weigh scale
	Code of production	Visual

In this research, the focus is production of base cake; a piece of cookies with texture on one side and flat on the other side, and then will be assembled to form of sandwich cookies. At least three quality characteristics of a cookies are considered important, i.e. (i) texture, and (ii) hardness level. The main ingredients are flour, fat and sugar. Sugar is the main ingredient affecting elasticity and cohesiveness. Accordingly, sugar affects the rough texture of cookies due to high rate of evaporation during baking process.

### 3.1 Define

KI operates 4 production lines producing different types of cookies. Observation was done at line 3 since it was the lowest production rate, and thus observation and experiment had minimum impact to shop floor operation. Initial observation for 6 production weeks of historical data found that weight, thickness and moisture had low process capability. It was an indicator of the existence of problem in line 3. Further observation found some defects as exhibits in Table 3.

Table 3: Defects in line 3.

Defects	Source of defects
Dough	Can be detected after baking; composition of ingredients in a batch; speed of mixer.
Over/under weight	Can be detected after forming or baking; composition of ingredients in a batch that impact dough hardness; control of moulder knife by operator.
Texture	Can be detected after forming or baking; moulder defect; composition of ingredients in a batch that impact dough hardness.
Thickness	Can be detected after forming or baking; gap between moulder and moulder knife;
pH	Can be detected after baking; composition of ammonium and water; oven temperature.
Moisture	Can be detected after baking; composition of ingredients in a batch; oven temperature.

Defect of pH is considered affecting customer health, and thus all defects product should be eliminated. Brainstorming in Six Sigma team (involving 5 manager and engineer) resulted in a decision to start with improving process capability of weight and thickness. These defects determine the weight of each ingredients that can be directly converted into production cost of

finished goods as an important strategic decision. As long as the production cost does not exceed the limit, then newly defined composition of ingredients is allowable for production.

### 3.2 Measure

Initial observation indicated a low process capability, which thus the measure step was performed to find the current process capability. Before collecting data, repeatability and reproducibility analysis was done to assure the accuracy and precision of measurement tools. Overview of sampling procedure was done to assure that operator performs inspection correctly. The data was collected during the period of January to March 2012 under condition that the machines and equipment's were in good conditions. However, at the end of January 2012, moulder was replaced, and thus the data only cover period of February to March 2012. Using 10 measurements, it was found that weight scale biased for 0.04 g, and caliper biased for 0,002 mm. Calibration could not be performed and thus all measured data during observation were compensate to amount of bias. Before calculating process capability, all collected data were evaluated for its stability. Figure 1 and Figure 2 exhibits example of stability analysis of weight and thickness respectively. It was found that only few data in unstable condition which then were eliminated only if they were caused by special or assignable causes.

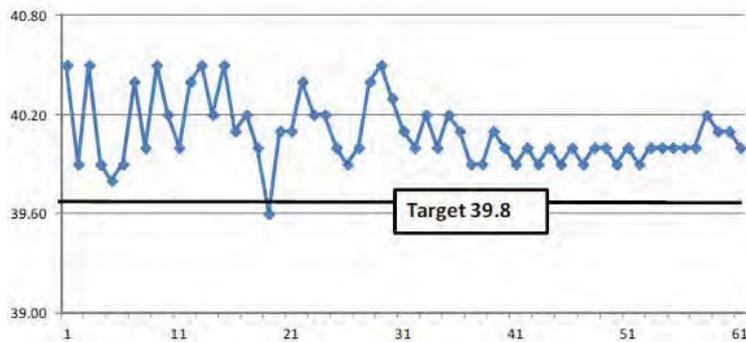

Figure 1: Example of data stability analysis of weight.

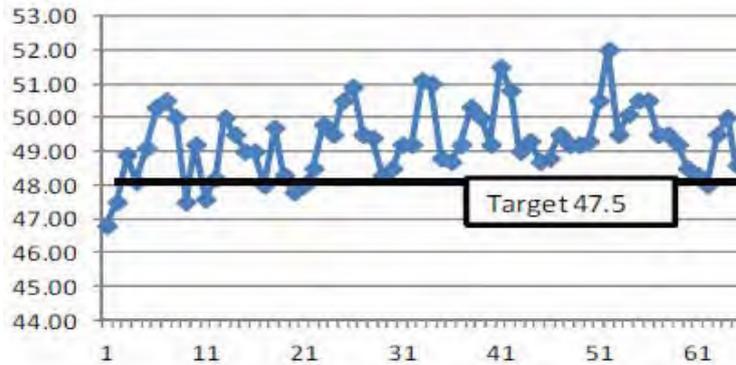

Figure 2: Example of data stability analysis of thickness.

Measurement of process capability used  $C_p$  or  $C_{pm}$  index as formulated in equation (1) and (2)

$$C_p = \frac{USL - LSL}{6\hat{\sigma}} \tag{1}$$

$$C_{pm} = \frac{USL - LSL}{6\hat{\sigma} \sqrt{1 + \frac{(\bar{X} - T)^2}{\hat{\sigma}^2}}} \tag{2}$$

where USL is upper specification limit, LSL is lower specification limit,  $\bar{X}$  is process mean,  $T$  is target value, and  $\hat{\sigma}$  is estimation of process standard deviation. For multiple characteristics, the standard deviation is a compound of standard deviation of weight and thickness. However, the team could not formulate multi response characteristics, and thus it is not necessary to analyze standard deviation as a compound standard deviation. KI determines specification limits of weight (37 g – 42.6 g), and for thickness is (46 mm – 49 mm). From the data it was found that estimate of standard deviation of thickness was

0.815 and estimate of standard deviation of thickness was 0.368. Bias of weight was 0.94, and bias of thickness was 1.21. Accordingly, process capability index of weight and thickness is given in Table 4.

Table 4:  $C_p$  or  $C_{pm}$  index of weight and thickness.

Factors	$C_p$	$C_{pm}$
Weight	1.14	0.75
Thickness	1.35	0.4

The capability process  $C_{pm}$  index of weight 0,75 was equal to 2.25 sigma level in Six Sigma measure, and  $C_{pm}$  index of thickness 0.4 was equal to 1.25 sigma level in Six Sigma measure, both with a possibility of deviation of 1.5 standard deviation. It can be concluded that the process capability of weight and thickness were low, and thus KI needed significant improvement.

### 3.3 Analyze

Different value between  $C_p$  and  $C_{pm}$  index indicated that KI had two problems caused in design and in manufacturing processes. Accordingly, Six Sigma with both approach of DMAIC and DMADV could come into consideration for improvement. To understand the low level of process capability, root caused analysis was done. At this stage, the Six Sigma team considered the use of defect material (called “meal”) to be used in the process. There was no standard of using meal for reuse in cookies production. Master formula and process operating guidelines (MFPOG) at KI only mention that meal can be used up to 80 kg, but KI did not have experience of using it.

Further analysis was conducted using FTA (fault tree analysis) and FMEA (failure mode and effect analysis) methods. From FTA, basic causes of low process capability were identified, i.e. no parameter for dough quality, calibration of measurement tools, inconsistent inspection procedure, and machine instability. From FMEA some potential causes were evaluated and found that the quality of dough had the highest risk priority number (RPN) compared to other causes. Accordingly, improving the quality of dough should have the highest priority. For this case, the use of meal was considered and at least two considerations were taken, i.e. conversion cost of ingredient composition, and (ii) health requirements. Brainstorming was conducted involving R&D division that resulted in permission for using defect dough material for health requirements. Further analysis was done to calculate the use of defect dough material to conversion cost and found that it was feasible.

### 3.4 Design

From the FMEA result, quality of dough was the main focus for improvement. The Six Sigma team discussed the suitable parameter to measure the quality of dough at mixing process and found that dough hardness was selected. Afterwards, the team preparing the measurement tool for dough hardness. Parameter dough hardness is also related to performance of moulder, which thus setting optimum value of dough hardness will determine the setting of moulder. To define the optimum level of dough hardness, a factorial experiment was designed.

Firstly, it was found that 11 factors affected the quality of dough, i.e. water, meal, mixing time, flour, vegetable oil, sugar, moulder speed, moulder knife gap, pressure of rubber roll, baking time, and oven temperature. Factors related to setting of machine or equipment was difficult to be included in the experiment. Some ingredients were also fixed, and thus only water, meal and sugar that were included as the variable of experiment. Using previous data, the level of experiment variable is given in Table 5.

Table 5: Level of experimental variables.

Variables	Low Level (-) in kg	High Level (+) in kg
Water	65	70
Meal	0	80
Sugar	138.85	277.7

Before performing the experiment, some preparations were made including raw material, experimental schedule, and experimental operator. For 3 factors in factorial experiment, 16 runs are required and performed randomly for two replications [9], and the result is given in Table 6. From this result water and meal were significant which was shown by p-value near zero and their main plot is given in Figure 3. Three combination of low level of water with high level of meal (run 5, 7 and 8) produced to hard dough hardness, and contrariwise four combinations of high level of water and low level of meal (run 2, 4, 11, and 15) produced to soft dough hardness, both were out of specification.

Table 6: Experimental results.

**Factorial Fit: Hardness versus Water, Meal, Sugar**

Estimated Effects and Coefficients for Hardness (coded units)

Term	Effect	Coef	SE Coef	T	P
Constant		2.5038	0.05416	46.23	0.000
Water	-1.3465	-0.6732	0.05416	-12.43	0.000
Meal	1.2113	0.6056	0.05416	11.18	0.000
Sugar	-0.2154	-0.1077	0.05416	-1.99	0.082
Water*Meal	-0.3359	-0.1680	0.05416	-3.10	0.015
Water*Sugar	-0.0714	-0.0357	0.05416	-0.66	0.529
Meal*Sugar	-0.0665	-0.0332	0.05416	-0.61	0.557
Water*Meal*Sugar	0.2083	0.1041	0.05416	1.92	0.091

S = 0.216632 PRESS = 1.50174  
 R-Sq = 97.36% R-Sq(pred) = 89.53% R-Sq(adj) = 95.09%

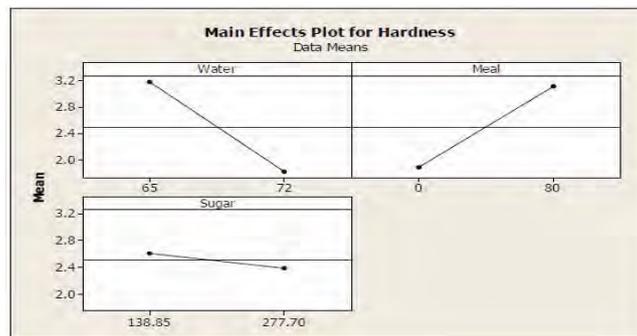

Figure 3: Main effect plot.

**3.5 Verify**

From the experiment, water and meal significantly affected dough hardness. More water reduced dough hardness but more meal increased dough hardness. There was no interaction between water and meal, and thus both factors affected dough hardness independently. Among experimental run, it was found that high level of water produced cookies weight closed to target (41.51 g) but was still higher than the target 39.8 g. However, if the meal was set at its higher level the weight was 41.46, slightly closer to the target, but had more variance (unstable). The effect of meal to the cookies thickness was not significant. This experiment verify that the use of meal as a reuse green manufacturing effort had a chance for production in the future, but detail experiment to find the optimal setting of using portion of meal still have to be done.

**4. CONCLUSION**

Concerns and practical efforts for green manufacturing processes are growing. This paper deals with an effort to reuse a certain amount of defect dough material known as meal, which supports implementation of green manufacturing. This effort is concurrently aimed at improving the quality of cookies using Six Sigma DMADV method. A factorial experiment method was performed at the design step of Six Sigma and found the possibility of using meal as reuse material. At the verify step, it can be concluded that the use of meal as an effort in green manufacturing had a chance for better production in the future, especially to improve cookies hardness. Further detail research is still to follow in order to set the optimal setting of amount of meal in the mixing process to produce the best product quality.

# Manufacturing Cycle Time Reduction For Product Flavors Food And Tobacco At PT IFF Indonesia Using Six Sigma

Rahmat Nurcahyo<sup>a</sup>, Ade Rahman<sup>b</sup>, Ricky Firdaus<sup>c</sup>

<sup>a, b, c</sup>Faculty of Engineering, University of Indonesia, Depok 16424  
E-mail : rahmat.nurcahyo@yahoo.co.id

## ABSTRACT

Cycle time is the time it takes a process from start to finish the process. Reducing manufacturing cycle times have an impact on increasing productivity, capacity, and production. Six Sigma is a management tool that focuses on reducing variation to explore the company's overall production system. The purpose of this research is to reduce manufacturing cycle times in food and tobacco flavorings products by using the six sigma through DMAIC cycle and implementation of DMA (Dynamic Material Allocation). Based on the results of a study of the manufacturing cycle time reduction in flavors food and tobacco products can be deduced that by using the six sigma method and DMA as improvement, to reduce cycle time from initial sigma value of 1.45 to 3.43 and reduced manufacturing cycle times from an average of 1.775 hours 2.985 hours.

## Keywords

*Cycle time, six sigma, DMAIC*

## 1. INTRODUCTION

Increasing of industry developments lead to every company should have a competitive advantage in improving customer satisfaction. One of the factors that can increase customer satisfaction is the reduction of cycle time. Cycle time is the total elapsed time to complete an operation or set of operations. Reducing manufacturing cycle times have an impact on increasing productivity, capacity, and production.

IFF PT Essence Indonesia is engaged in a flavor for food, beverages, and tobacco in smoking and also produced perfume products. Actually the company is already implement continuous improvement principle on its quality management system through the implementation of ISO 9001:2008 quality management system. However this system only puts on continuous improvement efforts based on consciousness independent of management. The system does not give the right solution is supposed to result in dramatically improved to the level of zero defects and cycle time reduction.

To reduce cycle time and level of defect in IFF PT Essence Indonesia can be done by using Six Sigma. Six Sigma is a method in the field of quality management. Six Sigma is a rigorous, focused, and highly effective implementation of proven quality principles and techniques which has the goal to eliminate defects in production, clamping production time and reduce costs. Incorporating elements from the work of many quality pioneers, Six Sigma aims for virtually error-free business performance (Pyzdek, T., Keller, Paul A., 2003:3). Six Sigma can be used as measures of performance industrial systems that enable the company to perform a remarkable improvement with the actual breakthrough strategy.

Six Sigma can also be viewed as controlling industrial process that focuses on the customer by taking into account the ability of the process. Achieving six sigma there are only 3.4 defects per million opportunities (Pyzdek, T., Keller, Paul A., 2003:7). The higher sigma level is achieved then the industry is improving system performance.

The purpose of this research is to reduce manufacturing cycle times in IFF PT Essence Indonesia as an effort to improve productivity, production capacity.

## 2. BASIC THEORY

### 2.1 Flavors

Production at IFF-PT Essence Indonesia is divided into 2 parts, namely the production of flavorings and the production of perfume. Production part of flavor is divided into 3 divisions: powders, liquids, and extract division. Production liquid division produces flavorings in the form of emulsion and non-emulsion. Flavor emulsion used as cloudifier, and flavors of the syrup. Non-emulsified flavorings are used to flavor foods and beverages and tobacco flavorings for cigarettes. Equipment used to produce the flavor of food / drink is distinguished by the equipment used to flavor tobacco production because the production

of tobacco flavorings usually use alcohol solvent so that is feared to contaminate the taste of food / beverage that must meet legal criteria.

## 2.2 Six Sigma

Since 1920's, the word 'sigma' has been used by the mathematicians and engineers as a symbol for a unit of measurement in a variety of quality products (Note sigma is written in lower case 's' as used in the context of units of measurement in general). In the mid 1980s, engineers at Motorola Inc., USA using the 'Six Sigma' as an informal name for the company's initiative to reduce errors in the production process, because it reflects the high level of quality as appropriate (Tennant, Geoff, 2001:6). (Note, the use of the word Sigma is here written with a capital letter 'S' for Six Sigma in this context is the name of 'brand' for the initiative Motorola.). Motorola is one of many U.S. and European corporate where they launch the product (along with food and other snacks) eaten by the competition from Japan. And the leader of Motorola's terrible to admit that the quality of their products. Like many companies at that time, Motorola did not have a quality program. Motorola has several programs, but in 1987, out of a new approach of Motorola's communications sector, at the time headed by Georghi Thiler who later became a top executive at Kodak, innovative improvement concept was "six sigma" (Pande, P.S., R. P. Neuman and R. R. Cavanagh, 2000:7).

Sigma is taken from 18<sup>th</sup> from the Greek alphabet ( $\sigma$ ), and used in the statistical sciences as a symbol standar deviation. The term "Six Sigma" itself comes from the understanding that if a value in a state of  $6\sigma$  between the midpoint closest to the limit deviation, can be said practically no product will not fail.  $6\sigma$  process control approach from Motorola allow for a shift in the average value from industrial processes amounted to  $\pm 1.5 \sigma$  that will generate the level of discrepancy of 3.4 per million opportunities (3.4 DPMO = defects per million opportunities), meaning that every one million opportunities 3.4 will have the possibility of incompatibility (Tennant, Geoff, 2001:25). This differs from the concept of  $6\sigma$  theory calculated based on the normal distribution centered will generate the level of mismatch of 0.002 DPMO .

Six Sigma has two key methodologies: DMAIC and DMADV, both of them take the concept of the PDCA cycle (plan-do-check-act) of W. Edwards Deming. DMAIC is used to improve business processes that are running, and DMADV used to create a new product or process design for defect-free performance (De Feo, Joseph A.; Barnard, William, 2005).

DMAIC is defined as (De Feo, Joseph A.; Barnard, William, 2005):

1. Define, determine the topic of problems.
2. Measure, measure the performance of processes that are running.
3. Analyze, analyze weaknesses in the process (such as the sources of disability), and makes the weaknesses in these processes as opportunities for improvement.
4. Improve, make improvements to the performance of the processes that had been weak.
5. Control, control performance of the processes that had been repaired to maintain profits.

## 2.3 Cycle Time

Cycle time is the time it takes an operator to complete one cycle of work includes to perform manual labor and walk. Sometimes defined as the time required to produce one unit of product, in this case is determined from the longest process (bottleneck), whether human or machine work.

Hansen & Mowen (1996:412), defines a cycle time as " Cycle time is the length of time it takes to manufacture a product (time dividend by unit of product)." To improve the performance of the company then the company needs to make continuous improvement in its business activities primarily in the production activity because this activity plays a pretty big company. In this production activities must have a benchmark that is by using cycle time and speed. This benchmark is important because it is an essential to measure the ability of the company in terms of increased production capacity based on time.

## 3. RESEARCH METHODOLOGY

This research will be done with the Six Sigma methodology as follows:

1. Define. Begin with determine project time and customer voice, creating a process map, SIPOC and Top Down Chart.
2. Measure. This steps are: manufacturing cycle time data collection, normality test and initial baseline measurement.
3. Data Analysis. The processing and analysis of data that have been taken using six sigma tools, which use Pareto Diagram, Cause and Effect Diagram and Pouring Analysis.
4. Improve. This phase consist of DMA / Modify preparation fixbin
5. Control. Consist of Run Chart.

## 4. DATA COLLECTION AND PROCESSING

#### 4.1 Define

Phase define a first stage in the implementation of six sigma methodology. In this phase, the author defines some important terms that describe the conditions or problems that would become the object of research. Some important things are define opportunities, voice of customers and mapping process that applies to PT IFF Indonesia. Objective of define opportunities is to define or identify and validate improvements will be made, prepare an effective team, determine customer requirements, and illustrate the business process.

##### 4.1.1 Team Charter

Making the team charter is an importance in define phase because it aims to establish and validate the team charter.

##### 4.1.2 Voice of Customer

Voice of customer is an important part in the work process that is observed. Voice of the customer obtained from brainstorming with all employees contained in the production department and the results of meetings between management and leadership.

There are several major problems that cause customers feel not satisfied and complained of condition to the production. The problem in question is not yet rated companies to meet the demand for customer orders quickly, especially when customers want a rush order. It should be considered in translating VOC into the CCR's (Critical Customer Requirements).

##### 4.1.3 Process Map

The next stage is to determine the process map to understand the importance of determining the business processes, SIPOC diagrams, and top-down charts.

Here is the map production process:

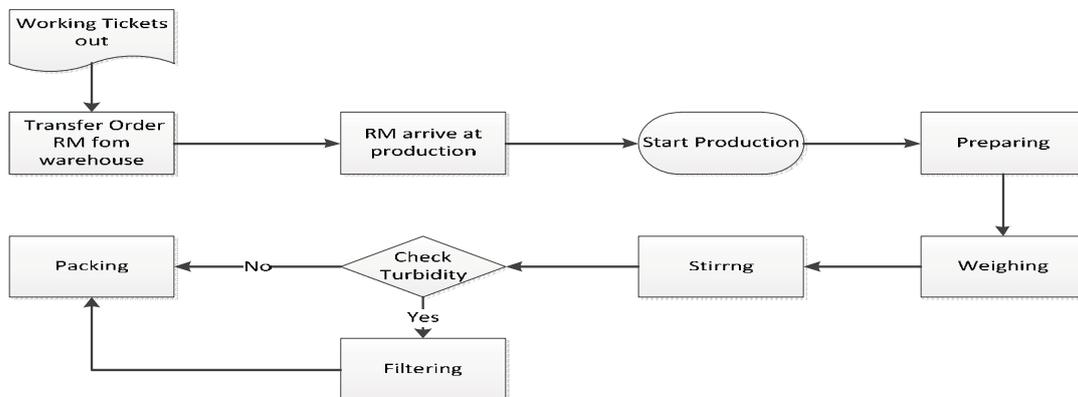

Figure 1: Manufacturing Process Map

##### 4.1.4 SIPOC

After known map process the next stage to determine SIPOC diagram. The steps to create SIPOC are as follows:

- Specify the name of the process
- Determine start and end points
- Specify output
- Determine customer
- List the main steps in the process
- Define input
- Determine supplier

<b>Project Name:</b>	<b>Manufacturing Cycle Time Reduction</b>
<b>Date:</b>	

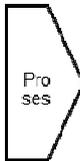

<b>Prepared By:</b>				
<b>Notes:</b>				
Suppliers	Inputs	Process	Outputs	Customers
RM Supplier	Raw Materials		Finished Product	Customer
Production Scheduler	Shop Floor Paper			
City electricity	Electricity			
Manufacturer	Equipment			
Air Conditioner	Temperature			
Suppliers	Packing Material			
	Compounder			
	Operators			

Figure 2: SIPOC Diagram

### 4.1.5 Top Down Chart

The next stage after making SIPOC is to determine the top-down chart which is a simple description of the process, using a top-down chart because it has two levels of levels that can explain the process. The first level is a major step in the process, while the second level is a list of sub-processes for each of these key processes.

Top-down chart serves to determine the factors that influence the production cycle time of this phase where we will get input, process and output indicators to be used as a measurement stage.

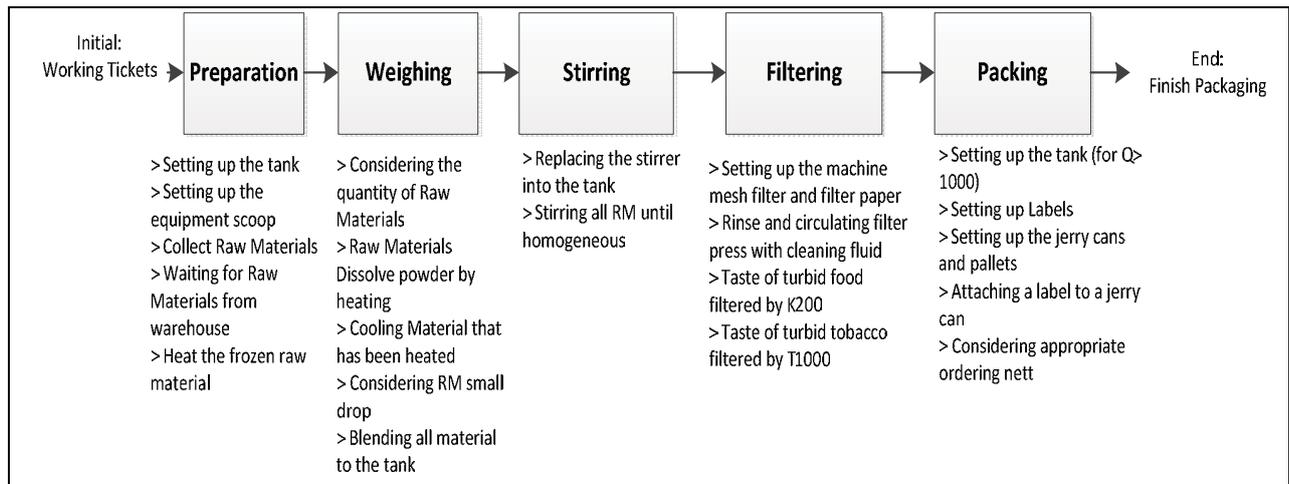

Figure 3: Top Down Chart Manufacturing Cycle Time

## 4.2 Measure Phase

After the voice of customer is translated into a critical part in the quality after that mapping the processes, then the next stage is to measure phase. Measure phase is a second phase in six sigma methodology. In this phase, the work process will be measured its ability to produce output based on the incoming input

### 4.2.1 Working Tickets Measurement

Data were collected during the twenty working days beginning on May 26<sup>th</sup> 2010 to June 18<sup>th</sup> 2010. During the twenty working days, the authors note that the number of working tickets produced for the flavor of food and tobacco are 75 tickets. Based the data of working ticket obtained as specified below.

Table 1: Results of Measurement Working Ticket

Parameter	Before Improvement
Sigma Level	1,45
Mean (hours)	2,985
Median (hours)	3,07
Modus (hours)	3,33
Standard Deviation	1,053
<i>p</i>	0,086
<i>n</i>	75
Preparing (hours)	32,34
Weighing (hours)	71,58
Stirring (hours)	30,3
Filtering (hours)	21,72
Packing (hours)	22,56

#### 4.2.2 Process Measurement Baseline

During the twenty days of observation obtained total Working tickets were observed is 75 Working tickets.

From the calculation results obtained defect rates by 52% so that the yield obtained at 0.83. Based on the obtained value of 173,333.33 DPMO and sigma value of 1.45. This indicates that process has outputs to the achievement of quality that is not fully optimized.

#### 4.2.3 Cause And Effect Diagram

To identify the root causes of the manufacturing cycle time used causal diagrams. This causal diagram is used to identify the root causes of a problem so that collective action can be taken to eliminate the cause.

#### 4.2.4 Cause and Effect Matrix

From the parameters of a causal diagram that was created, the next stage is to create a matrix of cause and effect of these data, in order to determine which data will be made to the measurement plan. Cause and effect matrix in this cycle time reduction can be seen in Table 4.

Table 2: Cause and Effect Matrix

No	----- Input/Process Indicators -----	Output #1	Output #2	Output Indicators	Measurement Plan
		10	10	Importance	
		Frequency of Occurrence	Overall Cycle Time		
		----- Correlation of Input to Output -----		----- Total -----	
3	Loss RM	9	9	180	Yes
5	Preparation	9	9	180	Yes
12	Filtering	9	9	180	Yes
19	Weighing	9	9	180	Yes
20	Packing	9	9	180	Yes

#### 4.2.5 Measurement Plan

After getting input / process indicators of the most influential, then we made measurements of the input plan. Measurement plan in this cycle time reduction can be seen in Table 5.

Table 3: Measurement Plan

No	Input/Process Indicators (X)	Operational Definition	Links to (Y)	Sample Size
1	Preparation time dan Material Loss	Time of Receiving Tickets compounder working until ready to weigh	Preparation time and time weighing Materials	75 Working tickets
2	Filtering	The time required from preparation to completion filtration filter machine	Filtering time	75 Working tickets
3	Weighing	The time needed compounder from start weighing raw materials until the beginning of the stirring	Weighing time	75 Working tickets
4	Packing	The time it takes operators starting from finished goods over the stirring until complete packing	Packing time	75 Working tickets

From that measurement plan we obtained the overall results as follows in table 6.

Table 4: Overall Results of the Measurements (in hours)

Input Indikator	Total Time	Mean	Modus	Median	Standard deviation
Preparation time dan Material Loss	40,44	0,54	0,50	0,50	0,25
Filtering	27,12	0,36	0,25	0,33	0,20
Weighing	89,49	1,19	1,00	1,00	0,66
Packing	28,24	0,38	0,25	0,33	0,25

## 5 DATA ANALYZE

Analysis of the data processing in this study, also the analyze and improve phase in six sigma methodology. The author uses data analysis and process analysis to identify what factors are affecting the manufacturing process cycle time.

### 5.1 Analyze Phase

#### 5.1.1 Analysis Using the Pareto diagram

The data from measurement phase is analyzed in advance using pareto diagram to know the longest stage which resulted in increased cycle time. Here is the result of cumulative data from 75 Working tickets analyzed. From the results of Pareto diagram can be concluded that 70.1% comes from the source of problems:

1. Weighing
2. Preparation time

To overcome the root cause is then necessary to determine the appropriate solution. For the weighting factor can be overcome with the purchase of new scales to cope with time while the preparation can be done through the regular preparation of the material in accordance with the frequency of usage.

#### 5.1.2 Pouring Analysis

Pouring analysis is an analysis of the casting material according to a certain quantity, this analysis is based on material consumption during the last 6 months. The data used is data in the period 1 January 2010 to 30 June 2010.

Pouring analysis was carried out on the shelves of material M, L, F, G, H, and Cool Room. With a neat placement of material compounder will more easily perform weighting in accordance with the materials listed in the Working ticket.

Pouring analysis was performed using the SAP transaction in the transaction ZDMA. The result is extracted into Microsoft Excel, and then analyzed. Here is a chart analysis conducted where results will be processed as a stage further improvements can be seen in table 7.

Table 5: Analysis of Pouring Shelf M, L, F,G,H

No	Input/Process Indicators (X)	Data Source and Location	Data Used	Sample Size
1	Placement of materials based on frequency of use	ZDMA Transactions in SAP from the rack (M, L, F, G, H)	Based on the usage of raw materials 6 months (1 January to 30 June 2010)	All raw material in rack M,L,F,G,H

## 5.2 Improve Phase

Improve phase, as described on the basis of theory, has the objective to find a solution to be implemented in order to create an amendment. The solution is an act which is considered able to eliminate the barriers that have been described in the analysis.

### 5.2.1 Measurement Improvement Results

After improvement is carried out measurements of the Working tickets with the same assumptions as the baseline measurement. The result can be seen in figure 9.

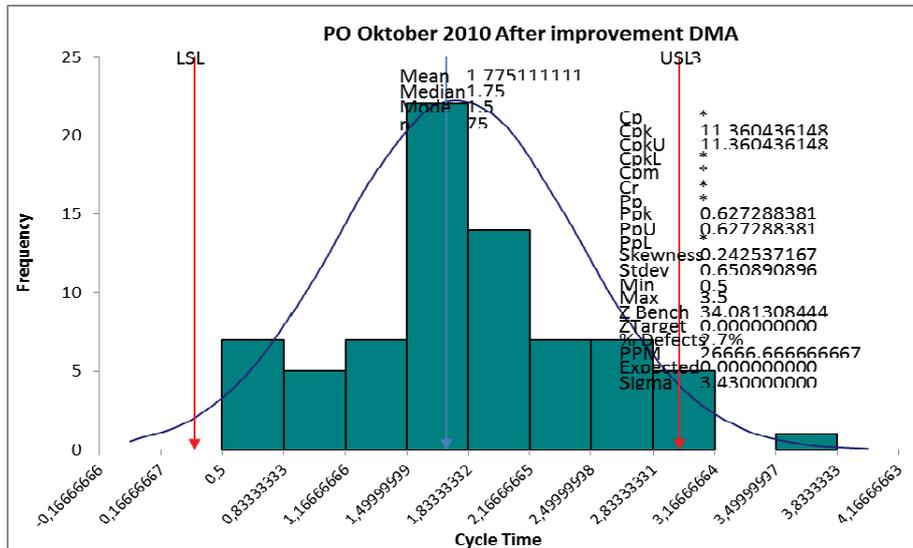

Figure 4: Sigma Level Oktober 2010 After Improvement

From the images obtained value of 3.43 sigma level. Thus an increase in the value of sigma from 1.45 to 3.43. The results are compared with the initial sigma measurement. The results can be seen in Table 11.

Table 6: Comparison of Sigma Level

Parameter	Before Improvement	After Improvement	Increasing
Sigma Level	1,45	3,43	1,98
Mean (hours)	2,985	1,775	-1,21
Median (hours)	3,07	1,75	-1,32
Modus (hours)	3,33	1,5	-1,83
Standard Deviation	1,053	0,651	-0,402
<i>p</i>	0,086	0,131	0,045

### 5.3 Control Phase

Control phase is the last stage of the analysis of Six Sigma projects that emphasize documentation and dissemination of action that has been done.

At this stage of control the thing done is to make a run chart of the Working ticket october 2010. At this stage the run chart serves to monitor the results that have been conducted over the use of six sigma method.

## 5 CONCLUSION

Based on the results of a study of the manufacturing cycle time reduction in flavors food and tobacco products can be deduced that by using the six sigma method and DMA as improvement, to reduce cycle time from initial sigma value of 1.45 to 3.43 and reduced manufacturing cycle times from an average of 1.775 hours 2.985 hours.

## ABSTRACT

To be competitive, every industry in manufacturing or services are increasingly required to be able to produce goods or services economically, and can deliver products on time according to customer needs. It occurs in a company that produces IMV Type of Drum Brake, which have problem with wastes as research object. The company's strategy to reduce or eliminate wastes in its production is to apply the concept of lean production, as both a method and philosophy. Methods and tools used to identify and analyze the production of this waste, consist of Waste Relationship Matrix (WRM), Waste Assessment Questionnaire (WAQ) and Value Stream Analysis Tools (VALSAT). The end result is the production line gets more streamlined (lean) and improvement in production performance according to the proposed VSM.

## Keywords

*Lean Production, Waste Relationship Matrix, Waste Assessment Questionnaire and VALSAT.*

## 1. INTRODUCTION

A manufacturing company that focused in production of car components, and produce brake for two-wheels vehicle (two wheels) and four wheels, is PT. Akebono Brake Astra Indonesia, now is keep trying to improve its competitiveness both for domestic and export markets. The strategy pursued by company to make it happen is through the implementation of lean manufacturing concepts, to improve the operating system and continuous improvement by reducing or eliminating the wasteful at operation stages.

On the concept of lean production or lean manufacturing, production processes that do not provide added value for example can be seen from the accumulation of raw materials and intermediate goods (WIP) on production floor, it cause by bottleneck. Bottleneck can occur due to imbalance time of processing on production that where there is a process that requires a longer time than other processes.

One cause of the length of time the process is due to the inefficiency of the management of existing resources. Therefore, the factors that have contributed in it, such as human resources, machines, materials, etc. should always be evaluated whether it was relevant to the business that is run or the need for revision/repair [1].

Process efficiency improvement should be conducted in accordance with the capabilities and resources available in the company. Because of that needed is an approach that is relatively simple and well structured to be easily understood, such as the approach of Lean Manufacturing.

## 2. LITERATURE REVIEW

Technique of "lean manufacturing" can help companies to become competitive, especially in terms of reduction wastes in their operation process. Lean manufacturing is defined as reducer from waste in any form/conditions to maximize the value-added activities [2]. Meyers dan Stewart (2002) explain that Lean means an effort by all elements of the company to eliminate the wastes together and it is one of tools that can be used to achieve optimum company's competitive advantage [3].

In recent years, the concept of lean has a lot to get a positive response from various types of businesses, not only in manufacturing but also in businesses of service sector. Some research show that lean production can increasing productivity, quality, and responsiveness of firms to be high [5].

Lean manufacturing should begin with a perfect understanding of business processes, not only production process and material flow but also information flow. One tool that extremely affordable and simple are often used to capture this information is VSM (Value Stream Mapping) [6].

Various types of information are uniquely displayed in Current State Map, such as information flow using a paper or electronic, cycle times, changeover times, amount of inventory, machine uptime, and amount of worker, but all the things that is often overlooked. With the lean approach, flow of information and raw from company are described with value stream mapping. So that it can be discovered with an overview of the existing waste. The main purpose of VSM is to understand and document (all the) current state (existing condition) and then produced a Proposed State Map that led to improvement in the process itself [7].

### 3. METHODOLOGY

The purpose of this research was to obtain a design of Lean Production System in production line for the type IMV of drum brake from company. Steps performed in this research, as shown in Figure 1, consist of eight stages:

1. Identify the problem through observation, interviews, and the preliminary data required.
2. Calculate the standard time of each process.
3. Make the current state map (CSVSM).
4. Collecting data to find relationships between the wastes in the company by using Waste Relationship Matrix (WRM).
5. Perform the weighting of the WRM to know the weight or the magnitude of the relationship between wastes.
6. Make Waste Relationship Matrix (WRM).
7. Perform the weighting of waste assessment questionnaire with used algorithm of Waste Assessment Questionnaire (WAQ).
8. Analyze effect between wastes by using VALSAT.

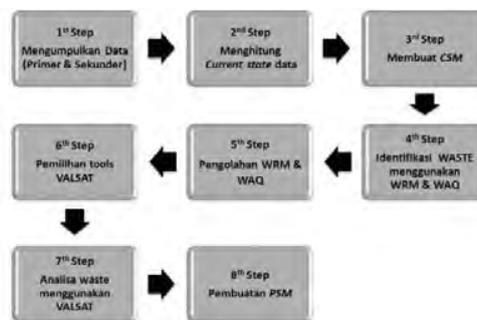

Figure 1. Flow of research

Area of research focuses on the backing plate assembly line that makes the brake drum type IMV for four-wheel vehicles, which consists of three work stations; those are backing plate welding work stations, work stations riveting and nut welding.

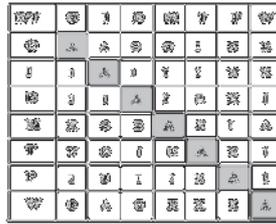

The first step, is taking measurements and collecting data in order for calculate the data needs to make current state map value stream map (CSMVSM). VSM is tool from lean manufacturing that for the first derived from the approach of Toyota Production System (TPS) which is known as “material and information flow mapping” [8]. Rother dans Shook (1999) define VSM as a powerful tool that not only can identify process inefficiencies, but also can be a guide in making improvements [9].

Jones dan Womack (1998) mention that VSM is a mapping flow of information and material which aims to set up methods and performance are better in a proposed future state map. This tool gives information flow of information and physic in system. In addition, the condition of production system such as lead time as required can also be described from each process characteristic that occurs [10].

After knowing the condition of production line through visualization of current state map value stream map, the next step to identify wastes used Waste Relationship Matrix (WRM) and Waste Assessment Questionnaire (WAQ). Use of the VALSAT techniques to analyze waste that occurs in a production line requires a proper weighting method so that tools selection and their correlation with wastes would be appropriate. Therefore, WRM & WAQ is used as a means to measure quantitatively relationship and types of waste that occurs in the production chain.

WRM is a matrix consisting of rows and columns. Each row shows the influence of each of six types of waste to other waste. Each column shows the waste that is affected by other waste. Diagonal matrix shows the relationship of the highest [11]. This indicates that each waste has a great relationship with itself.

Table 1: The Waste Relationship Matrix (WRM)

Explanation:

O = Overproduction  
 I = Inventory  
 D = Defect

M = Unnecessary Motion  
 T = Over transportation  
 P = Inappropriate process  
 W = Waiting

Table 2. Range Division of relationship between wastes

Range	Relation	Symbol
17-20	Absolutely necessary	A
13-16	Especially important	E
9-12	Important	I
5-8	Ordinary Closeness	O
1-4	Unimportant	U

While the Waste Assessment Questionnaire (WAQ) was made to identify and allocate the waste that occurs in the production line (especially the job shop type), Waste Assessment Questionnaire consists of 68 different questions, which represent the activity, condition or behavior in a specific production floor that can generate waste. Some questions are regrouped into a kind of "From" which means that the question refers to all types of waste that occurs which may lead to or result in the type of different waste. While the other questions that represent the type "To" which means all types of waste generated by other waste [11]. Each question consists of three pieces of the answer with their respective weights: 1, 0.5 and 0. Questions are categorized into 4 groups: man, machine, material and method.

Algorithm equations used to calculate tabulated in WAQ is using the following equation:

$$S_j = \sum_{k=1}^K \frac{W_{jk}}{N_i} \quad (1)$$

$$Y_j = \frac{S_j}{S_j} \times \frac{f_j}{F_j} \quad (3)$$

$$s_j = \sum_{k=1}^K X_k \times \frac{W_{jk}}{N_i} \quad (2)$$

$$Y_{jfinal} = Y_j \times P_j = \frac{S_j}{S_j} \times \frac{f_j}{F_j} \times P_j \quad (4)$$

Explanation:

$S_j$  = Sum of values in each column under each type of wastes (score of the waste).  
 $s_j$  = New score after the multiplication weight of answer each type of wastes.  
 $Y_j$  = Initial indication factor of each type of waste.  
 $Y_{jfinal}$  = Final waste factor each type of wastes.

With WAQ we obtained sequence of waste that occurs in production line based on their respective weights. Waste that has the greatest weight to the first rank and so on. The results obtained weight of each waste will be used to obtain the appropriate analysis tools VALSAT.

Value Stream Analysis Tools (VALSAT) use as a tool for detailed mapping which focuses on the flow of value adding process. Details of this mapping can be used to find the cause of waste that occurs [12]. There are seven kinds of detail mapping tools are used, are:

### 1. Process Activity Mapping

This tool maps each step of activity that occurs from operation, transportation, inspection, delay, and storage, and then classify them into types of activities available ranging from value adding activities, necessary non value adding activities, dan non value adding activities.

### 2. Supply Chain Response Matrix

This graph illustrates the relationship between inventories with lead time that can be used to identify and evaluate the increase or decrease inventory levels and long lead time in each area at supply chain.

### 3. Production Variety Funnel

This tool is used to identify the point at which a generic product is processed into a number of specific products. In addition, this tool can also be used to indicate areas of bottleneck in the design process used to plan inventory policy improvements.

### 4. Quality Filter Mapping

It is a tool that is used to identify the location of the problem of quality defects in the existing supply chain. Evaluation of the quality loss is often the case made for short-term development.

**5. Demand Amplification Mapping**

To visualize changes in demand throughout the supply chain. Information can be used in decision making and further analysis, either in anticipation of a change request, to manage fluctuations, as well as the evaluation of inventory.

**6. Decision Point Analysis**

Shows the various options of different production systems, the trade off between lead time of each option with a level of inventory required to cover during the lead time.

**7. Physical Structure**

This tool is used to understand the supply chain at the level of production. It is necessary to understand the industry condition, how its operations, and in directing attention to areas that may not get enough attention to the development.

The use from seven tools based on the proper selection based on the company itself. Selection of appropriate engineering tools with each type of waste is based on the weight system, as shown in Table 3.

Table 3: Relationship between VALSAT and 7 Wastes

Wastes/structure	Mapping tool						Physical structure (a) volume (b) value
	Process activity mapping	Supply chain response matrix	Production variety funnel	Quality filter mapping	Demand amplification mapping	Decision point analysis	
Overproduction	L	M		L	M	M	
Waiting	H	H	L		M	M	
Transport	H						L
Inappropriate processing	H		M	L		L	
Unnecessary inventory	M	H	M		H	M	L
Unnecessary motion	H	L					
Defects	L			H			
Overall structure	L	L	M	L	H	M	H

Note:

- H = High correlation and usefulness (multiplier factor of 9)
- M = Medium correlation and usefulness (multiplier factor of 3)
- L = Low correlation and usefulness (multiplier factor of 1)

Meanwhile, to get a tool where appropriate in the mapping process, the selection matrix is used as Table 4.

**4. RESULTS AND DISCUSSION**

After all data has been collected and processed into the current state, further data was made current state map. This Current state map shows the actual conditions that occur in production floor as Figure 2.

In the current state map is shown Total Lead Time in the production of drum brake plate assy that come from the Cycle Time of each process to the material delay in the inventory and transportation time from one work station to work station to another. From the sum of these three variables we obtained Total Lead Time = 3.64 days. In the current state map is also seen that the greatest contribution that make the lead time of 3.64 days are inventory at the beginning and end of the process of painting, and painting processes are carried out by the partner company which is for 3.5 days. Total value stream attribute the current state map can be seen in Table 5.]

Next step is to identify and analyze the waste in the backing plate assembly area that consists of three working station ie, backing plate welding (BDW-1), riveting (RVT-1) and nut welding (NWD). Material flow and cycle time of each process can be seen in Figure 2 the current state map.

**Result and Discussion of WRM.** On Table 6. can be shown that the from over production and from defect have the greatest percentage of 17.9%, which means that over-production waste and defects in the event have a considerable influence to cause another waste.

Table 4: Matrix of VALSAT Selection

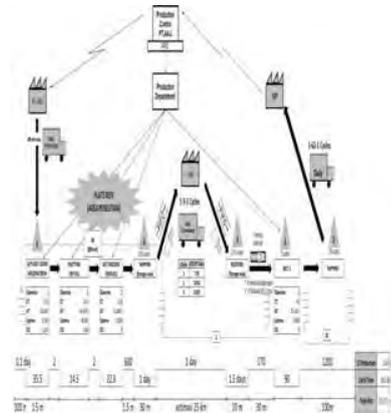

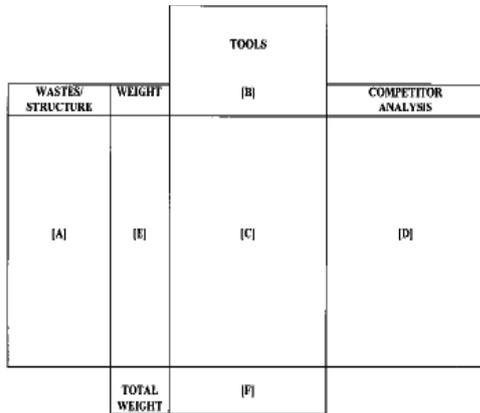

Figure 2: Current state map

Table 5: Metrics Current State Map

Metric	Baseline
Total Value stream Inventory	655 units
Total product cycle time	162.8 seconds
Total value stream lead time	3.64 days
Uptime	96.4 percent

Meanwhile, to inventory has the greatest percentage of 19.4% which indicates that the waste from inventory is the most waste resulting from the other waste. On the other hand inventory just resulted another waste of 12.7%.

**Result and Discussion of WAQ.**

In Table 7 it is found that the biggest waste caused by the inventory has a percentage of 20,41%. The second Waste is motion with 17.97%, and overproduction in the sixth with a 13.08%

Table 6: Waste Relationship Value

F/T	O	I	D	M	T	P	W	Score	%
O	10	10	6	8	8	0	6	48	17.9
I	4	10	4	8	8	0	0	34	12.7

P <sub>i</sub> factor	239.86	246.38	281.03	218.44	189.23	80.4	163.28
Final result (Y <sub>final</sub> )	118.19	184.40	119.25	162.35	137.06	62.22	119.94
Final result (%)	13.08	20.41	13.20	17.97	15.17	6.89	13.28
Rank	6	1	5	2	3	7	4

**Result and Discussion of VALSAT.** After getting the final results of the weighting process by using WRM and WAQ, the next step is selection of detail mapping tools appropriate to type of waste that occurs in the company. This selection process is done using VALSAT. Table 10. Shows the mapping tool according with waste type that occurs.

**Use of VALSAT**

Weight (bobot) that had been previously obtained through an assessment process using the WRM and WAQ, then calculated again using selection matrices for seven of VALSAT. Final calculation of matrix selection of seven VALSAT indicated on table 8.

From table 8 can be obtained the process activity mapping ranks first with a score 567.27, the second is supply chain response matrix with score 360.41, and the third is demand amplification mapping with score 262.78. Selection is made on two VALSAT analysis tools that have the greatest scores are obtained, the process activity mapping and supply chain response matrix.

From Table 9 then classified based on the activities of the value-added activities (VA), which is not value-added activities, but still needed (NNVA) and activities that have no value at all (NVA). Of the grouping can be known what the most dominant activity occurred on a production line backing plate assembly.

Table 8: Selection Result of VALSAT

Value	Weight	Mapping						
		Process Ability Mapping	Supply chain responsiveness	Production Validity	Quality Filter Mapping	Direct application Mapping	Discrepancy analysis	Physical status Mapping
Operational	133	133	325	0	133	325	325	0
Inventory	241	623	330	623	0	330	623	241
Defect	130	130	0	0	130	0	0	0
Unrecovery	129	129	0	0	0	0	0	0

<b>TOTAL</b>	<b>927</b>	<b>3041</b>	<b>957</b>	<b>137</b>	<b>228</b>	<b>1420</b>	<b>333</b>	

Table 9. Process Activity mapping backing plate assembly

No	Aktivitas	Area/Mesin/Alat	Jarak (meter)	Waktu (seconds)	Jumlah Operator	Aktivitas					VA/VA/NNVA
						O	T	I	S	D	
1	Kedatangan bahan baku	Mobil Box	100	2400	1		x				NNVA
2	Menunggu antrian untuk di proses			1200							NVA
3	Transfer ambil bahan baku ke mesin	Manual	1.5	20			x				NNVA
4	Setting mesin			90				x			NNVA
5	Ambil dust cover letakkan pada jig			2.5			x				NNVA
6	Ambil backing plate letakkan pada jig			5	1 (operator yang sama)		x				NNVA
7	Proses welding	Mesin BDW		27.5			x				VA
8	Ambil backing plate hasil welding letakkan di mesin			5			x				NNVA
9	Ambil assy anchor dan pasang pada backing plate			3			x				NNVA
10	Proses rivet	Mesin Rivet		7			x				VA
11	Menunggu proses rivet			8							NVA
12	Ambil backing plate taruh di elektroda			3			x				NNVA
13	pasang nut welding 1			1.2			x				NNVA
14	Proses welding	Mesin Nut welding		3.2			x				VA
15	Angkat backing plate pasang nut kanan pada elektroda			2			x				NNVA
16	Proses welding	Mesin Nut welding		3.2			x				VA
17	Ambil backing plate taruh di polybox			2					x		NNVA
18	Transfer Hasil nut welding ke fixed trolley	Manual	1.5	60				x			NNVA
19	Ambil polybox berisi backing plate taruh di pallet	Manual	1	60	1			x			NNVA
20	Simpun pallet di area before shipping menunggu untuk		30	180				x			NNVA
21	Menunggu untuk painting	Store		7 jam					x		NVA
22	Ambil hasil painting taruh area receiving	Forklift	30	120	1			x			NNVA

Based on table 10, the time required for the entire process on the backing plate assembly are 29402.6 second. Total activity in this process as many as 22 activities. Of the 22 activities, 11 activities are operation activities, six transport activities, two activities of storage and only a single delay and inspection activities. Only four activities are classified on activities that value-added (VA) or at 0139% of overall activity, while for value-added activities that are not at all (NVA) as much as three pieces with percentage is 89.82% from NNVA by 10.046%.

Supply Chain Response Matrix consists of two axes, which are axes of vertical and horizontal. Vertikal axis express cumulative inventory in each stage on supply chain, while horizontal axis express cumulative lead time to plan and move the product. The data required in making of SCRM on line of backing plate assembly as follows:

- The cumulative data of raw material arrival.
- The cumulative data of component production result in area of backing plate assembly such as WIP.

Average needs and material making of dust cover and backing plate is 720 units/days and 90 units/decision while lead time just one hour. Part of PPIC has determined inventory duration (day's physical stock) keep in level 0.25 days. Table 11 below described days of physical stock for two of raw material.

Graph 1 shows lead times supply in production area of backing plate assembly during 1.1 days while the duration of inventory in system is 2.35 days so the total of response time supply in system is 3.45 days.

Table 10: Total Percentage Activity VA, NVA, NNVA

Aktivitas	Jumlah	Waktu (second)
Operation	11	62.6
Transport	6	2840
Inspection	1	90
Storage	2	25202
Delay	2	1208
VA	4	40.9
NVA	3	26408
NNVA	15	2953.7
<b>TOTAL WAKTU (second)</b>		<b>29402.6</b>
% VA		0.139
% NVA		89.815
% NNVA		10.046

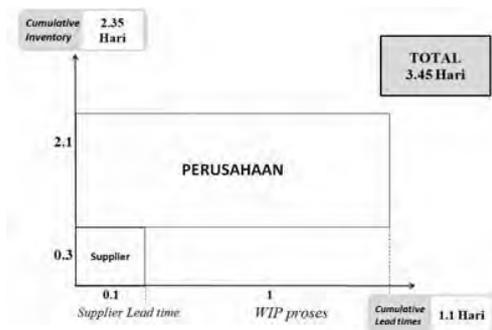

Table 11: Days Physical Stock and Lead Time Raw Material

Bahan Baku	Days physical stock	Rata-rata Lead times
Dust cover	0.25	0.1 hari
Backing plate	0.25	0.1 hari

Component of production result are dust cover and backing plate, they are assembled into a B/P Assy and then store as WIP to wait painting process. From data held by PPIC average length of WIP is system is 2.1 days while lead time from WIP until after painting process and until will process in next process takes 3.5 days can be seen on table 12 below.

Table 12: Days Physical Stock and L/T WIP

Nama komponen	Days physical stock	Rata-rata Lead times
B/P Assy	2.1	1 hari

Graph 1: Supply Chain Response Matrix

### Proposed value stream map

The focus of the proposed improvements are based on analysis has been done before by using process mapping activity and the supply chain response matrix. In both tools are clearly illustrated that the Inventory is a problem with the onset of production lead time is long enough. This is also supported by results assessment questionnaire of WAQ that mention Inventory ranks the first waste.

- **Eliminate waste inventory**

Process activity mapping shows amount of WIP that should wait to painting process is 7 hour and this activity is classified as non value added activity (NVA). Material results of backing plate assembly can not be directly applied to the work station BELT 3 because of having to go through the process of painting. The painting process conducts in outside the plant, which is a partner company. With the arrival of the cycle 1-3-3 then, the company must make a safety stock of WIP for 3.5 days which is useful as a buffer so that the process can be run normally. The Company is building a line so that the whole process of painting is not something to do outside. By conducting the processes of painting in the plant (in house) then, the waiting times are inevitable happens.

- **Eliminate waste transportation**

In the process mapping activity clearly illustrated that there is six times the transport process and all of which belong to the NNVA activity, activity that is necessary but not value added. During the observations made of this transport activity. distance between the work area should not be too far away and can be brought closer. In Figure 3 proposed value stream map shows that the receiving area close to the shipping area can reduce waste transportation along 11.

- **Eliminate waste waiting**

Waiting is the fourth largest waste by weight as 13:28% by WAQ assessment. waste waiting occurs at the time of raw material waiting to be processed and at operator of nut welding waiting backing plate that process result from welding dan riveting.

Work area of BDW dan RVT done by same operator is systematic working from welding process in machine of BDW and after that make do rivet in machine of RVT. Waiting occurs when the operator nut welding process must wait for B / P assy

results Rivet process. Because the actual standard time for this process amounted to only 14.5 seconds while machine time was only 4.2 seconds.

On the other hand BDW and RVT operator also have waiting time. After pressing the ON button on the machine operator BDW directly to process Rivet, because the cycle time of RVT is less than BDW so after rivet, operator still wait to finish BDW machine for welding and waiting time about 25 second. To eliminate the waiting time, incorporation three of machine ini with concept of U-cell shape and just run by one operator alone can save on labor while reducing the total cycle time in all three processes. In the proposed state map figure 3 can be shown the total cycle time of 125.5 seconds that before as 162.8 second, that there is a cutback of 37.3 seconds (22.9%).

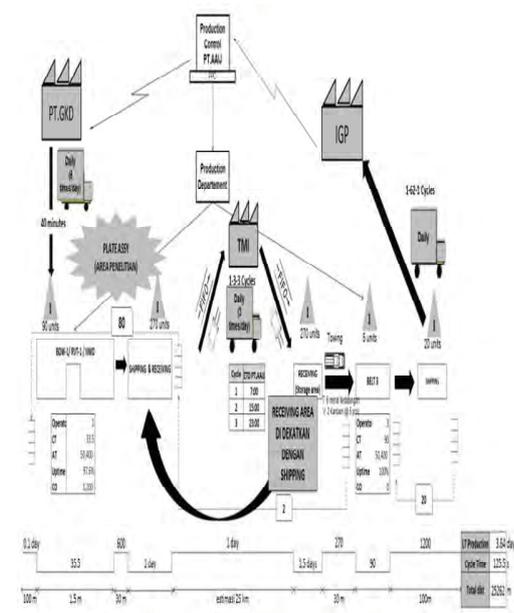

Figure 3. Proposed State map

## 5. CONCLUSION

1. Initial assessment of WRM and WAQ are obtained four types of largest waste according with order in their respective weights are: inventory by weight (20.41%), motion (17.97%), transportation (15,17%), and waiting (13.28).
2. Using the selection matrix of VALSAT for the fourth largest types of waste can be obtained two of detail mapping tools
  - Process Activity Mapping with score is 567.27
  - The second of Supply Chain Response Matrix score is 360.41
3. Process Activity mapping (PAM) showed that:
  - Activities that value-added (VA) for 0139% from total of all activities, activities that are not value-added but still required (NNVA) is 10.0% and not value-added activities (NVA) reached is 89.82%.

From supply chain response matrix shown total lead time of supply chain in area for backing plate assembly is 1.1 days, while inventory duration in system is 2.35 days so that the total of response time to supply in system is 3.45 days. This illustrates that the WIP process produces the greatest lead time and directly proportional to the existing inventory in system that cause companies must make a WIP for 2.1 days.

## ABSTRACT

Lean manufacturing is a proven approach for manufacturing industries efficiency strategies. Radical change of goal, system and organization culture is required in the transition to lean manufacturing. There are several manufacturing industries which failed to implement lean manufacturing system. In order to minimize the high failure rate of implementation, this research is conducted to analyze some factors affecting the lean manufacturing implementation in SMEs. The first part is focused on reviewing the lean practices based on SMEs characteristics. The data were then verified and used to evaluate some manufacturing waste. Further, a manufacturing improvement program is developed for sustainability of SMEs. The research shows that the SMEs faces some problems related to seven type manufacturing waste including overproduction, defects, unnecessary inventory, inappropriate processing, excessive transportation, waiting and unnecessary motion. Lean practices such as 5S, quality control, worker empowerment and supervision, production control and standardization are least investment cost and feasible to implement in SMEs.

## Keywords

*Lean manufacturing, Lean practices, SMEs*

## 1. INTRODUCTION

In the industrial world, the company has always put efficiency in various fields to improve the performance and profitability of the manufacturing company. There are some system or philosophy to realize that manufacturing company' goals. Lean manufacturing system has been broadly accepted by manufacturing industries in some areas to improve its operational performance.

Many researchers has studied and documented their analysis on lean manufacturing application. Lean manufacturing implementation will provide a better utilization of manpower and factory floor space which have a positive impact to productivity in a garment manufacturing industries [1]. This research also conclude that a good relationship among the workers will help the management to coordinate and integrate the factory production.

A significant positive relationship between lean production and firms' profitability of 50 manufacturing companies in Iran have been found [2]. To implement lean production to achieve a superior performance, company should distinguish customers needs and satisfy their needs. Further, managers should eliminate wastes within company. Beside that tools selection to improve manufacturing and generate desired advantage should based on focus area for improvement and current condition of the company [3]. Over all, lean manufacturing is a way for improving manufacturing to make the organization more productive, profitable, and customer oriented.

There are some tools which being used to implement lean manufacturing in a company. Based on the research, there are six tools were chosen by two Serbian food companies to implement lean manufacturing, namely: total productive maintenance, poka yoke, batch reduction, layout improvement, standardization of work and visual management [4]. The objective of green manufacturing is achieved through lean manufacturing tools such as six sigma and quality function development, just in time, poka yoke, flexible manufacturing system, supply chain management, cellular design and setup reduction [5]. Some value addition process and elimination of wastes can be used to improve productivity in Coal mining industry [6]. This process is done by using lean philosophy application in production process such as: elimination of waste activities and overall effective use of resources by less number of drill bits, grinding wheels, electrical power, human energy and more coal production to wheel the development of the nation.

Lean manufacturing tools can be easily implemented with radical change of goal, system and organization culture through the company. It is suggested that, if a company is to change to a lean organization, the company also needs to change the way they value the different dimensions of work [7]. The similar research also stated that there are some elements as critical success factors on lean production practices implementation in automotive sector of Brazil and Spain. The most impacting elements are: ethics and organization, personnel and human resources, customer/ supplier and organization rapport, product and product management [8].

PT. M, one of small and medium enterprise sector metal processing industry in Indonesia, have already introduce the concept of lean production in its daily production. The introduction phase of this concept is chosen as a way to minimize or eliminate some production problem such as down time of production process which often occur due to problems in production facilities, scheduling that do not correspond to the actual situation and so on. But the company faces some challenges in implementing this concept. In order to minimize the high failure rate of lean manufacturing implementation in PT M, this research is conducted to give manufacturing improvement program based on review of lean practices based on SMEs characteristics.

## 2. THEORETICAL BACKGROUND

Lean manufacturing is a systematic approach for identifying and eliminating waste through continuous improvement, moving the product at the pull of the customer in pursuit of perfection. This approach is different from traditional one which in practice does not emphasize on the elimination of waste and short output time (throughput time). Where both of that reduction can lead to low inventories. So the main purpose of lean manufacturing implementation is to increase productivity, improve quality, shorten lead times and reduce costs.

The main characteristics of lean manufacturing can be summarized as follows [9]:

- Production is based on customer demand
- All activities are organized and focused on the major role of product assembly lines with functional departments
- All activities are based on team and organization oriented more horizontally than vertically
- The overall system involves fewer people which integrated between each other
- There is a high level of information exchange between all the role and transparent financial structure
- Activities are coordinated and evaluated by the flow of work through the team or factory
- Discipline is very important in the system in terms of activating and shows the problems posed and total quality in the company and the supplier and dealer performance evaluation
- If possible, the responsibility was developed at the lowest level, the manufacturer or supplier
- Manufacturing systems based on stable production volumes but with the flexibility specifically in terms of product assortment
- Relationships with employees, suppliers, and dealers based on mutual obligations

The main elements of manufacturing can be summarized as three overlapping suppression element [10]. First is waste elimination. Secondly, the involvement of all staff in the improvement operations. The goal is to encourage personal responsibility, commitment and a sense of having a job. And third, the notion that improvement must be continuous (continuous improvement).

Waste is any non value adding activity in the process, in which those activities using only the resources but do not provide added value to customers. While variation is inconsistency or variability that occurs in the process so as to produce defective products. In general understanding of waste are [11]:

- Resources consumed by inefficient or unnecessary activities
- Excess material to leave the production process, or output that has no sale value
- Process or material that does not add value to the goods or services
- Non value added materials, storage, or disposal of material within a certain amount of environmentally harmful

Waste or better known as "muda" can be grouped into seven types, namely [12]:

- Overproduction  
Excessive production occurred when producing the goods when it is not needed, before the customer orders or before the next process begins its production. Excessive production is a result of the lack of flow of goods and information, and resulted in a lot of inventory that may interrupt the flow of material and decrease productivity and quality.
- Defects  
There are several types of defect, first is defect which contain a defective product that can not be economically repaired. Second, rework is a product that has experienced an error and can be fixed by reworking so that the product can be expected according to specifications. Third, customer returns is products returned by customers because it does

not correspond to the expected specifications. Fourth, customer dissatisfaction is some dissatisfied customers that lead to product claim.

- Unnecessary inventory  
 Basically inventory simply hide the problem and cause additional handling activities should not be needed. Inventory also resulted in extra space, extra cost. Too many goods stored in warehouses and delay the flow of information or product, resulting in increased storage costs and poor customer service.
- Inappropriate processing  
 It is a process that includes all unnecessary and inefficient additional processes or activities using improper equipment, system or procedure errors.
- Excessive transportation  
 Move the material or activity within a great distance from one process to the next process will resulted in the addition of material handling time. Too much movement of people, information, or material resulting in a waste of time, effort and cost.
- Waiting time  
 The length of waiting time for either the human, material and information will result in poor flow and long lead times.
- Unnecessary motion  
 Unnecessary movements due to poor facility layout arrangement or any movement of people and machines that do not add value to the goods or services will only adds time and costs only. Back and forth frantically looking for something is an activity that includes waste, because it gives no added value to product.

Some of the root causes of variation and waste in the workplace are:

- Bad factory and office layout
- Long setup of equipment and machinery
- Bad organization work
- Improper or insufficient training
- Working methods are not standardized
- Do not follow procedures and work instructions
- Low process capability
- Bad planning
- Material quality problems
- Inaccurate measurement equipment
- A poor work environment

Some approach that can be done to eliminate seven waste are as follow:

- Simplification is an approach to eliminate waste where a process will be simplified to reduce the core itself.
- Incorporation is an approach to eliminate waste by combining two kinds of tasks that can be performed by a single worker.
- Deletion is an approach to eliminate waste by eliminating the processes / activities that are not necessary so that processing time can be shortened.

### 3. RESEARCH METHOD

This research phase contains several steps that begins with problem formulation, observation and data collection then analyzing. First stage in this research is the study of existing production problem of metal processing industry in PT M Hospital Equipment Units for non stainless welding parts. Then data collection was generated to evaluate the production process based on lean manufacturing practices. The data is related to seven type manufacturing waste including overproduction, defects, unnecessary inventory, inappropriate processing, excessive transportation, waiting and unnecessary motion. Data is used to determine the root cause of each type of waste. Further, a depth analysis of real production system is done to develop a manufacturing improvement program based on lean manufacturing practices for sustainability of SMEs.

### 4. RESULT AND DISCUSSION

The analysis will be divided in two categories, presenting identified typical wastes and its root cause in PT M Hospital Equipment Units for non stainless welding parts. Second is analysis of possible manufacturing improvement program based on some lean tools in SME. The first category consist of:

- a. Overproduction (Excess Production)

Producing components by an amount that exceeds from its demand that caused by greater setup time than the processing time. Some components are produce in large batch such as in component 32901 and 73006 there are excess production in hinges, nut M5 and buss hinges as can be seen in Figure 1. The other cause is when a defective component occur, new parts are come from the warehouse component so the components will not be rework and become a waste. The root cause of excessive production are a process bottleneck, unbalanced production capacity, bad shipping, bad layout, more emphasis on the workers to continue working rather than maximizing the use of materials.

Figure 1: Over Production

b. Defects

Product defects resulting in rework or scrap cost. These costs include quarantining inventory, re-check, re-scheduling, and loss of capacity. There are some product defect occur in production process, such as chassis beds that do not match to its standard size and the welds are not strong. The other is center mat 73004 had a dent in its centre area as can be seen in Figure 2. The root cause of defective products is the presence of a processes variation while process control is weak, the amount of component inventory that is not balanced, poor instructions and human error.

Figure 2: Defect Components

c. Unnecessary inventory

Work in process is directly the result of excessive production and waiting time. Excess inventory tends to hide problems in the factory which should be identify and repair to increase the lead-time, productive use of floor space, the identification of issues to be delayed, and hinder communication. Based on observation, there are some components inventory which corrosion occurs as can be seen in Figure 3. This unnecessary inventory caused by demand uncertainty, forecast poorly, and poor market information. In production process also have some contribution to that, such as long production lead time, the time of set up time, and the capacity of the equipment used is not balanced.

Figure 3: Unnecessary Inventory

d. Inappropriate processing

Based on observation, there are inappropriate processing occur such as when welding box and parts box processing. Sometimes the welding point is too thick or large because high amperage is used during the process of grinding/ deburring trouble and proceed in long time. The other is component 33104, the base frame is too narrow so frond frame can't be

can be seen in Figure 7. The cause of this waste are messy work, arrangement of the components are not balanced, irregular work methods, work in large batch sizes, the component does not have a name and number information.

Figure 7: Unnecessary Motion

Based on that analysis of typical wastes and its root cause in PT M Hospital Equipment Units for non stainless welding parts, there are some possible manufacturing improvement program as follows:

- a. Use a pull system in production where a single product is produced according to the requirement or order, leveling production or heijunka, implementing kanban system, preventive maintenance independently by the operator.
- b. Produce product according to specification limit and based on standard operational procedures. Doing good material handling with standard capacity on each pallet and perform frequent inspection.
- c. Perform production line balancing and coordinate with component warehouse in order to adjust to the situation.
- d. Perform planning and scheduling with better balance or level out the workload, working on the production according to demand and standard operational procedures.
- e. Using five S (5S) method to reduce unnecessary movement through of identification and removing unnecessary items in the workplace, grouping goods, mark boundaries of each production area, make a production map and its characteristic, provision of hygiene, cleaning work, marking on a machine that can not be repaired, determination of control points and make a fixed place for each item.

## 5. CONCLUSION

The research shows that the SMEs faces some problems related to seven type manufacturing waste including overproduction, defects, unnecessary inventory, inappropriate processing, excessive transportation, waiting and unnecessary motion. To overcome this problem, a manufacturing improvement program such as 5S, quality control, worker empowerment and supervision, production control and standardization are least investment cost and feasible to implement in SMEs.

## ABSTRACT

All companies want to achieve optimal productivity, but on the other hand achieving optimal productivity has many obstacles. These obstacles that often occur in the production system area are seven wastes (over production, over inventory, inefficient transportation, unnecessary motion, waiting, defect and inappropriate process). Reducing this waste can use Value Stream Mapping (VSM) which is one of Lean Manufacturing tools. Advantage of Value Stream Mapping can describe activity flow of Value Added (VA), Necessary but Non Value Added (NNVA) and Non Value Added (NVA). Result of Current VSM is used as basic of improvement in production system. Besides that, doing improvement at some workstations will deliver Propose VSM and doing simulation of Value Stream Mapping will give approach or mimic the real situation. This research have some purposes, like to reduce some wastes that inhibit productivity of Industry Dairy Toddlers, get Value Stream Mapping of the production flow to achieve Lean Manufacturing, and get design a better production system through object oriented simulation. Results of this research are reduction of lead time to be faster 19%, reduction of transport activity by 11%, reduction in inventory by 16% and increase production throughput by 24%.

## Keywords

*Lean manufacturing, value stream mapping, simulation, waste*

## 1. INTRODUCTION

In the past decade, consumer goods industries have a very significant growth that be driven by increasing of consumption. One of significant grows of consumer goods is toddler dairy industry. Increasing demand for dairy goods toddler is an opportunity to do business in this field. Management of this industry always works harder to improve of productivity and efficiency of the activity production to obtain the optimal profit. But on the other hand, achieving optimal productivity has many obstacles. These obstacles that often occur in the production system area are seven wastes (over production, over inventory, inefficient transportation, unnecessary motion, waiting, defect and inappropriate process).

Lean manufacturing is a systematic approach to identify and eliminate seven wastes through continuous improvement activities. Reducing seven wastes of production system will be faster of lead time, on time products delivery, reduce production costs, reduce the amount of work in process (WIP) and increase the utilization of production resources, so that companies can increase productivity (Rother, 1999). One of Lean Manufacturing tools to reduce wastes is Value Stream Mapping or VSM (Liker, 2004). Advantage of VSM can be visualization Value Added (VA), Necessary but Non Value Added (NNVA) and Non Value Added (NVA). Value Stream Mapping can describe information and material flows that are not neat, so it is easy to identify and redesign for improving system production (Liker, 2004).

Companies that have traditional approaches to their manufacturing systems will difficult to be commitment implementation of lean manufacturing (Abdulmalek, 2007). Managers have also been hesitant to adopt lean manufacturing tools because of other characteristics that are typical in this sector. These include large, inflexible machines, long setup times, and the general difficulty in producing in small batches (Abdulmalek, 2007). One of tools that can transformation redesign traditional manufacturing to lean manufacturing is simulation. Using of simulation for lean manufacturing approach, especially in the Value Stream Mapping was developed by Standridge (2006). Simulation is process to design a model in the real system and be connected in the experiment. Simulation tries to approach in the real situation (Solding, 2009). The use of simulation in the Value Stream Mapping is an interesting because the simulation will be known miniature movement of materials and information on the actual production system, without disrupting the continuity of manufacturing conditions that exist today (Solding, 2009). The information from simulation can be compare current condition and propose condition after have done some improvement (Detty, 2000).

The research gap of this paper is still a bit of research that combines value stream mapping and object oriented simulation on the dairy industry toddler in Indonesia, so that this study becomes important looks into this matter. This research have some purposes, like to reduce some wastes that inhibit productivity of Industry Dairy Toddlers, get Value Stream Mapping of the production flow to achieve Lean Manufacturing, and get design a better production system through object oriented simulation.

## 2. OVERVIEW OF LEAN MANUFACTURING AND VALUE STREAM MAPPING

Lean manufacturing is a systematic approach to identify and eliminate waste (Non Value Added) activities through continuous improvement. Lean manufacturing approach tries to neat in flow of products with pull system by attention of customer satisfaction viewpoint (Tapping , 2002). Lean manufacturing concept was originally introduced by Taiichi Ohno (Toyota Motor Corp.) that this concept is commonly called the Toyota Production System (TPS). Furthermore the concept of lean manufacturing is adopted by several large companies in the U.S. and Europe for their industrial application, because the concept proves successful to improve productivity through the elimination of wastes production.

Value Stream Mapping (VSM) is one of lean manufacturing tools that is proven effective to eliminate waste (non-added value) and tries mapping information and material flow in production systems. Value Stream Mapping was first introduced by Moki Rother and John Shook in his book "Learning to See", this book explains how uses of mapping process flow of value added activity and non value added activity in production floor to achieve lean manufacturing conditions. Value Stream Mapping was born from the concept of Toyota Production System (TPS), in which the TPS is known as "Material and Information Flow Mapping (MIFC)".

Value Added (VA) activity is all of process that provides transformation raw material to be more added value, wherein the previously raw material less valuable is transformed to more valuable and the customer is willing to pay for this activity (Liker, 2004). Necessary but Non Value Added (NNVA) activity is all of process that not adds value to the product but this process must be done, whereas Non Value Added (NVA) activity is all of process that does not provide added value to a product, and has potential to use of higher cost (Womack, 1994). All activities of Value Added (VA), Necessary but Non Value Added (NNVA) and Non Value Added (NVA) will be transformed into units of time (cycle time), where times of NNVA and NVA activity will try to be reduced, that is expected to become more effective and efficient in its production system.

There are several steps that must be done to make Value Stream Mapping (Rother, 1999), these stages are:

- i) Select target of product family that will be improvement. The selection of product family is essential because this can focus on one product, clear boundaries and not be bias.
- ii) Describe the Current VSM that important part captures how current conditions of production systems.
- iii) Identify of waste that exist in Current Value Stream Mapping.
- iv) Make improvements in some areas.
- v) Describe Propose VSM which displays images of the production system after improvement activity.

Besides that, Methodology to establish Value Stream Mapping and Simulation in this research is presented in this following;

- Gathering Data of Cycle time or processing time
- Gathering Data of Changeover time.
- Gathering Initial data collection on overall cycles times, waste time, in-process queue time.
- Gathering Data gathering for % rejects and work-in-process
- Establishing Current Value Stream Mapping
- Improvement
- Establishing Propose Value Stream Mapping
- Making Simulation
- Verification and Validation of simulation
- Analysis

## 3. ANALYSIS AND DISCUSSION

### 3.1 Collections Data

Data was taken in one of dairy toddler industry that has 5 workstation; premix/ribbon, prior, tumbler, filling and packaging. Data of cycle time and changeover time each workstation can look in table 1. Cycle time is added value activity that will be described in Current Value Stream Mapping. Changeover time occurs when there is replacement a type of product, whereas these activities includes of dry cleaning and deep cleaning.

*Table 1: Data of Cycle Time and Changeover Time*

	Unit	Premix/Ribbon	Prior	Tumbler	Filling	Packaging
Cycle Time	Seconds	1224.4	785.7	876.1	1449.9	1072.1
Changeover Time	Seconds	5400	2700	0	2700	1800

Inventory and work in process (WIP) have functions as buffer on production system. This buffer has function to keep production system running in smooth flow and no idle the next process. The data of inventory and WIP is as follows:

Table 2: Number of Actual Inventory

	Place or Workstation	Number of Inventory
Raw Material	Batching Area	60 pallets
Work In Process	Preparation Batching	7 pallets
Work In Process	Beside of Tumbler and Filling	3 BIN
Finish Goods	Warehouse Finish Goods	20 pallets

### 3.2 Data of Takt Time

Takt time is ideal time to complete making one product in production system (Rother, 1999). Takt time is very useful to know how the actual condition of the speed of the production process should be run. In this case study, Takt Time is composed of 2 kinds, it is Box and BIN. It is occurred because the unit in this system production is difference. In the station of premix, prior, tumbler and filling use BIN unit, so the form of takt time in this area shaped takt time BIN. Whereas, in the packaging area and warehouse use Box unit. So we call takt time Box.

$$\text{Takt Time} = \frac{\text{net available time}}{\text{demand produksl}} \quad (1)$$

$$\text{Takt Time BIN} = \frac{25.200 \text{ second}}{18 \text{ BIN}} = 22,5 \frac{\text{minutes}}{\text{BIN}}$$

$$\text{Takt Time Box} = \frac{25.200 \text{ second}}{1316 \text{ Box}} = 19,14 \frac{\text{seconds}}{\text{box}}$$

Takt time BIN 22.5 minutes/BIN indicates that the ideal time of workstation premix, prior, tumbler and filling finish its job every 22.5 minutes. Takt time Box 19.14 seconds/box indicates that ideal time of workstation packaging finish its job every 19.14 seconds. Besides that, instruction withdrawal of finished goods uses term of pitch. Pitch is the time interval required to take goods in the form of a finish goods (Tapping, 2002).

$$\begin{aligned} \text{Pitch} &= \text{Takt Time} \times \text{Pack Out Quantity} & (2) \\ \text{Pitch} &= 19.14 \times 54 \text{ boxes} = 1034 \text{ seconds} = 17 \text{ minutes } 13 \text{ seconds} \end{aligned}$$

Pitch value 17 minutes 13 seconds indicates that there is a withdrawal of finish goods from the packaging station to finish goods warehouse area. This pitch will be the basis for calculating the waiting time finish goods in warehouse.

### 3.3 Current Value Stream Mapping

Current VSM describes actual condition as baseline of production system before doing some improvement. This is necessary to know gap of target condition and actual condition. Current VSM has 3 main components:

- Time line consists of value added and non-value added.
- Material flow from raw materials to finished goods
- Command information production and information supply chain on the supplier and customer.

Figure 1 describes a Current VSM that suppliers come every 3 hours, whereas the finished goods are taken by truck every 2.5 hours in the shipping area. Lead time material from raw material until delivery finish goods needs 22 hours 36 minutes. Whereas the Value Added activities have done for 1 hour 10 minutes 48 seconds, and Non Value Added activities have done for 21 hours 26 minutes 24 seconds. This Current VSM describes that actual lead time in this company approximately 94% is non value added activities and just 6% is value added activity. From actual condition, it has to do improvement in some workstation.

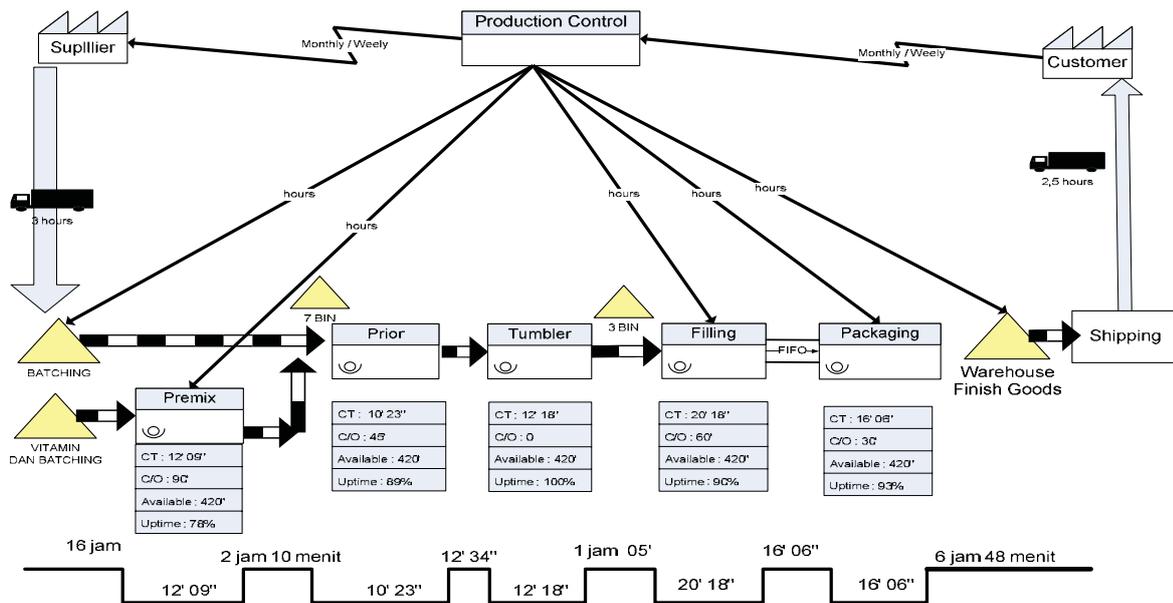

Figure 1: Current Value Stream Mapping

Visualization of current value stream has been established, and then is done some improvement at some point to increase the efficiency of the company. The summaries of improvement activity will display in table 3.

Table 3: Summaries of improvement

	Improvement	Reason	Result
1	Improvements of placement raw material in area batching, this improvement by grouping of raw material so that the operator easy takes of raw material.	Some of raw material mingled with another raw material. Operator search with difficulty of raw material presence.	Searching of material by operator will be easier and will reduce raw material out of date.
2	Reduction operators from 3 operator becomes 2 operator in area premix	Cycle time of this area still under from takt time. So that, there is idle of operator	Efficiency of using operator
3	Improvement of transfer box in workstations premix, there must be a special door to entrance the material and a special door to exit the material	During this time, the entrance and exit of material in premix area just have one door, whereas the door was busy quite high. So there is waste waiting in this area.	Materials will be more smooth flow and will reduce waiting time on the process material
4	Using safety stock of inventory is 2 BIN between workstation tumbler and filling.	In the actual safety stock of inventory in this area is 3 BIN that become waste inventory	Occurred saving time 1200 seconds
5	Using supermarket design to pull finished goods in warehouse.	In the before arrangement of finished goods in the warehouse so less of tidy, not in accordance with the pitch and not use the FIFO concept	There is no delay in sending finished goods to consumers

### 3.4 Propose Value Stream Mapping

Propose VSM will be used as new system production that has been develop by some improvement. Lead time material from raw materials until becomes finished goods needed 17 hours 24 minutes. Reducing time occurred because done some improvement in the factory, so that the continuous flow can run better and some waiting time can be reduced.

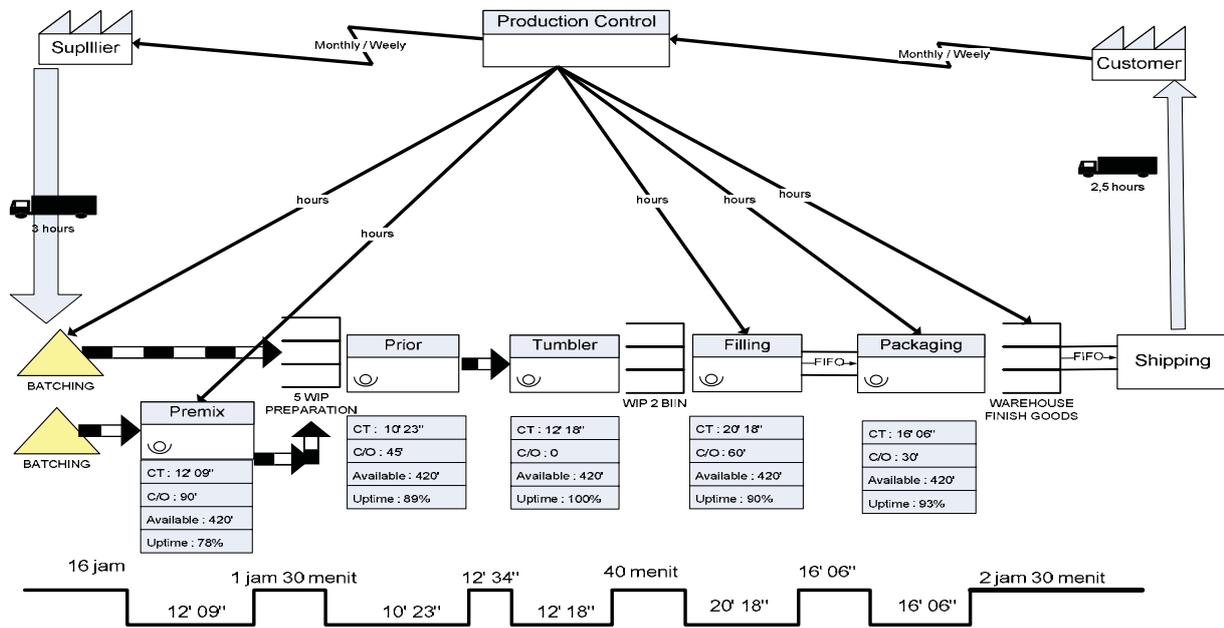

Figure 2: Propose Value Stream Mapping

In the Propose VSM shows that there are several points using of supermarket, where the supermarket serves as a place to put inventory with FIFO and there are maximum and minimum standard. So it becomes clear inventory limits in place. Because in previously system production, limitation of inventory is not clear inventory number of maximum and minimum.

### 3.5 Simulation Model of Current VSM and Propose VSM

The model will be simulated of Propose Value Stream Mapping. The simulation model will be known whether the model Propose VSM can be applied or not on production systems. In this research, before making simulation models of Propose VSM in plant simulation software, the authors made simulation model of Current VSM to testing verification and validation of simulation model.

#### 3.5.1 Verification

Verification has goal to see whether the logic and simtalk models are correct or not that has been made in plant simulation software. Some things must be done in the verification is as follows

- check all code models, entities, and the variables used.
- observe the material flow simulation and whether the model is in accordance with reality.

At the time the model was running, if the debug dialog screen appears, the model was still not able to run as expected by the user. So, users have to do the repairs continued until the model is correct and there is no display debug dialog. After some verification had done on the model and when the model was run, if the debug dialog was not reappear, the model had been verified correctly.

#### 3.5.2 Validation

After verifying the model Current Value Stream Mapping, the next step was validation model. Purpose of validation was whether the model was going according to the real condition or not. Validation of this study was done by comparing the output of the process in a real situation and output in the computer simulations. In the simulation model of Current VSM run for 8 hours produces 19 units of output, whilst the average output in real terms is 18 units. Outputs between simulation and real conditions have different 1 unit or 6%. So, the current simulation model is validated.

### 3.6 Comparison of Current Condition and Propose Condition

Table 4: Comparison of Current Condition and Propose Condition

No	Comparison	Current Condition	Propose Condition	Unit
1	Lead Time	22.6	17.4	Time (Hours)
2	Throughput Production	19	25	Pallet
3	Waste Transportations	187.4	167.4	Meters
4	Inventory & WIP	90	76	Pallet & BIN

Lead time Current VSM from raw material until becomes finish goods and ready delivery to customer needs 22 hours 36 minute. Beside that, lead time of Propose VSM needs 17 hours 24 minutes in new system production. In the propose condition there is a reduction about 19%, time reduction occurs because there are some improvement on the workstation layout premix, transfer box setting in workstation premix, fixes the amount of inventory at some point, reduction of waste transport in finished goods warehouse.

Production throughput can be viewed by plant simulation software. The simulation model is run for one shift of 8 hours and there is time reduction with time of rest, prayer and meals for 1 hour, so we got the net available time during 420 minutes or 7 hours. Throughputs Current VSM in this simulation model are 19 units. Whereas, the resulting throughput on Propose VSM is 25 units, there is an increased throughput by 24%. This is occurring because there are some of the improvements.

Transport distance at the Current VSM is 187.4 meters. Transportation consists of batching area, preparation, premix, prior, tumbler, filling, packaging and finished goods warehouse. Whereas this research will improve the finished goods warehouse area, which was added in the form of rail conveyors. So, the finish goods directly fed into the conveyor and immediately pushed forward in the rail conveyors. This design will reduce traveling activity by the operator. The results of calculation transportation savings in Propose VSM is 11%. After the improvement of transport distance becomes 167.4 meters.

Amount of inventory in Current VSM is 90 units. Whereas amount of inventory in Propose VSM is 76 units, there is 16% reduction inventory after improvement. This is the analysis of it, in the batching area there is not reduction inventory because in this area will need enough material to prepare processed in next 11 hours letters. After there is improvement in preparation area, Work In Process of this area becomes 5 units. Waiting time required after improvement becomes 1 hour 32 minutes (5 units x 1114 seconds = 5571 seconds).

In the area between workstation tumbler and filling amount of the previous Work in Process is 3 BIN, but after the count and using the existing Work in Process improvement in this area becomes 2 BIN because the condition of the filling process is longer than the tumbler. Target Work in Process becomes 2 BIN in this area to keep handy if there is fluctuation of demand or any engine problem on the previous workstations. Through this reduction of Work in Process, waiting time will become just 40 minutes.

At the area of finish goods warehouse was done improvements by using rail conveyor. Whereas the mechanism for finish goods be placed in the rail conveyor, so that the queue of finish goods become FIFO (first in first out). Every 2 hours and 30 minutes will be transported as many as 8 units to 9 units. Using this rail conveyor becomes no material that settles again in area of finish goods warehouse. Overall inventory reduction in the production system is 11 units or 16%.

### 3.7 Analysis of Simulation

Throughput of Current VSM for 2 shifts is 35 units. Whereas throughput on the first shift is 16 units, so throughputs the second shift after all materials filling buffer stock of each workstation are 19 units. Besides that, Throughput of Propose VSM is 45 units during the second shift, where the throughput on the first shift of Propose VSM is 20 units, so throughput the second shift is 25 units. This simulation can describe that throughput of Propose VSM increase to be 24%. Simulation model using Plant Simulation Software of Propose VSM can be seen in this Figure 3.

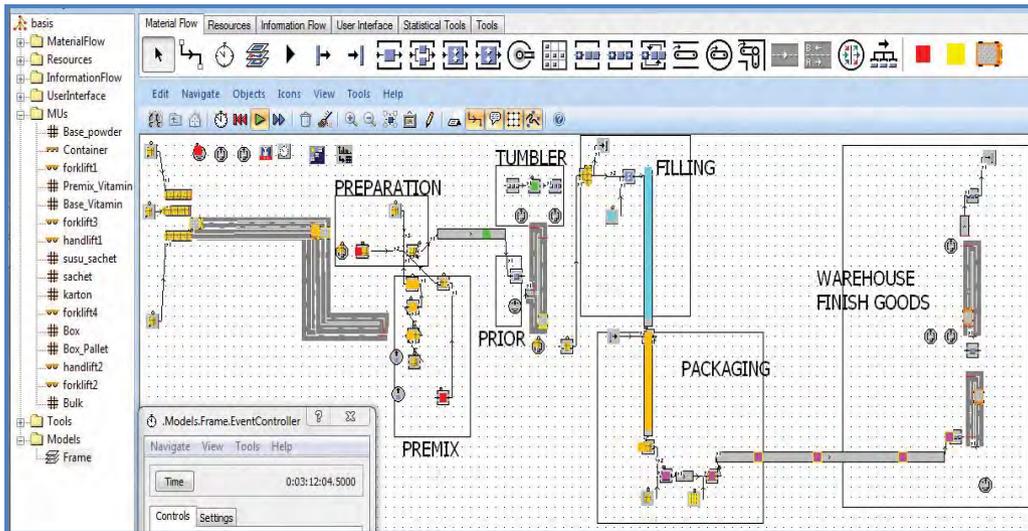

Figure 3: Simulation Model of Propose Value Stream Mapping

The performance of simulation Current VSM and Propose VSM can be seen in this comparison table 5 and 6. Several name in this simulation differ with Value Stream Mapping because this simulation have been broken-down becoming some machine to approach detail condition. Several object of this simulation are tumbler, dismantleStation, konveyor\_filling, ribbon, blend, prior, konveyor\_packaging, packaging\_karton, palletisasi and coins. The comparison performance by simulation of Current VSM and Propose VSM for all categories show that model Propose VSM better than the current VSM.

Table 5: Simulation Result of Current VSM

Object	Working	Waiting	Blocked	Failed	Paused	Unplanned	Set-up	Empty

#### 4. CONCLUSION

Implementation of Lean Manufacturing is an effort to increase the productivity of the company. Lean manufacturing proved effective in reducing waste in the production system. Through the identification of all the waste, it will be easier to solve the problem and be better condition of production system. The conclusions of this study are as follows:

- The application of continuous flow on premix workstation layout can be achieved with improvements in the area of premix. Earlier in this area often have bottlenecks at the transfer box door because the door is only one transfer box. Having improvement door transfer box into two where there is a separation between the entrance and the exit of material, so the material can be run smooth flow.
- The production lead time is faster; the Current VSM takes 22 hours 36 minutes, whereas on Propose VSM has a lead time for 17 hours and 24 minutes, there been a reduction in production lead time is around 19%.
- Throughput on Propose VSM increases by 24%. In the Current VSM throughput of production is 19 units, whereas the throughput of Propose VSM is 25 units.
- Transport activity of Current VSM is far as 187.4 meters, whereas transport activity of Propose VSM is far as 167.4 meters. It is saving transport waste by 11%.
- The number of inventory before improvement is 90 units. After re-calculation and improvement in some areas, the number of inventory becomes 76 units in the whole system. It is reduction of inventory by 14 units or 16%.

## ABSTRACT

This research is a part of the Total Ergonomic Approach Model (TEAM) that measures 8 aspects consisted of 4 tangible aspects, such as muscle measurements and working condition, and 4 intangible factors. This paper presents industrial performance design which considers worker's measurements in cultural and environmental aspects as intangible aspects. The analysis includes four related aspects: information, time, socio-cultural and human-machine interaction. Preliminary research in shop floor found that manual production result note taking, non-computerized and duplicated process in the existing business process, delayed decision making by the Top Management, low worker loyalty, low worker welfare, and the non-existence of display application use. In this research, the measurement of intangible factors is analyzed: information and time aspects using the Time Function Mapping method, socio-cultural and human-machine interaction aspects using questionnaire. After measuring the weight, the research found poor result in information, time, socio-cultural aspects and very poor result in human-machine interaction aspect that required immediate attention for improvement.

## Keywords

*TEAM, measurements, socio-cultural, human-machine interaction.*

## 1. INTRODUCTION

According to Adiatmika (2011) Total Ergonomic Approach Model (TEAM) is an implementation of total ergonomic approach in the industrial environment. The concept adopted is to introduce simple ergonomic concepts to workers or officers based on their daily working conditions. By understanding each working conditions, officers will know which working condition is ergonomic and which is not. The officers will realize and seek to conduct simple improvement using resources available in their working environment. The improvement concept from expert center to worker center according to Kogi (2006); Manuaba (2000); Sutajaya (2005), in Adiatmika (2011) is a concept of change by empowering workers through total ergonomic approach. In this matter, workers can be trained to improve their knowledge in ergonomic through seminars, workshops, and classes so that they are aware of the ergonomic aspects of their work and working conditions and willing to improve them. The total ergonomic approach [1] [2] was used as a form of ergonomic intervention that is willing to gain a more humane, competitive, and lasting method. This approach begins with problem identification consisted of 8 aspects: (a) nutrition, (b) work posture, (c) muscle use, (d) work environment, (e) time condition, (f) information condition, (g) socio-cultural condition, (h) human-machine interaction. The total ergonomic approach by Manuaba, (2004, 2005) in Adiatmika (2011) is a form of approach using a systemic, holistic, inter-discipline, and participative or known for short as SHIP. In choosing the working condition corrections, several aspects were taken into consideration. They are technical, economic, ergonomic, socio-cultural, energy save, and environmental friendly (the proper use of technology).

This research was conducted in an automotive parts and components manufacturer. These products require good worker stamina since the manufacturing processes involve heavy materials and repetitive works. The problem appears as there are no measurement standard for intangible aspects such as information and time. This research analyze information and time using time function mapping method, and socio-cultural and human-machine interaction aspect in cooperation to implement ergonomic principle as solution. The purpose is to analyze and design work condition (socio-economic and culture) measurement as part of Total Ergonomic Approach Model (TEAM), especially intangible factors.

## 2. METHOD

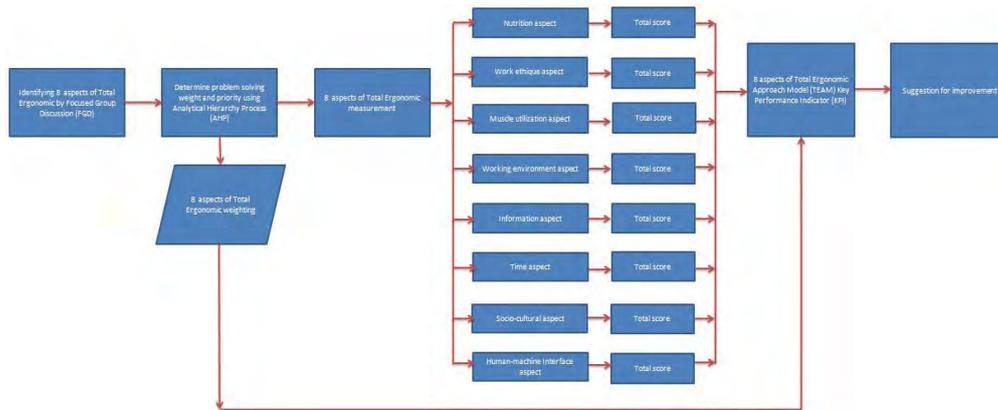

Figure 1: Research methodology

## 3. RESULTS AND DISCUSSION

The findings from the measurement of the nutrition aspect are analyzed using the Body Mass Index (BMI) method. The work posture aspect is analyzed using the Rapid Upper Limb Assessment (RULA) method. The muscle use aspect is analyzed using the Recommended Weight Limit (RWL) and Lifting Index (LI) and the work environment aspect is analyzed using the OSHA 1910.95 method scale. Analysis shows that the company is bad and need immediate improvements.

### 3.1. Information and Time Aspects

Analysis of information and time aspects are based on *Business Process Existing* (BPE) where in BPE there were many duplications and wasted time that needs to be reduced using Time Function Mapping method.

Table 1: Scoring Standard Operating Procedure

Information Delay Time (day)	Classification	Score	Information Delay Time (day)	Classification	Score
<3	Very good	5	6 - 8	Average	3
3 - 5	Good	4	9 - 11	Poor	2
			>12	Very Poor	1

Financial department has 20 days delay time - scored 1, PPIC Manager 6 days delay time - scored 3, QC Manager 11 days delay time - scored 2 to the Director. The conclusion is that majority (66.67%) of information transfer to Director are delayed with average classification score of 2.

### 3.2. Socio Cultural Aspect

**1. Validity Test :** 30 questionnaire regarding employee's welfare is distributed to 30 respondents with degree of freedom = 30, trust level 5%, hence  $r_{tabel} = 0.361$ . Validity test was run by comparing Corrected Item-Total Correlation with  $r_{tabel}$ . If Corrected Item-Total Correlation  $> r_{tabel}$  then the instrument point is declared valid and vice versa. Result showed one instrument point KES03 that is not valid. Validity test with Corrected Item-Total Correlation more than  $r_{tabel}$  (0.05; 30) = 0.361, then accept Ho. Result showed all instrument points tested are valid.

**2. Reliability Test :** Instrument point is declared reliable, if Cronbach's Alpha value  $> 0.7$ . Calculation showed Cronbach's Alpha value is 0.944 ( $> 0.7$ ), then accept Ho. Result showed 23 instrument points tested are reliable.

### 3.3. Organizational Culture Aspect

**1. Validity Test:** 30 questionnaires regarding employee's welfare were distributed to 30 respondents with degree of freedom = 30, trust level 5%, hence  $r_{tabel} = 0.361$ . Validity test was run by comparing Corrected Item-Total Correlation with  $r_{tabel}$ . If Corrected Item-Total Correlation  $> r_{tabel}$  then the instrument point is declared valid and vice versa. Result showed 4 instrument points (BUD01, BUD02, BUD03, and BUD27) not valid. Validity test with Corrected Item-Total Correlation more than  $r_{tabel}$  (0.05; 30) = 0.361, then accept Ho. Result showed all instrument points tested are valid.

2. Reliability Test : Instrument point is declared reliable, if Cronbach's Alpha value > 0.7. Calculation showed Cronbach's Alpha value is 0.892 (> 0.7), then accept Ho. Result showed 26 instrument points tested are reliable.

Table 2: Socio-cultural Aspect Measurement Scoring

Very good	Dominant score is 5	Average	Dominant score is 3
Good	Dominant score is 4	Poor	Dominant score is 2
		Very poor	Dominant score is 1

Respondents' answer to socio-cultural questionnaire showed 2 as the modus scored. This means that the respondents consider the socio-cultural value is poor.

### 3.4. Human-Machine Interface Aspect

Human-machine interface aspect is analyzed based on the use of company display attribute. The company is not using any display so the evaluation result is as below

Table 3: Direct Observation Result on the Use of Display Attribute

No	Statement	Answer		
	<b>Detection</b>			
1	Visibility	Good	<input type="checkbox"/>	Poor <input checked="" type="checkbox"/>
2	Angle	Good	<input type="checkbox"/>	Poor <input checked="" type="checkbox"/>
3	Parallax presence	Yes	<input type="checkbox"/>	No <input checked="" type="checkbox"/>
4	Contrast view with surrounding (e.g. any advertisement board or trees blocking view)	Good	<input type="checkbox"/>	Poor <input checked="" type="checkbox"/>
5	Glaring	Yes	<input type="checkbox"/>	No <input checked="" type="checkbox"/>
6	Adequate lighting	Good	<input type="checkbox"/>	Poor <input checked="" type="checkbox"/>
	<b>Recognition</b>			
7	Visual acuity	Good	<input type="checkbox"/>	Poor <input checked="" type="checkbox"/>
8	Display's shape	Good	<input type="checkbox"/>	Poor <input checked="" type="checkbox"/>
9	Character or picture size	Good	<input type="checkbox"/>	Poor <input checked="" type="checkbox"/>
10	Color of background	Good	<input type="checkbox"/>	Poor <input checked="" type="checkbox"/>
	<b>Understanding</b>			
11	Color contrast between characters and background	Good	<input type="checkbox"/>	Poor <input checked="" type="checkbox"/>
12	The use of correct symbol or codes	Good	<input type="checkbox"/>	Poor <input checked="" type="checkbox"/>
13	Language	Understandable	<input type="checkbox"/>	Not <input checked="" type="checkbox"/>
14	Sentences	Understandable	<input type="checkbox"/>	Not <input checked="" type="checkbox"/>

Table 4: Display Aspect Measurement Scoring

Score 5	Very good	11 - 14 display attribute fit and 0 - 1 attribute unfit
Score 4	Good	8 - 10 display attribute fit and 4 - 6 attribute unfit
Score 3	Average	5 - 7 display attribute fit and 7 - 9 attribute unfit
Score 2	Poor	2 - 4 display attribute fit and 10 - 12 attribute unfit
Score 1	Very Poor	No display attribute exist

Observation showed that the company did not use any display, so the score for human-machine interface aspect is 1 very poor.

## 4. CONCLUSION

Based on the analysis result, it can be concluded that the ergonomic problem identification through the intangible factors. The Total Ergonomic Approach Model (TEAM) is more comprehensive in dealing with the company's ergonomic problem by providing integrated improvement to obtain a total solution. The result for Information and Time aspect using *Time Function Mapping* method is 66.67% immediate redesign is needed.

Socio-cultural aspect using questionnaire method means company needs to improve work condition and worker welfare. Human-machine interface aspect is very poor, therefore immediate attention and improvement is needed. Redesigning Information and Time aspects should not be using Business Process Existing (BPE) because it does not represent the real condition, has many duplication of process, and wasted time. Proposed solution for Socio-cultural aspect are to create solid regulation and punishment, salary adjustment, and benefits improvement for workers. From the point of view of Human-machine interface, it is recommended for the company to apply the use of visual display instead of auditory display due to noisy environment, company's performance indicating the overall working environment as 'poor' and improvement is needed.

## ACKNOWLEDGEMENT

The authors thank the Industrial Engineering Department Trisakti University for sponsoring this research for Quality In Research 2013.

## ABSTRACT

Moore's Law stated that number of inexpensive transistors that placed in printed circuit board will be double every 1.5 years, even though the theory was developed long time ago in the mid of 1960s, nowadays it is unquestionable reality that the development of semiconductor enable high speed computing process. The rise of semiconductor industry over the year helped the software industries to develop product that will be used by students and engineers, either for research or business purpose. Minitab is one of the well known application software used not only for statistical computation purpose, but also quality control and design of experiment. The research focused on usability according scheme of dimensions defined by Nielsen (1993) and ISO-9241. Learnability measured by pre-test and number of module seen by respondent. Efficiency calculated from time of completion the task and correction recorded in pretest. Number of mistakes is accumulated to be defined in error dimension. Memorability is defined in number of mistakes during post test, while satisfaction as the last dimension is obtained based on satisfaction through questionnaires. Activities covered in the research include decision on experiment location, criterion of respondent, indicator for usability, module creation and questionnaire, training, pretest, post test, and filling the questionnaire. Experiment applied to 58 industrial engineering active students of class 2008-2010 resulted that usability of EWMA control chart is 0,61 (*good*), in details for every dimension as followed: learnability 0.71 (*good*), efficiency 0.64 (*good*), errors 0.44 (*moderate*), memorability 0.30 (*poor*), and *satisfaction* 0.81 (*excellent*).

## Keywords

*Usability, learnability, efficiency, memorability, satisfaction*

## 1. INTRODUCTION

Usability is part of the concept Human Computer Interaction, where the study area is make the computer system easy to be learned and used (Preece et al. 2002). Usability study consists of several dimension according to Nielsen (1993) and ISO-9241, which are learnability, efficiency, memorability, errors, and *satisfaction*. Result of the study can be used by user in condition of choosing software that is user friendly, comfortable, not take long time to operate and achieve user's objective. On software developer side, usability study will benefit the team to develop product that meet close customer needs.

### 1.1. Objective

Usually software house attach the control chart module to equip the product to be more powerful. The control chart itself is widely used in business and education since first time invented by Shewhart and tested through long period of application. The research is designed to measure usability EWMA control chart built in Minitab software.

### 1.2. Scope

The respondents are limited to the IE active students, range from class of 2008 until 2010. There is consideration why the respondent taken from the same department, there is probability that in other engineering, the control chart is not taught yet or not included in curriculum.

## 2. RESEARCH METHODOLOGY

Initial phase of the research begin with searching important literature study such as the theory released by Nielsen and official document from ISO 9421 that will be used as reference point for further steps. After that, next is to define the objective, to measure usability using dimensions covered in the theory. The experiment was initiated with location decision, material - tools selection, respondent criterion, research indicators, module creation, training the respondents, and fill the pre-test until post test and finally distributing-collecting questionnaire. The test divided

into two different period, pre-test consists of three problems with each of the case have different number of step to be completed and then one week after pre-test, the respondents enter post-test phase which require them to redo the same questions and then each students need to fill the questionnaires. Tests applied are normality, homogeneity and mean test using ANOVA or Kruskal-Wallis applied to observation data, while for questionnaire result will be examined by validity test using corrected item-total correlation approach, and reliability test based on cronbach alpha. Normalization phase run with objective to have one measurement scale between dimension, before the whole total value and each factor of usability taken place.

### 3. DATA COLLECTION AND DISCUSSION

In the initial phase, some type of data such as variable and attribute data were collected and summarized in one table. Table 1 below showed the average and standard deviation of the pre-test score, time to finish the task given, time required to correct mistake and number of mistake made by respondents. Number of dimension covered in first phase is three, while memorability and satisfaction will be conducted on the next stage.

Table 1: Data Collection Phase 1

Class	Learnability Dimension							Efficiency Dimension					
	a. Pretest Score						b. Avg part of module seen	a. Time to Finish Pre-Test (second)					
	Mean	Stdv	Mean	Stdv	Mean	Stdv		Mean	Stdv	Mean	Stdv	Mean	Stdv
	Q1	Q1	Q2	Q2	Q3	Q3	Q1	Q1	Q2	Q2	Q3	Q3	
2008	77.19	8.75	84.69	6.18	91.56	5.69	3.44	98.25	25.54	148.50	32.11	178.94	28.35
2009	86.20	7.54	90.60	5.46	96.20	3.89	2.44	51.08	16.59	122.76	19.17	135.80	19.68
2010	78.82	6.97	81.76	6.74	89.41	4.96	3.88	99.41	24.68	163.29	24.95	187.12	31.44
Error Dimension													
Class	Number of Mistake						b. Time to Correct Mistake (second)						
	Mean	Stdv	Mean	Stdv	Mean	Stdv	Mean	Stdv	Mean	Stdv	Mean	Stdv	
	Q1	Q1	Q2	Q2	Q3	Q3	Q1	Q1	Q2	Q2	Q3	Q3	
2008	4.56	1.75	3.06	1.24	1.69	1.14	4.56	5.53	13.94	8.93	23.44	14.92	
2009	2.76	1.51	1.88	1.09	0.76	0.78	1.08	0.95	6.28	6.75	11.04	8.15	
2010	4.24	1.39	3.65	1.27	2.12	0.99	5.12	5.44	13.53	11.79	21.82	9.84	

After the data collection of the first stage finished, the respondents gathered again to finish the same task given. They were tested to know whether still remember the steps to finish the problem and do the mistake. Table 2 summarizes the average error of comparison between pre-test and post-test.

Table 2: Data Collection Phase 2

Class	Memorability Dimension											
	Average Error of Test						Stdev Error					
	Q1	Q1	Q2	Q2	Q3	Q3	Q1	Q1	Q2	Q2	Q3	Q3
	Pre	Post	Pre	Post	Pre	Post	Pre	Post	Pre	Post	Pre	Post
2008	4.56	6.00	3.06	4.63	1.69	2.69	1.75	1.86	1.24	1.63	1.14	1.14
2009	2.76	4.52	1.88	3.68	0.76	1.72	1.51	1.39	1.09	0.90	0.78	0.89
2010	4.24	6.35	3.65	4.76	2.12	2.59	1.39	1.77	1.27	0.75	0.99	1.18

To measure satisfaction score, the respondents were given questionnaire to filled and submitted to surveyor. They had to complete 20 questions using likert scale from lowest 1 which is strongly disagree until the highest 5 if they are strongly agree about satisfaction using EWMA control chart of the software. The accumulation maximum score will be 5800, get from multiplication number of highest likert scale of 5 number of questions and number of respondents.

$$\% \text{Satisfaction} = \frac{4.181}{5.800} \times 100\%$$

$$\% \text{Satisfaction} = 72.086\%$$

The score 4181 of total 5800 result around 72% and this value belongs to category satisfy in range 61% - 80%.

#### 3.1. Normality Test

Null hypothesis in normality test using Kolmogorov Smirnov state that data is normally distributed, while H<sub>1</sub> is vice versa. The p-value needs to be larger than 0.05 in order null hypothesis accepted. The normality test result that only time taken to finish pre-test is normal distribution, but for pre-test score, time to correct mistake, number of error, and number of error in post-test as followed: *Box-Cox Transformation, Largest Extreme Value, 3-Parameter Lognormal, and 3-Parameter Weibull.*

Table 3: Normality Test

Normal Distribution Test: Kolmogorov Smirnov				Non Normal Distribution	
Dimension	Item	P-value	Normal Distribution?	AD Score	Distribution
Learnability	Pre-test score	0.01<0.05	N	2.894	Box Cox Transformation
Efficiency	Time to Finish pre-test	0.15>0.05	Y	-	-
Efficiency	Time to Correct Mistake	0.01<0.05	N	6.206	Largest Extreme Value
Error	Number of Mistake	0.01<0.05	N	2.989	3 Parameter Lognormal
Memorability	Number of Error in Post-Test	0.01<0.05	N	2.055	3 Parameter Weibull

### 3.2. Homogeneity Test

Homogeneity test with prerequisite condition that data is normally distributed using Bartlett method was run to test whether two or more samples of same population also have the same variance. This will be applied to time taken to conduct pre-test for the reason that it is the only one that passed the category. Null hypothesis for homogeneity test states that there is no difference in variance between three cases if p-value greater than 0.05. The p-value from computation using software is 0.537, therefore null hypothesis is accepted.

### 3.3. ANOVA Test

ANOVA test is run to test whether there is mean difference between the three problems in pre-test. Furthermore, the same test will be applied to see whether difference between the classes of respondents. In condition there is difference among the mean, next Post Hoc Test assumed equal variance with Tukey method will take place to reveal which population is distinctive, which required data normally distributed and homogenous. Table 4 exhibits the significant value of both ANOVA test is zero which is less than 0.05, so it can be stated to reject the null hypothesis since there is mean difference between each case and between each class.

Table 4: ANOVA Test

	Between Class Respondents					Between Three Problems				
	Sum of Squares	df	Mean Square	F	Sig.	Sum of Squares	df	Mean Square	F	Sig.
Between Groups	79868.484	2	39934.242	21.034	.000	224429.011	2	112214.506	106.551	.000
Within Groups	324649.889	171	1898.537			180089.362	171	1053.154		
Total	404518.374	173				404518.374	173			

Table 5 section post hoc tests between cases exhibits that beside all significant value are less than 0.05, there are star sign in mean difference for each row which mean the three cases have mean significant different. Same approach applied to post hoc test between class and the result is significant different between class 2008-2009 and 2009-2010.

Table 5: Post Hoc Test

Post Hoc Test Between Case					Post Hoc Test Between Class				
(I) Case	(J) Case	Mean Difference (I-J)	Std. Error	Sig.	(I)Class	(J) Class	Mean Difference (I-J)	Std. Error	Sig.
Case 1	Case 2	-63.483 <sup>*</sup>	6.026	.000	2008	2009	38.683 <sup>*</sup>	8.054	.000
	Case 3	-84.483 <sup>*</sup>	6.026	.000		2010	-8.045	8.762	.630

Case 2	Case 1	63.483 <sup>+</sup>	6.026	.000	2009	2008	-38.683 <sup>+</sup>	8.054	.000
	Case 3	-21.000 <sup>+</sup>	6.026	.002		2010	-46.728 <sup>+</sup>	7.908	.000
Case 3	Case 1	84.483 <sup>+</sup>	6.026	.000	2010	2008	8.045	8.762	.630
	Case 2	21.000 <sup>+</sup>	6.026	.002		2009	46.728 <sup>+</sup>	7.908	.000

### 3.4. Kruskal Wallis Test

Kruskal Wallis Test which is similar with ANOVA test is non-parametric technique used to measure mean difference from non-normally distributed data. The point of interest is where  $H_0$  state no difference between the mean and null hypothesis accepted if sig value is greater than 0.05. Mann-Whitney test will be applied as the next step after Kruskal Wallis Test, similar with Post-Hoc Test in ANOVA. Data that will be examined in the test as follow: pre-test score, time to correct the mistake during pre-test, number of error during pre-test and number of mistake during post-test.

Table 6: Kruskal Wallis & Mann Whitney Test

Dimension	Item	Sig Value		Note	Mann-Whitney Test's Sig Value		Note	Note
		Case	Class		Case	Class		
Learnability	Pre-test score	0.000	0.000	Reject Ho	<0.05	<0.05	Case & Class 1, 2, 3	Mean Different
Efficiency	Time to Correct Mistake	0.000	0.000	Reject Ho	<0.05	<0.05	Case & Class 1, 2, 3	Mean Different
Error	Number of Error in Pre-Test	0.000	0.000	Reject Ho	<0.05	0.556	Class 2008 vs 2010	Not different for class 2008 vs 2010
Memorability	Number of Error in Post-Test	0.000	0.000	Reject Ho	<0.05	0.927	Class 2008 vs 2010	Not different for class 2008 vs 2010

### 3.5. Validity Test

In this validity test, the objective is to measure is the satisfaction of respondent when using the software by looking value of Corrected Item-Total Correlation. The questionnaire valid if the counted r-value is larger than r-table from Product Moment. Degree of freedom is 56, resulted from number of respondents deducted by 2. As with degree of freedom 56 not included in the table, the calculation to get result is by using interpolation.

$$\frac{56-55}{60-55} = \frac{r-0.266}{0.254-0.266}$$

$$r = 0.2636$$

R-value for each of 20 questions are larger than 2.636, with 0.278 is the minimum value of r. Therefore as all the value pass r-table, it can be concluded that 20 indicators is valid.

### 3.5. Reliability Test

Reliability test using statistical software show that the cronbach'alpha score 0.833 as shown in table which is greater than 0.7. Therefore with confidence level 95%, the questionnaire distributed to students is reliable.

Table 7: Reliability Test

Reliability Statistics	
Cronbach's Alpha	N of Items
.833	20

### 3.6. Normalization

The purpose on this activity is to eliminate the unit from each attribute, so that each will have the same measurement unit. It is necessary step for five dimension to test whether the usability of this control chart's software good or not based on category table 8, which defined by Chiew and Salim 2003.

Table 8: Category of Normalization Value

Points, x	$0 \leq x \leq 0,2$	$0,2 < x \leq 0,4$	$0,4 < x \leq 0,6$	$0,6 < x \leq 0,8$	$0,8 < x \leq 1,0$
Usability Level	Bad	Poor	Moderate	Good	Excellent

First step in normalization is summarize data per respondent as follow: the average score of each respondent for pre-test score, frequency of number of module seen which can be zero if respondent not looking the module, average time needed for each respondent to complete the pre-test, average time to correct mistake, average number of mistake, average number of error for pre-test, average number of error for post test. Next is to calculate normalization value for each respondent. For instance, when calculating pre-test score it is known that the bigger the score the better the usability value, so divide score each respondent for each category with the biggest value on that column. After normalization for each dimension is completed, the final step is compute an average usability value to represent the level usability level of the software

$$\begin{aligned}
 Usability\ Level &= \frac{\text{Average Normalization Every Indikator Usability}}{\text{Number of indikator usability}} \\
 &= \frac{0.87 + 0.55 + 0.61 + 0.68 + 0.44 + 0.30 + 0.81}{7} \\
 &= 0.61
 \end{aligned}$$

When the average value 0.61 compared with the table 8, the score fall into category good where its range is vary between 0.6 until 0.8. It means that the usability level for EWMA control chart of this software is good.

#### 4. CONCLUSION

From the experiments, it can be concluded overall usability of the software is good with the score 0.61, however not all dimension belong to good category. The result good category is the same for the first two dimension, where learnability get 0.71, efficiency get 0.64, but error dimension get moderate score of 0.44, memorability get poor level of 0.3, and satisfaction get 0.81 which is excellent.

E-mail : patricia.hanna@ui.ac.id

## ABSTRACT

Given the fact that Indonesia is on the equator zone with abundant sunshine, the utilization of solar cell technology to generate electricity is still not well developed. On the other side, demand for electricity is steadily increasing, especially from household consumers. This study aims to determine the technical utilization of solar power system as a source of electricity generator and its feasibility to be used in middle-class residential houses. Two types of solar power system being reviewed are stand-alone system and grid connected system. The result shows that installation of the system in a middle-class resident may not be economically rewarding due to high cost of the solar system investment compared to the electricity cost from conventional system. However, the sensitivity analysis shows the systems are being economically feasible in certain circumstances.

## Keywords

*Solar cell, feasibility study, middle-class residential houses, sensitivity analysis*

## 1. INTRODUCTION

Electrical problem in Indonesia begins from the fact that the energy need increases more than the ability of the State Electric Company (Perusahaan Listrik Negara, PLN) fulfills the required energy. Electricity demand from year to year increases with rate about 7.2% per year while the electricity generation capacity development grew steadily of 5.1% per year [1]. According to the reference [2], household and industry sector are the biggest electrical energy consumers. This fact is supported by the population of Indonesia reached 237 million with the population growth rate of 1.49% per year (BPS, 2010). Electricity demand growth in Indonesia causes existing primary energy deposit is diminishing. This prompts the government to look for alternative energy resource to produce substantial amount of energy but does not have negative impact for the environment.

Solar energy is one of potential renewable energy sources to use in Indonesia. The energy received by the earth's surface is only 51% of the total solar radiant energy. On a sunny day, solar radiation can reach 1000 watt/m<sup>2</sup>. If a semiconductor device (solar cell module) of 1 m<sup>2</sup> has an efficiency of 10%, then, it is capable to provide electric power in about 100 Watt. Right now the efficiency of commercial solar cell modules ranging from 5% -15%. As addition to energy, solar cell panels do not produce pollution.

One constraint on the solar cell utilization in Indonesia is technology availability for its production. Indonesia has only solar cell assembly industry. Raw materials are imported from other countries. Because of this, the solar cell price is expensive. The life time of solar cells commonly referred as photovoltaic (PV) that currently applied is 25 years [3]. Based on data collection from 18 locations in Indonesia, solar radiation in Indonesia can be classified as follows: in Western Indonesia has approximately 4.5 kWh/m<sup>2</sup> daily with monthly variation 10%, and in Eastern Indonesia has approximately 5.1 kWh/m<sup>2</sup> daily with monthly variation 9%. For this reason Indonesia has a quite large potential of solar energy. With the high potential solar radiance in Indonesia, it is expected that the use of solar cells as a source of electrical energy in residential house can be a part of proper solution. Thus, the objectives of this study is to investigate what system and capacity of solar panels can be used as the source of electrical energy in the middle-class resident. This research is continued to determine the feasibility of using solar cell as a source of electrical energy with the most favorable scenario and the most influential factor in the investment project.

## 2. METHODOLOGY

### 2.1 The Technical Calculation of Solar Power System

For technical system design installation of solar cells, the type of house and direction of the building are identified. This study is using Cyber Orchid Town Houses Residential. The house classification is used for estimating future technical (mounting of the tilt) of solar panels to be placed on the roof area.

Category A, building's size: 85, building's side: north - south

Category B, building's size: 85, building's side: west - east

Category C, building's size: 40, building's side: - south

Category D, building's size: 40, building's side: west - east

Area of all roof is evenly 32 m<sup>2</sup>. The monthly electrical energy usage for each house is known from PLN Depok. The result, the average electric energy utilization per day is 10.03 kWh. Hence, in calculating the area of solar power system to generate that amount of energy can use the formula:

$$\frac{E_L}{G_{av} \times \eta_{pv} \times TCF \times \eta_{out}} = PV \text{ Area}$$

The average daily consumption of electric energy in this residential ( $E_L$ ) is 10.03 kWh.  $G_{av}$  is the value for daily isolation every hour approximately 0-1 kWh/m<sup>2</sup> from 06:00 until 18:00 (according to the daily sun movement).  $\eta_{pv}$  is the value of the solar panel efficiency 14.5%. The value of  $\eta_{out}$  is the compound of all components efficiency of the solar power system. Solar system also consists of battery, inverter and controller. Then, the  $\eta_{out}$  value gets from the multiplication of the components efficiency.

$$\eta_{out} = \eta_b \times \eta_i \times \eta_c = 0,95 \times 0,97 \times 0,98 = 0,903$$

Standard temperature for the solar panels can work well is 25°C. Meanwhile, according to geographic data from NASA, the maximum temperature is 27.1°C in Depok. So there will be a reduction in generated power when the temperature rises. So, the TCF value is 0,9895. If the values of  $G_{av}$ ,  $\eta_{pv}$ , TCF,  $\eta_{out}$  are being substituted to the formula of PV area, then the result is:

$$\frac{10.03 \text{ kWh}}{3,3 \text{ kWh/m}^2 \times 0,145 \times 0,9895 \times 0,903} = 24,748 \text{ m}^2 \approx 25 \text{ m}^2$$

Components of solar power system are as follows:

- Solar Panel. Solar panel in this case is using the same specification with ASL-M50 from PT. Azet Surya Lestari. This solar panel has capacity at standard conditions 50 watt-peak. The area of solar panels which is used in the installation plan of solar power system is a 25 m<sup>2</sup>. It can be filled with 56 pieces of solar panels. The solar panel arrangement is divided into two sections to the side of the roof. Installation is directed to the north at an angle of 25° on both sides of the roof [4]. Because of Depok is located in the south of equator (6°LS), the solar panel should be oriented to the north.
- Battery. Battery capacity in the solar power system is a deep cycle battery which has a capacity of storing energy by 1000 ampere-hour and voltage of 2V. The cycle of this battery is specifically designed for energy storage. This battery is suitable for renewable energy systems because it has long life cycles (thousands cycles) and has a capacity of 80% for use before recharging. Ideally, a battery's bank of energy should be able to store electrical energy for 3-5 days. If the battery bank capacity is less than 3 days, it will affect the cycle of battery life that will make the battery life becomes shorter.
- Inverter. The inverter is using the same specification with SUNNY BOY 5000TL.
- Controller. Controller in this case is using the same specification with Sunny Backup 2200.

The solar power system is generally divided according to the configuration of its components. There are 2 types of solar power system which is widely known.

- The grid connected system. This system is the union of solar power system with other power lines (conventional or grid electricity from renewable energy systems). The most important component in this system is inverter. Inverter serves to convert the DC which generated by solar panels into AC and it is adjusted to suit the requirements to other connected power grid. In this system, other components are not necessary because electric energy from batteries which generated from solar panels will be replaced by conventional power grid (in this study is PLN). When the solar panels are not generating the electrical energy, conventional grid will fulfill of the electrical energy needs.
- The stand alone system is designed to operate in producing electrical energy self-sufficient for electricity needs in one place. In other words, the type of power system is only activated by solar panels. The most important component in stand-alone solar power system is battery because it is used for backup storage and distribution of electrical energy generated. When the solar panels cannot generate electricity, then the electrical energy will be drawn from the battery.

## 2.2 Calculation of Solar Power System Feasibility

The period of the study is 25 years (the life time of solar panel). The feasibility of the investment of solar power system can be calculated by following methods [5]:

- Net Present Value (NPV). The calculated value of cash flow to get the NPV is the sum of the value of money in period zero or known by the present value to the value of net cash flow (income minus expenses) are calculated using the present worth factor as a benchmark for the balance of the existing present value.
- Payback Period (PB) is the length of the period to restore the value of the investment through revenues generated by the project. Discounted payback period (DPB) is the refund period is calculated using the discount factor.
- Benefit Cost Ratio (BCR) is another method for validating the results of the evaluation projects that has been done with other methods before. This method is properly to use in order to evaluate the government projects that have direct impacts in communities (public government project).

The components of the initial investment costs: cost for solar power system components, rack panel installation costs and installation costs the system. The component cost of solar power system is for solar panels, batteries, inverter and controller. Because there are two types of solar power system which are being studied then there are also 2 types of investment options:

- Investment of stand-alone solar power system: Rp. 389 542 418, -
- Investment of grid connected solar power system: Rp. 226 584 018, -

Yearly operational and maintenance cost for solar power system is generally calculated as 1% of the total initial investment cost for components of solar power system [6] Therefore, the total cost of operation and maintenance of both types of systems solar power in the case study research are:

- Operational and maintenance (O&M)costs for stand-alone solar power system = 1% x (Rp 126 million, - + Rp. 17,795,798, - Rp. 162 958 400, - + Rp. 23,888,220, -) = Rp. 3,306,424, -
- O&M costs for grid connected solar power system = 1% x (Rp 126 million, - + Rp. 17,795,798, - Rp. 23,888,220, -) = Rp. 1,676,840,-

Component for an income or cash-in in stand-alone solar power system is monthly electricity bill which is saved of using solar power system. Cash-in for grid connected in cash flow of solar power system is from the electrical energy sold to PLN system and being valued according to the feed-in-tariff regulations. From the regulation of Minister of Energy and Mineral Resources No. 4 of 2012, the cost of purchasing electric energy from renewable energy sources is Rp. 1.004,-/kWh for Java-Bali region. While in President Regulation no. 8/2011 explains the cost of electricity for household level is Rp. 790,-/kWh up to Rp.795,-/kWh.

### 3. RESULTS AND DISCUSSION

Tables 1 and 2 below show calculation results of stand-alone and grid connected system, respectively. The tables indicate none category of the resident has positive NPV. Considering that the initial investment of this project is very large (approximately Rp. 390.000.000,-) but the money saved from the electric bill is very small (only about Rp. 400.000,-) monthly. In addition, solar power system is also incurred operating and maintenance cost each year that further reduces the cash inflow values. In conclusion, this project is not economically feasible. For the grid connected system (table 2), PLN buying price is Rp. 1.004, -/kWh. This value of is apparently not big enough to recover the huge amount of initial costs. For the house category A and category B their PB is unknown due to the value of the cash-in flow is smaller than the cash out flow.

Table 1: Results from Stand Alone Solar Power System

House Category	Feasibility Indicator		
	Net Present Value (NPV)	PB (year)	B/C Ratio
Category A	(Rp. 382.532.914,-)	63	0,089
Category B	(Rp. 371.910.857,-)	54	0,31
Category C	(Rp. 376.963.904,-)	57	0,27
Category D	(Rp. 376.963.904,-)	57	0,27

Table 2: Results from Grid Connected Solar Power System

House Category	Feasibility Indicator		
	Net Present Value (NPV)	PP (year)	B/C Ratio
Category A	(Rp. 241.694.242,-)	-	0,15
Category B	(Rp. 232.818.351,-)	-	0,15
Category C	(Rp. 222.700.150,-)	63	0,15
Category D	(Rp. 225.990.353,-)	81	0,15

Sensitivity analysis was then performed to see how any changes in the cash flow components such as lowering the initial investment cost, reduction of O&M cost, rising PLN buying price and increasing solar system efficiency influence the NPV (see figures 1 and 2).

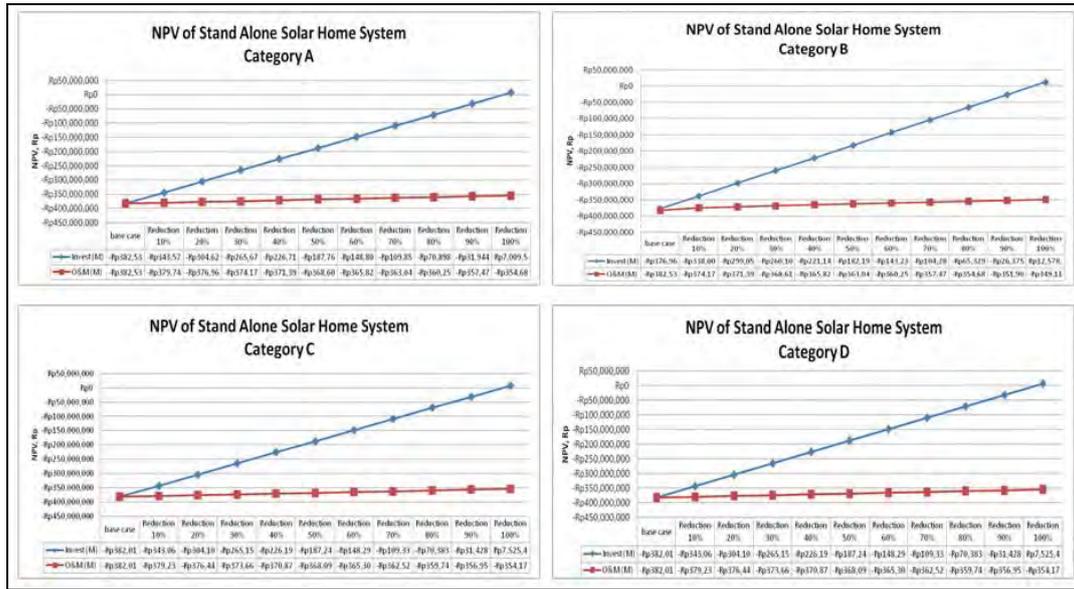

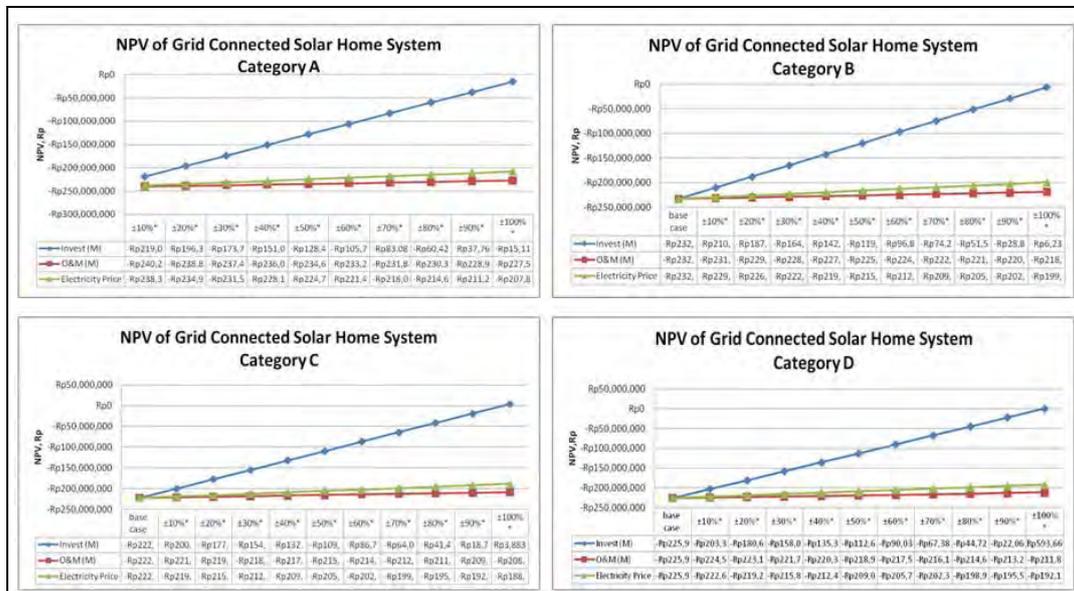

Figure 1: Sensitivity Analysis Cash Flow for Stand Alone Solar Power System

Figure 1 and 2 show that the NPV turned out to be positive if the initial investment decreases by 100%. This condition might be applicable if the government totally subsidizes PV likes happen on the kerosene to liquefied petroleum gas (LPG) conversion program. At that time, the government provides incentives by giving the LPG bottle freely (Presidential Decree 104/2007). As for the change in the operational and maintenance costs, they do not give significant effect on the NPV values. The slopes are fairly flat. The situation also occurs for the electricity buying price. The NPV is not changed much. Even the impact is slightly less than the impact of O&M costs likes the slopes depicted.

\*- for reduction investment and yearly O&M cost; + for the rising of selling price of electricity

Figure 2: Sensitivity Analysis Cash Flow Grid Connected Solar Power System

Sensitivity analysis results for 2 variables such as changes in initial investment costs and in O&M costs stand alone solar power system are shown in figures 3 and 4. A decrease of 100% is equated with the concept of calculation of leveling cost of

electricity (LCOE) [7]. The results shows that for all types of houses, the NPV will be positive when the initial investment reduced by 100% and O&M costs by 10%.

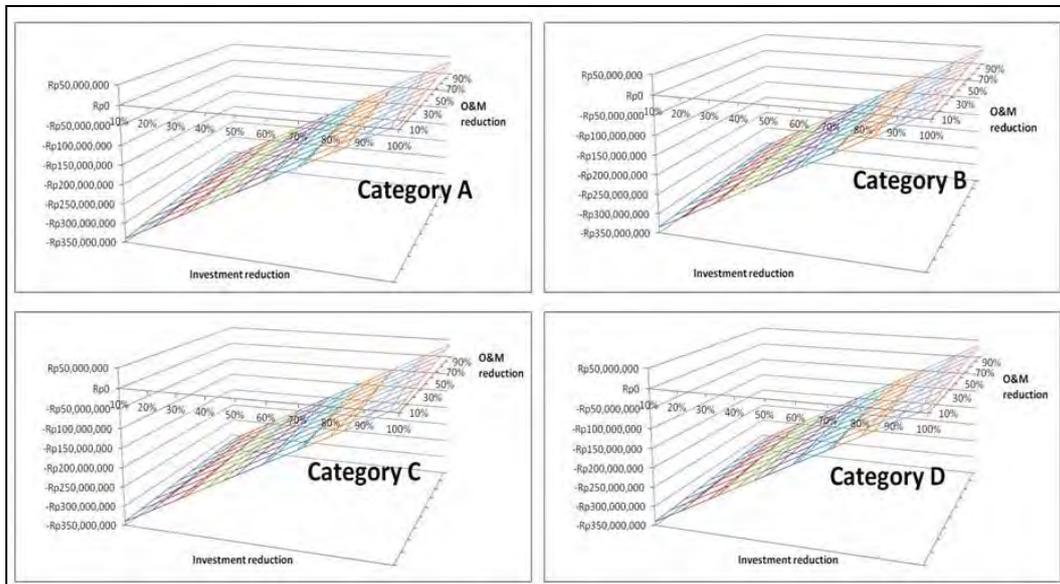

Figure 3: Sensitivity Analysis Cash Flow Stand Alone Solar Power System

For the grid connected system, the NPV is checked when a combination of falling prices and rising investment occur. The graph shows the changes of slope which means both components are the most sensitive to affect the NPV. Figure 4 shows the NPV will be positive if the initial investment drops by 100% and the electricity price increases at 30% -50%.

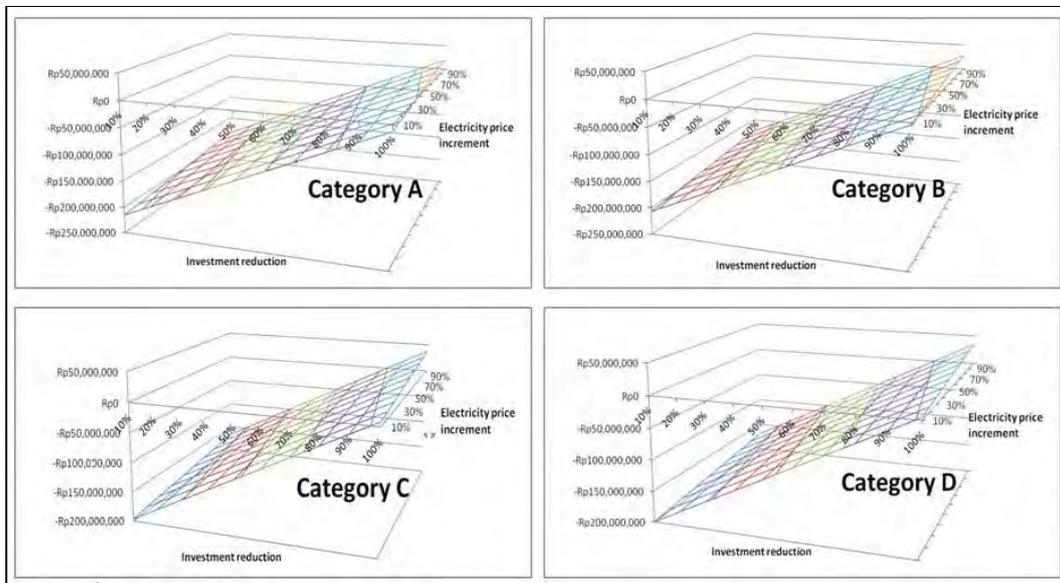

Figure 4: Sensitivity Analysis Cash Flow Grid Connected Solar Power System

Figure 5 shows the effect of efficiency to the NPV. Currently the solar panels achieve the highest efficiency at the rate of 18% - 20%. This efficiency is quite small compared to other power generation systems, for example landfill gas combustion engine efficiency. The waste power plant efficiency rate is 84.2%. Figure 5 clearly shows that even with efficiency 80%, the NPV is still not positive. In this case, to have NPV positive the efficiency should reach 95%. None generating system can produce 100% efficiency.

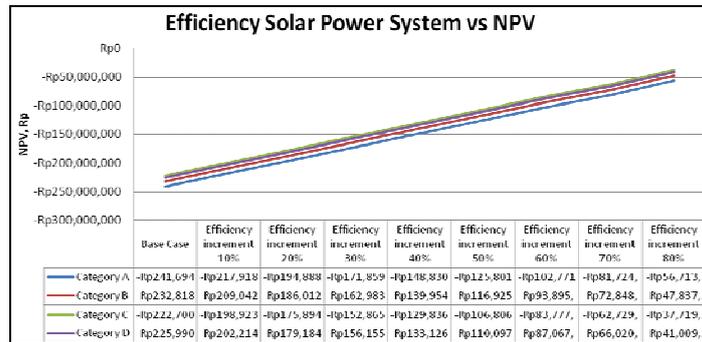

Figure 5: NPV versus Efficiency Grid Connected Solar Power System

#### 4. CONCLUSION

Solar power system suitable for middle-class residential should be designed to generate power up to 1.1 kW as the needs of electricity from Cyber Orchid Town Houses, Depok indicated. With that design, the solar system can generate electrical energy of approximately 10.95 kWh daily or 3997 kWh yearly. However, the NPV calculated for 25 years of the system life time ends up as negative. This means solar cell system is not suitable to be used as electricity generator for middle class houses. The result is reasonable due the fact that the initial investment of the system is very high. But, on the other side, it gives a very small cost saving each year. Sensitivity analysis results show the most sensitive factor for NPV is the decreasing of investment costs and raising electricity price. Sensitivity analysis also shows that optimal system to be used is solar cell system with battery.

E-mail: dsihono@yahoo.com

## ABSTRACT

*Main problem of how to improve motorcycle user satisfaction as dependent variable is not only to find independent variables and its impacts, but also intervening variables and its types and magnitude of intervention. This proposition is a new and better construct than current mainstream of customer satisfaction paradigm that more focused on finding out of independent variables and its impacts. So, objectives of this research were to define those intervening variables and to show empirical evident of its intervention coefficients. Subject of this research were two group of motor cycle users based on type of vehicle, automatic and manual category of motor cycle, in Jakarta, Bogor, Depok, Tangerang and Bekasi. They were asked to indicate their perceptions on the six-point Likert-type scale. Structural equation modeling (SEM) applied to manifest the model suitability and develop a standard questionnaire to obtain user's perceptions about customer satisfaction and its independent as well as intervening variables. This research found out a new empirical evident that both Vehicle Operation Knowledge and Vehicle Operation Discipline intervened between those relationship. This conclusions provide valuable insight into motor cycle manufacturers that their efforts in improving product quality, performance and reliability were not always resulted with better user's satisfaction.*

## Keywords

*satisfaction, intervening variables, motor cycle*

## 1. INTRODUCTION

Motorcycles have become a very interested transportation for most of society in Indonesia. Motorcycles are regarded as means of transport which are relatively easily affordable to buy, both in urban and rural areas. The low of income, bad infrastructure and undeveloped mass transportation system making the society choosing the motorcycle became an important transportation tool.

Competition between manufacturers continually increase along with the rapid growth of Motorcycle Industry. Therefore, it is a challenge for the motorcycle to improve the company's competitive advantage in order to be successful in capturing market share competition.

For that purpose, the company's ability to meet the needs and satisfaction of the customers is one very important thing. This ability was strongly influenced by level of quality provided. The higher of company quality level given to customers, it can increase the level of customer satisfaction. But, if there is a gap between the level of quality provided the company with customer expectation, it will causes dissatisfaction of customers that affect to decrease the company market share

## 2. LITERATURE STUDY

Customer satisfaction has a direct relationship with sales and profit. If customer satisfy, they can be a loyal customers. The loyal customers not only repeat to buy but also recommend the product to other people based on the quality of products they experienced as stated by Conklin [1].

The determination of product quality dimension may refer to Garvin Eight Dimensions [2]:

1. *Performance*, the product's primary operating characteristic, especially with a function. It is main characteristic that people consider to buy the product.
2. *Features*, are additional characteristics that enhance the appeal of the product or service to the user.

3. *Reliability*, Probability of successfully performing a specified function for a specified period of time under specified conditions
4. *Conformance*, Degree to which a product's design and operating characteristics meet established standards.
5. *Durability*, reflection of the economical age or product lifetime
6. *Serviceability*, ease of service or repair when needed.
7. *Aesthetics*, it is about display, packaging, flavour, sound, smell.
8. *Perceived Quality*, quality are received or accepted by customer.

Chiu, et al. in 2011 [3] shows some factors that can affect to customer satisfaction of car at Taiwan. These factors are *Image*, *Customer Expectation*, *Perceived Quality* and *Perceived Value* as following picture:

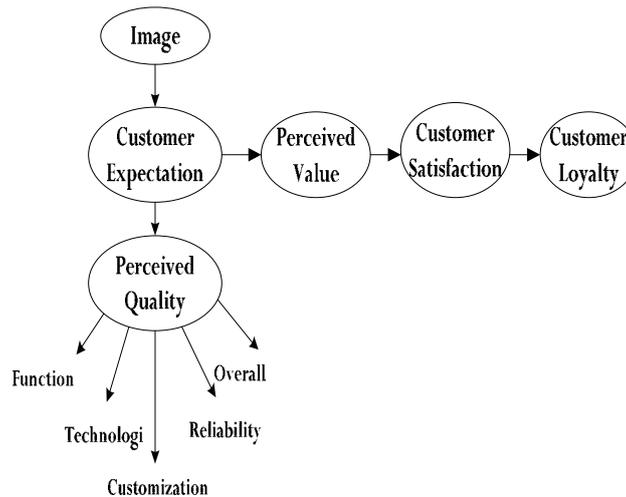

Figure 1: Cars Customer Satisfaction Model at Taiwan [3]

### 3. METHODOLOGY

This research was conducted to determine the comparative relationship some subject with sample of respondents examined through data capture in the short term. The population was observed in this study are the users of motorcycles with the type of duck and matic in Jakarta, Bogor, Depok, Tangerang and Bekasi. Because the population is too large, the research uses sampling method.

This research using Structural Equation Modeling method [4] usually abbreviated with SEM. Below is the initial model of the research that will be tested first.

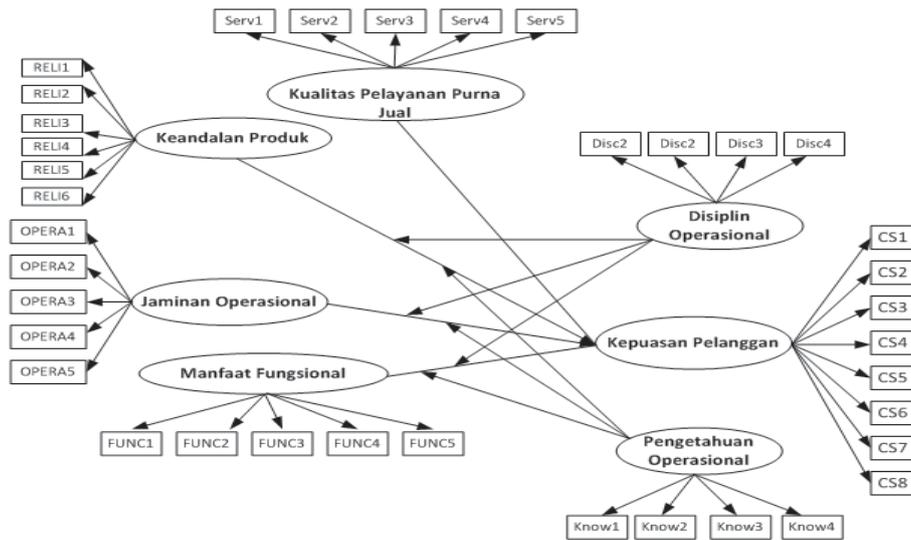

Figure 2: Research Initial Model

The hypothesis will be tested in this research is:

- H1: Customer satisfaction motorcycles positively influenced by fulfillment of Functional Benefits.
- H2: Customer satisfaction motorcycles positively influenced by fulfillment of Operational Guarantee.
- H3: Customer satisfaction motorcycles positively influenced by fulfillment of Vehicle Reliability.
- H4: Customer satisfaction motorcycles positively influenced by fulfillment of the quality of after-sales service.
- H5: Operational knowledge positively strengthen the relationship between the Functional benefits of Fulfillment with customer satisfaction.
- H6: Operational knowledge positively strengthen the relationship between the fulfilment of Operational Assurance with customer satisfaction.
- H7: Operational knowledge positively strengthen the relationship between the reliability of vehicles with customer satisfaction.
- H8: Operational discipline positively strengthen the relationship between the Functional benefits of Fulfillment with customer satisfaction.
- H9: Operational discipline positively strengthen the relationship between the fulfilment of Operational Assurance with customer satisfaction.
- H10: Operational discipline positively strengthen the relationship between the reliability of vehicles with customer satisfaction.

The questionnaire contains two major parts, the question of respondent information and related variables of user gratification motorcycles using 6 category likert scale. These are all factors (variables) are tested on research:

1. Functional Benefits Fulfillment (*Functions*): The fulfillment of customer benefits that related to functional properties of motorcycles according to Chiu et al statement [3].
2. Operational Guarantee Fulfillment (*Assurance*): The fulfillment of customer assurance that related to operational characteristic of motorcycles
3. Vehicle Reliability (*Reliability*): The size of the possibility of such a product (vehicles) will not be damaged during a specific time period according to Kotler [5].
4. The Quality of Service (*Service Quality*): Customer perception of maintenance fulfillment guarantees of vehicles as well as relational comfort with service providers according to Kotler [5].

The proposed intervening variable is:

1. Operational Knowledge: User knowledge of motorcycle-related expertise and skills necessary to take advantage of the bike properly.
2. Operational Discipline: The discipline of motorcycle users to meet the technique requirements needed to use a motorcycle properly.

#### 4. RELATIONSHIP BETWEEN VARIABLES

After a pilot test, reliable and valid questionnaire is used in collecting data process according to sample number needed. This process was undertaken from April until may 2012 and have 517 questionnaires. From 517 questionnaires, found 22 questionnaires was invalid because some of the answers are empty, so only 495 questionnaires which can be used in data processing. Following are the results of data processing using SEM:

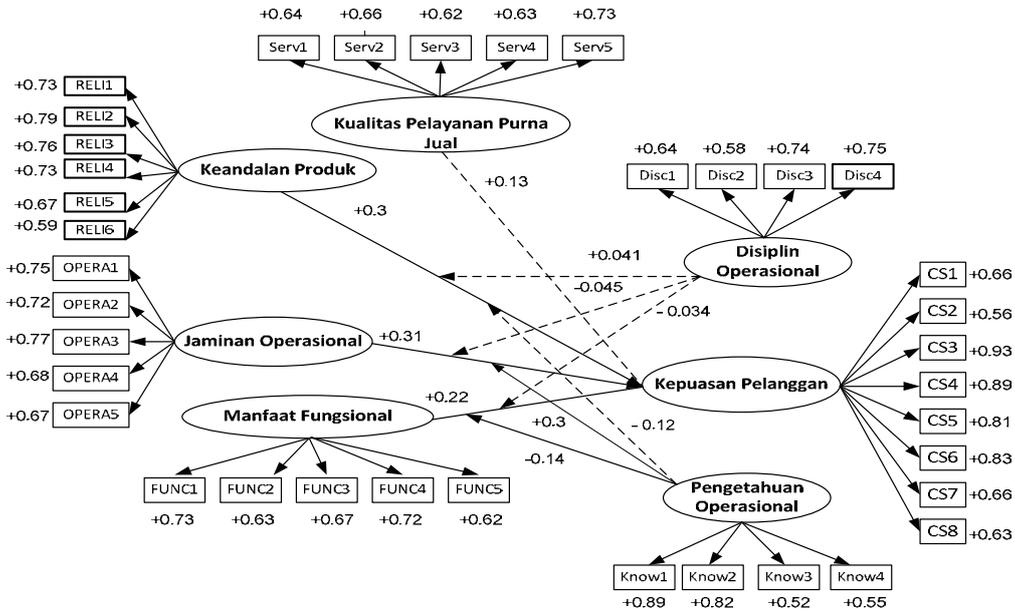

Figure 3: Relationship between variables of the motorcycle matic type users

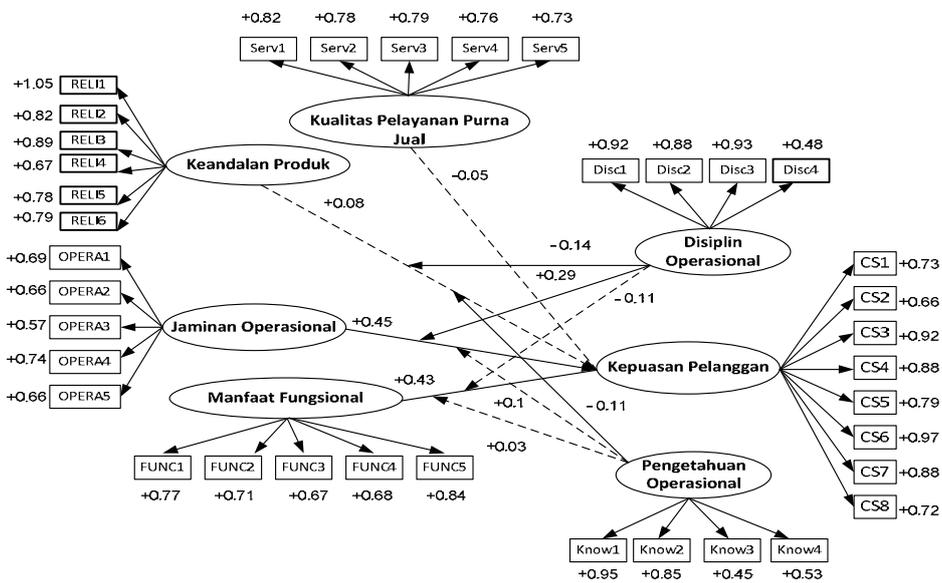

Figure 4: Relationships between variables of the motorcycle type duck users

Table 1: Comparison of variable between duck and matic motorcycle type

No	Relationship	Duck Type		Matic Type	
		Coefficient Value	Conclusion	Coefficient Value	Conclusion

**Description:**

- FUNC: Functional Benefits Fulfillment
- OPERA: Operational Assurance Fulfillment
- RELI: Vehicle Reliability
- SERV: Quality of After Sales Service
- KNOW: Operational Knowledge
- DISC: Operational Discipline
- KNOWFUNC: Operational Knowledge\*Functional Benefits Fulfillment
- KNOWOPERA: Operational Knowledge\* Operational Assurance Fulfillment
- KNOWRELI: Operational Knowledge \*Vehicle Reliability
- DISCFUNC: Operational Discipline\*Functional Benefits Fulfillment
- DISCOPERA: Operational Discipline\*Operational Assurance Fulfillment
- DISCRELI: Operational Discipline \* Vehicle Reliability

**5. DISCUSSION AND BENEFIT OF RESEARCH RESULTS**

According to the hypothesis, on the motorcycle duck type, the role of one of the intervening variable is proven, the higher Operational Knowledge will increase the influence of Operational Guarantee Fulfillment variable against customer satisfaction.

On the contrary, intervening variable of Operational Knowledge thus weaken influence Functional Benefit Fulfillment against customer satisfaction. Contradiction of this hypothesis may caused by perception towards the low fulfillment of functional benefit on motorcycle duck type and also decrease their satisfaction. Although these allegations still needed to be tested further. On the duck type: the sequence of significant variable

The results on duck type: the sequence of significant influence variables towards customer satisfaction are Operational Assurance Fulfillment, Vehicle Reliability and Functional Benefit Fulfillment. Quality of after sales service is not significant influence towards customer satisfaction. This happen because most of them didn't use official workshop.

While on the matic type, intervening varibale of operational knowledge will decrease influence of vehicle reliability variable towards customer satisfaction. Contradiction of this hypothesis may caused by low perception of vehicle reliability and also causes low customer satisfaction. But this assumption still needed to be tested further.

Operational discipline variable can increase the influence of operational assurance variable towards customer satisfaction, according to proposed hypothesis. Thus, the sequence of significant variable are: Operational Assurance Fulfillment, Functional Benefit Fulfillment and Vehicle Reliability.

The result of this research can use by motorcycle company as consideration in order to satisfy the customers. Intervening variables of Operational Knowledge and Operational Discipline can influence relationship between independent and dependent variable. Because of that, the influence of this variable should be studied by each company and according to certain brands. On the motorcycle duck type, the company should pay attention in company efforts to increase operational knowledge of users because it significants influence relationship between operasional assurance fulfillment and customer satisfaction. While on matic type, the company should increase operational discipline of users in order to increase relationship between operasional assurance fulfillment and customer satisfaction. For intervening variable that have negative impact, the company should be vigilant, because these happens as a result of low motorcycle performance, so still need to be studied further.

This research is limited to learn some of variables that affect to customer satisfaction, and its increase or decrease by two kinds of intervening variable. Because of that, this model potentially developed by adding new variables to see its effect on customer satisfaction comprehensively. This research also have limited in responent scope that only covers some of the motorcycle users in the area of Jabodetabek.

## ABSTRACT

This research is focused on product development of Cylinder Head, an engine of motor cycle component. The product development is critically important to fulfill customer needs to apply this component in motorcycle racing event. In this case, the customer is eight Partner Teams of the manufacturer that follow Indoprix motorcycle race event. Quality Function Deployment method is used to connect customer needs with manufacturer strategy. Some tools of Value Analysis, such as Mudge Diagram, Matrix of Resources, and Comparison Matrix are implemented to analyze data. The output of this research is a specification of Cylinder Head that can be produced by the manufacturer. This research also determined production cost and the importance of customer need.

## Keywords

*QFD, Value Analysis, Mudge Diagram, Resources Matrix, Comparison Matrix*

## 1. INTRODUCTION

The business process of product development must be focused on the customer. In fact, if it is not customer-based, it will consume more time to deal with customer later [1]. The customer needs can contradict with manufacturer's capability, because customer demands maximum satisfaction, however manufacturers have limitations to fulfill customer needs. In this case, product development attempts to bridge customer needs and manufacturer's strategy. Product development is not a temporary process with haste activity, but need a systematic, measurable, dan limitable steps. Product development process is defined as sequence of steps or activities to arrange, design, and commercialize a product, giving added value to reduce gap with customer need fulfillment [2]. In this research, the product development process is based on Quality Function Deployment (QFD) and Value Analysis (VA) approach.

QFD concept is introduced by Dr. Yoji Akao in Japan in 1966. Akao defines QFD as a systematic method to define design quality to be customer expectation and translate them to be design target and critical quality point, so that can be used in production or service development phase. QFD is an effective total quality management tool based on customer need, and commonly used in product or service development in industry [3]. QFD is consist of 4 phase, are Product Planning Phase, Product Design Phase, Process Planning Phase, and Production Planning Phase. Value Analysis is an investigation method for all components of products to find and eliminate unnecessary cost without damage, disturb, or reduce performance of product [4]. The main purpose of VA study is increased the value for maintaining and increase product performance, while in same case, reduce cost entirely. Value increases if cost reduces with product performance maintaining. Value will also increase if customer wants to pay more [5].

Some of Value Analysis Tools used are Mudge Diagram, Resources Matrix, and Function & Cost Percentage Comparison Matrix. Mudge Diagram is a diagram which describes the importance level of customer needs that have passed pairs comparison before [6]. Resources Matrix is deployment of total cost to fulfill customer needs. The cost is defined to have more detail attribute and illustrated in Resources Matrix [7]. Comparison Matrix of Function and Cost Percentage is a comparison between function importance level in Mudge Diagram with cost percentage in Resources Matrix. This matrix can explain how much cost will be paid to fulfill customer need, with the importance of customer need [7].

This research takes place in a manufacturer who is a market leader in motorcycle industry in Indonesia and primary agent from one of motorcycle trademark from Japan. This manufacturer leads the market and motorcycle selling in Indonesia with

2,701,278 unit sold in 2009, and 3,416,049 unit sold in 2010. However, in 2011, market competition is harder than before. There was 80,000 unit sold difference with competitor in February 2011, and 20,000 unit sold difference in March 2011. Therefore, it is important to apply some new marketing strategies, which is giving attention and special promotion in racing segmentation. The actual marketing activity is become an official sponsorship for eight Team Partners who follow Indoprix motorcycle racing event, the most popular and highest level racing event in Indonesia. This research is based on dissatisfaction of cylinder head component that is produced by manufacturer for Indoprix event. Until now, manufacturer just provides Cylinder Head mass pro standard. It is not suitable, and need a lot of adjusting and modification for racing application.

Cylinder Head is a component motorcycle engine that stay over the Cylinder Comp. Cylinder Head close upper Cylinder Comp, forming combustion chamber. Cylinder Head is vital component that influences engine performance, because one of part of Cylinder Head named porting as intake port and exhaust port for fuel from carburetor or injector to combustion chamber. Cylinder Head is also used for Camshaft seating. Figure 1 describes cylinder head component more specifically.

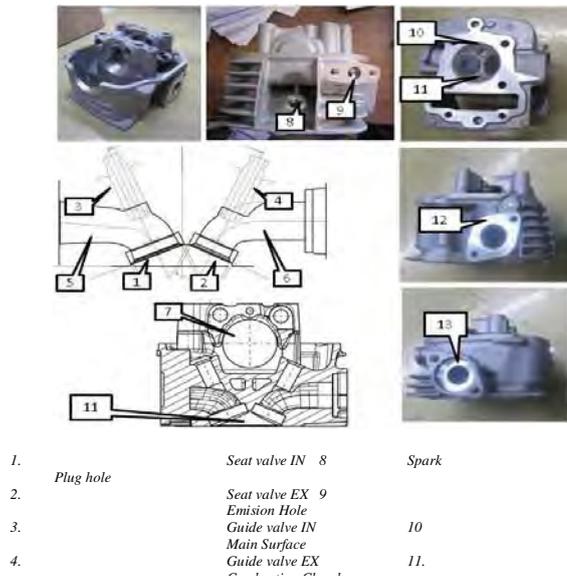

Figure 1: Cylinder Head Illustration

This Product development of Cylinder Head Component with racing specification is critically important. From the previous research, effectiveness of Cylinder Head can contribute 30% to increase Rear Wheel Power. From survey, it is known that modification cost for build Cylinder Head racing specification is the most expensive compared to other components. Besides that, longer modification time is needed, and the continuous quality and performance of Cylinder Head component can not be maintain continuously because Team Partners still use manual manufacturing system.

## 2. METHODS

Data source for this research generates from four types. The first one is observations and benchmarking Cylinder Head modification by Team Partner, by collecting Cylinder Head and comparing quality, performance, and product characteristic. The second one is customer need and complaint data collecting for Cylinder Head mass production standard. The method is collecting by survey method with some question. Third one is observation of Cylinder Head mass production standard manufacturing process, and fourth one is observation of Cylinder Head modification manufacturing process by Team Partner.

Based on data above, requirement interpretation is formed to describes customer needs. Because there are many customer needs, we can classify them into some groups, using Affinity Diagram. Not all customer needs are important, therefore, we must make priority level of customer need using Mudge Diagram tool. Mudge Diagram can be formed after pass Pairs Comparison method before. Pairs Comparison are against every customer needs and giving score for importance level. Moreover, we can start QFD Phase 1. QFD Phase 1 can be called product planning phase. QFD phase 1 can be done with focus group method involving customer, marketing staff, product engineering staff, and manufacturing engineering staff. QFD phase 1 defines customer need to be quality characteristic. In QFD phase 2, the quality characteristic in phase 1 is defined to be part characteristic that discuss product specification technically. This phase is named product desain and can be done by focus group with product engineering staff majority. QFD phase 3 wants define part characteristics to be process parameters, all of manufacturing effort to make Cylinder Head racing specification, appropriate with consideration in part characteristic in phase

2. Phase 3 finds all of detailed activities to manufacture Cylinder Head with special specification with their relative importance.

Detail of activities to manufacture Cylinder Head with racing specification is very important to determine source of cost from every customer needs. Cost calculation consists of man power cost, machining cost, material cost, and sub assembly component cost. Then, all of costs are calculated before product development until after product development. It is important to classify parts of variable cost and fixed cost (new machine investment, new cutting tools buying, desain and programming cost, dies investment). Determination of a detailed cost attributes cost is necessary to construct a Resources Matrix. Resources Matrix consists of customer needs items, and how much the cost to fulfill each consumer needs. Cost contains a detailed cost breakdown of each activity. We can construct a percentage cost of each requirement. Furthermore, we can form Comparison Matrix, a comparison between percentage of importance ratio of customer need with percentage of cost for each customer needs. This matrix is very useful for analyzing cost allocation for each customer need, to allocate higher cost in important customer needs, and allocate lower cost in unimportant customer needs.

From comparison matrix we can determined how much allocated higher cost in unimportant customer need. If that situation happens, our manufacturer will be losed out, and we have ineffective effort. In other case, we can know how much allocated lower cost in customer need. The ideal case is lower cost should be allocated in unimportant customer need, and higher cost should be allocated in a very important customer need. Determining final specification is considered by 2 suggestions which are: form Relative Importance (RI) in QFD phase 3, and from Comparison Matrix. If there are unimportant customer needs, but need higher cost, we can envisage them to be erased, so they will not affect them in final specification. In final parts, we can compare value of Cylinder Head between before and after development, by considering cost and performance.

### 3. RESULTS AND DATA ANALYSIS

From survey, there are a massive customer needs of Cylinder Head with racing specification that are determined as raw customer need. Therefore, we must filter and classify them using Afinity Diagram. The customer needs is shown in Table 1. After determined customer needs, we define relative importance level using Mudge Diagram which has passed Pairs Comparison. Relative Importance level can be seen in Table 2. Customer Needs A.3 has highest relative importance level than others. Relative Importance level will be used in Importance Ratio in QFD Phase 1. In QFD phase 1, the main activity is product planning, to define the customer needs, become quality characteristic. Result of QFD 1 are technical responses can be seen in Table 3, together with Relative Importance value (RI).

The purpose of QFD phase 2 is product design by translating quality characteristic become component characteristics. Results of QFD phase 2 are technical responses that can be viewed in Table 4. QFD phase 3 is about process planning by determining part characteristic to be process parameters. Results are technical responses that are shown in Table 5. From QFD phase 3, activity D.6 is the most importance because has highest RI than others. Activity D.1, D.2, and D.11 have smaller RI. RI percentage graphic from each technical targets. That activities can be seen in figure 2.

Table 1: Customer Needs

Number	Customer needs
A.1	Can accommodate high compression ratio
A.2	Can accommodate higher Camshaft lift
A.3	Porting modification fleksibility
A.4	Contonous manufacturing identically
A.5	Use bigger Seat Valve
A.6	Durable Seat Valve and Guide Valve
A.7	Main surface is not leak
A.8	Left out emission leakage

Table 2: Relative Importance Level

								Total	Name	Percentage	Priority
A.1	A2.2	A3.2	A4.3	A5.2	A6.1	A7.3	A1.2	2	A.1	4.08%	8
	A.2	A3.3	A4.2	A5.1	A6.2	A7.2	A8.1	2	A.2	4.08%	7
		A.3	A3.1	A3.1	A6.1	A7.2	A3.2	11	A.3	22.45%	1
			A.4	A4.2	A4.1	A7.2	A4.2	10	A.4	20.41%	2
				A.5	A6.1	A5.2	A5.1	6	A.5	12.24%	5
					A.6	A6.1	A6.2	8	A.6	16.33%	3
						A.7	A8.2	7	A.7	14.29%	4
							A.8	3	A.8	6.12%	6
TOTAL								49		100%	

Table 3: Technical Response of of QFD Phase 1

Item	Technical Response	Technical Target	RI
B.1	Reduce combustion chamber volume	Reduce to be 3.6 cm <sup>3</sup>	2.24 %
B.2	Camshaft Lift	accomodate Lift max.9,5 mm	2.98 %
B.3	Wide Area of Port IN	To be 14,2 cm <sup>2</sup>	13.54 %
B.4	Engine Power difference	± 10%	15.28 %

C.8	Chamfering 45° Surface Roughness	Ra 0,8µm (N6)	8.48 %
C.4	Weldless manufacturing	weldless	7.44 %
C.9	Surface Roughness	Ra 0,8µm (N6)	6.51 %
C.10	Surface Flatness	0,003 (standard)	7.93 %
C.11	Close Emission Hole	0 diameter	2.79 %

Table 5: Technical Response of QFD Fase 3

Item	Technical Response	Technical Target	RI
D.1	Main Mold	Make new Main Mold	1.91 %
D.2	Dies Sand Core Camshaft	Make new Dies Sand Core Camshaft	2.38 %
D.3	Add Core Camshaft material	Increase material cost	8.60 %
D.4	Dies Slide Core	Make new Dies Slide Core	14.12 %
D.5	Increase production cost	Calculating man power and machining cost	9.15 %
D.6	CAM (Computerized Aided Manufacturing)	CAM (Computerized Aided Manufacturing)	19.41 %
D.8	Valve Angle by CAD simulation	CNC Programme Editing	5.68 %
D.9	Seat valve KWC & Guide valve KWW Assembling	Seat valve KWC & Guide valve KWW Assembling	9.56 %

Item	Technical Response	Technical Target	RI
D.7	Decrease Chamfering feed	Production Cost Addition	16.03 %
D.10	CNC Programm Editing: rpm & feed	CNC 1 Programm Editting	11.02 %
D.11	CNC Programm Editing: Emission Hole	CNC 2 Programm Editting	2.13 %

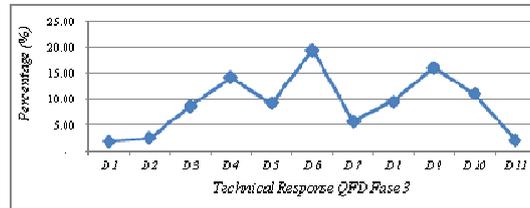

Figure 3: Relative Importance Percentage in QFD Phase 3

Furthermore, we can form resources matrix that describe all of cost in each customer needs. Cost calculation is based on man power, machining, material and sub assembly cost. The resume of resources matrix can be seen in Tabel 6. From Mudge Diagram and Resources Matrix, we can build Comparison Diagram, that can be seen in Figure 4.

Table 6: Resources Matrix Resume

Customer Need	% Function	Cost	% Cost
A.1	4.08	63,000,000.00	33.21
A.2	4.08	48,017,823.33	25.31
A.3	22.45	41,001,855.71	21.61
A.4	20.41	37,274,414.29	19.65
A.5	12.24	170,746.43	0.09
A.6	16.33	227,661.90	0.12
A.7	14.29	8,131.67	0.00
A.8	6.12	1,733.33	0.00

Figure 4: Comparison Matrix

From figure 4, we can know that customer needs A.1 and A.2 has a lower relative importance level, but has higher cost. Therefore, we can suggest to erase A.1 and A.2 in final specification determination.

From considering RI QFD 3 and comparison matrix, we can define final specifications as below:

- Port IN Cylinder Head wide area is increased to be 14,2 cm<sup>2</sup> by making new Dies Slide Core.
- Manufacturing process of porting uses CAM (Computerized Aided Manufacturing)
- Use size 28 and 24 seat valve size from KWC motorcycle.
- Seat valve surface roughness is Ra 0,8 μm (N6).
- Use Guide Valve mass production standard from KWW motorcycle.
- Erase machining process in Emission Hole.
- All of Cylinder Head modification and manufacturing can be applied in manufacturer's plant.

After obtaining final specification, we must determine comparison of cost before development and cost after development. Calculating and classifying all of cost to be variable cost and fixed cost. Modification process is moved from Team Partner Workshop into manufacturer fabrication, production cost in manufacturer become higher than before, from variable or fixed cost. But, if we look in a whole picture, Team Partner is not necessarily obtains modification again, so that modification cost in Team Partner workshop become zero. Because until now, modification cost in Team Partner is funded by manufacturer, cost

production in manufacturer is cheaper for 100 lot production, therefore, production cost of manufacture Cylinder Head with racing specification is cheaper than before. The comparison of cost can be seen in Table 7.

Table 7: Comparison of Cost before and after Development

Cost Name		Before Development	After Development
Fixed Cost	Dies Slide Core Investment	-	60,800,000
	Tool CAM Investment	-	6,000,000
	Tools Desain & Programming Cost	-	3,235,770
	Man Power Desain Investement	-	2,450,000
Variable cost (100 pcs)	Machining Cost	2,077,689	7,071,861
	Man Power Cost	315,250	2,011,946
	Material Cost	4,494,000	4,899,200
	Sub Assembly component Cost	2,338,000	2,421,000
	Total	9,224,939	16,404,007
Modification Cost by Team Partner	100 pcs x Rp 1.500.000	150,000,000	0
Total		168,449,878	105,293,784

Therefore, if we compare the value by value analysis concept, Cylinder Head component after development have higher value because decrease of modification and manufacturing cost is happened. Because value is determined as comparison between performance and cost, if cost after development decreases with the same performance, The value will increased. Moreover, performance of Cylinder Head will be increased because manufacturing system in manufacturer is more precision than manufacturing process in Team Partner workshop. The detailed comparison can be seen in Table 8 below.

Table 8: Comparison between value before with after development

	Before	After
Value	<u>Performance</u>	<u>Performance</u>
	<u>Cost</u> (Rp1,500,000/component)	<u>Cost</u> ↓ (Rp 888,898/component)

#### 4. CONCLUSION

There are some conclusions from this research:

- All of customer needs will not be applied in specification of Cylinder Head racing specification because importance ratio is low, or cost of production is too expensive
- QFD phase 1, 2, and 3 are very useful to define possibility cost to fulfill customer needs. Cost data is used to arrange Resources Matrix.
- Value of Cylinder Head after development is higher than before development, if has 100 pcs per lot production. Cost for production 100 Cylinder Head inplant PT.A is cheaper than modifying in Team partner workshop.
- Much production can reduce cost for every component, that influence price of component.
- The final specification is just suggestion and not tested yet. But, some items in Technical response have been applied in temporary specification. We suggest to take durability testing for final specification in Cylinder Head, that must be reflected into performance of component. Furthermore, manufacturer must evaluate sponsorship financial fund to Team Partner research. Because cost of development and production of Cylinder Head is expensive, manufacturer must rearrange sponsorship financial value.

### ABSTRACT

*Batik crafting is a job done in a sitting position. The design of a stool itself affects the sitting position of workers using it. This paper proposes an optimal design for batik stool (dingklik) which is tested using the task analysis toolkit in the virtual environment with the Jack™ 6.1 software. An anthropometric measurement is done to create the suitable dimension for all users of the batik stool. This research is conducted to reduce MSD found in previous research, by designing ergonomically friendly stool to support batik crafters. This improved design is proved to be ergonomically friendly due to the decreased PEI result compared to the current design.*

## ABSTRACT

The study of human body surface area has been a concern for many experts in several research fields. Having unique anthropometry characteristics, every human race should have certain formula that fit those characteristics. Generated using strong based data taken with high accuracy 3D Anthroscan. This study obtain a new BSA formula,  $BSA = 0.0113 \times W^{0.1956} \times H^{0.8169}$  that will potentially fit Indonesian anthropometric characteristics. A geometrical interpolation model also proposed for a more personal BSA calculation.

## Keywords

*Anthropometry, Body Surface Area (BSA), Formula, Interpolation Method*

## 1. INTRODUCTION

Anthropometry is a branch of ergonomics science related to the study of human body measurements which encompass body size, shape, strength and work capacity [1]. Anthropometric become important because there is a significant difference in body size between the human races of the world, so it is necessary to categorize the anthropometry's design that fits in each characteristics. One of the most important applications of anthropometry is about Body Surface Area (BSA) study. Body Surface Area (BSA) has long been considered as an important element in the study of anthropometry. BSA is a very important parameter in several ways, such as in knowing the quality of the physiology of the body, drug dosage calculations, estimating of burns, and studying of the mechanisms of heat transfer body [2]. In many countries, there are project data collection and preparation of the BSA database for its citizens, such as 3D Body Taiwanese Bank in Taiwan, Civilian American and European Surface anthropometry Project Resource (CAESAR) for European citizens and a few other examples [3].

In the drug industry, BSA also used to determine the dose of the drug, especially in the treatment involving drugs with side effects such as chemotherapy treatment. BSA was also used for estimating burns suffered by patients [4]. These calculations are often performed by partial injured body part or as a whole if the burns occur quite severe. The results of these calculations become basis for determining the amount of replacement tissues that should be given to patients in order to reduce the impact of fatal skin loss.

Determination of the temperature of the room is also closely related to BSA calculation. In terms of air associated with this study is known as thermal comfort. Thermal comfort is a condition in which the human mind satisfied or according to the temperature of the surrounding environment (standard AHSRAE 55). In practice, determining the temperature of the room will be charged the amount of power adjustable with a maximum capacity room. The calculation is related to the area of the human body which assumed to fill the room.

The human body calculation has attracted the attention of experts from different disciplines over the years. Many researchers had been trying to formulate area of the human body calculation. In 1879, for example, a researcher named Mech noted that he had succeeded in measuring body surface area of six adults and ten children with method such as by providing certain geometrical patterns on the body was being measured. The pattern geometry is then transferred onto a transparent thin paper and the pieces of paper that are not irregular. Other researchers such as Funke, did the measurement by measured body lining with adhesive material similar to papers plastered with a square, where the paper was used as a reference to calculate the area of the human body [5].

Figure 1: Du Bois method

In 1916, Du Bois published a formula of BSA, which until now has been used with the following formulation [6].

$$\text{BSA (m}^2\text{)} = 0.007184 \times \text{Height (cm)}^{0.725} \times \text{Weight (kg)}^{0.425} \quad (1)$$

By doing a variety of improvements in the methods and sampling. Some formulas are often used in various purposes BSA including [7]:

- Monstaller (1908):
  - $\text{BSA (m}^2\text{)} = ([\text{Height (cm)} \times \text{Weight(kg)}] / 3600)^{1/2} \quad (2)$
- Haycock (1978):
  - $\text{BSA (m}^2\text{)} = 0.024265 \times \text{Height(cm)}^{0.3964} \times \text{Weight(kg)}^{0.5378} \quad (3)$
- Gehan and George (1970):
  - $\text{BSA (m}^2\text{)} = 0.024265 \times \text{Height(cm)}^{0.3964} \times \text{Weight(kg)}^{0.5378} \quad (4)$

In use, the formulas of BSA are often required to provide a high level of accuracy. High degree of accuracy would be very difficult to achieve if the formula is offered only limited empirical formula and little accuracy of technology because still using conventional method.

In this research, we develop BSA formulation based on Indonesian as a cutting-edge for national database of BSA. We want to develop the BSA formula using case studies of male students in Universitas Indonesia. This research will produce a formula that can calculate the human body in Indonesia accurately because data collection of human body size that is used to construct this formula will use the 3D Body scanner technology. So, it can generate measurement data with high accuracy. This research can also be for anthropometric ergonomic research that will further enrich our knowledge of the human body anthropometric Indonesia.

## 2. METHOD

The main tool to be used on the project anthropometric data collection Indonesia's population is 3D Body Scan or also known as Anthroscan. The results of this scanning three-dimensional objects can calculate 151 variables measuring dimensions of the human body.

In this research, we also have following boundaries of research such as:

- a. Data taken from the student (male) in Universitas Indonesia in the range of 17-25 years.
- b. The variables measured in the study of human body dimensions are variable based on 3D Body Scanner amounted to 151 variables as a basis for obtaining the interpolation of the human body surface area of Indonesia.
- c. Through pilot research project conducted only as an example to model the human body area calculation formula Indonesia with a limited number of samples. Not for human anthropometric characteristics portray Indonesia nationally.
- d. The design of the human body area calculation formula based interpolation method synthesized the literature on the sources of data that have been owned.

Table 1: Responding Category

Category	Group
Gender	Male
Age	17-25 years old
Ethnic	South East Asiatic
Location	Java Island
Posture	Standing

In order to obtain data that is constant and steady, and in accordance with the expected quality parameters, there are several stages of anthropometric data collection using Anthroscan. The stages are:

- Calibrating Anthroscan
- Setting laser
- Preparing the subject
- Scanning data using Vitus Control - Scan Wizard
- Validating data using Measurement Tools
- Improving data manually using the Ruler Tools 52

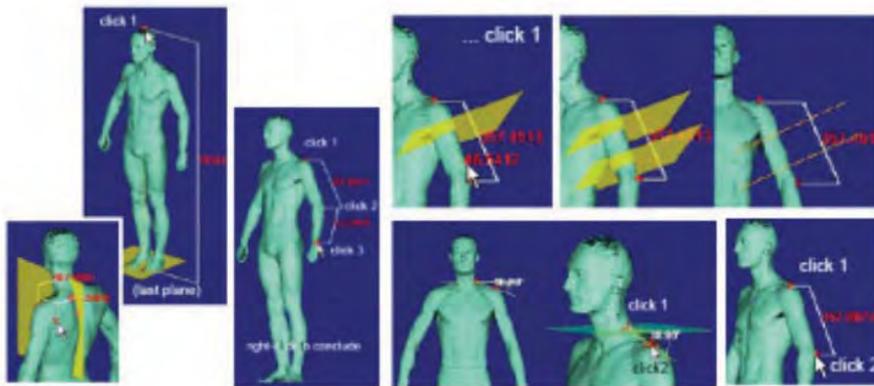

Figure 2: Interactive Body Measurement

Figure 3: Standard Posture Scanning

In this research, after performing calibration and subject preparation, we scan the data for each respondent and calculated about 151 body size points. These body size points can be seen in Table 2 and Table 3.

Table 2: Body Size Point

No	Body Dimension	No	Body Dimension
1	3D waist band	36	Crotch height
2	3D waistband back height	37	Crotch length
3	3D waistband back to vertical	38	Crotch length at waistband
4	3D waistband front height	39	Crotch length at waistband
5	3D waistband front to vertical	40	Crotch length, front

6	3D waistband left to crotch	41	Crotch length, rear
7	3D waistband right to crotch	42	Dev. waist band from waist (back)
8	Across back width	43	Dev. waist band from waist (front)
9	Across back width (armpit level)	44	Dev. waist band from waist (side)
10	Across front width	45	Distance 7CV - vertical
11	Ankle girth left	46	Distance abdomen to vertical
12	Ankle girth right	47	Distance across back width (armpit level) - waist
13	Ankle height	48	Distance back in belly height to vertical
14	Arm length left	49	Distance back in breast height to vertical
15	Arm length right	50	Distance back in hip height to vertical
16	Arm length to neck back left	51	Distance back in maximum belly height to vertical
17	Arm length to neck back right	52	Distance belly to vertical
18	Arm length to neck left	53	Distance breast to vertical
19	Arm length to neck right	54	Distance buttock to vertical
20	Belly circumference	55	Distance crotch to waistband
21	Belly circumference height	56	Distance front in hip height to vertical
22	Body height	57	Distance maximum belly to vertical
23	Breast height	58	Distance neck front to vertical
24	Bust point to neck left	59	Distance neck to hip
25	Bust point to neck right	60	Distance neck-knee
26	Bust points around neck	61	Distance scapula to vertical
27	Bust points width	62	Distance waist back to vertical
28	Bust/chest girth	63	Distance waist-knee
29	Bust/chest girth (horizontal)	64	Distance waistband - buttock
30	Buttock girth	65	Distance waistband-high hip back
31	Buttock height	66	Distance waistband-knee
32	Calf girth left	67	Elbow girth left
33	Calf girth right	68	Elbow girth right
34	Cross shoulder	69	Forearm girth left
35	Cross shoulder over neck	70	Forearm girth right

Table 3: Body Size Point

No	Body Dimension	No	Body Dimension
71	Forearm length left	106	Shoulder angle left
72	Forearm length right	107	Shoulder angle right
73	Head circumference	108	Shoulder width left
74	Head height	109	Shoulder width right
75	Height of shoulder blades	110	Side upper torso length left
76	High hip girth	111	Side upper torso length right
77	High waist girth	112	Sideseam 3D waistband left
78	High waist height	113	Sideseam 3D waistband right
79	Hip girth	114	Sideseam ankle left
80	Hip height	115	Sideseam ankle right
81	Hip/thigh girth	116	Sideseam at waist left
82	Inseam left	117	Sideseam at waist right

No	Body Dimension	No	Body Dimension
83	Inseam right	118	Sideseam left

146	Waistband to buttock height left		

### 3. RESULTS AND DISCUSSION

By obtaining database as a result of the study, it was necessary to calculate formula that can be widely used and practical in accordance with the characteristics of human anthropometry Indonesia. After finding data based on the body size, we used the correction factor and multiplication factor instead of body proportions were not scanned. The results of calculations that have been corrected can be seen in table 4.

Table 4: Total Area after Correction

Sampling Point	Weight (kg)	Height (cm)	Total Area (m <sup>2</sup> )
92	74.40	170.80	1.769255376
93	48.60	158.50	1.503045093

137	65.1	174.6	1.562449463
142	78.5	179.5	1.888157238
143	62.7	169	1.6791933
144	64.5	169	1.712490842

Sampling Point	Weight (kg)	Height (cm)	Total Area (m <sup>2</sup> )
145	72.2	183.4	1.830785379
146	58.6	178	1.72025244
147	64.1	172.9	1.748132653
148	53.4	163.6	1.621764758
150	94.3	182	1.982839024
151	63.6	178	1.741047208
152	63.5	168.3	1.670630034

For further calculations that aimed to determine the empirical formula connecting the wide body, weight and height of the human body, it used mathematical principle BSA which have the following basic formula:

$$L = \gamma \times W^\alpha \times H^\beta \quad (5)$$

$$\ln L = \ln \gamma + \alpha \ln W + \beta \ln H \quad (6)$$

By using the Matlab that used to solve the equations on simple geometric interpolation approach, it would result the matrix to triangle interpolation on the data format stereolytography which have following value:

$$\begin{aligned} \ln \gamma &= -4.4846 \\ \alpha &= 0.1956 \\ \beta &= 0.8169 \\ \gamma &= 0.0113 \end{aligned}$$

So, it yielded the following formulation as the potential BSA formulation in Indonesia :

$$L = 0.0113 \times W^{0.1956} \times H^{0.8169} \quad (7)$$

Based on formula above, it will give correction to previous BSA formulation which developed by Du Bois, Haycock, and Mosteller consequently about 4.38%, 4.92%, and 4.61%.

#### 4. CONCLUSION

In this research, it used interpolation body surface area method by simplifying the shape of the human body into basic geometric shapes. It can be the basis for processing anthropometric data were obtained from three-dimensional scanners high accuracy including 38 body dimensions. With the widespread use of three-dimensional scanner, it can also be opportunity to use the interpolation technique in a human body area calculation Indonesia, so it can also improve the accuracy of the empirical formula correlating vast body weight and height.

The data used in this research have stereolytography format. It is the basic form of rapid prototyping modeling language that transforms the scan object surfaces into triangles form or another simple polynomial-up based on coordinates of the point. One of the weakness of the format based on Stl, it has an opportunity emergence redundant triangles or double triangles coincide which potentially increase the area of the cumulative area of the triangle to be much larger than factual. This weakness can be overcome by testing the reliability of the measuring instrument by using the three-dimensional scanner and using factor correction.

Based on calculations using a varied tube length relationship between the results obtained with an actual scan, it found that correction factors are obtained for 2541 with the addition of constants  $-34473.2343 \text{ mm}^2$ . Therefore, any calculations used in the present study must first be divided by a correction factor of 2541 and added with a constant area of  $34473,234 \text{ mm}^2$ . It was also multiplied by a correction factor proportions which are not scanned by 1018 times, and then processed to get the empirical formula.

Based on this research, potential new BSA formula has a higher accuracy rate for Indonesian people become  $BSA = 0.0113 \times W^{0.1956} \times H^{0.8169}$ . It will provide a correction of about 4-5% when compared with the calculation formula BSA three most frequently used of Du Bois, Haycock and Mosteller.

## ABSTRACT

To reduce the use of gasoline, the government has recently re-issued a policy about restriction of gasoline subsidy and diversion of gasoline to Compressed Natural Gas (CNG). As a result, the need for new CNG fueling station will be higher since the estimated number of vehicles powered by natural gas (NGV) will increase. However, the government is constrained by limited funding from APBN to invest in CNG fueling station. This makes investment from private investors become urgent. The fact is many investors who invest in CNG fueling station are not based on adequate understanding about its feasibility. Therefore, this study analyzes the feasibility of CNG Fueling Station investment under acceleration scenario using NPV, IRR, and Payback Period followed by sensitivity analysis. The study shows that the best location to build a CNG fueling station is on Budi Utomo Street. The feasibility analysis shows that build CNG fueling station on Budi Utomo Street under acceleration scenario is feasible even when worst case demand occur (demand only from Busway) and NPV is positive with Rp 4.929.489.648.

## Keywords

CNG Fueling Station, NPV, IRR, Payback Period, Sensitivity Analysis

## 1. INTRODUCTION

To reduce the use of gasoline, the government has recently re-issued a policy about restriction of gasoline subsidy and diversion to compressed natural gas (CNG). CNG has been found to be effective to meet the ever-growing demands of transport vehicles [1]. CNG for natural gas vehicle (NGV) is more suitable for public transportation under fixed routes. CNG was chosen because the total gas reserves are abundant as described in the master plan of the expansion and development acceleration in Indonesia. The total reserves of natural gas is currently about 165 trillion cubic feet (TCF). This policy is supported by Regulation of the Minister of Energy and Mineral Resources No. 19, 2010 about the use of natural gas for transportation and the National Energy Policy 2010-2050 which has mission to enhance the role of alternative energy. As the remainder of previous CNG policy, Jakarta has only five operating CNG fueling stations; three in East Jakarta, one in West Jakarta, and one in South Jakarta. This lack of infrastructure causes long queues at the station and many NGVs switch back to use gasoline as reluctant to queue [2]. Due to the policy to use gas and lack of infrastructure, the need for new CNG fueling station is high in order to well serve the increasing number of NGV. Jakarta has Transjakarta (busway) that uses gas as its fuel. However, one barrier to address this problem is limited funding for CNG fueling station investment, whether it is sourced from the state budget or private.

2008 state budget allocated to energy sector, including for infrastructure development was only 1.6%. Therefore, this makes investment from private investors is crucial. On the other hand, private investors who invest in this downstream oil and gas business are still not sufficient. To mention some, PT.Petross Gas, PT. T-Energy, Perum PPD, PT. Aksara Andalan Prima (AAP), PT. CNG (in Palembang) and its subsidiaries, PT. CNE (in Surabaya), are companies that have tried to set up this business. Even though demand of gas for transportation is inevitable and the government plans to rerun a conversion program from gasoline to gas, why industry does not invest their money on CNG fueling station? What is the station minimum demand in order an investment on this facility is profitable? If the government delay (or even cancel) the conversion program, is the investment still justified? Those the questions addressed on this study. This study will use company owned company operated (COCO) type of CNG Fueling Station that located in Central Jakarta under acceleration scenario using net present value, internal rate of return and and payback period methods.

## 2. METHODOLOGY

Techno-economics analysis provides a quantitative basis in the monetary unit for making a decision. Concern is emphasized on technical and economic aspects towards a problem completely [3]. Techno-economic analysis is closely related to problem-solving techniques which using indicators of economic efficiency as alternative selection criteria. The results of this analysis

will determine the feasibility of investment. Investment methods that are used are Net Present Value, Internal Rate of Return, and Payback Period.

### 2.1 Net Present Value (NPV)

Method of NPV analyzed finance by considering the changes in value of money due to the time. This method calculates the difference between the present values of cash flow with the initial investments:

$$(1) \quad NPV = \sum_{n=1}^n \frac{CFI_n}{(1+r)^n} - I_0$$

where  $CFI_n$  is the net annual cash flow from year one to year- $n$  (Rp.),  $r$  is the discount rate which is used to find the present value (%),  $n$  is duration of the project (year), and  $I_0$  is the initial investment in year-0 (Rp). Criteria for assessment of NPV are:

- i). If  $NPV > 0$  then the business investment proposal is feasible to be implemented,
- ii). If  $NPV < 0$  then the business investment proposal is not feasible to be implemented,
- iii). If  $NPV = 0$  then the value of the company is fix although business investment proposal will accept or reject.

### 2.2 Internal Rate of Return (IRR)

IRR is interest rate that makes the present value (PV) of investments and the net proceeds that are expected during the running of project or business to be equal to 0 (zero). Same as NPV, internal rate of return method or IRR is also a method that considers the value time of money. IRR can be obtained through trial and error by determining the NPV at some discount rate to obtain a negative and a positive NPV. Then, do interpolations in which NPV equal to 0 (zero). To obtain IRR by interpolation using the equation below:

$$(2) \quad IRR = P1 - \left( C_1 \times \frac{P_2 - P_1}{C_2 - C_1} \right)$$

where  $P1$  is discount rate 1 (%),  $P2$  is discount rate 2 (%),  $C1$  is Net Present Value (NPV) 1 (Rp), and  $C2$  is Net Present Value (NPV) 2 (Rp). A trial and error method could be used to find the optimal Internal Rate of Return (IRR). Criteria for assessment of IRR are;

- i). If  $IRR >$  rate of capital or MARR, then the project is feasible to be implemented and the investment will get a surplus after the payment of obligation (to return capital + interest).
- ii). If  $IRR <$  rate of capital or MARR, then the project is not feasible to be implemented.

### 2.3 Payback Period (PB)

PB is the period that is needed to cover initial cash investment by using cash flow [5]. It means the shorter of payback period, the better of investment. To obtain Payback Period using the equation below:

$$(3) \quad PP = \frac{\text{The investment Value}}{\text{Net Cash Inflow}} \times 1 \text{ year}$$

where Payback Period (PB) is the Payback Period which is sought (year), the investment value is the initial investment in year  $n$  (Rp), and Net cash inflow is the present value (PV) from cash inflow or operating cash flow (Rp). Criteria for assessment Payback Period are:

- i.) If Payback Period  $<$  the maximum time of projections, then the proposed project is accepted,
- ii.) If Payback Period  $>$  the maximum time of projections, then the proposed project is rejected.

## 3. RESULTS AND DISCUSSION

For the purpose of this study, primary and secondary data are collected. Secondary data was obtained from reading journals and previous thesis which discuss about CNG fueling station, Badan Pusat Statistik (BPS), Public Service Board of Transjakarta, Ministry of Energy and Mineral Resource, and Department of Transportation. Primary data was collected through observation and interview to the two owner of COCO CNG fueling station in Pinang Ranti, managed by PT. T-

Energy and in Perintis Kemerdekaan, managed by PT. Petross Gas. Some supporting data were collected from CNG fueling station at Jalan Pemuda. On this study, data were processed using Microsoft Excel 2007.

### 3.1 Selection of Location

CNG station location determination is conducted by inspection (qualitative in sense). Observing that none of the five existing stations is located in Central Jakarta and North Jakarta, the location candidate is between those two regions. Furthermore, Central Jakarta is selected as the candidate location because Central Jakarta is a center of trade and services. Therefore, many vehicles will pass it. In addition, travel business and hotel has minibus that potential as a consumer. Central Jakarta is passed by PT.PGN gas pipelines; At Central Jakarta, there is Harmoni Shelter which serve 3 corridors of TransJakarta and Senen Bus Station. This last reason indicates the potential of vehicles to fueling CNG.

Five alternative sites for CNG fueling station are considered that are 1) Gajah Mada Street; 2) KH. Hasyim Ashari Street; 3) Budi Utomo Street; 4) Gunung Sahari Street; and 5) Kramat Raya Street. The alternatives were scored according to the criteria listed below:

1. Proximity to gas pipeline
2. Located in commercial rather than residential areas
3. The site at least has 4000 m<sup>2</sup> area
4. Location is not far from the end of the Busway corridor
5. The vehicles pass through or close to public transportation seem like bus station, Busway's pool, or shelter.
6. Location does not cause queue when fueling CNG
7. Strategic and easy to access the location

By multiplying the weight and score from all alternative location based on criteria that are determined, the results are shown in Table 1.

Table 1: Alternative locations assessment

Criteria	Weight	Alternative Location				
		1	2	3	4	5
Proximity to gas pipeline	0.30	9	9	8	6	5
Minimum area	0.25	7	8	9	10	8
Many vehicles pass through or close to public transport terminals, pool Busway, or shelter	0.25	9	9	8	9	8
Effect to the surrounding environment (not in residential areas or doesn't cause queue)	0.15	5	8	9	6	7
Strategic and easy access location	0.05	8	5	9	8	8
Total Score	100%	7.85	8.40	8.45	7.85	6.95

From the total results that were obtained by multiplying the weight and score (0-10) above, then the selected location with the highest total score is considered as the best location for the construction of CNG fueling station. And the best location is on Budi Utomo Street with the total score are 8.45.

### 3.2 Estimation of Investment Cost under Acceleration Scenario

Acceleration was made by reducing the duration of construction CNG fueling station. This causes the increase in number of construction workers and their working hours. If there is no acceleration, the construction will conduct during 10 months by 13 construction workers. However, under acceleration, the construction will conduct during 4 months by 23 construction workers. Presence the acceleration has an impact on expenditure, i.e., for machineries, equipments, and construction materials. It happens because there is the force to make the procurement process quickly, especially for the machines which order from abroad (import). The funds that will use to invest in CNG Fueling Station is 50% own equity: 50% equity loan. The loans were obtained from the Local Government Bank that is followed by interest rates for the investment (investment loans) is 12%.

Selected location on Budi Utomo Street has a distance 1966 meters from the nearest gas pipeline. Percent of rising prices under acceleration scenario is assumed to appropriate under difference percentage in the construction costs by 15%. Working capitals are for the preparation of gas by PT PGN, the budget for the employees and the cost of machining operations. The preparations of gas for the first 3 months appropriate with the capacity of CNG Fueling Station. For the pipe's installation, the amounts are Rp 800,407 per meter and for the telephone's installation are Rp 500,000. Electric insatallation is assumed as the

tariff class B3 based on interviews with the owners of Pemuda CNG Fueling Station. And for its calculations are based on the Regulation of the President Republic of Indonesia No. 8, 2011 regarding tariff which is provided by PT. PLN. Table 2 shows the estimation of CNG Fueling Station investment costs under acceleration scenario The table shows that the total investment costs under acceleration scenario are Rp 16,296,834,369.

Table 2: Investment costs of CNG fueling station under acceleration scenario

Assets	Amount	Unit	Per Unit (Rp)	Cost (Rp)	Cost + 15% (Rp)
<b>Fixed Assets</b>					
<b>Building and Licensing</b>					
Construction				403.315.706	403.315.706

<b>Working Capital</b>					6.314.782.068
Total					16.296.834.369

### 3.3 Costs and Expenses

Costs and expenses of CNG Fueling Station consists of gas purchase costs, electricity costs, employee salaries, land rent, promotion, administration and office needs, maintenance, insurance, telephone and water, investor interest, and incentives. Total costs and expenses that CNG Fueling Station should spend in the first year is Rp. 977.810.062.

### 3.4 Demand Projection

Project analysis will be conducted for the next 10 years. The cases are distinguished in two ways:

1. Worst Case, where the revenue only by the sale of gas to Busway. This case assumes that there is no conversion of fuel to gas by mikrolet.
2. Best Case, where the revenue by the sale of gas to Busway and mikrolet. Percent conversion of public transportation based on the target conversion by Pertamina, which is 100%.

Based on data from the Public Service Board of TransJakarta, currently the corridors that stills operate is corridor 1-11. And corridor 1 is still using biodiesel fuel. The new CNG Fueling Station will be built on Budi Utomo Street, where is not far from the shelter Harmony. Therefore, the potential corridors that will pass it are corridor 1, 2, 3, 5, and 8. From the entire corridor, the amounts of potential Busway are 280 buses. However, in the case of fueling gas, the capacity of each CNG Fueling Station should consider. In addition, the entire number of busway has been divided into 5 CNG Fueling Station that still operates.

The data from *Bina Sarana Transportasi Perkotaan* (BSTP) shows that the number of Busway will be increase in the future. Based on these data, we did the forecast demand for the worst case until 2022. The assumptions that were used are any additions Busway will be distributed evenly across the corridors and every year there will always be the addition of two CNG Fueling Stations in Central Jakarta. These will affect the number of demand for CNG Fueling Station that will be built. The addition of CNG Fueling Station has impact to amount of demand significantly. It is because there is currently no CNG Fueling Station in Central Jakarta. In one day, Busway do fueling as much as 125 lsp (liter premium equivalent). The forecast demand in 2021 and 2022 shows that the stagnancy due to the limit of its capacity

On the other hand, the best case scenario also calculated the potential number of mikrolet. It was known that total of mikrolet at Senen Bus Station are 1180 units, whereas mikrolet in Jakarta are 8046 units. From that data, we know that mikrolet at Senen Bus Station take 15% from the total of mikrolet in Jakarta. It means that the potential of mikrolet that will do fueling CNG in this CNG Fueling Station are 15% from the total mikrolet in Jakarta. After that, the demand projection is made based on planning to increase the number of mikrolet in Jakarta (source: BSTP). The assumption is from the potential amount of mikrolet that was obtained, there are only 80% mikrolet will be operated. The data of mikrolet was added with the previous demand projection of Busway. Total demand projection results for worst case and best case scenario are shown in Table 3.

Table 3: The demand projections for worst and best case

Type of Case	Demand Projection									
Year	2013	2014	2015	2016	2017	2018	2019	2020	2021	2022
Worst Case										
Busway	41	41	54	93	127	150	175	199	200	200
Best Case										
Busway	41	41	54	93	127	150	175	199	200	200
Mikrolet	38	458	462	404	369	345	329	316	307	299

### 3.5 Cash Flow

Cash flow can provide information about the number of cash which are required to start a business, investment planning, and ensure compliance cash to expenditures that will spend in the future. Indirect method is the method that is used in this cash flow. This includes depreciation and amortization as non-operating expenses. Cash flow is divided into two, there are cash inflow and cash outflow. Cash inflow includes profit after tax, depreciation, and amortization while cash outflow just include debt principal repayments. The difference between both of them is the net cash flow.

Cash flow's percentages that increase in the price of CNG are 4% with reference to the historical data since 1986. Tax which is considered here are PPN and PPKB. They are deposited into the country in which the amounts are 5% for PPKB and 10% for PPN. And the percentages that increase the costs and expenses are 6.42% refers to the average inflation rate over the last 5 years.

Table 4 : The net cash flow for worst and best case

Type of Case	Net Cash Flow				
Year	2013	2014	2015	2016	2017
Best Case	(Rp 1.176.369.268)	(Rp 1.188.572.014)	(Rp 230.093.399)	Rp 923.311.612	Rp 6.050.042.908
Worst Case	(Rp 1.916.283.850)	(Rp 1.188.654.995)	(Rp 168.878.775)	Rp 1.062.086.573	Rp 5.833.426.982
Year	2018	2019	2020	2021	2022
Best Case	Rp 10.388.931.303	Rp 10.792.622.413	Rp 13.490.929.545	Rp 14.059.859.578	Rp 14.537.856.908
Worst Case	Rp 6.126.486.700	Rp 10.756.784.010	Rp 13.576.832.549	Rp 14.293.458.937	Rp 14.949.606.571

### 3.6 Investment Feasibility Analysis

To analyze the feasibility this CNG Fueling Station investment NPV, IRR, and Payback Period using the equation (1) - (3) are used. The specified amount of MARR at 14% is derived from the Government Bank Local Investment Interest Rate at 12% plus 2% (from risk). MARR is used to compare the benefits that can be given from the Interest Rate of Bank in CNG fueling station investment and period is analyzed from the first year to the ten years. The calculation results for best case and worst case scenario are shown in Table 5.

Table 5: The calculation results of NPV, IRR, and Payback Period

Investment Criteria	Best Case Demand	Worst Case Demand
NPV	Rp. 7.310.840.986	Rp. 4.929.489.648
IRR	19.5%	17.7%
Payback period	7.2	7.8

From the calculation results for best case demand, the NPV is Rp 7.310.840.986. Because NPV value is greater than zero or positive, it can be concluded under acceleration scenario and best case demand (the demand from Busway and mikrolet), CNG fueling station is feasible to build. Similarly, IRR with 19.5% means the IRR is greater than the MARR, set as 14% by the company. This IRR value consistent with the NPV. And the last investment criteria are payback periods. The results show payback periods are 7 years 3 months that show the return on investment from the business of CNG Fueling Station investment relatively less than the project analysis which was done for 10 years. It also shows that CNG Fueling Station investment is feasible to build. The second calculation is investment criteria for worst case demand. It was obtained NPV with Rp 4.929.489.648. Even though the NPV is smaller than the best case demand scenario but NPV is still greater than zero or positive, it can be concluded that CNG Fueling Station investment under this scenario still feasible to build. This result is consistent with IRR. The IRR is 17.7% is which greater than MARR of 14%. And payback periods are 7 years 10 months that less than the project analysis duration of 10 years.

### 3.7 Sensitivity Analysis

Sensitivity analysis was conducted to determine how sensitive a decision on the change of the variables or parameters that influence it. The sensitivity analysis was performed only on the worst case demand scenario. Variable was changed to see the level of sensitivity including the bank interest rate, life years, operations and maintenance (O & M) costs, investment costs, and demand. Sensitivity analysis in this study only considers to the impact by changing variables on NPV worst case demand scenario that would be base case NPV.

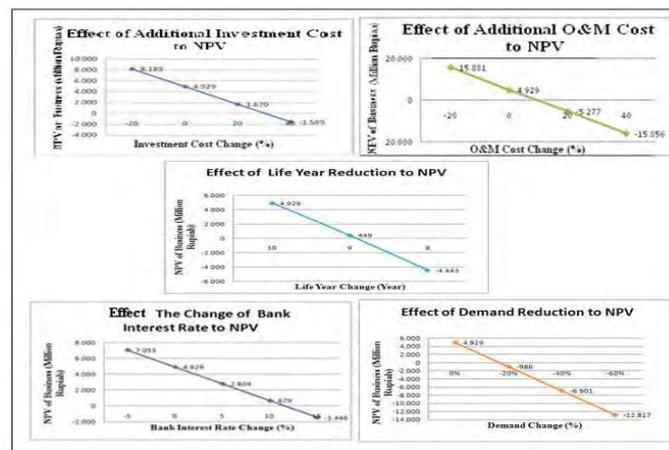

Figure 1 : Sensitivity analysis

The increase of investment cost is possible due to the rising price of machines, raw materials, and others. Based on the graph in Figure 1, it can be seen that the project can match the increase of investment cost at the level of 30.25% (point between 20% and 40%). After that point, the NPV begins to be negative. Thus, if the investment costs increase up to 30.25% or Rp. 21.226.626.765, CNG Fueling Station project under acceleration scenario and the demand from Busway (worst case) is still feasible and able to attract investors to invest.

O & M cost is possible to increase for example because of the increase of rent land, the increase of electricity costs, maintenance costs, etc. (excluding depreciation and amortization). Based on the graph in Figure 1, it can be seen that the Station can match the increase of O&M cost to the level of 10% (point between 0% and 20%) Thus, if the O&M costs increase up to 10%, CNG Fueling Station projects under acceleration scenario and only consider the demand from Busway (worst case) is still feasible and able to attract investors to invest.

Demand is possible to change when BSTP Policy as reference for demand projection do not proceed according to plan or the user communities that interest to switch to CNG fuel are lacking, thus the number of demand not in accordance under previous estimates. Based on the graph in Figure 1, it can be seen that the business or project CNG Fueling Station can match the demand reduction at the level of 17% (point between 0% and -20%) because at that point the NPV begin to be negative. Thus, if the demand decreases up to 17%, this CNG Fueling Station project is still feasible and able to attract investors to invest.

Life year could be decrease from the projection or expectation early. This may be happen due to CNG Fueling Station where is located in Central Jakarta area close to Tanjung Priok. It makes the water is salty. The water might be causing the machines break down quickly or damaged easily then should be making the new investments. Based on the graph in Figure 1, it can be seen that the business or project CNG Fueling Station can match the life year reduction only 2 years, specifically 1 year 8 months. It's because at that point the NPV begin to be negative.

The change of Bank interest rate may be happen. The changes are fluctuating. It is influenced by inflation because basically a bank determines the interest rate with reference by the inflation rate. Based on the graph in Figure 1, it can be seen that the business or project CNG Fueling Station can match Bank Interest Rate at 24% or increase in interest rates by twice from the base case because at that point the NPV begin to be negative. That means, when interest rate more than 24% or increase in interest rates by twice, CNG Fueling Station is not feasible to build.

### 3.7.1 Two-Dimensional Sensitivity Analysis

Investment and O & M costs are two parameters that are regarded as the most described the outflow (cash out). Based on the graph in Figure 1, O&M costs parameter line is more slope than other to decline NPV. The increase of 10% has made the NPV is negative while the investment cost is less critical because it can touch negative NPV when the increase reaches about 30%. After know that O&M cost is the most critical as cash out then comparison to the cash in variable, i.e., demand. Three-dimensional sensitivity analysis that is taken between the demand and O & M cost can be seen in figure below:

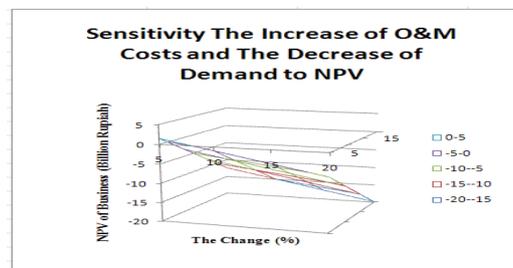

Figure 2: Three-dimensional sensitivity analysis

From the graph in Figure 2 can be analyzed that NPV is positive, or the business is still considered to be feasible along with the increase of O & M costs and the decrease of demand only by 5%. It indicates that when the decrease of demand is more than 5% and at the same time there was also the increase of O & M cost, the business or project of CNG fueling station is not feasible to run because the NPV value is negative.

## 4 CONCLUSION

There are some conclusions that can be concluded from this research. The best location to build CNG fueling station is on Budi Utomo Street, Central Jakarta. Feasibility analysis showed that building CNG fueling station on Budi Utomo Street under acceleration scenario is feasible even when worst case demand occur (demand only from Busway) and NPV is positive with Rp 4.929.489.648, IRR with 17.7% and Payback period for 7 years 10 months. Results of two-dimensional sensitivity analysis show that the most sensitive factor is the change in NPV because of the increase in O&M cost which the increase can not exceed 10%. And results from three-dimensional sensitivity analysis show that the NPV value is quite sensitive because it still considered regarded to be feasible along with the increase of O & M cost and decrease of demand only by 5%. It indicates that when the decrease of demand is more than 5% and at the same time there was also the increase of O & M cost, the business or project of CNG fueling station is not feasible to run anymore.

## ABSTRACT

This study aim to analyze cellular phone design based on user-centered design for college student. Method of user-centered design that used is usability testing, which is exploring the emotional usability through conjoint analysis to determine the combination of mobile phone design that desired by college student and behavior usability through usability assessment QWERTY keypad. Through this study showed that mobile phone design that are desired by the students is candy bar model (4 cm x 10 cm), QWERTY keypad design, touch screen navigation system, and screen sizes 2-3 inch width. The value of efficiency, performance, feedback, and satisfaction of QWERTY keypad design is higher than 12 button keypad and it also produces high mental workload, effort, and the frustration level.

## Keywords

Cellphone, user-centered design, usability, QWERTY keypad, college student

## 1. INTRODUCTION

There is no any other technology that is more distinctively developed and more influential in humanity's life than technology of communication. Paisley stated that technology transformation has put communication in the frontline of civilization's revolution [1]. The development of technology communication is mostly seen in electronica inventions. For example, cellphone is developed really advanced and rapidly, far beyond other technology inventions.

As a result, there are many variance of cell phone in order to fulfill market's demand and there are also various trends for example in its physical appearance. The most noticeable difference in cell phone evolution from times to times is the combination of its design. Cell phone's design aspect varies from its model, keypad, and navigation system. Those aspects are affecting the usability of the cell phone. Across the world, mobile phones are mostly used for the SMS and social media features within it. According to the survey named Global Attitudes Project that is held on 21<sup>st</sup> of March to 15<sup>st</sup> of May 2011 and made by Pew Research Centre, generally 85 percent of mobile phone users in the word send at least one text message every day. Based on the survey conducted by Vlingo Corporation, teenagers (13-19 years old) and adults (20-29 years old) tend to use short message service feature more often than any other age group.

## 2. LITERATURE REVIEW

### 2.1. Cellular Phone Design

In order to comprehend the usability of cellular phone, there should be an understanding in the main area of cellular phone design that affects user experience. The main areas are industrial design, mechanical concept, hardware, software, type of user interface. Industrial design has exceptional impact on product success. For example, watches and shoes are often sold based on design instead of their function. A cellular phone is identified and distinguished through its industrial design. Keinonen stated that the size of cellular phone keeps shrinking, the new model always lighter, more flat, and shorter. The small size and simple appearance have been a major challenge for industrial designer (Keinonen, 2000). Mechanical concept of product is an implementation of industrial design in detail. Mechanical design initially defined as physical product implementation, such as material, dimension, and position of product component. Hence, industrial design along with mechanical design is decision key for ergonomic design. Hardware defines the main performance of cellular phone, such as screen resolution, battery consumption, memory capacity, and processor efficiency. Hardware supports a specific software performance. Therefore, software functionality depends on hardware. The development of cellular phone starts as design focused on hardware. However, the increasing importance of software and software function convincemanufacturer to develop cellular phone, especially smart phone, with extensive software design. Software design defines all possible software to be implemented with reasonable effort, and software architecture defines how flexible this design, particularly with complex product that rapidly undergoes technological change. The function of software design and user interface style depends on each other. Selection of software design, for example Symbian design, determines the principals of user interface style for product, selection of user interface style is used to guide company in selecting software design, for example Microsoft CE. User interface style is a

framework that portrays interaction style and object, including look and behavior (Hix and Hartson, 1993). In computer termination, user interface style has same meaning with user interface software (display). For cellular phone, user interface style is translated as appearance, button, and key needed on a device. Some companies have many different user interface style.

### 2.1.1. Cellular Phone Component

Previous studies indicated that cellular phone interfaces consist of four components: hardware user interface, software user interface, external interface, and service interface [2]. Hardware user interface includes ergonomics hardware, input method, and communication method, while software user interface focuses on menu design such as phone size, color, and navigation menu logic. External interface involve feature that help on using device, but not physically part of the device itself, such as user support elements, accessories, and supporting software. Lastly, service interface is a component that facilitate the usage of phone service that provided by service provider or carrier, such as special calling plan services, text messaging services, and business practices including calling plan agreement, sales communication, other information resources, and phone bill.

### 2.1.2. User Centered Design

User centered design term has a tight relation with product, service, and experience design to match the need and capability of user. Donald Norman in *The Design of Everyday Things* stated that many designers have lost user touch that resulted on devices that unfriendly, inconvenient, and unsafe for user. Norman suggested user centered design which utilizes the nature of human so that user can operate the device without instruction. Nonetheless, for the fully user centered design, further studies are needed to adapt product with physical and cognitive needs along with user ability. Using user centered design approach can optimize usability. Four main principals in user centered design are (ISO, 1997p.7): (1) User active involvement, (2) Function allocation between user and system, (3) Iteration of design solution, (4) Multidisciplinary design team. Meanwhile, four major activities of user centered design are (ISO, 1997p.10): (1) Understand and determine usage context, (2) Determine user and organization needs, (3) Produce design solution (prototype), (4) Design evaluation with user towards requirements.

There are several methods of user centered design. These methods along with the sub-technique and output can be seen in the figure below:

Method	Sub-Technique	Output
Laddered Grid Method	One-to-one interview Think aloud Expert Review	Navigation flow diagrams
Focus Group	Consensus Usability heuristics	Selection and modification of navigation flow diagrams Final design mock-up Mid-to-high fidelity Flash prototype
Usability Testing	Performance Testing Retrospective think aloud (RTA) Questionnaire	Navigation diagram Critical incidents Usability problem list High fidelity Flash prototype
Expert Review	Heuristic analysis Usability walkthrough Questionnaire	Usability problem list Design recommendations Final Flash prototype

Figure 1: User centered design methods (Source: Young Sam Ryu, 2006)

### 2.1.3. Usability

According to ISO 9241-11 (ISO, 1998), the definition of usability is how far a product can be used by particular user to reach particular objective with effectiveness, efficiency, and satisfaction in particular usage context. Effectiveness is described as rate of accuracy and completeness of user objectives is satisfied. Efficiency refers to system usage effectiveness related to cost of effort or time. Satisfaction relates to user convenience and their acceptance in working with their system. Logan revealed that usability is divided into behavioral usability, which means ability to finish some functions, or objectives that directly related into tasks with reasonable time and emotional usability, which means how far the desired product can fulfill and serve other needs outside functional objectives [3]. Hassenzahl, Platz, et al. suggested and tested research model related to ergonomic (usability and hedonic aspect) as key factor to make attractive and satisfying product. It consists of three separated layers: (a) product quality objective (determined by designer), (b) perception and evaluation of subjective quality (cognitive assessment by user), (c) consequences of behavior and emotional (for user) [4].

## 2.2. Conjoint Analysis

Conjoint analysis is a statistic technique used in Multivariate Analysis that specifically used to understand how respondent build preferences towards a product. This technique is based on simple premise that consumer evaluate value from a product/service/idea through combining separated value that are contributed by each attribute. In conjoint analysis, there

should be a product (item or service) made before, either real or hypothetic by combining selected levels from each attributed. These combinations then revealed to respondents that will give evaluations towards each combination. In order to get good results, the product that will be valued should be described completely with its attributes and all relevant values for each specific attributes of a product. Meanwhile, possible values from each factor are defined as levels. In conjoint analysis, a product is described into levels from factors that form it. There are seven steps in doing conjoint analysis: (1) Objectives selection, (2) Conjoint analysis experiment design, (3) Conjoint analysis assumption, (4) Model estimation and accuracy assessment, (5) Interpreting the result, (6) Validating the result, and (7) Applying the conjoint result.

### 2.3. Quality Function Deployment

Yoji Akao defined Quality Function Deployment (QFD) as a method used to develop design quality in order to satisfy consumers and translate consumers' needs into target design and quality assurance. Voice of customer is used to explain this term and state customer needs or requirements. Voice of customer is obtained through several ways such as direct discussion or interview, survey, focus group discussion, customer specification, observations, and field study. This understanding then being summarized into product plan matrix or House of Quality (HOQ). The main objective of QFD is to assure product quality from the development stage. Furthermore, QFD is a method that enables establishment and development of consumer needs into quality characteristics in order to create a product which can fulfill all the customer needs.

### 2.4. Type of Keypad

There are two types of cellular phone keypad:

#### 2.4.1. Alphanumeric keypad

Alphanumeric keypad consists of numeric button (0-9) and two additional buttons (\* and #). A to Z characters spread on button 2 until 9 alphabetically. Character layout is identical in every cellular phone and becomes international standard (Grover, King, and Kuschler 1998).

#### 2.4.2. QWERTY keypad

This kind of keypad places its characters similar with a computer keyboard. This keypad can be found in Blackberry phones or Nokia Communicator Series.

### 2.5. Keypad Usability Study

Usability that is measured using both qualitative and quantitative technique relied mainly on user experience level with the interface. Direct usability from the interface for beginner user is important because their initial reactions will determine their needs to invest time and effort needed to expertise it (Scheidermann, 1998). Previous evaluation focused on collecting quantitative indicator especially text entry speed measurement (words per minute) and accuracy (failure rate), rather than the qualitative one (James & Reischel 2001, Mackenzie et al. 1999). However, accurate interpretation from quantitative measurements needs subjective response from participants for an interface, which can only be caught up by qualitative test.

### 2.6. Factorial Design

Factorial design is the most efficient method to analyze effect from two or more factors. Through factorial design, we interpret that in every replication, all combination from each level of factors are applied. For example, if there are  $a$  levels for A factors and  $b$  levels for B factors, then every replication consists of  $ab$  treatment combinations. The effect from experiment factors can be seen from response change that created by level change from these factors. This effect is called main effect.

## 3. METHODOLOGY

### 3.1. Students Preference Survey

In the early stage of research, a student's preference survey was conducted by spreading questionnaire into bachelor degree students of Universitas Indonesia using random sampling. The desired information from this questionnaire is respondent profile, reasons in having cellular phone, frequently used application, determining factors in choosing cellular phone, cellular phone specifications preference.

### 3.2. Conjoint Analysis

In the first step of the conjoint analysis, factors determination from a product that will be studied is specified. Previous studies show that cellular phone interface consists of four components: hardware user interface, software user interface, external interface, and service interface. After determining the factors, the next step is specifying level from each factor. In order to do that, an observation of cellular phone sales in Indonesia was conducted to perceive cellular phone specification in the market.

The selected level is the one that mostly chosen by student in order to balance the number of each factor, since more levels required more combination. Besides, so as to be carried a fractional factorial design to produce an optimal stimuli so that the resulted stimuli is not excessive and disconcerting other respondents.

The assumption of conjoint analysis is determining composition rule and model shape that are used to estimate conjoint result. In this research, the model shape used is additive model. Part-worth estimation and importance level measurement is conducted aggregately for respondent. Estimation is done through using MONANOVA (Monotomic Analysis of Variance) method, which is an ANOVA model used in ordinal data. Meanwhile, goodness-of-fit analysis model is done using Kendall's tau correlation coefficient to measure accuracy and respondent consistency in value giving. All these estimation and measurement is done by using SPSS software. An observation towards part-worth estimation for each factor is commonly done to interpret the conjoint results. As the part-worth increases (positive or negative), the effect it gives to utilities in general are increasing. Therefore, this part-worth value is usually converted into general scale in order to identify the pattern of the results and contribution of each factor in total utility.

### 3.3. Quality Function Deployment

In this research, the QFD method will be combined with Conjoint Analysis. The stages that will be done in QFD-Conjoint Analysis method combination are: (1) Conjoint Analysis is used as conceptual bridge for discrepancy between consumers and designers, and also to balance the variety of consumer needs level. Conjoint analysis is also applied to enable consumer needs prioritization; (2) Market segmentation approach with consumer grouping into homogeneity segment; (3) Conjoint analysis is done on every segment accurately with the similar procedure in the first stage; (4) A traditional HOQ process to prioritize technical requirements for every consumer segment; (5) Result and integration of conjoint analysis-HOQ analysis.

The first three stages in QFD-conjoint analysis combination have been done in conjoint analysis stage. The remaining stages are HOQ making process, the steps in making HOQ are: (1) Determining customer requirement factor. For this step, the determination of importance factors is taken from factors used on previous conjoint analysis; (2) Determining priority of customer requirement factor based on importance level; (3) Determining technical response. Technical response is activity development planning that is usually done by company in developing cellular phone product.

### 3.4. Usability Study QWERTY keypad

In reviewing behavioral usability, this research focuses on ergonomic quality value on cellular phone. Based on previous survey, teenagers in age 13-19 and adults in age 20-29 are using their cellular phone for SMS more. Therefore, behavioral usability that will be conducted is about usability study QWERTY keypad. Through factorial design method, this research aims to answer the following questions: how the effect of keypad type differences in typing effectiveness and efficiency? Are the factors interacted in impacting the typing effectiveness and efficiency? Are respondent difference factors that are used as blocking affect one typing effectiveness and efficiency?

Linear statistic model for factorial design with blocking is stated on equation below:

$$X_{ijk} = \mu + \tau_i + \beta_j + (\tau\beta)_{ij} + \delta_k + \epsilon_{ijk} \begin{cases} i = 1, 2, \\ j = 1, 2, 3, 4 \\ k = 1, 2, \dots, n \end{cases} \quad (1)$$

$\tau_i$  = effect of keypad type

$\beta_j$  = effect of typing type

$(\tau\beta)_{ij}$  = effect of interaction between two factors

$\delta_k$  = effect of k-th block. K refers to number of replication used in this research. Since 1 replication is done by 1 respondent, k = number of respondent

Then, hypotheses submissions for this case are:

- $H_0 : \tau_1 = \tau_2 = \tau_3 = 0$   
 $H_1 : \text{at least one } \tau_i \text{ is not zero}$
- $H_0 : \beta_1 = \beta_2 = \beta_3 = 0$   
 $H_1 : \text{at least one } \beta_i \text{ is not zero}$
- $H_0 : (\tau\beta)_{ij} = 0 \text{ for all } i \text{ and } j \text{ value}$   
 $H_1 : \text{at least one } (\tau\beta)_{ij} \text{ is not zero}$
- $H_0 : \delta_k = 0 \text{ for all } k \text{ value}$   
 $H_1 : \text{at least one } \delta_k \text{ is not zero}$

If p value less than 0.05, researcher has sufficient proof to accept  $H_1$  that keypad type, typing type, and/or blocking factors are significant toward typing effectiveness and efficiency.

#### 4. DISCUSSION

##### 4.1. Students Preference Survey

The number of respondent that participated in the questionnaire consists of 63% female and 37% male. Questionnaire deployment into every faculty is spread evenly with majority of respondents come from engineering faculty (20%). Respondents consist of 57% of 2006 batch, 18% of 2008 batch, 15% of 2007 batch, and the remaining percentage from 2009 batch. Respondent's age range from 18-24 years old. The first information obtained is about the reason for students to have a cellular phone. The common reason is the main function of cellular function itself, to communicate. This reason is followed by the needs to save important data, either file, music, or photo, and also for entertainment. Therefore, the desired cellular phone is the one that has sufficient memory capacity, and many features for their entertainment. For the most used application, it is found sequentially as followed: short message service, phone call, alarm, internet, Bluetooth, calendar, camera, music, notes, and dictionary. Based on the survey, in choosing cellular phone students consider factors, such as price, brand, hardware and software.

##### 4.2. Conjoint Analysis

Based on the conjoint analysis calculation, it is found that utility value for each level in each factor: (1) Cellular phone model that has high utility value is candy bar model. This means students prefers candy bar model over slide model phone; (2) For dimension factor, dimension with highest utility value is 4 cm x 10 cm, 6 cm x 11 cm, and 5 cm x 10 cm; (3) Keypad design that is most preferred by students is QWERTY; (4) Utility value for navigation button, from the highest sequentially is touch screen, track ball, button; (5) Screen size that is preferred by students is in range 2-3 inch

The most preferred cellular phone combination is cellular phone with candy bar model, in size of 4 cm x 10 cm, with QWERTY keypad, screen size around 2-3 inch, and using touch screen as its navigation system.

Result obtained from part worth estimation in conjoint analysis is importance level from every factor. Here is the value of importance level for every factor

From the view of importance factor, it is found that students' preference towards cellular phone is mostly affected by its model with 27.601%. From the most important, design factors that mostly affecting students in selecting cellular phone are: model, navigation button, dimension, keypad design, and screen size.

The next step is market segmentation based on gender to find the preferences for each segment. It is shown the result of conjoint analysis in Table 1, where red font color indicate highest utility value for each level.

Table 1: Utility value for each segment

Utility			
Factor	Level	Male	Female
Model	Candy bar	0,6736	0,6491
	Slide	-0,6736	-0,6491
Dimension	4 cm x 10 cm	0,0722	0,1004
	5 cm x 10 cm	-0,1986	-0,0502
	6 cm x 11 cm	0,1264	-0,0502
Keypad Design	QWERTY	0,1111	0,3223
	non QWERTY	-0,1111	-0,3223
Navigation Button	Button	-0,4407	-0,1667
	Touchscreen	0,6398	0,2987
	Trackball	-0,1991	-0,132
Screen Size	> 3 inch	-0,2319	-0,1762
	2-3 inch	0,2319	0,1762
(Constant)		8,2226852	8,5737952

Based on utility table for each existing level, the combination for each segment is not really different, which is cellular phone candy bar model with QWERTY keypad design, touch screen navigation system, and screen size about 2-3 inch. However, there is a difference in dimension factor, where female prefers smaller dimension (4 cm x 10 cm), while male prefers wider dimension (6 cm x 11 cm)

##### 4.3. Quality Function Deployment

Based on HOQ above, company is able to know what action should be done for every market segment and what factors should be put into consideration and prioritized to implement the existing strategy.

Table 2: House of Quality

Consumers' Needs	Technical Response			Relative Importance Level			Importance Ranking		
	Product Diversification	Making user-friendly product	New Technology Development	All	Male	Female	All	Male	Female
Dimension	9	1	3	19,493	19,008	19,88	3	3	3
Model	9	3	1	27,601	30,332	24,497	1	1	2
Keypad Design	9	9	9	14,58	14,355	14,643	4	4	4
Navigation Button	9	9	9	27,304	25,94	29,15	2	2	1
Screen Size	9	3	3	11,021	10,365	11,83	5	5	5
Absolute Importance	Male	558,72	311,5						
	Female	531,11	424,42						
Relative Importance	Male	47,04%	26,23%						
	Female	32,31%	25,82%						
Male Ranking	1		3						
Female Ranking	2		3						
All Absolute Importance	539,33		300,37						
All Relative Importance	46,94%		26,14%						
All Ranking	1		3						

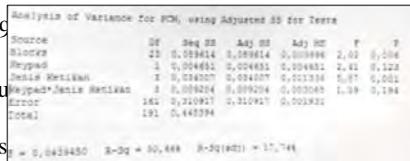

#### 4.4. Usability QWERTY Keypad

Factorial design statistic model results an analysis in a form of ANOVA table below

##### 4.4.1. Effectiveness

Table 3: ANOVA Effectiveness

Based on Table 8, using level of confidence 9

```

Analysis of Variance for WCH, using Adjusted SS for Tests
Source          DF    Seq SS    Adj SS    Adj MS    F      P
Keypad          2    0,009614   0,009614   0,004807   2,02   0,128
Keypad*Jenis    2    0,004612   0,004612   0,002306   0,91   0,402
Keypad*Jenis*  2    0,008204   0,008204   0,004102   1,69   0,194
Error          162   0,210917   0,210917   0,001302
Total          166   0,443394

R-sq = 0,0428450    R-sq (adj) = 0,04488    R-sq (pred) = 17,746
  
```

- On hypothetic test (a), researcher has sufficient proof to accept  $H_0$ , which means keypad type does not affect significantly towards typing effectiveness.
- On hypothetical test (b), researcher has sufficient proof to accept  $H_0$ , which means typing style affects significantly on effectiveness
- On hypothetical test (c), researcher has sufficient proof to accept  $H_0$ , which means the interaction between keypad type and typing style does not affect significantly toward typing effectiveness.
- On hypothetical test (d), researcher has sufficient proof to decline  $H_0$ , which means blocking between respondent affects significantly on typing effectiveness.

Model assumption about residual normality (error) is fulfilled to make the model accurate enough to be used as baseline. The other thing that should be put in consideration is R-square value about 30.66% which means 30.66% of existing variability in typing effectiveness can be explained by the model. The correlation level is medium, showed by correlation degree (R)  $=\sqrt{0.3066}=0.5537$

##### 4.4.2. Efficiency

Table 4: ANOVA Efficiency

Source	DF	Seq SS	Adj SS	Adj MS	F	P
Blocks	23	213,53	213,53	9,28	1,29	0,183
Keypad	1	144,92	144,92	144,92	20,37	0,000
Stimulus	5	3872,28	3872,28	2840,74	400,87	0,000
Keypad*Stimulus	5	149,98	149,98	54,65	7,66	0,000
Error	141	1241,00	1241,00	8,80		
Total	171	10282,69				

Based on Table 9, using level of confidence 95%, researcher concludes that:

- On hypothetic test (a), researcher has sufficient proof to decline  $H_0$ , which means keypad type affect significantly towards typing time needed.
- On hypothetical test (b), researcher has sufficient proof to decline  $H_0$ , which means typing style affects significantly on typing time needed
- On hypothetical test (c), researcher has sufficient proof to decline  $H_0$ , which means the interaction between keypad type and typing style affect significantly toward typing time needed.
- On hypothetical test (d), researcher has sufficient proof to accept  $H_0$ , which means blocking between respondent does not affects significantly on typing time needed.

Model assumption about residual normality (error) is fulfilled to make the model accurate enough to be used as baseline. The other thing that should be put in consideration is R-square value about 88.80% which means 88.80% of existing variability in typing effectiveness can be explained by the model. The correlation level is medium, showed by correlation degree (R)  $=\sqrt{0.8888}=0.942762$

#### 4.4.3. Satisfaction

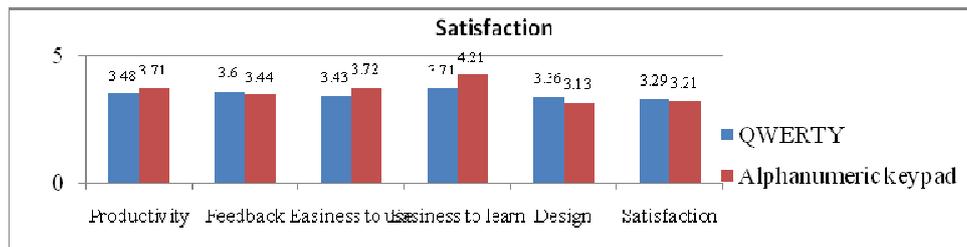

Figure 2: Satisfaction

Through the assessment of 6 satisfaction factors it is found that QWERTY keypad has feedback, design, and satisfaction value higher than alphanumeric keypad. This indicates that esthetical value of QWERTY makes satisfaction level assessment of user considerably high. For alphanumeric keypad, it has productivity, easiness to use, and easiness to learn value higher than QWERTY keypad. This indicates that satisfaction value of alphanumeric keypad comes from its simplicity that makes its user can be more productive.

## 5. CONCLUSION

Based on conjoint analysis result, the combination of cellular phone factor for students is a cellular phone with candy bar model (4 cm x 10 cm), QWERTY keypad design, touch screen navigation system, and screen size about 2-3 inch. The main consideration factors for students in selecting their cellular phone are model, navigation button, dimension, keypad design, and screen size. Considering market segmentation, there is difference in female and male preference when selecting cellular phone, which lay in the cellular phone dimension. Based on usability keypad, it is resulted that the keypad type, either QWERTY or alphanumeric do not affect significantly on typing effectiveness. However, QWERTY keypad has higher efficiency value than alphanumeric keypad in typing sentence and symbol. While in typing number, alphanumeric keypad is much more efficient. Aesthetical value of QWERTY keypad makes satisfaction assessment of user is higher because of its feedback and design factor rather than alphanumeric keypad. On the other hand, the satisfaction value of alphanumeric keypad is high in productivity, easiness to use, and easiness to learn value which makes the user can be more productive.

## ABSTRACT

Due to several advantages of conventional anthropometry methods, conventional anthropometry methods used tools such as measuring sticks or calipers have endured to the present day and they are also still widely used in many researches. However, the conventional methods are clumsy and time consuming. As the one of the solutions, utilizing two-dimensional images offers an opportunity for covering the shortcoming of the conventional anthropometry methods. According to this explanation, a digital anthropometric measurement system using two-dimensional images will be designed in this research. As the results of the design process, hardware setting and customized software will be established. The hardware will be used for producing the two-dimensional image that will be the input of the system, while the software will be used for processing the two-dimensional image. By processing the image, several anthropometric dimensions can be determined. After that, for answering whether the proposed system fulfills the requirements of the measurement system, accuracy and reliability test will be conducted. By using this design, the proposed system can be used for measuring sixty anthropometric dimensions. Afterwards, according the results of the accuracy and reliability test, the proposed system seems accurate and reliable. In addition, for increasing the accuracy of several variables, it is better if when measuring using the proposed system, the measuring object wear special clothes such as swimming head gear and swimwear.

## Keywords

*Anthropometry, two-dimensional images, accuracy and reliability tests*

## 1. INTRODUCTION

Anthropometry can be defined as a science of human body dimension measurements [1]. The term of anthropometry comes from two Greek words, *anthropos* that means human and *metron* that means measure [2]. Anthropometry is widely used by ergonomic experts as the basis of product or layout dimensions [1] which is purposed for increasing the human well-being in a system.

There are a variety of methods available for anthropometry measurements which range from highly sophisticated equipment such as 3-D scanners to traditional tools [3]. Traditional or conventional anthropometry methods and tools use tools such as measuring sticks or calipers [2]. Due to several advantages of this method, these conventional methods and tools have endured to the present day and they are also still widely used in many researches [4], [3], [5], [6]. In addition, these conventional methods are the golden standard of anthropometry measurement because they are accurate and relatively cheaper than the other advance tools like 3-D scanner [3].

Although the conventional ones seem very beneficial, the conventional methods have several disadvantages too. Kroemer *et. al.* [7] stated that the traditional method is clumsy and time consuming. Not only that, measuring human dimensions using conventional tools also makes part of the human body directly contacted with the measurement tools. According to that, Hung *et. al.* [8] stated that the conventional methods are invasive methods.

As the one of the solutions, utilizing two-dimensional images offers an opportunity for covering the shortcoming of the conventional anthropometry methods. By using a two-dimensional image, the measuring objects do not need directly contacted with the measurement tools. In addition, producing the two-dimensional image of human body do not also need expensive and sophisticated technology like 3-D scanner. It only needs a standard digital camera that may be one of the daily gadgets nowadays.

According to the previous explanations, a digital anthropometric measurement system using two-dimensional images will be proposed in this research. As the results of the development process, hardware setting and software will be established. The hardware following certain setting will be used for producing the two-dimensional image that will be the input of the system, while the software will be used for processing the two-dimensional image. By processing the image, several anthropometric dimensions can be determined. After that, for answering whether the proposed system fulfills the requirements of the measurement system, validation and reliability test will be conducted. If the proposed system fulfills the requirements, it can be stated that the proposed system is valid and reliable, so it can be used as an alternative for anthropometric measurement.

## 2. MATERIALS AND METHODS

### 2.1. Anthropometric Dimensions

Sixty human body dimensions, both in standing and sitting posture will be accommodated in the proposed system. Several body dimensions and measurement definitions, such as popliteal height and span, were adopted from Pheasant [9]. The sixty body dimensions accommodated in the proposed system can be seen in Figure 1 and Table 1.

### 2.2. System Design

There are two main parts of the system design in this research: set the supporting hardware and create the system software. Several hardware such as digital camera and tripod will be set up using a specific setting thus it can be used for capturing the two-dimensional image of the objects. The two-dimensional images captured will be used as the input in the proposed system. The hardware used in this research are Canon EOS 1000D digital DLSR camera, calibration board, tripod, and a computer with a Pentium Core 2 Duo processor 1.83 GHz with 2 GB of RAM. The calibration board used in this research is a board that has a length of 15 cm.

After that, if the hardware is used for producing the input, a customized software is needed for processing the input. The software built in this research accommodates several functions that can be used to transform the two-dimensional images into several anthropometric dimensions. The software will be built using Matlab R2009a software.

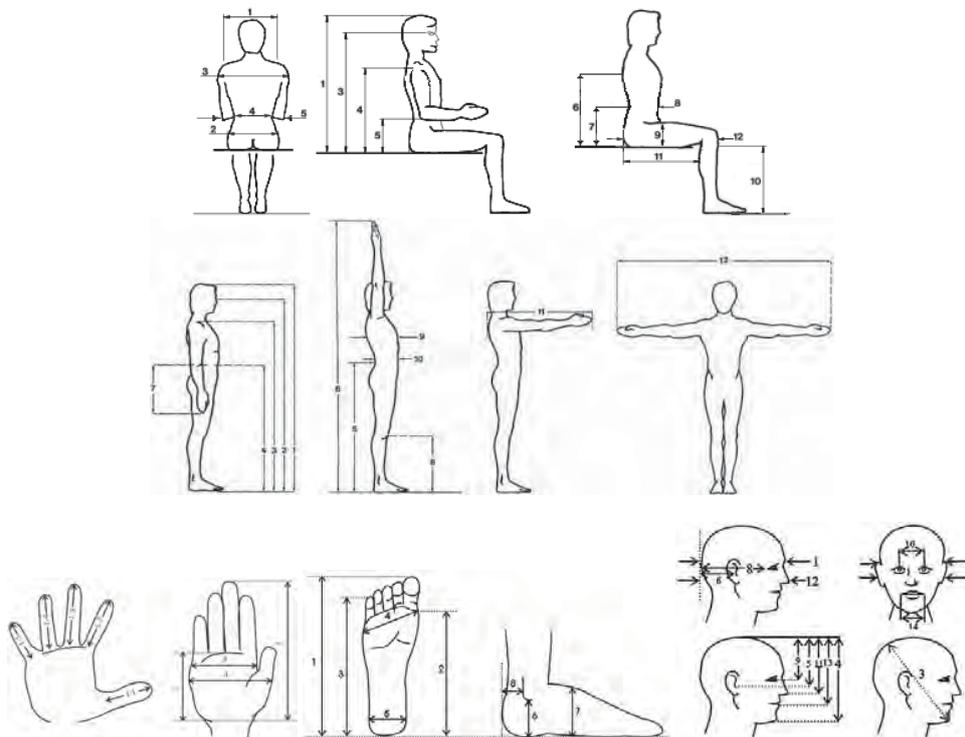

Figure : Anthropometric Dimensions

10	Distance between pupils
11	Nose to top of head length
12	Nose to back of head length
13	Mouth to top of head length
14	Mouth breadth

### 2.3. Accuracy and Reliability Test

Accuracy and reliability test on the system is intended to answer whether the proposed system fulfill the system requirements or not. The first test carried out on the accuracy of the system measurement. Accuracy test aims to determine how close the anthropometric measurements results from the proposed system compared with the conventional anthropometric measurement results. Slightly different with the accuracy test, the reliability test aims to determine how consistence the anthropometric measurements result using the proposed system.

To determine the accuracy level of the proposed system measurement, paired t-test or Wilcoxon signed rank test will be performed. Paired t-test will be performed if the data are normally distributed, while Wilcoxon signed rank test will be performed if the data are not normally distributed. If the value of the p-value is more than the confidence interval (in this case we use 5%), it can be concluded that the proposed system is accurate.

After that, to determine the reliability of the proposed test-retest reliability will be used. Test-retest reliability will be done by comparing two sets of measurement data using the proposed system. The data used for comparison must come from same system operator. The proposed system can be reliable if there is no significance differences between the measurement results on the first measurement compared with the second measurement. The differences between the first and the second measurement will be established by performing paired t-test or Wilcoxon signed rank test.

Data used on the accuracy and reliability tests taken from measurement data from 12 objects. Each of objects will be measured using the traditional tools and the proposed system. Due to the needs of reliability tests, measurement using the proposed system will be done twice. Objects were 12 men with age range 21-23 years old (median = 22 years old). It consists of 9 Javanese, 2 Chinese, and 1 Sundanese.

## 3. RESULTS AND DISCUSSION

### 3.1. System Design Results

#### 3.1.1. Hardware Setting

As mentioned before, several hardware such as digital camera and calibration board will be set up using specific setting, so they can be used for producing the two-dimensional images. Several setting attempted in this proposed system are: (1) locating the calibration board in the same line with the measuring object; (2) locating the camera attached in the tripod in front of the measuring object. Illustration of the hardware setting can be seen in Figure 2. This setting will be used for capturing several images representing the sixty anthropometrics dimensions.

#### 3.1.2. Software Design

Each image captured will be inserted in the software. Illustration of the software interface can be seen in Figure 3. For determining an anthropometric dimension, four landmarks need to be determined by the software operator. Two landmarks are the end to end of the body landmarks representing the anthropometric dimension, while the rest of the two landmarks are the end to end of the calibration board landmarks representing the calibration dimension. Both of the dimension units are pixel. Illustration of these landmarks is shown in Figure 4.

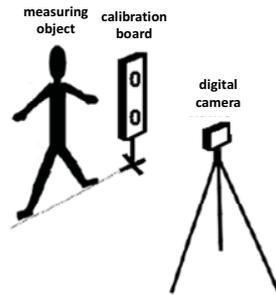

Figure 2 : Hardware Setting

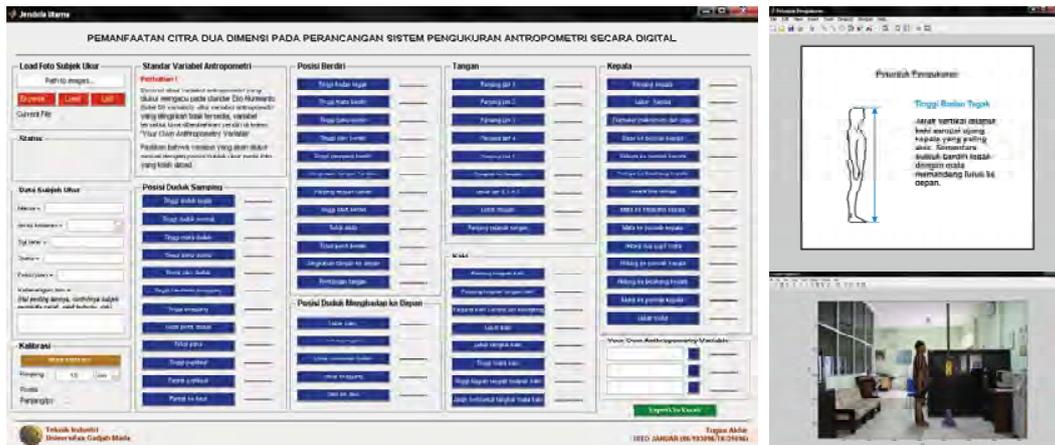

Figure 3 : Software Interfaces (in Bahasa Indonesia)

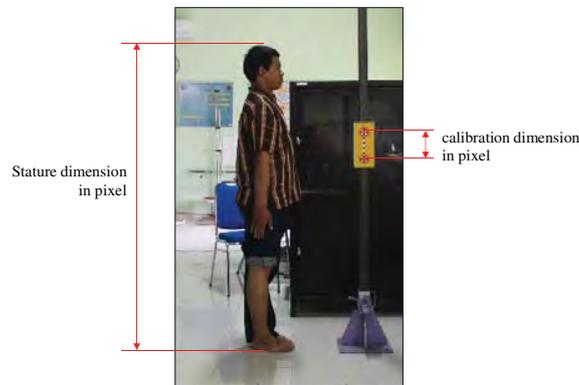

Figure 3 : Four Landmarks representing the anthropometric and calibration dimension

After both of the anthropometric and calibration dimensions can be determined, by adding the actual dimension of the calibration in millimeters, the actual anthropometric dimension in millimeters can be also determined. Illustration of this equation is shown in Equation 1.

$$\frac{\text{Calibration Dimension in mms}}{\text{Calibration Dimension in pixel}} = \frac{\text{Anthropometric Dimension in mms}}{\text{Anthropometric Dimension in pixel}} \quad (1)$$

### 3.2. Accuracy and Reliability Test Result

#### 3.2.1 Accuracy Test Results

Complete accuracy test results expressed using p-value of the paired t-test or Wilcoxon signed rank test are shown in Table 2.

Table 2. Accuracy Test Results

Name of Variable	p-value	Name of Variable	p-value
Erectly sitting Height	0.026*	Index finger length	0.033*
Normal sitting height	0.108	Middle finger length	0.074
Eye height (sitting)	0.755	Ring Finger length	0.223
Shoulder height (sitting)	0.477	Little finger length	0.705
Elbow height (sitting)	0.057	Palm width	0.059
Backrest height	0.583	Total finger breadth	0.365
Waist height (sitting)	0.350	Hand breadth	0.136
Abdominal depth (sitting)	0.476	Hand length	0.036*
Thigh breadth	0.609	Foot length	0.782
Popliteal height	0.782	Foot breadth	0.467
Upper limb length	0.220	Sole length (up to little toe)	0.717
Buttock knee length	0.421	Sole breadth	0.257
Shoulder Breadth (Biacromial)	0.181	Hind foot breadth	0.046*
Hip Breadth	0.037*	Ankle height	0.091
Shoulder Breadth (Bideltoid)	0.530	Foot center height	0.572
Waist Breadth	0.814	Ankle length	0.411
Elbow to elbow Breadth	0.084	Head length	0.474
Stature	0.088	Head breadth	0.341
Eye Height	0.010*	Maximum diameter of head	0.003*
Shoulder Height	0.609	Chin to top of head length	0.020*
Elbow Height	0.081	Ear to top of head	0.665
Hip Height	0.014*	Ear to back of head	0.141
Vertical grip reach (Standing)	0.138	Distance between ears	0.928
Lower hand length	0.539	Eye to back of head	1.000
Knee height	0.682	Eye to top of head	0.008*
Chest Depth	0.646	Distance between pupils	0.089
Abdominal Depth (Sitting)	0.695	Nose to top of head	0.755
Forward reach	0.059	Nose to back of head	0.029*
Span	0.504	Mouth to top of head	0.969
Thumb length	0.145	Mouth Breadth	0.073
<b>Mean</b>	0.353		
<b>Minimum</b>	0.003		
<b>Maximum</b>	1.000		

\*Significant at  $p < 0.05$

According to Table 2, the p-value of the 49 dimensions is more than 0.05, while the rest of the p-value is less than 0.05. The mean of p-value is 0.353, while the minimum and the maximum value of the p-value are 0.003 and 1.000.

### 3.2.2 Reliability Test Results

Complete reliability test results expressed using pearson's or spearman's correlation coefficient are shown in Table 3.

Table 3. Test-retest Reliability

Name of Variable	Correlation Coefficient (r)	Name of Variable	Correlation Coefficient (r)
Shoulder Breadth (Biacromial)	0.988	Index finger length	0.924
Hip Breadth	0.986	Middle finger length	0.978
Shoulder Breadth (Bideltoid)	0.990	Ring Finger length	0.857
Waist Breadth	0.972	Little finger length	0.956
Elbow to elbow Breadth	0.964	Palm width	0.943
Erectly Sitting Height	0.904	Total finger breadth	0.913
Normal sitting height	0.855	Hand breadth	0.945
Eye height (sitting)	0.921	Hand length	0.982
Shoulder height (sitting)	0.846	Foot length	0.981
Elbow height (sitting)	0.950	Foot breadth	0.942
Backrest height	0.612	Sole length (up to little toe)	0.946
Waist height (sitting)	0.682	Sole breadth	0.728
Abdominal depth (sitting)	0.978	Hind foot breadth	0.854
Thigh breadth	0.826	Ankle height	0.705
Popliteal height	0.597	Foot center height	0.832
Upper limb length	0.926	Ankle length	0.895
Buttock knee length	0.951	Head length	0.900

Name of Variable	Correlation Coefficient (r)	Name of Variable	Correlation Coefficient (r)
Stature	0.998	Head breadth	0.723
Eye Height	0.999	Maximum diameter of head	0.761
Shoulder Height	0.997	Chin to top of head length	0.948
Elbow Height	0.993	Ear to top of head	0.914
Hip Height	0.966	Ear to back of head	0.862
Vertical grip reach (Standing)	0.996	Distance between ears	0.875
Lower hand length	0.983	Eye to back of head	0.873
Knee height	0.979	Eye to top of head	0.924
Chest Depth	0.937	Distance between pupils	0.878
Abdominal Depth (Sitting)	0.964	Nose to top of head	0.888
Forward reach	0.996	Nose to back of head	0.876
Span	0.995	Mouth to top of head	0.909
Thumb Length	0.941	Mouth Breadth	0.456
<b>Mean</b>	<b>0.898</b>		
<b>Minimum</b>	<b>0.456</b>		
<b>Maximum</b>	<b>0.999</b>		

According to Table 3, the correlation coefficients of the 59 dimensions are more than 0.500. The mean of the correlation coefficient is 0.898, while the minimum and the maximum value of the correlation coefficient are 0.456 and 0.999.

### 3.3. Discussion

Based on the previous explanation, by using a specific hardware setting and a customized software, the proposed system has been established for measuring the anthropometric dimensions. The proposed system can be used for measuring sixty anthropometric dimensions as explained in the Figure 1 and Table 1.

After that, according to the results of accuracy and reliability tests, generally, the proposed system is accurate and reliable. However, when it was used for measuring several dimensions such as erectly sitting height, hip breadth, eye height, hip height, index finger length, hand length, hind foot breadth, maximum diameter of head, chin to top of head length, and nose to back of head length, significant differences between the measurement results using the proposed system and the conventional methods happen.

For several dimensions such as erectly sitting height, maximum diameter of head, chin to top of head length, and nose to back of head length, the differences can occur because of the measuring object's hair. When it measured using the traditional tools, the caliper or the anthropometer can push the hair. However when captured using the digital camera the hair cannot be pushed. After that, for the other dimensions such as hip breadth and hip height, the differences happen due to measuring object's cloths. The cloths of the objects make the body landmarks are difficult to find.

Slightly different with the result of the accuracy test, according to the results of the reliability test, the significant differences between the two measurements only occurs in the mouth breadth dimension. It can occur because when the objects captured for the first and the second image, the objects may change their mouth position.

## 4. CONCLUSION

By using the two-dimensional images as the input on the proposed system, a digital anthropometrics measurement system has been established. The proposed system consists of the supporting hardware setting which is utilizing digital camera, calibration board, and tripod and a customized software. By using this design, the proposed system can be used for measuring sixty anthropometric dimensions. After that, according the results of the accuracy and reliability test, the proposed system seems accurate and reliable. In addition, for increasing the accuracy of several variables, it is better if when measuring using the proposed system, the measuring object wear special clothes such as swimming head gear and swimwear.

### ABSTRACT

Well designed elementary school desk and chair might accommodate in-classroom-learning process. How well designed a school furniture can be assessed on its comfort, usability and aesthetic. On the previous research with 2000 elementary school pupils in Surakarta as the sample, it had been concluded that those three requirements are not well considered in desk and chair design. This research is purposed to optimize the function of elementary school desk and chair as one of education facilities by proposing design alternatives. The alternatives that are designed ergonomically and aesthetically could be appropriate in reaching learning goal. The research was conducted in several steps. It was started by reviewing anthropometric data from the previous research. The data was used as basic reference in dimension for designing the furniture set. The next step was evaluating the existing elementary school desk and chair in ergonomic and aesthetic aspects. The result shall support in creating the more detail and applicative design. The design was made in 1:5 scale model. In three-dimensional model, it was easier to assess its proportion and aesthetic. The assessment led to final design recommendation as the result of this research.

### Keywords

*Elementary school desk and chair, anthropometry, aesthetic.*

### 1. INTRODUCTION

Elementary school desk and chair that are well designed might accommodate in-classroom-learning process. How well designed a school furniture can be assessed on its comfort, usability and aesthetic. On the previous research [1], it had been concluded that there has been a little attention of those three qualities requirement on current desk and chair design used in Indonesia with schools in Surakarta as the sample.

The lack of anthropometric aspect considerations has been found on the unsuitable furniture dimension and pupil dimension. The finding was tested with mannequin software compared with furniture used currently by the students. Similar research [2] recommends desk and chair design; however it has not related to dimension and anthropometric issue. This in-appropriateness has been discussed by some researches [3-13]. It may lead to student un-comfort sitting position during classroom activities [14-16]. Another research results design prototype for desk and chair [17-20]. However, the design has not been tested in laboratory or direct user assessment.

On the previous research [1], it has been found that the inappropriateness of desk and chair design with their function especially related to student-centered in moving class learning method curricula. The furniture is presented in heavy and static hence represents un-moveable design. Similar result has been presented [2] so it becomes one factor why student active learning is hard to be applied [21] beside interior and building lay out [22]. Moreover, the additional facility for bag storage seems not to be considered [23].

The last point of the research founding [1] is the appearance of the desk and chair that is less considering aesthetic aspect. They are made in conventional design with small modification in color variation. There are some design improvement with aesthetical variable but still do not fit with student anthropometry. The main result has recommended desk and chair dimension based on pupil anthropometry.

Based on the results, the next research was conducted to further explore in desk and chair function related to learning activity. The function includes personal function to accommodate variation student body dimension and also moveable class learning method. The result from previous research was re-assessed to find out the final data with considering functionality and possibility for mass-producing. The second term research results prototype model for elementary school desk and chair that can be a reference in making better school furniture.

## 2. RESEARCH METHOD

The first step of the second term research was begun with assessing anthropometry data gained from previous term. The data was re-analyzed and re-classify in simple variation hence it might be more economical to be applied. The second step was reviewing design recommendation from the first year with supervision from research partner team purposed to acquire more ideal design recommendation. The third step was collecting and evaluating existing school desk and chair design in ergonomic and aesthetic aspects. This evaluation will be compared to the design proposed by this research for creating more detail and applicable design. The fourth step was conducting design workshop several times for creating design alternatives to be discussed and developed. The recommended dimension was then used in the designs based on pupil anthropometry. Those designs then were made in 1:5 scale models for easier visual evaluation. Some improvements are added before making it in 1:1 scale prototype. This prototype will be tested directly by the user in the next term research.

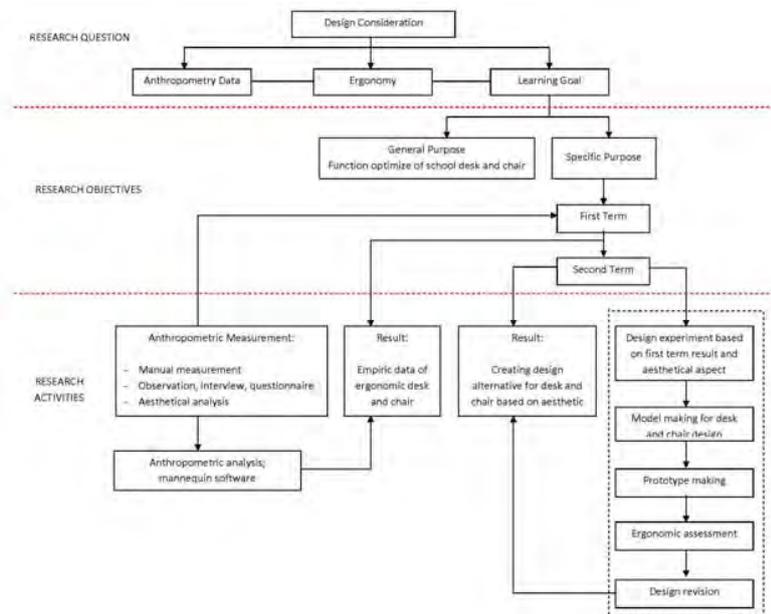

Figure 1: Reseach method

## 3. DISCUSSION

The discussion below is the report of the workshop session and design experimental process. Some possible design sketches were assessed in their aesthetic approach. Assessment focused on material and finishing used in the relation with learning process and goal to be achieved. Analysis concerned on how aesthetic approach can support functionality achievement. The furniture should be moveable but in anthropometric and function consideration. This requirement was based on the need of active learning activities for changeable classroom lay out.

### 3.1. Desk Design Alternatives

First and second desk designs combine two types of materials. The table clearance and drawer surface are made from wood. The desk legs are made from iron in 1/2inch diameter. It will be covered by duco paint in grey color.

Figure 2: Desk design model; first alternative (2 images on the left) and second alternative (2 images on the right)

The desk surface has an additional element for rubber for avoiding injuries in direct contact with sharp corner of the surface. The second alternative has an additional leg cover that is made from wood. However, this component then is cancelled in prototype model since it will raise the budget and not support attitude lesson for having polite sitting position.

In prototype model, the first design alternative is presented in half sliding surface of the top table proposed for writing and other activities that might need wider clearance. The adjustable surface might be suitable with student hand reach. It makes the student does not have to move the chair when needed [when need to stand for example] and might also minimize the lordosis effect. When needed to be moved, the sliding surface can be totally pushed hence appropriate with child hand and easier to be moved. Under the table drawer area can be made bigger that it used for the sliding surface works in solving minimal free space need for knee height.

Figure 3: Desk design improvement; first alternative (left) and second alternative (right)

On the second desk, the design has static work surface. The storage is placed on the right side of under table area. Therefore, the standing drawer must have enough width to put bag with books without disadvantage the need of free leg space under the table. Side storage might be more accessible. Its static work surface might seem more realistic to deliver, easy maintenance and simple construction system to be used in public facilities in such as public schools.

Table : Recommended dimension of desk design alternatives based on anthropometry data

Desk Dimension	Grade 1,2,3		Grade 4,5,6	
	Recommendation Range	Final Dimension	Recommendation Range	Final Dimension
Desk Length	minimum 37 cm	50 cm	minimum 42 cm	60 cm
Desk Width	45 - 62 cm	50 cm	54 - 71 cm	60 cm
Desk Height	maximum 57 cm	52.5 cm	maximum 77 cm	60 cm
Drawer Height (alternative 1)	10-15 cm	12 cm	10-15 cm	12 cm
Drawer Width (alternative 2)	10-15 cm	12 cm	10-15 cm	12 cm
Footrest height		10 cm		10 cm

## 2.1 Chair Design Alternatives

Chair design with two separated back support is purposed to accommodate a variety range of lumbar height with economical consideration. This budget limitation might lead to inflexibility lumbar support in moving and dimension. It needs aesthetic improvement as well.

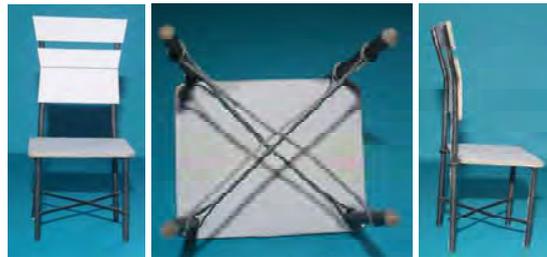

Figure 4: Chair design model; first alternative

In prototype model, the first design looks like conventional existing chair. The research result improve the design by giving comfort in appropriateness with child anthropometry. This chair is the pair of the table with sliding work surface. Adjustable requirement of the furniture has been represented by the table so the chair can be designed in static performance. Over adjustment might not beneficial as pupil mobility has to be limited for learning process effectiveness.

Figure 5: Chair design improvement; first alternative (left) and second alternative (right)

The second design offers mobility advantage as it is paired with static work surface table. This chair can be moved forward or backward so it is possible for the user to adjust his sitting position while studying. Wheels are placed on the back of chair legs so it will easier to be moved. The wheels can be locked for safety purpose. The user only needs to stand, elevate the front part of the sitting surface and pull it forward or push it backward. There are no wheels on the front chair legs. It is an effort to limit the mobility that may disturb the learning process and endanger the user.

Table 2: Recommended dimension of chair design alternatives based on anthropometry data

Chair Dimension	Grade 1,2,3		Grade 4,5,6	
	Recommendation Range	Final Dimension	Recommendation Range	Final Dimension
Seat Height	maximum 27 cm	25 cm	maximum 31cm	30 cm
Back Support Height	13 - 26 cm	22 cm	17 - 26 cm	24 cm
Seat Width	minimum 28 cm	30 cm	minimum 32 cm	35 cm
Seat Depth	maximum 32 cm	30 cm	maximum 37 cm	35 cm

#### 4. CONCLUSION

Desk and chair redesigning for Indonesia elementary school of this research has considered function, comfort, dimension, and aesthetic aspect. The result can be alternatives to be applied although it still needs to be redeveloped. The crucial problem of the design process is the difficulty of fulfilling ergonomic requirement with low production budget. Therefore, it can be a further research to explore potential local material that might be affordable and applicable to accommodate active learning method.

#### ACKNOWLEDGMENT

This paper is based on research funded by Directorate of Higher Education on Universities Research Collaboration scheme [PEKERTI]. Therefore we thank Yassierli Ph.D as the research partner for assisting and supervising during the research.

## ABSTRACT

UPH library website is one of the supporting media for teaching and learning process at UPH. Therefore, the content of library website should be designed in such a way for ease of use by students. Over the past, the usability of UPH library website was not known. Therefore, this study is conducted to evaluate the usability of UPH library website based on WEBUSE indicator. In addition, experimentation is conducted to test the ease of use of several website features. A questionnaire is used to determine the usability level of library website. Based on the results of the questionnaires, it is known that the usability of library website for three categories, which are: content, organization and readability; Navigation and links; as well as Performance and Effectiveness are moderate. With each usability point respectively are 0.60; 0.59 and 0.58. For user interface category, UPH library website is assessed to have good usability level (0.640). Experiments are carried out to determine the usability problems directly, by observing respondents when they are doing several tasks using UPH library website. Based on the experimental results, it is known that the respondents are still facing difficulties to use some features available on the UPH library website. This can be known from the low effectiveness (average task score = 51.67 out of 100) and low efficiency (the average completion time is 5 times longer than expert time and the average number of clicks required is 2-3 times more than the expert click). Some of the problems found are the search function that does not work, the location for important information is on the bottom side and there are some uncommon names of menus or less likely to represent the content.

## Keywords

*usability, website library, WEBUSE indicator*

## 1. INTRODUCTION

Internet is widely used in education since it makes it easy for students to access any information without the need to travel long distances. One way to know whether a website is easy to use is by doing usability testing. Usability is closely related to the interaction between the user and the computer (human-computer interaction). UPH library website is supposed to be useful for students to get any information regarding learning media, such as books and journals. UPH library website is often used by students who do their thesis. Over the past, the usability level of UPH website library has not been known. Therefore this research is conducted to measure the usability level of UPH library website from different aspects, such as navigation, content and website structure. By conducting usability test, it is known which functions or features are not user-friendly enough so that they could be improved. The improvements are expected to increase the utilization of UPH website library. There were some previous researches about website usability test. Jumeno and Putri [1] studied the usability testing of website by using 9 variables, which were accessibility; feedback mechanism; navigation link; update information; simplicity; user freedom, control and help; consistency and visibility of website structure; readability and aesthetics of website; and learnability and memorability. Nawangpalupi [2] studied website car sharing by using 3 variables, which were effectiveness, efficiency and user satisfaction. Meanwhile Chiew and Salim [3] used a combination of methods to develop Website Usability Evaluation Tool (WEBUSE). WEBUSE is chosen as a tool to measure the usability level of UPH website library.

## 2. RESEARCH METHOD

The research method consists of six steps as follows:

### 2.1 Problem identification and formulation

One of the supporting facilities for learning process in higher education is library website. Students can use this website to find any information needed. Website should be designed properly so that the users are able to gather the needed information easily. Therefore, it is important to measure the usability level of UPH library website so that it could be known which features need improvement and how the students could find any information easier.

**2.2 Research objective determination**

This research aims to measure the usability level of UPH library website by using WEBUSE indicator. From the result, any problems related to the website usability will be identified so that improvement could be proposed. The website usability will be classified into 4 categories, which are: content, organization and readability; navigation and link; user interface design; performance and effectiveness [3]. The description of each category is as follows [4]:

1. Content, Organization, and Readability describes website material contents, organization and updating, and defines how much these contents are clear, easy to find and read.
2. Navigation and link defines how clear and consistent is the navigation mechanisms used in the website.
3. User Interface defines different interface issues such as the availability and helpfulness commands, menus design, and the use of Graphical User Interface (GUI) designs.
4. Performance and Effectiveness defines how much time, and how many steps, are required for people to complete online basic tasks?

From all categories, it can be determined which category is less optimal. Furthermore, an experiment will be conducted to identify any problems happen during the usage of UPH library website.

**2.3 Data collection method**

Data are collected by distributing questionnaires using purposive random sampling. Questionnaires are distributed to respondents, UPH active students from third semester onwards, who have used UPH library website before. The target students are chosen from UPH Business School, Faculty of Social and Political Science, Faculty of Design and Planning as well as Faculty of Industrial Technology, because the total number of active students from those four faculties reaches 63% of total UPH students. The questionnaire consists of two parts. The first part consists of 7 questions to know the characteristics of UPH library website users as well as their purpose in using the website. The second part is the WEBUSE questionnaire. The questionnaire consists of 24 questions with possible answer from “strongly disagree” to “strongly agree”. All of the 24 questions are classified into 4 main categories, which are Content, Organization and Readability; Navigation and Links; User Interface Design; Performance and Effectiveness. The minimum number of sample required is calculated using a formula,

below:  $n = \frac{1}{\alpha^2}$ .....(1)

With significance level ( $\alpha = 0.1$ ), the minimum number of sample was 100.

**2.4 Questionnaire data processing**

Each answer from respondent is converted to usability merit according to the matrix shown in Table 1.

*Table 1: Options for WEBUSE Questionnaires and Corresponding Merits [3]*

Option	Strongly disagree	Disagree	Fair	Agree	Strongly agree
Merit	0.00	0.25	0.50	0.75	1.00

The merits are then accumulated based on the four usability categories. Mean value for each category is considered as the usability point for that category. Overall website usability point is the mean value of usability points for the four categories.

Usability point for a category,  $x$ , is defined as [3]:

$x = [ \sum(\text{Merit for each question of the category}) ] / [ \text{number of questions} ]$ .....(2)

Usability level is determined by the usability points (as shown in Table 2)

*Table 2: Usability Points and Corresponding Usability Levels [3]*

Point, $x$	0 ≤ $x$ ≤ 0.2	0.2 < $x$ ≤ 0.4	0.4 < $x$ ≤ 0.6	0.6 < $x$ ≤ 0.8	0.8 < $x$ ≤ 1.0
Level Usability	Bad	Poor	Moderate	Good	Excellent

The last step is calculating *Cronbach alpha coefficient*,  $\alpha$ . This coefficient is used to test the reliability of WEBUSE. The greater the coefficient means the more reliable the measurement. When the questionnaire is found reliable, then the result of usability level for each category will be used as a based to develop some tasks for the experiment. Tasks are developed according to the category that has the lowest usability level, so that the experiment can be conducted toward the right direction.

**2.5 Experiment**

Experiment is conducted by using laptop, CamStudio software (to record all screen activity), question sheet, questionnaire and internet connection (to access UPH library website). The respondents are students who have used UPH library website before. In this experiment, the chosen respondents are students from industrial engineering class of 2008 and 2009. Respondents are asked to complete some tasks by using UPH library website. After they completed the task, they need to fill the questionnaire

regarding the problems faced during the experiment. Evaluation of website usability is based on three parameters, which are: score, time of completion, and the number of clicks to complete the tasks. These three parameters are used to measure two aspects, which are effectiveness and efficiency.

### 2.6 Analysis of experiment's result

The result of the experiment is presented by using descriptive statistics. Analysis of the result is based on the three parameters used in the experiment. Based on the questionnaire distributed among the respondents, some usability problems can be identified, and the suggested improvement can be determined. After doing the analysis, the conclusion can be drawn regarding the usability level of UPH library website.

## 3. RESULT AND DISCUSSION

### 3.1 Analysis of Questionnaire

The total number of distributed questionnaire is 244, but only 234 questionnaires are completely filled in so that they can be processed further. The first part of the questionnaire shows the characteristics of the respondents. Majority of the respondents are female (63%). Most of the respondents access the UPH library website from their own laptop (86%). About 53% of the respondents are students in 7<sup>th</sup> semester. Majority of the respondents have accessed the library website to search for and read the journal. Most of them only use library website once or twice in a semester.

The second part of the questionnaire is WEBUSE questionnaire. The 234-participant response for 24-question showed that the Cronbach's alpha coefficient took value that was greater than 0.6 (0.9288). This implies that the evaluation is reliable. The usability point is calculated for each category by using formula 2 and the usability level is determined according to table 2. The result of usability point and level for each category can be seen in table 3.

Table 3: Usability Level for UPH website library

Category	Usability Criteria	Point	Usability Level	Usability level for category
Content, Organization and Readability	This website contains most of my interest material and topics and they are up-to-date.	0.59	Moderate	Moderate (0.60)
	I can easily find what I want at this website	0.55	Moderate	
	The content of this website is well organized	0.61	Good	
	Reading content at this website is easy.	0.60	Moderate	
	I am comfortable and familiar with the language used	0.61	Good	
	I need not scroll left and right when reading at this website	0.63	Good	
Navigation and links	I can easily know where I am at this website	0.55	Moderate	Moderate (0.59)
	This website provides useful cues and links for me to get the desired information	0.58	Moderate	
	It is easy to move around at this website by using the links or back button of the browser	0.65	Good	
	The links at this website are well maintained and updated.	0.65	Good	
	The website does not open too many new browser windows when I am moving around.	0.65	Good	
	Placement of links or menu is standard throughout the website and I can easily recognize them	0.48	Moderate
